The Power of Simplicity

Four Js Genero Business Development Language User Guide

Contents

Genero Business Development Language User Guide..... 15

What's new in Genero Business Development Language, v 3.00..... 18

General..... 22

Documentation conventions..... 22
- Syntaxes..... 22
- Warnings..... 22
- Code examples..... 23
- Enhancement references..... 23

General terms used in this documentation..... 23
Introduction to Genero BDL programming..... 24
- Overview of Genero BDL..... 25
- Genero BDL concepts..... 26

Installation..... 33

Documentation resources for upgrades..... 33
Software requirements..... 33
- Supported operating systems..... 33
- Database client software..... 33
- C compiler for C extensions..... 34
- Java™ runtime environment..... 34
- IPv6 support with Genero..... 35

Installing Genero BDL..... 35
Upgrading Genero BDL..... 35
Platform specific notes..... 36
- HP-UX configuration notes..... 36
- IBM® AIX® configuration notes..... 36
- Mac OS X configuration notes..... 37
- Microsoft™ Windows™ configuration notes..... 38
- Web Services platform notes..... 39

Upgrading..... 40

New features of Genero BDL..... 40
- What's new in Genero Business Development Language, v 3.00 (Maintenance Releases)... 41
- What's new in Genero Business Development Language, v 3.00..... 41
- What's new in Genero Business Development Language, v 2.51..... 45
- What's new in Genero Business Development Language, v 2.50..... 48
- What's new in Genero Business Development Language, v 2.41..... 51
- What's new in Genero Business Development Language, v 2.40..... 51
- What's new in Genero Business Development Language, v 2.32..... 55
- What's new in Genero Business Development Language, v 2.30..... 56
- What's new in Genero Business Development Language, v 2.21..... 58
- What's new in Genero Business Development Language, v 2.20..... 62
- What's new in Genero Business Development Language, v 2.11..... 65

What's new in Genero Business Development Language, v 2.10 ... 68
What's new in Genero Business Development Language, v 2.02 ... 71
What's new in Genero Business Development Language, v 2.01 ... 72
What's new in Genero Business Development Language, v 2.00 ... 72
What's new in Genero Business Development Language, v 1.33 ... 76
What's new in Genero Business Development Language, v 1.32 ... 76
What's new in Genero Business Development Language, v 1.31 ... 77
What's new in Genero Business Development Language, v 1.30 ... 78
What's new in Genero Business Development Language, v 1.20 ... 82
What's new in Genero Business Development Language, v 1.10 ... 84
Frequently asked questions ... 85
FAQ001: Why do I have a different display with Genero than with BDS V3? ... 85
FAQ002: Why does an empty window always appear? ... 86
FAQ003: Why do some COMMAND KEY buttons no longer appear? ... 86
FAQ004: Why aren't the elements of my forms aligned properly? ... 87
FAQ005: Why doesn't the ESC key validate my input? ... 88
FAQ006: Why doesn't the Ctrl-C key cancel my input? ... 88
FAQ007: Why do the gui.* FGLPROFILE entries have no effect? ... 89
FAQ008: Why do I get invalid characters in my form? ... 89
FAQ009: Why do large static arrays raise a stack overflow? ... 89
FAQ010: Why do I get error -6366 "Could not load database driver *drivername*"? ... 90
Upgrade Guides for Genero BDL ... 90
General upgrade guide ... 90
3.00 upgrade guide ... 91
2.51 upgrade guide ... 101
2.50 upgrade guide ... 106
2.40 upgrade guide ... 109
2.32 upgrade guide ... 112
2.30 upgrade guide ... 113
2.21 upgrade guide ... 116
2.20 upgrade guide ... 117
2.11 upgrade guide ... 122
2.10 upgrade guide ... 123
2.02 upgrade guide ... 123
2.01 upgrade guide ... 123
2.00 upgrade guide ... 123
1.33 upgrade guide ... 129
1.32 upgrade guide ... 129
1.31 upgrade guide ... 130
1.30 upgrade guide ... 130
Planned desupport ... 139
Migrating from IBM® Informix® 4gl to Genero BDL ... 139
Introduction to I4GL migration ... 140
Installation and setup topics ... 140
User interface topics ... 141
4GL programming topics ... 147
Migrating from Four Js BDS to Genero BDL ... 151
Installation and setup topics ... 152
User interface topics ... 153
4GL Programming topics ... 161

Configuration ... 164
The FGLPROFILE file ... 164
Understanding FGLPROFILE ... 164
FGLPROFILE entry syntax ... 165

List of FGLPROFILE entries..... 166
Environment variables..... 169
Setting environment variables on UNIX™..... 169
Setting environment variables on Windows™..... 170
Setting environment variables in FGLPROFILE (mobile)..... 170
Operating system environment variables..... 171
Database client environment variables..... 173
Genero environment variables..... 173
Configuring the front-end connection..... 186
Configuring the database server connections..... 186

Language basics..... 188
Syntax features..... 188
Lettercase insensitivity..... 188
Whitespace separators..... 189
Quotation marks..... 189
Escape symbol..... 189
Statement terminator..... 190
Comments..... 190
Identifiers..... 191
Preprocessor directives..... 191
Data types..... 191
BIGINT..... 192
BYTE..... 193
BOOLEAN..... 195
CHAR(size)..... 195
DATE..... 197
DATETIME qual1 TO qual2..... 198
DECIMAL(p,s)..... 200
FLOAT..... 202
INTEGER..... 202
INTERVAL qual1 TO qual2..... 203
MONEY(p,s)..... 204
SMALLFLOAT..... 205
SMALLINT..... 205
STRING..... 206
TINYINT..... 207
TEXT..... 208
VARCHAR(size)..... 210
Type conversions..... 211
When does type conversion occur?..... 211
Data type conversion reference..... 212
Handling type conversion errors..... 216
Formatting numeric values..... 217
Formatting DATE values..... 220
Formatting DATETIME values..... 221
Formatting INTERVAL values..... 223
Literals..... 225
Integer literals..... 225
Numeric literals..... 225
Text literals..... 226
Datetime literals..... 227
Interval literals..... 228
Expressions..... 229
Understanding expressions..... 229

Boolean expressions... 230
Integer expressions... 231
Numeric expressions... 231
String expressions... 232
Date expressions... 232
Datetime expressions... 233
Interval expressions... 233
Operators... 234
Order of precedence... 234
General warnings regarding expressions... 236
List of expression elements... 236
Flow control... 267
CALL... 268
RETURN... 270
CASE... 270
CONTINUE *block-name*... 272
EXIT *block-name*... 273
FOR... 274
GOTO... 275
IF... 276
LABEL... 276
SLEEP... 277
WHILE... 277
Functions... 278
Understanding functions... 278
FUNCTION blocks... 278
Using functions in programs... 279
Examples... 280
Variables... 281
Understanding variables... 281
DEFINE... 281
Declaration context... 282
Structured types... 283
Database column types... 283
User defined types... 284
Variable initialization values... 284
INITIALIZE... 285
LOCATE (for TEXT/BYTE)... 286
FREE (for TEXT/BYTE)... 287
LET... 288
VALIDATE... 288
THRU operator... 289
Examples... 290
Constants... 291
Understanding constants... 291
CONSTANT... 291
Examples... 293
Records... 294
Understanding records... 294
DEFINE ... RECORD... 294
Examples... 296
Arrays... 296
Understanding arrays... 297
DEFINE ... ARRAY... 297
Static arrays... 298
Dynamic arrays... 300

Array methods..... 302
Copying complete arrays.....302
Examples..... 302
Types..... 303
Understanding type definition.....303
TYPE.....303
Using types in programs..... 304
Examples..... 305

Advanced features.....307

Localization.....307
Application locale.....307
Localized strings.....327
Runtime stack.....336
Passing simple typed values as parameter..... 336
Passing a record as parameter.....337
Passing a static array as parameter..... 337
Passing a dynamic array as parameter..... 338
Passing objects as parameter.....338
Passing a TEXT/BYTE as parameter.....339
Returning simple typed values from functions..... 339
Returning dynamic arrays from functions.....339
Returning TEXT/BYTE values from functions..... 340
Implicit data type conversion on the stack.....340
Exceptions..... 340
Understanding exceptions..... 341
Exception classes.....341
Exception actions.....341
WHENEVER instruction.....342
TRY - CATCH block.....344
Tracing exceptions.....345
Default exception handling..... 346
Non-trappable errors.....346
Examples..... 346
OOP support.....349
Understanding classes and objects.....349
DEFINE ... *package.class*.....349
Distinguish class and object methods.....349
Working with objects.....350
What class packages exist?.....351
XML support..... 351
DOM and SAX standards.....351
DOM and SAX built-in classes.....351
Limitations of XML built-in classes.....352
Exception handling with XML classes.....352
Controlling the user interface with XML classes.....352
Globals.....353
Understanding global blocks..... 353
GLOBALS..... 353
Rules for globals usage.....353
Database schema in globals.....354
Content of a globals file.....354
Examples..... 354
Database schema.....355
Understanding database schemas.....356

SCHEMA....356
Structure of database schema files....357
Database schema extractor options....364
Programs....368
Structure of a program....368
Structure of a module....368
The MAIN block....370
Importing modules....371
Predefined constants....376
Configuration options....378
Program registers....387
Program execution....390
Executing programs....390
RUN....391
EXIT PROGRAM....394
BREAKPOINT....394
Front calls....395
Understanding front calls....395
ui.Interface.frontCall....395
User-defined front calls....397

SQL support....398
SQL programming....398
SQL basics....398
SQL security....410
SQL portability....412
SQL performance....452
Database connections....457
Understanding database connections....457
Opening a database connection....458
Database client environment....459
Connection parameters....461
Connection parameters in database specification....464
Direct database specification method....465
Indirect database specification method....466
IBM® Informix® emulation parameters in FGLPROFILE....466
Database vendor specific parameters in FGLPROFILE....469
Database user authentication....473
Unique session mode connection instructions....476
Multi-session mode connection instructions....477
Miscellaneous SQL statements....480
Database transactions....480
Understanding database transactions....481
BEGIN WORK....482
SAVEPOINT....483
COMMIT WORK....483
ROLLBACK WORK....484
RELEASE SAVEPOINT....484
SET ISOLATION....485
SET LOCK MODE....486
Static SQL statements....486
Understanding static SQL statements....487
Using program variables in static SQL....487
Table and column names in static SQL....488
SQL texts generated by the compiler....488

INSERT ... 489
UPDATE ... 490
DELETE ... 492
SELECT ... 493
SQL ... END SQL ... 495
CREATE SEQUENCE ... 496
ALTER SEQUENCE ... 496
DROP SEQUENCE ... 497
CREATE TABLE ... 497
ALTER TABLE ... 497
DROP TABLE ... 498
CREATE INDEX ... 498
ALTER INDEX ... 499
DROP INDEX ... 499
CREATE VIEW ... 499
DROP VIEW ... 499
CREATE SYNONYM ... 499
DROP SYNONYM ... 499
RENAME ... 500
Dynamic SQL management ... 500
Understanding dynamic SQL ... 500
PREPARE (SQL statement) ... 501
EXECUTE (SQL statement) ... 502
FREE (SQL statement) ... 503
EXECUTE IMMEDIATE ... 504
Result set processing ... 504
Understanding database result sets ... 504
DECLARE (result set cursor) ... 506
OPEN (result set cursor) ... 509
FETCH (result set cursor) ... 510
CLOSE (result set cursor) ... 511
FREE (result set cursor) ... 512
FOREACH (result set cursor) ... 512
Positioned updates/deletes ... 514
Understanding positioned update or delete ... 514
DECLARE (SELECT ... FOR UPDATE) ... 515
UPDATE ... WHERE CURRENT OF ... 516
DELETE ... WHERE CURRENT OF ... 517
Examples ... 517
SQL insert cursors ... 517
Understanding SQL insert cursors ... 518
DECLARE (insert cursor) ... 520
OPEN (insert cursor) ... 521
PUT (insert cursor) ... 521
FLUSH (insert cursor) ... 521
CLOSE (insert cursor) ... 522
FREE (insert cursor) ... 522
Examples ... 522
SQL load and unload ... 524
LOAD ... 524
UNLOAD ... 527
SQL adaptation guides ... 529
SQL guide for IBM® Informix® database servers 5.x, 7.x, 8.x, 9.x, 10.x, 11.x ... 529
SQL adaptation guide for IBM® DB2® UDB 10.x ... 540
SQL adaptation guide for IBM® Netezza® 6.x ... 572
SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 ... 592

SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x....625
SQL adaptation guide for Oracle Database 11, 12....643
SQL adaptation guide for PostgreSQL 9.x....683
SQL adaptation guide for SQLite 3.x....709
SQL adaptation guide for SAP Sybase ASE 16.x....723

User interface....747
User interface basics....747
The dynamic user interface....747
The abstract user interface tree....749
Genero user interface modes....752
Establish a GUI front-end connection....755
Special user interface features....759
Configuring a text terminal....762
Form definitions....769
Windows and forms....769
Using images....782
Accessibility guidelines....791
Message files....794
Action defaults files....796
Presentation styles....799
Form specification files....853
Form rendering....1002
Toolbars....1021
Topmenus....1027
Dialog instructions....1034
Static display (DISPLAY/ERROR/MESSAGE/CLEAR)....1034
Prompt for values (PROMPT)....1042
Ring menus (MENU)....1048
Record input (INPUT)....1060
Read-only record list (DISPLAY ARRAY)....1075
Editable record list (INPUT ARRAY)....1098
Query by example (CONSTRUCT)....1128
Multiple dialogs (DIALOG)....1144
Parallel dialogs (START DIALOG)....1199
User interface programming....1249
Dialog programming basics....1249
Input fields....1260
Dialog actions....1276
Table views....1345
Tree views....1384
Split views....1395
Drag & drop....1411
Web components....1416
Canvases....1448
Start menus....1454
Window containers (WCI)....1458

Reports....1460
Understanding reports....1460
XML output for reports....1461
Writing an XML report driver and routine....1461
Structure of XML report output....1462
Conditional statement output in XML reports....1462

The report driver....1464
START REPORT....1465
OUTPUT TO REPORT....1467
FINISH REPORT....1468
TERMINATE REPORT....1468
The report routine....1469
The report prototype....1471
DEFINE section in REPORT....1471
OUTPUT section in REPORT....1472
ORDER BY section in REPORT....1473
FORMAT section in REPORT....1474
Prohibited report routine statements....1480
Two-pass reports....1480
Report instructions....1480
EXIT REPORT....1480
PRINT....1481
PRINTX....1483
NEED....1484
PAUSE....1485
SKIP....1485
Report operators....1486
LINENO....1486
PAGENO....1486
SPACES....1487
WORDWRAP....1487
Report aggregate functions....1489
COUNT....1489
PERCENT....1490
SUM....1490
AVG....1490
MIN....1491
MAX....1491
Report engine configuration....1492

Programming tools....1493
Command line tools....1493
fglrun....1493
fglform....1495
fgl2p....1496
fglcomp....1497
fgllink....1499
fglmkmsg....1500
fglmkext....1500
fgldb....1501
fgldbsch....1502
fglmkstr....1503
fglwsdl....1503
fglpass....1506
fglWrt....1507
Compiling source files....1508
Compiling form files....1508
Compiling message files....1509
Compiling string files....1510
Compiling source code....1510
Importing modules....1511

Linking libraries....1511
Linking programs....1512
Using makefiles....1515
Module build information....1515
Source code edition....1516
Choosing the correct locale....1516
Avoid Tab characters in screen layouts....1517
Code completion and syntax highlighting with VIM....1517
Source documentation....1517
Understanding source code documentation....1518
Prerequisites for source documentation generation....1518
Documentation structure....1518
Adding comments to sources....1519
Run the documentation generator....1521
The preprocessor....1522
Understanding the preprocessor....1522
Compilers command line options....1522
File inclusion....1523
Simple macro definition....1525
Function macro definition....1527
Stringification operator....1529
Concatenation operator....1529
Predefined macros....1530
Undefining a macro....1530
Conditional compilation....1530
The debugger....1531
Understanding the debugger....1531
Prerequisites to run the debugger....1532
Starting fglrun in debug mode....1532
Attaching to a running program....1533
Debugging on a mobile device....1534
Stack frames in the debugger....1535
Setting a breakpoint programmatically....1536
Expressions in debugger commands....1536
Debugger commands....1537
The profiler....1556
Syntax of the program profiler....1556
Usage....1556
Example....1558
Optimization....1559
Runtime system basics....1560
Check runtime system memory leaks....1561
Optimize your programs....1561
Logging options....1563

Extending the language....1564
The Java™ interface....1564
Prerequisites and installation....1565
Getting started with the Java™ interface....1566
Advanced programming....1568
Examples....1592
C-Extensions....1597
Understanding C-Extensions....1597
Header files for ESQL/C typedefs....1598
Creating C-Extensions....1598

Creating Informix® ESQL/C Extensions....1599
The C interface file....1600
Linking programs using C-Extensions....1601
Loading C-Extensions at runtime....1601
Runtime stack functions....1602
C-Extension data types and structures....1606
Calling C functions from programs....1609
Calling program functions from C....1610
Sharing global variables....1611
Simple C-Extension example....1612
Implementing C-Extensions for GMI....1613
User-defined front calls....1615
Implement front call modules for GDC....1615
Implement front call modules for GMA....1620
Implement front call modules for GMI....1624
Implement front call modules for GWC - HTML5 theme....1631
Implement front call modules for GWC - JavaScript....1632
Web Components....1636

Library reference....1637
Built-in functions....1637
Built-in functions....1637
List of desupported built-in functions....1666
The key code table....1666
Utility functions....1667
Common dialog utility functions (IMPORT FGL fgldialog)....1668
Database utility functions (IMPORT FGL fgldbutl)....1672
Front-end dialog utility functions (IMPORT FGL fglwinexec)....1676
vCard utility functions (IMPORT FGL VCard)....1679
Built-in packages....1687
BDL data types package....1687
The base package....1703
The ui package....1755
The om package....1833
Built-in front calls....1881
Built-in front calls....1881
Extension packages....1947
The util package....1947
The os package....1990
The com package....2009
The xml package....2103
The security package....2278
File extensions....2296
Genero BDL errors....2297

Web services....2400
General....2400
Introduction to Web Services....2400
SOAP Web Services basics....2404
RESTful Web Services basics....2416
Getting started and examples....2416
Debugging....2416
Platform-specific notes....2416
Known issues....2419

Legal Notices.....2419
Concepts.....2419
High-level and low-level web services APIs.....2420
SOAP features.....2420
Stateful web services.....2422
Encryption, base64 and password agent with fglpass tool.....2429
HTTP compression.....2432
SOAP multipart style requests in GWS.....2434
Security.....2435
Encryption and authentication.....2435
Accessing secured services.....2438
HTTPS configuration.....2440
Certificates in practice.....2441
Examining certificates.....2443
Troubleshoot common issues.....2446
The Diffie-Hellman key agreement algorithm.....2447
SOAP Web Services.....2450
Writing a Web Services client application.....2450
Writing a Web Services server application.....2468
How To's.....2484
RESTful Web Services.....2505
Deploy a Web Service.....2506
Web services server program deployment.....2506
Configuring the apache web server for HTTPS.....2507
Reference.....2509
Web services configuration.....2509
Attributes to customize XML serialization.....2517
Error handling in GWS calls (STATUS).....2546
Interruption handling in GWS calls (INT_FLAG).....2546
Server API functions - version 1.3 only.....2546
Configuration API functions - version 1.3 only.....2552
Using fglwsdl to generate code from WSDL or XSD schemas.....2555

Mobile applications.....2557
Types of Genero Mobile apps.....2557
Language limitations.....2560
Environment variables on mobile.....2560
App localization.....2560
Apps user interface.....2561
Action rendering.....2561
Images and icons.....2562
Keyboard type.....2563
List views.....2563
Split views.....2564
Toolbars.....2565
Topmenus.....2565
Front call support.....2566
Color and theming.....2566
Database support on mobile devices.....2567
Using SQLite database in mobile apps.....2567
Accessing device functions.....2569
Web Services on mobile devices.....2569
Debugging a mobile app.....2570
Deploying mobile apps.....2572
Deploying mobile apps on Android™ devices.....2572

Deploying mobile apps on iOS devices..... 2584
Running mobile apps on an application server..... 2595

What's new in Genero Business Development Language, v 3.00

This topic lists features added for the 3.00 GA release of the Genero Business Development Language.

Important: Please read also:

- What's new in Genero Business Development Language, v 3.00 (Maintenance Releases) on page 41, for a list of features that were introduced with the Genero BDL 3.00 Maintenance Releases.
- What's new in Genero Business Development Language, v 2.51 on page 45, for a list of features that were introduced with the Genero Mobile 1.0 release.

Table 1: Core language

Overview	Reference
The fglmkext command line tool can build your C Extension library.	See fglmkext on page 1500.
New fglcomp warning for invalid NULL usage in expressions like var==NULL.	See Compiler warning -6636.
C Extension runtime stack introspection (parameter type and actual string value size in bytes).	See Runtime stack functions on page 1602.
Temporary file name creation with `os.Path.makeTempName()`.	See os.Path.makeTempName on page 2002.
Attach the debugger to a running program with `fgldb -p` *`process-id`*.	See Attaching to a running program on page 1533.
Improved compilation time (`fglcomp` and `fglform`)	See Improved compilation time on page 98.
Datetime-related utility methods.	See util.Datetime.getCurrentAsUTC on page 1951, util.Datetime.format on page 1949, util.Datetime.parse on page 1951.
Date-related utility methods.	See util.Date methods on page 1947.
Interval-related utility methods.	See util.Interval methods on page 1955.

Table 2: User interface

Overview	Reference
Autocompletion in text edit fields with the COMPLETER attribute.	See Enabling autocompletion on page 1274.
Centralization of icon definitions with the FGLIMAGEPATH environment variable.	See Providing the image resource on page 784, FGLIMAGEPATH on page 182, Built-in front-end icons desupport on page 97.
Defining an action for `IMAGE` form items (clickable images).	See Defining action views in forms on page 1276, Defining actions on list columns with images on page

Overview	Reference
	1355, IMAGE item type on page 888.
Resizable `SCROLLGRID` containers (`WANTFIXEDPAGESIZE=NO`).	See WANTFIXEDPAGESIZE attribute on page 994.
Detect window resizing or device orientation change with the `windowresized` predefined action.	See Adapting to viewport changes on page 1003.
Dialog methods to convert the program array row index to the visual index, and the opposite.	See ui.Dialog.arrayToVisualIndex on page 1796, ui.Dialog.visualToArrayIndex on page 1815.
The `ON SORT` dialog control block can be used to execute code when the record list is re-ordered by the user.	See List ordering on page 1356, Populating a DISPLAY ARRAY on page 1372, ON SORT block on page 1091, ui.Dialog.getSortKey on page 1802, ui.Dialog.getSortReverse on page 1802.
`ON TIMER` trigger in dialogs, to execute a block of code at regular intervals.	See Get program control on a regular (timed) basis on page 1255.
Dynamic dialog creation.	See Implementing dynamic dialogs on page 1255.
Providing application image resources to Web Components with `ui.Interface.filenameToURI()`.	See Using image resources with the gICAPI web component on page 1430, ui.Interface.filenameToURI on page 1759.
Binding structured ARRAYs in DISPLAY ARRAY and INPUT ARRAY.	See Structured ARRAYs in list dialogs on page 100.

Table 3: SQL databases

Overview	Reference
Support for PostgreSQL 9.4.	See Database driver specification (driver) on page 462.
Support for Sybase ASE 16.x.	See Database driver specification (driver) on page 462.
Support for SQL Server 2008, 2012 and 2014 with FreeTDS driver (using FreeTDS 0.95)	See FreeTDS driver supports SQL Server 2008, 2012, 2014 on page 97.
SQL interruption is now supported with MySQL.	See SQL interruption on page 405.
MySQL VARCHAR(N) can be used when N is greater as 255.	See MySQL VARCHAR size limit on page 95.
MySQL DATETIME can store fractional seconds.	See MySQL DATETIME fractional seconds on page 96.

Overview	Reference
Maria DB support (V5.5 and V10): Use the dbmmys driver.	See MariaDB support on page 97.
Dynamic cursor built-in class `base.SqlHandle`.	See The SqlHandle class on page 1725.
Native Oracle NUMBER type (without precision/scale) can be extracted by fgldbsch.	See Oracle DB NUMBER type on page 95.
Serial emulation based on triggers and sequences with SQL Server 2012 and +.	See SERIAL data types on page 606.
PostgreSQL connection string option specification in the `source` parameter.	See Database source specification (source) on page 461, Prepare the runtime environment - connecting to the database on page 684.

Table 4: Web Services

Overview	Reference
Flushing immediately the response of a web service operation with `com.WebServicesEngine.flush`.	See com.WebServiceEngine.Flush on page 2026.
Base64 / Hexadecimal / Digest methods using a specific character set for string data.	See security.Base64.FromStringWithCharset on page 2282, security.Base64.ToStringWithCharset on page 2285, security.HexBinary.FromStringWithCharset on page 2288, security.HexBinary.ToStringWithCharset on page 2290, security.Digest.AddStringDataWithCharset on page 2293.
`com.WebServiceEngine` option `server_readwritetimeout` to define a server socket read/write timeout.	See Web Services changes on page 93, WebServiceEngine options on page 2032.
IPv6 support for Web Services clients.	See Configure a WS client to use IPv6 on page 2464.
Specific APIs for Apple Push Notification Service support.	See The APNS class on page 2095, com.TCPRequest.setKeepConnection on page 2091, com.TCPRequest.doDataRequest on page 2087, com.TCPResponse.getDataResponse on page 2093, Push notifications on page 2599.
Methods to perform RESTful requests using files on disk.	See com.HTTPServiceRequest.readFileRequest on page 2046, com.HTTPServiceRequest.sendFileResponse on page 2048,

Overview	Reference
	com.HTTPRequest.doFileRequest on page 2058, com.HTTPResponse.getFileResponse on page 2073, com.HTTPPart.getAttachment on page 2080, com.HTTPPart.CreateAttachment on page 2080.
FGLPROFILE entries to define XML Signature and XML Encrypted data prefix: `xml.signature.prefix` and `xml.encrypted.prefix`.	See XML configuration on page 2514.
SOAP fault handling works now when HTTP error 200 is returned by the server.	See SOAP fault handling in client stub on page 93.
Client stub multipart supports now optional parts.	See Optional multipart handling in client stub on page 94

Table 5: Mobile apps

Overview	Reference
Starting remote applications from a mobile device with the `runOnServer` front call.	See Running mobile apps on an application server on page 2595.
Extended feInfo front call options for mobile devices (deviceModel, deviceId, freeStorageSpace, iccid, imei, ppi, windowSize, and so on).	See feInfo on page 1893.
New `materialFABType` and `materialFABActionList` style attributes for Window class, to control the FAB button on devices following material design guidelines.	See Floating action button on Android devices on page 1286.
Front call to display a box controlling debug settings on GMA.	See showSettings (Android) on page 1941.
Push notification APIs for Google Cloud Messaging (GMA) and Apple Push Notification Service (GMI), with new predefined actions (`notificationpushed`).	See Push notifications on page 2599.
Command line tools to build mobile apps.	See Building Android apps with Genero on page 2574, Building iOS apps with Genero on page 2586.
Automatic FGLAPPDIR environment variable (defining the path to the *appdir*), and automatic FGLDIR environment variable, when executing on mobile devices.	See FGLAPPDIR on page 181, FGLDIR on page 181, Setting environment variables in FGLPROFILE (mobile) on page 170.
Front calls to take or choose videos on mobile devices.	See chooseVideo on page 1927, takeVideo on page 1939 front calls.

Table 6: Experimental features

Overview	Reference
Stacked form definition in .per files with the new STACK container, for mobile programming.	See Stack-based layout on page 1017, STACK container on page 914.

General

These topics provide an introduction to the Genero Business Development Language

- Documentation conventions on page 22
- General terms used in this documentation on page 23
- Introduction to Genero BDL programming on page 24
- Frequently asked questions on page 85

Documentation conventions

Learn about documentation conventions regarding syntax, warnings, code examples, and enhancement references.

- Syntaxes on page 22
- Warnings on page 22
- Code examples on page 23
- Enhancement references on page 23

Syntaxes

The term *syntax* is global and indicates the way to use a product function.

For example, it can be used to describe a language instruction or a command-line tool:

```
CALL function ( [ parameter [,...] ]  )
   [ RETURNING variable [,...] ]
```

Language keywords are written in uppercase.

Variable elements in a syntax definition are written in *italic*.

Wildcard characters in syntax definitions are marked with an underscore:

Table 7: Wildcard characters

Wildcards	Description
[*e*]	Square braces indicate an optional element in the syntax.
[*e1* | *e2* ...]	Square braces with pipe indicate an optional element to be selected from the list.
{ *e1* | *e2* ... }	Curly braces with pipe separator indicate a mandatory element the be selected from the list.
[...]	Indicates that the previous element can appear more than once.
[,...]	Previous element can appear more than once, and must be separated by a comma.

Warnings

Warnings are noticeable technical remarks, describing special behavior of the product function you must be aware of.

> **Important:** When a DATE, DATETIME or INTERVAL constant cannot be initialized correctly, it is set to NULL.

Some Genero features are not supported on all back-end or front-end platforms. The following note will warn you about the limitation:

Important: This feature is not supported on mobile platforms.

Important: This feature is only for mobile platforms.

Important: This feature is experimental, the syntax/name and semantics/behavior may change in a future version.

Code examples

Code examples contain code that can be copied as-is.

Code examples appear in the documentation as follows:

```
MAIN
  DEFINE a1 ARRAY[100] OF INTEGER,
         a2 ARRAY[10,20] OF RECORD
         id INTEGER,
...
```

Enhancement references

In some parts of the documentation you can find enhancement reference notes with a number identifying the request in our internal database.

Enhancement reference: BZ#1827

General terms used in this documentation

This documentation uses several terms that must be clarified for a good understanding.

Application	The *application* defines all software components that compose the information system managing a given domain. Usually, the domains covered by programs written in BDL are business oriented.
End user	The *end user* is the person that uses the application; that person works on hardware called the workstation.
Programs	The *programs* are the software components that are developed and distributed by the supplier of the application. Programs typically implement business logic. Programs are executed by the runtime system. Program components are typically p-code modules, forms and additional resource files.
Developer	The *developer* is the person in charge of the conception and implementation of the application components.
Application data	*Application data* defines the data manipulated by the application. It is typically managed by one or more database systems. The application data has a volatile state when loaded in the runtime system, and it has a static state when stored in the database system.

Database	The *database* is a logical entity regrouping the application data. It is managed by the database system.
Database system	The *database system* is the software that manages data storage and searching; it is usually installed on the database server machine and is supported by a tier software vendor.
Development database	The *development database* is the database used in the application development environment.
Production database	The *production database* is the database used on production sites.
Front end	The *front end* is the software that manages the display and input of the user interface on the workstation machine. This component is historically called "the client". It is the software handling the presentation. There are different sort of front-ends available, for desktop workstations (GDC), for web-browsers (GAS), and on mobile devices (GMA/GMI).
Runtime system	The *runtime system* is the software that manages the execution of the programs, where the business logic is processed. The runtime system is also known as the *Dynamic Virtual Machine* (DVM - fglrun).
User interface	The *user interface* defines the parts of the programs that interact with the end user, including interactive elements like windows, screens, input fields, buttons and menus. It is managed by the front-end.
Graphical user interface	The *graphical user interface* (GUI) mode identifies the user interface displayed on a remote machine via a front end. The GUI mode is active when the FGLGUI environment variable is set to 1 or when not set (GUI mode is the default).
Text user interface	The *text user interface* (TUI) mode identifies the user interface displayed on dumb terminals (TTY on UNIX™ or Console Window on MS Windows™). The TUI mode is active when the FGLGUI environment variable is set to 0.
Workstation	The *workstation* identifies the hardware used by the end user to interact with the front end. It can be an dumb terminal, a computer, or mobile device, as long as a front end is available on the hardware.

Introduction to Genero BDL programming

Understand the basics about programming, compiling and deploying an application.

- Overview of Genero BDL on page 25
- Genero BDL concepts on page 26

Overview of Genero BDL

Genero Business Development Language (BDL) is a program language designed to write an *interactive database application*.

A Genero BDL application is a set of programs that handle the interaction between a user and a database. Programs communicate with the database server with Structured Query Language (SQL), and execute interactive instruction controlling application forms, to manage user input.

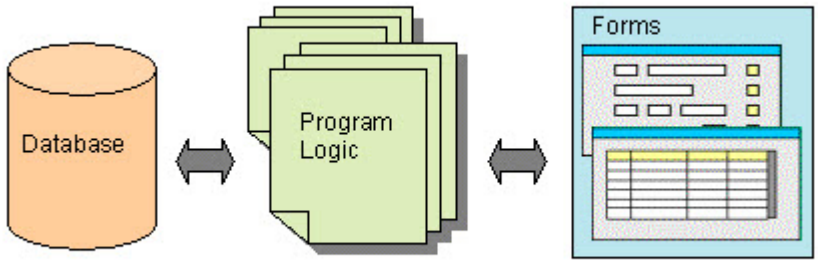

Figure 1: Interactive database applications with Genero

An important feature of the language is the ease with which you can design applications that allow the user to access and modify data in a database. The language syntax includes a set of SQL statements to manipulate the database, powerful interactive instructions that provide simple record input, read-only and read-write record list handling, as well as database query to search the database, by using forms supporting a large variety of graphical widgets.

The program sources are compiled to *p-code* modules, which can be interpreted on different platforms by the *Dynamic Virtual Machine* (the Runtime system).

- Separation of business logic and user interface on page 25
- Portability - write once, deploy anywhere on page 25

Separation of business logic and user interface

Genero BDL separates business logic and the user interface to provide maximum flexibility.

- Intensive use of *XML standards* ensures that user interface is well separated from the program logic.
- *Forms* define the user interface are designed in a simple-to-understand and simple-to-read syntax.
- The *business logic* is written in .4gl source code modules.
- High-level interactive instructions called *dialogs* let you write form controllers in a few lines of code.
- *Action views* (buttons, menu items, toolbar icons) in the form definition can trigger *actions* defined in the business logic.
- The user interface can be *manipulated at runtime*, for example to enable/disable fields and action views dynamically.

Portability - write once, deploy anywhere

Genero application can be deployed for different kinds of display devices, operating systems and database servers, by using the same source code.

Application forms can be displayed with a graphical front-end device based on native desktop frameworks, in web browsers, as well as on simple dumb terminals. Genero programs can be executed on major Operating Systems such as UNIX™, Linux™, Windows™ and Mac OS X® SQL can be performed by IBM® Informix®, or any other major database server such as Oracle DB, IBM® DB2®, Microsoft™ SQL Server, PostgreSQL, Oracle MySQL, Sybase ASE.

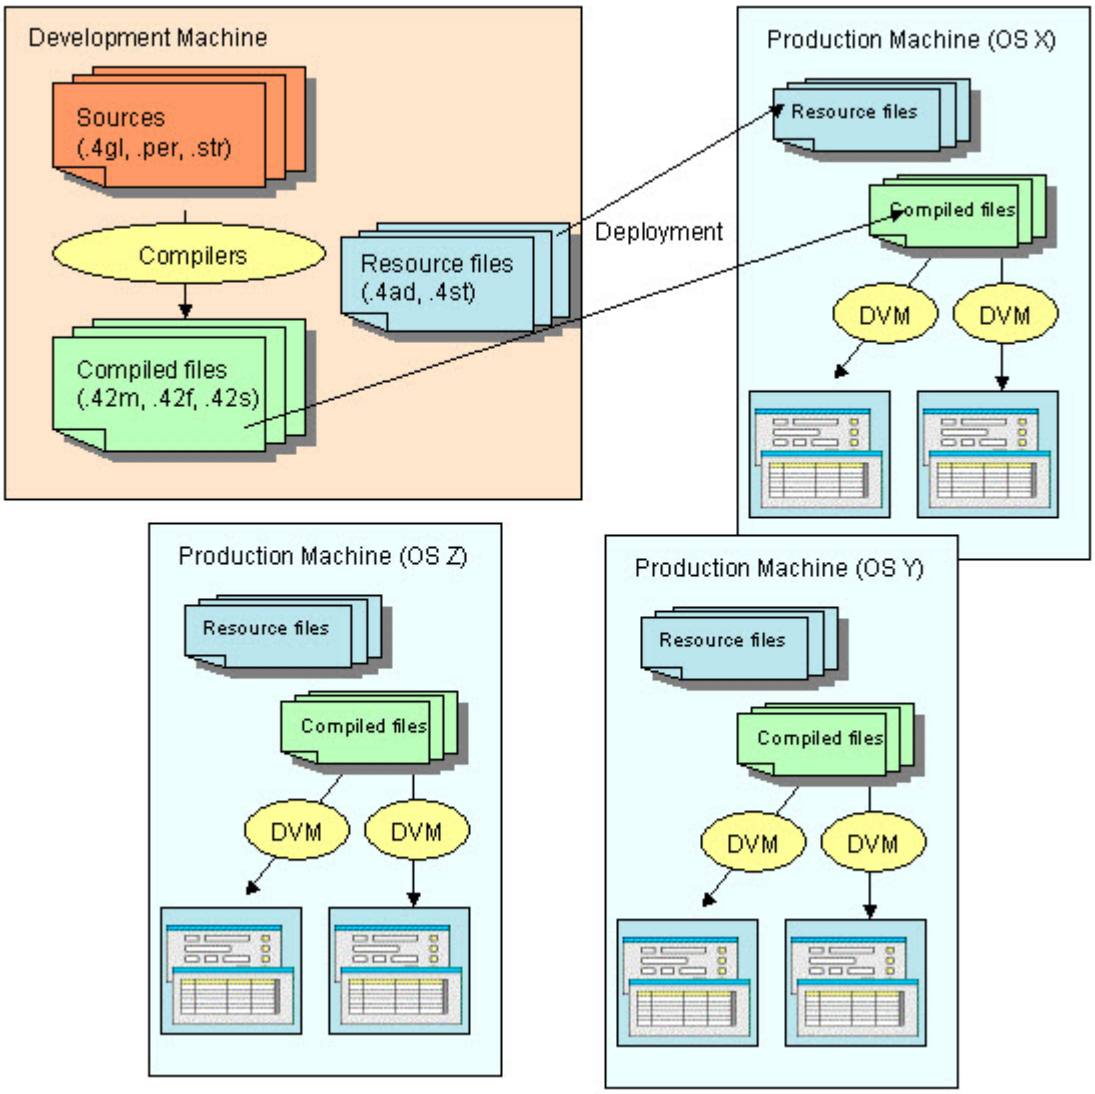

Figure 2: Genero portability

- Extending the language on page 30
- Programming tools on page 30

Genero programs

Genero Business Development Language (BDL) is a programming language based on simple and readable syntax.

The program logic in written in text files with the `.4gl` file extension, called *program source modules*. Module sources are compiled (fglcomp) into p-code modules with the `.42m` file extension, that can be executed by the *runtime system* (fglrun). Application programs are build with a group of `.42m` modules.

Integrated SQL support

A set of SQL statements are part of the language syntax and can be used directly in the source code, as a normal procedural instruction.

The static SQL statements are parsed and validated at compile time. At runtime, these SQL statements are automatically prepared and executed. Program variables are detected by the compiler and handled as SQL parameters. Common SQL statements such as SELECT, INSERT, UPDATE or DELETE can be directly written in the source code, as part of the language syntax:

```
MAIN
  DEFINE n INTEGER, s CHAR(20)
  DATABASE stores
  LET s = "Sansino"
  SELECT COUNT(*) INTO n FROM customer WHERE custname = s
  DISPLAY "Rows found: " || n
END MAIN
```

Dynamic SQL management allows you to execute SQL statements that are constructed at runtime. The SQL statement can use SQL parameters:

```
MAIN
  DEFINE txt CHAR(20)
  DATABASE stores
  LET txt = "SET DATE_FORMAT = YMD"
  PREPARE sh FROM txt
  EXECUTE sh
END MAIN
```

Through the database drivers, the same program can open database connections to any of the supported databases.

XML support

The language provides XML support through different classes, according to the needs.

Genero XML support is provided in two forms:

- For basic XML tasks related to the user interface, use the built-in XML classes.
- For complex XML tasks, and Web Services functions, use the full-featured XML classes provided in the web services extension.

The user interface

The Genero user interface technology is based on the sharing of an abstract representation between the runtime system and the front-end.

When a program starts, the runtime system creates the *abstract user interface* (AUI) tree and passes this tree to the front-end. The front-end renders the abstract element as real graphical objects on the workstation.

When an interaction statement takes control of the application, the tree on the front-end is automatically synchronized with the runtime system tree. Runtime system and front-ends communicate with the *front end protocol*, through the computer network. The AUI tree and the protocol are using XML standards.

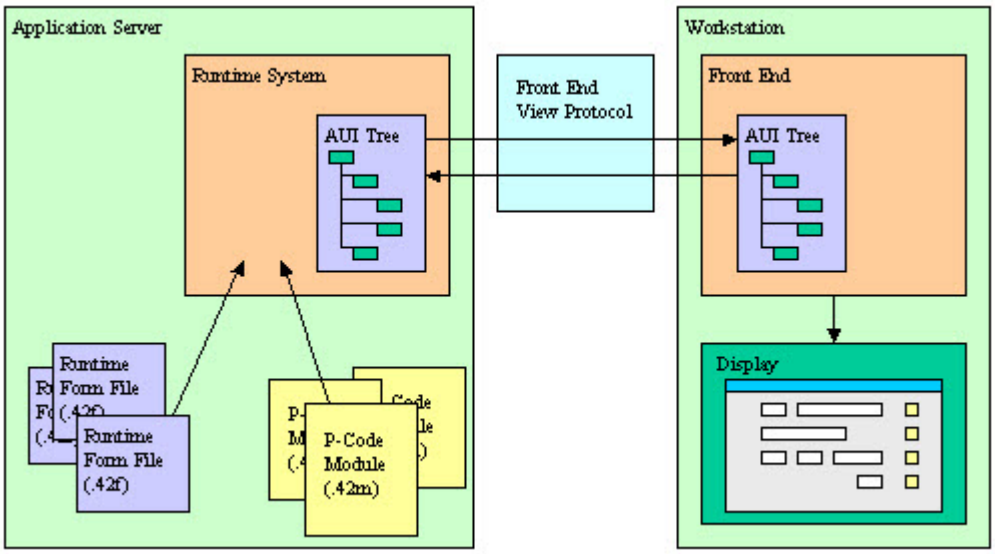

Figure 3: AUI tree synchronization

Resource files describe the appearance (decoration) of some of the graphic objects. Default resource files (`default.4ad`, `default.4st`) are provided and can be customized, or replaced with your own versions.

The elements of the AUI tree can be manipulated at runtime with built-in utilities.

Language library
Several utility packages are provided to ease programming in different domains.

Utility functions and classes are available in different forms, including built-in classes, built-in functions, and loadable modules.

Windows and forms
Programs manipulate window and form objects to define display areas controlled by interactive statements.

The forms are defined in text-based *form specification files* (.per). These form files are transformed by the fglform compiler to produce the *runtime form files* (.42f) that are deployed in production environments. The resulting (.42f) files are XML documents that describe the form elements, enabling portability across display devices. The XML file can also be written directly, or it can be generated or modified from your program at runtime with XML utilities.

Interactive instructions
Control application forms with interactive instructions that perform field input and action handling.

These *interactive instructions* allow the program to respond to user actions and data input. For example the `INPUT BY NAME` block controls a set of form fields where the user can enter data:

```
DEFINE cust_rec RECORD LIKE customer.*
INPUT BY NAME cust_rec.*
    ...
    BEFORE FIELD cust_name
        ...
    ON ACTION print
        ...
END INPUT
```

Interactive instructions can be implemented as modal or parallel dialogs. *Modal dialogs* control a given window, and that window closes when the dialog is accepted or canceled. The window displays on the top of any existing windows which are not accessible while the modal dialog executes. *Parallel dialogs* allow access to several windows simultaneously; the user can switch from on window to the other.

Responding to user actions
Clicking a form button or pressing a key triggers *actions* that can invoke the execution of program of code called *action handlers*. Form elements that can trigger actions are called *action views*.

Action handlers are defined in interactive statements with the `ON ACTION` clause. The code defined in action handler blocks is executed when an action is fired. Action objects are created and linked to action views when such `ON ACTION` handlers are seen by the runtime system. Common action handlers, such as `accept` (dialog validation) and `cancel` (dialog cancellation), are created automatically in accordance with the interactive instruction.

By configuring *action defaults*, you define the default decoration attributes (text, image) and functional attributes (accelerator keys, context menu display) for the action views associated with actions.

Producing reports
The language allows you to implement reports easily, producing different sort of output formats.

Page headers and footers, with page numbers, can be defined. Data can be grouped together, with group totals and subtotals shown. The output from a report can be sent to the screen, to a printer, to a file, or (through a pipe) to another program, and report output can even be redirected to an SAX filter in order to write XML data, that can be transformed into HTML, PDF or any other document format that can be generated from an XML source.

Internationalization
The language supports single-byte and multi-byte internationalization.

The language supports single-byte such as ISO-8859-1, as well as multibyte character sets such as BIG5 or UTF-8.

Length semantics to define variables and manipulate character string data can be based on byte or character units.

Labels and messages can be separated from programs and forms, to customize your application for specific subsets of for the user population, whether it is for a particular language or a particular business segment.

The source files (`4gl`, `per`, `4ad`, and so on) can be written in a specific encoding, however, we recommend you to keep sources in ASCII, and store locale-dependent strings in external strings files (`str`).

Web services support
The Genero Web service library allows to implement web service clients and servers.

Web services are a standard way of communicating between applications over an intranet or Internet. They define how to communicate between two entities:

- A server that exposes services
- A client that consumes services

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.

The Genero Application Server is required to manage your Web Services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

Extending the language

You can extend the language using C or Java™.

Using C

The language can be completed with *C extensions*. This allows you to implement specific function libraries in C, callable from the program modules. C extension libraries are typically used to interface with specific devices, such as barcode scanners or biometric identification devices.

Using Java™

You can instantiate Java™ objects from your programs by using the *Java™ interface*. This allows you to take benefit of the huge class library of Java™.

Programming tools

Genero BDL includes several programming tools in addition to compilers.

A set of useful programming tools is provided, to help you in the application development process, for debugging, optimization and source documentation production.

Compiling a program

You need to compile the source files in order to run the application.

A program can consist of a single source code module, but generally it will be organized in multiple modules, will involve form specification files and perhaps localized string files.

Database schema files are required when you define program data types and variables in the terms of an existing database column or table, by using the `DEFINE ... LIKE` statement.

Before running your application with the runtime system, you need to use compilation tools in order to build the various runtime files.

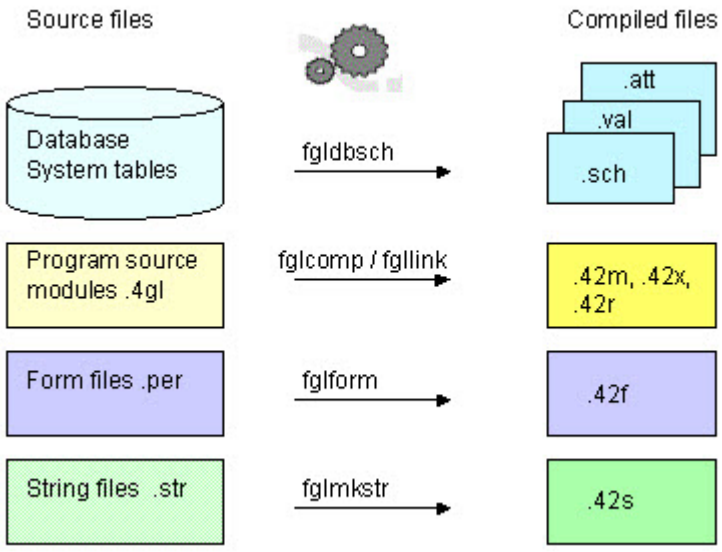

Figure 4: Genero compilation tools

The compiled source code modules can be linked into a .42r program that can be executed by the Runtime System. Compiled modules can also be grouped together into a.42x library that can then be used to build .42r programs.

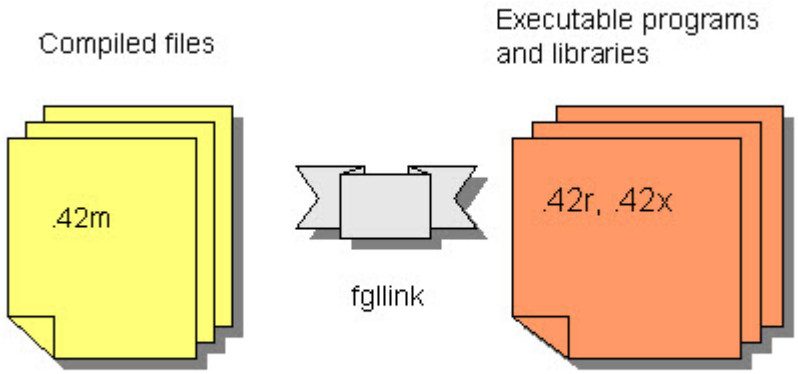

Figure 5: Linking of compiled modules

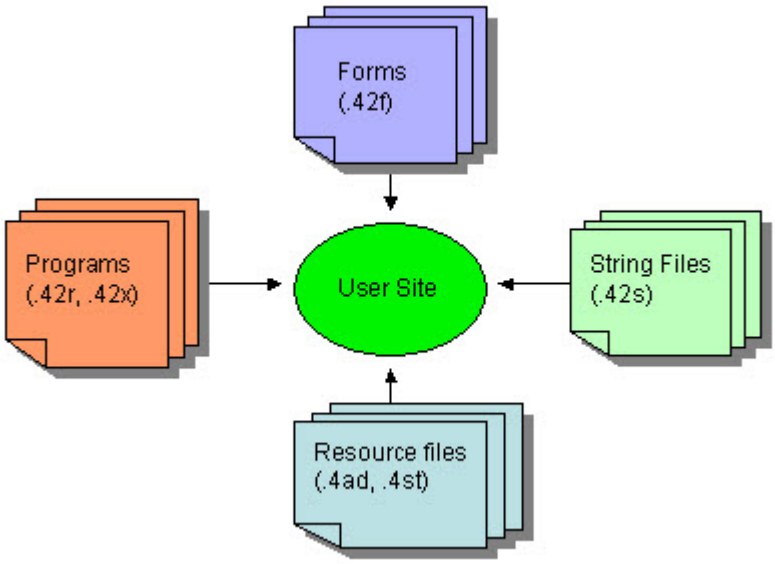
It is also possible to declare what modules are needed by the current module with the `IMPORT FGL` instruction, in order to define the dependency between .4gl modules. When using this language feature, it is no longer required to link modules together to build a program.

```
IMPORT FGL cust_module
MAIN
    DATABASE stores
    CALL cust_module.input_customer()
END MAIN
```

Importing modules is the preferred solution.

Deploying an application
To deploy an application, you must deploy all of the required runtime and resource files. Many (but not all) of these files are compiled from the source files.

Figure 6: Deployment files



These program files must be deployed at the user site:

- `.42r`, `.42x`, `.42m` - Executable programs and libraries, compiled modules
- `.42f` - Runtime form files
- `.42s` - compiled localized string files, if used in your applications
- `.4sm` - your custom Start Menu XML file, if created
- `.4ad`, `.4st` - these default XML files, provided with Genero, must be distributed with the runtime system files; if you have customized these files, or created your own versions, your versions must be deployed instead.

Runtime environment settings

The fglprofile configuration file and environment variables can be used to change the behavior of programs.

Installation

This chapter contains installation and setup instructions.

  - C compiler for C extensions on page 34
  - Java runtime environment on page 34
- Installing Genero BDL on page 35
- Upgrading Genero BDL on page 35
- Platform specific notes on page 36
  - HP-UX configuration notes on page 36
  - IBM AIX configuration notes on page 36
  - Mac OS X configuration notes on page 37
  - Microsoft Windows configuration notes on page 38

Documentation resources for upgrades

Version-specific upgrade guides describe potential compatibility issues with new product releases.

Product improvements can be found in the new features section of this documentation.

Contact you support channel to get the list of corrected defects in the new version.

Software requirements

Before installing, ensure that your system meets the minimum system requirements and additional software.

Supported operating systems

Details of the supported operating systems for the Genero Business Development Language.

Genero Business Development Language is supported on a large brand of operating systems, such as Linux™, IBM® AIX®, HP-UX, SUN Solaris, Mac OS X® and Microsoft™ Windows™.

You must install the software package corresponding to the operating system that you use. For the detailed list of supported operating systems, refer to the relevant installation guide or contact your support center.

Database client software

To connect to a database server, the database client software must be installed on the system where you run the Genero BDL programs.

The Genero runtime system uses database drivers to connect to database servers, as a database client program. Database vendor-specific client software needs to be installed on the system where you run the Genero programs.

Example of database client software:

- IBM® Informix® Client SDK (with ESQL/C)
- IBM® okDB2 Connect® (with CLI)

- Oracle® Client (with OCI)
- Oracle® MySQL client (libmysqlclient)
- Microsoft™ SQL Server Native Client(with ODBC driver)
- PostgreSQL client (libpq)
- FreeTDS ODBC client (libtdsodbc)
- Easysoft™ ODBC client for SQL Server (libessqlsrv)
- SQLite 3.x (libsqlite3)
- SAP Sybase ASE™ OCS client

Database drivers are shipped as shared libraries and require a database client software shared library. The database driver to be selected must correspond to the database client type and version.

C compiler for C extensions

Ensure you have a C compiler and linker to compile your C-Extensions.

Applications using C extensions, need a C compiler and linker to build the C extension library that will be loaded by the runtime system.

C compiler On UNIX™ platforms

On UNIX platforms, you need a cc compiler on the system where you create the C extension libraries. Some systems may not have a C compiler by default. Make sure you have a C compiler on the system.

C compiler On Microsoft™ Windows™ platforms

On Windows platforms, it is mandatory to install Microsoft Visual C++ 2010 (also known as Visual C++ 10.0) on the system where you create the C extension libraries.

C compiler On Mac OS X™ platforms

On Mac OS X platforms, it is mandatory to install XCode 6.1, on the system where you create the C extension libraries.

Java™ runtime environment

Software requirements when using the Java™ Interface

In order to use the Java™ Interface in your application programs, you need the Java software installed and properly configured.

- Install a Java™ Development Kit on development sites (if you need to compile your own Java classes)
- Install a Java™ Runtime Environment on production sites (on the server where your programs are running)

The Java™ classes defined by Genero (`com.fourjs.fgl.lang.*`) are compiled with `javac -source 1.5 -target 1.5`, to be Java™ **1.5+** compatible. Therefore the minimum theoretical Java™ version is **1.5**. However, according to the platform, the minimum required version is **Java™ 1.6** or **1.7**.

The version of the installed Java software can be shown with the command:

```
java --version
```

In order to execute Java byte code, the Genero runtime system uses the JNI interface. The JVM is loaded as a shared library and its binary format must match the binary format of the Genero runtime system. For example, a 64-bit Genero package requires a 64-bit JVM.

When implementing Java classes for Genero Mobile for Android (GMA), check the JDK version required by the Android™ SDK. For more information, see the Android Studio web site.

IPv6 support with Genero

Network interface configuration for IPv6 support

IPv6 basics

IPV6 is the successor for IPv4, to increase the possible number of nodes of a computer network.

IPv6 support for WS clients

A Web Services client program can by default access to a WS server using IPv6. For more details, see Configure a WS client to use IPv6 on page 2464.

> **Note:** Web Services server programs work only in IPv4 to communicate with the GAS (since there is no need for IPv6 on a localhost). It's up to the web server to support IPv6 for the internet access of WS clients.

Installing Genero BDL

Different forms of installation programs are provided, as individual package or bundeled with other Genero components. Refer to the appropriate installation guide for a detailed description of the installation procedure. Do not hesitate to contact your support if you need help.

After installing a package, you should:

1. Set the FGLDIR environment variable to the installation directory.
2. Set the PATH environment variable to (FGLDIR)/bin in order to run compilers and runtime system tools from the command line.
3. Set the database client software environment (INFORMIXDIR, ORACLE_HOME, DB2DIR, SYBASE, PGDIR, LD_LIBRARY_PATH, etc)
4. Set access path to database client software DLLs (PATH), or Unix shared libraries (LD_LIBRARY_PATH, SHLIB_PATH, LIBPATH)
5. According to the database server you want to connect to, set up the correct database driver in FGLPROFILE. The default database driver is Informix®.
6. Depending what rendering mode you want to use (text mode or graphical mode), you will have to set environment variables such as FGLGUI, FGLSERVER, TERM, INFORMIXTERM.
7. If your application uses C-Extensions, a C compiler is required and you must recompile your C-Extensions as shared libraries.

Upgrading Genero BDL

After upgrading to a newer version, follow these next steps:

1. If the new version is a major upgrade (for example, from 2.20 to 2.21), recompile the sources and form files. While recompilation is not needed when migrating to maintenance release versions (for example, from 2.21.01 to 2.21.02), it is recommended to benefit from potential p-code optimizations.
2. If required, you may need to recreate the C-Extension libraries. C extension libraries must be provided as dynamically loadable modules and thus should not required a rebuild. However, if the C-Extension API header files have changed, consider recompiling your C sources. Check *`FGLDIR`*`/include/f2c` for C Extension API header file changes.

Platform specific notes

HP-UX configuration notes

Thread Local Storage in shared libraries

On HP-UX, the shared library loader cannot load libraries using Thread Local Storage (TLS), like Oracle `libclntsh`. In order to use shared libraries with TLS, you must use the LD_PRELOAD_ONCE environment variable. For more details, search for "shl_load + Thread Local Storage" on the HP support site.

PostgreSQL on HP-UX LP64

On HP-UX LP64, the PostgreSQL database driver should be linked with the `libxnet.sl` library if you want to use networking. You can force the usage of libxnet by setting the LD_PRELOAD_ONCE environment variable to `/lib/pa20_64/libxnet.sl`.

Java™ Interface

When using the Java™ Interface with the HotSpot JVM on HP/UX:

If you get an error when fglcomp or fglrun try to load the libjvm library, use the LD_PRELOAD environment variable:

```
$ LD_PRELOAD=libjvm.sl
$ export LD_PRELOAD
```

Using LD_PREPLOAD can make other applications fail. LD_PRELOAD should only be set for the runtime system. If you need to run other applications in the same environment as your application programs, you can set the LD_PRELOAD_ONCE or JAVA_PRELOAD_ONCE variable in the shell scripts found in FGLDIR/bin.

IBM® AIX® configuration notes

LIBPATH environment variable

The LIBPATH environment variable defines the search path for shared libraries. Make sure LIBPATH contains all required library directories, including the system library path `/lib` and `/usr/lib`.

Shared libraries archives

On AIX®, shared libraries are usually provided in .a archives containing the shared object(s). For example, the DB2® client library `libdb2.a` contains both the 32-bit (`shr.o`) and the 64-bit (`shr_64.o`) versions of the shared library. Not all products follow this rule; for example Oracle 9.2 provides `libclntsh.a` with `shr.o` on 64-bit platforms, and Informix® provides both `.a` archives with static objects and `.so` shared libraries as on other platforms.

The runtime system database drivers are created with the library archives or with the .so shared objects, according to the database type and version. No particular manipulation is needed to use any supported database client libraries on this platform.

The dump command

On IBM® AIX®, you can check the library dependencies with the `dump` command:

```
$ dump -Hv -X64 libstckp.so
```

Unloading shared libraries from memory

In production environments, AIX® loads shared libraries into the system shared library segment in order to improve program load time. Once a shared library is loaded, other programs using the same library are attached to that memory segment.

Once a shared library is loaded by the system, you cannot copy the executable file unless you unload the library from the system memory. This problem will occur when installing a new version of the software, even if it is installed in a different directory. Since shared libraries will have the same name, AIX® will not allow multiple versions of the same library to load. Therefore, before installing a new version, make sure all shared libraries are unloaded from memory.

The `genkld` command prints the list of shared libraries currently loaded into memory. The `slibclean` command unloads a shared library from the system shared library segment.

POSIX Threads and shared libraries

When using a thread-enabled shared library like Oracle's `libclntsh`, the program using the shared object must be linked with thread support, otherwise you can experience problems (like segmentation fault when the runner program ends). IBM® recommends using the xlc_r compiler to link a program with pthread support.

By default, the runtime system provided for AIX® platforms is linked with pthread support.

Java™ Interface

When using the Java™ Interface with the IBM® Java™ VM (J9VM) on AIX®, you may need to set the path to native shared libraries in the LIBPATH environment variable, if you get `java.lang.UnsatisfiedLinkError` exceptions:

```
$ LIBPATH=$JAVA_HOME/jre/bin:$JAVA_HOME/jre/bin/j9vm:$JAVA_HOME/jre/lib/
ppc64:$LIBPATH
$ export LIBPATH
```

This is required when using Java code that needs to access native code supplied as part of the JRE. For example, without setting LIBPATH to the appropriate path, the JVM cannot find the shared library `libnet.so`.

Using the `-Djava.library.path=`*`path-to-native-library`* java VM option does not seem to help.

Mac OS X configuration notes

DYLD_LIBRARY_PATH denied in OS X 10.11

Starting with Mac OS X 10.11 (El Capitan), if the System Integrity Protection (SIP) is enabled, the DYLD_LIBRARY_PATH environment variable is no longer exported in sub processes. This variable could be used to define the shared library search path for software components used by the Genero runtime system. This was required especially for database client libraries installed in directories other than `/usr/lib` and `/usr/local/lib` (the default location for shared libraries).

As DYLD_LIBRARY_PATH cannot be used, the proper workaround is to install all required shared libraries in `/usr/local/lib`. A good practice is to create the installation directory of the software component in `/usr/local/`*`product/version`*, and create symbolic links to the required shared libraries in `/usr/local/lib`.

> **Important:** You might need to install several shared libraries in `/usr/local/lib`: To make sure that all required libraries are available, check the dependencies with the `otool -L shared-library.dylib` command.

For example:

```
$ mkdir /usr/local/postgresql
$ mkdir /usr/local/postgresql/9.5.1

... install PostgreSQL in /usr/local/postgresql/9.5.1 ...

$ cd /usr/local/lib
$ ln -s /usr/local/postgresql/9.5.1/lib/libpq.5.dylib libpq.5.dylib
$ otool -L /usr/local/lib/libpq.5.dylib
...
```

Java™ Interface

When using the Java Interface, the runtime system is able to find automatically the `libjvm.dylib` according to the JAVA_HOME environment variable.

For more details, see Platform-specific notes for the JVM on page 1566

Microsoft™ Windows™ configuration notes

Microsoft™ Visual C++ version

When using C-Extensions, you need Microsoft™ Visual C++ compiler to compile and link your C sources. Make sure you have installed the software package corresponding to the MSVC version installed on your system. The MSVC version is identified in the software package name.

Checking binary dependencies

Microsoft™ Visual C++ provides the **dumpbin** utility to extract information from a binary file.

Use the **/dependents** option to check for DLL dependencies:

```
C:\ dumpbin /dependents mylib.dll
Microsoft (R) COFF/PE Dumper Version 7.10.3077
Copyright (C) Microsoft Corporation.  All rights reserved.

Dump of file mylib.dll

File Type: EXECUTABLE IMAGE

Image has the following dependencies:

isqlt09a.dll
MSVCR71.dll
KERNEL32.dll

Summary

1000 .data
1000 .rdata
1000 .text
```

Changing the stack size of fglrun

On Windows™ platforms, the fglrun.exe binary has a predefined C stack size. In some rare cases (for example, when programs do deep recursion), the stack size of fglrun.exe binary needs to be changed to avoid a stack overflow. The stack size of fglrun can be changed this permanently by patching the EXE

file with the Microsoft™ Visual C++ **editbin** utility. Check the stack size by running the **dumpbin** utility on fglrun.exe as follows:

```
C:\ dumpbin /headers %FGLDIR%\bin\fglrun.exe
```

Search for the line containing "stack reserve" words in the OPTIONAL HEADER VALUES section:

```
OPTIONAL HEADER VALUES
    ...
    100000 size of stack reserve
```

The stack size is displayed in hexadecimal value. So for example, a value 100,000 means1,048,567 bytes = 1MB.

In order to modify the stack size of fglrun.exe, run the **editbin** utility on fglrun.exe with the /stack option:

```
C:\ editbin /stack:1000000 %FGLDIR%\bin\fglrun.exe
```

See Microsoft™ Visual C++ documentation for more details.

Web Services platform notes

Genero Web Services reference documentation contains a list of platform specific notes to consider. For more details, see Web Services platform specific notes.

Upgrading

These topics talk about what steps you need to take to upgrade to the next release of Genero Business Development Language, and allows you to identify which features were added for a specific version.

- New features of Genero BDL on page 40
- Frequently asked questions on page 85
- Upgrade Guides for Genero BDL on page 90
- Planned desupport on page 139
- Migrating from IBM Informix 4gl to Genero BDL on page 139
- Migrating from Four Js BDS to Genero BDL on page 151

New features of Genero BDL

These topics provide an look back at the new features introduced with each release of the Genero Business Development Language.

- **Product line 3.0x**
  - What's new in Genero Business Development Language, v 3.00 (Maintenance Releases) on page 41
  - What's new in Genero Business Development Language, v 3.00 on page 18
- **Product line 2.5x**
  - What's new in Genero Business Development Language, v 2.51 on page 45
  - What's new in Genero Business Development Language, v 2.50 on page 48
- **Product line 2.4x**

- **Product line 1.1x:**
  - What's new in Genero Business Development Language, v 1.10 on page 84

What's new in Genero Business Development Language, v 3.00 (Maintenance Releases)

This topic lists features added for 3.00 MRs of the Genero Business Development Language.

Important: Please read What's new in Genero Business Development Language, v 3.00 on page 18, for a list of features that were introduced with Genero 3.00 General Availability release.

Table 8: User interface

Overview	Reference
The `standard.openFile` frontcall is now supported with GWC-JS.	See standard frontcall support matrix.
The `dictionariesDirectory` parameter for the `standard.feInfo` frontcall can be used to get the directory where spell checker dictionary files can be uploaded.	See `standard.feInfo` frontcall.

Table 9: Mobile apps

Overview	Reference
Front call to ask user for Android permissions.	See askForPermission (Android) on page 1940 front call.
GMA buildtool clean option to cleanup the scaffold directory in case of interruption or failure in prior build.	See Building Android apps with Genero on page 2574.

Note: The new features listed in this topic are available in the lastest version of the related products. Contact your support channel for more details.

What's new in Genero Business Development Language, v 3.00

This topic lists features added for the 3.00 GA release of the Genero Business Development Language.

Important: Please read also:

- What's new in Genero Business Development Language, v 3.00 (Maintenance Releases) on page 41, for a list of features that were introduced with the Genero BDL 3.00 Maintenance Releases.
- What's new in Genero Business Development Language, v 2.51 on page 45, for a list of features that were introduced with the Genero Mobile 1.0 release.

Table 10: Core language

Overview	Reference
The fglmkext command line tool can build your C Extension library.	See fglmkext on page 1500.
New fglcomp warning for invalid NULL usage in expressions like var==NULL.	See Compiler warning -6636.
C Extension runtime stack introspection (parameter type and actual string value size in bytes).	See Runtime stack functions on page 1602.

Overview	Reference
Temporary file name creation with `os.Path.makeTempName()`.	See os.Path.makeTempName on page 2002.
Attach the debugger to a running program with `fgldb -p process-id`.	See Attaching to a running program on page 1533.
Improved compilation time (`fglcomp` and `fglform`)	See Improved compilation time on page 98.
Datetime-related utility methods.	See util.Datetime.getCurrentAsUTC on page 1951, util.Datetime.format on page 1949, util.Datetime.parse on page 1951.
Date-related utility methods.	See util.Date methods on page 1947.
Interval-related utility methods.	See util.Interval methods on page 1955.

Table 11: User interface

Overview	Reference
Autocompletion in text edit fields with the COMPLETER attribute.	See Enabling autocompletion on page 1274.
Centralization of icon definitions with the FGLIMAGEPATH environment variable.	See Providing the image resource on page 784, FGLIMAGEPATH on page 182, Built-in front-end icons desupport on page 97.
Defining an action for `IMAGE` form items (clickable images).	See Defining action views in forms on page 1276, Defining actions on list columns with images on page 1355, IMAGE item type on page 888.
Resizable `SCROLLGRID` containers (`WANTFIXEDPAGESIZE=NO`).	See WANTFIXEDPAGESIZE attribute on page 994.
Detect window resizing or device orientation change with the `windowresized` predefined action.	See Adapting to viewport changes on page 1003.
Dialog methods to convert the program array row index to the visual index, and the opposite.	See ui.Dialog.arrayToVisualIndex on page 1796, ui.Dialog.visualToArrayIndex on page 1815.
The `ON SORT` dialog control block can be used to execute code when the record list is re-ordered by the user.	See List ordering on page 1356, Populating a DISPLAY ARRAY on page 1372, ON SORT block on page 1091, ui.Dialog.getSortKey on page 1802, ui.Dialog.getSortReverse on page 1802.
`ON TIMER` trigger in dialogs, to execute a block of code at regular intervals.	See Get program control on a regular (timed) basis on page 1255.

Overview	Reference
Dynamic dialog creation.	See Implementing dynamic dialogs on page 1255.
Providing application image resources to Web Components with `ui.Interface.filenameToURI()`.	See Using image resources with the gICAPI web component on page 1430, ui.Interface.filenameToURI on page 1759.
Binding structured ARRAYs in DISPLAY ARRAY and INPUT ARRAY.	See Structured ARRAYs in list dialogs on page 100.

Table 12: SQL databases

Overview	Reference
Support for PostgreSQL 9.4.	See Database driver specification (driver) on page 462.
Support for Sybase ASE 16.x.	See Database driver specification (driver) on page 462.
Support for SQL Server 2008, 2012 and 2014 with FreeTDS driver (using FreeTDS 0.95)	See FreeTDS driver supports SQL Server 2008, 2012, 2014 on page 97.
SQL interruption is now supported with MySQL.	See SQL interruption on page 405.
MySQL VARCHAR(N) can be used when N is greater as 255.	See MySQL VARCHAR size limit on page 95.
MySQL DATETIME can store fractional seconds.	See MySQL DATETIME fractional seconds on page 96.
Maria DB support (V5.5 and V10): Use the dbmmys driver.	See MariaDB support on page 97.
Dynamic cursor built-in class `base.SqlHandle`.	See The SqlHandle class on page 1725.
Native Oracle NUMBER type (without precision/scale) can be extracted by fgldbsch.	See Oracle DB NUMBER type on page 95.
Serial emulation based on triggers and sequences with SQL Server 2012 and +.	See SERIAL data types on page 606.
PostgreSQL connection string option specification in the `source` parameter.	See Database source specification (source) on page 461, Prepare the runtime environment - connecting to the database on page 684.

Table 13: Web Services

Overview	Reference
Flushing immediately the response of a web service operation with `com.WebServicesEngine.flush`.	See com.WebServiceEngine.Flush on page 2026.

Overview	Reference
Base64 / Hexadecimal / Digest methods using a specific character set for string data.	See security.Base64.FromStringWithCharset on page 2282, security.Base64.ToStringWithCharset on page 2285, security.HexBinary.FromStringWithCharset on page 2288, security.HexBinary.ToStringWithCharset on page 2290, security.Digest.AddStringDataWithCharset on page 2293.
`com.WebServiceEngine` option `server_readwritetimeout` to define a server socket read/write timeout.	See Web Services changes on page 93, WebServiceEngine options on page 2032.
IPv6 support for Web Services clients.	See Configure a WS client to use IPv6 on page 2464.
Specific APIs for Apple Push Notification Service support.	See The APNS class on page 2095, com.TCPRequest.setKeepConnection on page 2091, com.TCPRequest.doDataRequest on page 2087, com.TCPResponse.getDataResponse on page 2093, Push notifications on page 2599.
Methods to perform RESTful requests using files on disk.	See com.HTTPServiceRequest.readFileRequest on page 2046, com.HTTPServiceRequest.sendFileResponse on page 2048, com.HTTPRequest.doFileRequest on page 2058, com.HTTPResponse.getFileResponse on page 2073, com.HTTPPart.getAttachment on page 2080, com.HTTPPart.CreateAttachment on page 2080.
FGLPROFILE entries to define XML Signature and XML Encrypted data prefix: `xml.signature.prefix` and `xml.encrypted.prefix`.	See XML configuration on page 2514.
SOAP fault handling works now when HTTP error 200 is returned by the server.	See SOAP fault handling in client stub on page 93.
Client stub multipart supports now optional parts.	See Optional multipart handling in client stub on page 94

Table 14: Mobile apps

Overview	Reference
Starting remote applications from a mobile device with the `runOnServer` front call.	See Running mobile apps on an application server on page 2595.

Overview	Reference
Extended feInfo front call options for mobile devices (deviceModel, deviceId, freeStorageSpace, iccid, imei, ppi, windowSize, and so on).	See feInfo on page 1893.
New `materialFABType` and `materialFABActionList` style attributes for Window class, to control the FAB button on devices following material design guidelines.	See Floating action button on Android devices on page 1286.
Front call to display a box controlling debug settings on GMA.	See showSettings (Android) on page 1941.
Push notification APIs for Google Cloud Messaging (GMA) and Apple Push Notification Service (GMI), with new predefined actions (`notificationpushed`).	See Push notifications on page 2599.
Command line tools to build mobile apps.	See Building Android apps with Genero on page 2574, Building iOS apps with Genero on page 2586.
Automatic FGLAPPDIR environment variable (defining the path to the *appdir*), and automatic FGLDIR environment variable, when executing on mobile devices.	See FGLAPPDIR on page 181, FGLDIR on page 181, Setting environment variables in FGLPROFILE (mobile) on page 170.
Front calls to take or choose videos on mobile devices.	See chooseVideo on page 1927, takeVideo on page 1939 front calls.

Table 15: Experimental features

Overview	Reference
Stacked form definition in .per files with the new STACK container, for mobile programming.	See Stack-based layout on page 1017, STACK container on page 914.

What's new in Genero Business Development Language, v 2.51

This topic lists features added for the 2.51 release of the Genero Business Development Language.

> **Important:** Most of the new features of BDL 2.51 have been added for Genero Mobile. The features designed for Genero Mobile may not be supported by desktop and web-browser front ends in the coming releases.

Genero Mobile V 1.0 (FGL 2.51.06)

Table 16: Core language

Overview	Reference
The channel methods `openServerSocket()` and `readOctets()`	See base.Channel.openServerSocket on page 1713, base.Channel.readOctets on page 1715.
The `sort()` method of ARRAY variables.	See DYNAMIC ARRAY.sort on page 1700.

Overview	Reference
Remote debugging through network TCP socket	See Debugging on a mobile device on page 1534.
Datetime-related utility methods.	See util.Datetime methods on page 1949.
String-related utility methods.	See util.Strings methods on page 1956.
Write to stdout with `om.XmlWriter.createFileWriter(NULL)`.	See om.XmlWriter.createFileWriter on page 1878.

Table 17: Core language (mobile apps)

Overview	Reference
FGLPROFILE settings to define environment variables	See Setting environment variables in FGLPROFILE (mobile) on page 170.
The method `base.Application.isMobile()`	See base.Application.isMobile on page 1706.
FGL Java class to access Android™ JVM context	See Standard Java and Android library usage on page 1587.
VCard utility functions.	See vCard utility functions (IMPORT FGL VCard) on page 1679.

Table 18: User interface

Overview	Reference
Dialog-level action attribute definitions with `ON ACTION` *name* `ATTRIBUTES()`.	See Configuring actions on page 1318.
URL-based Web Components	See Using a URL-based web component on page 1419.
The `DATETIMEEDIT` form item type	See DATETIMEEDIT item type on page 884.
New `ON SELECTION CHANGE` control block.	See Multiple row selection on page 1381.

Table 19: User interface (mobile apps)

Overview	Reference
`START DIALOG` / `TERMINATE DIALOG` / `fgl_eventLoop()`	See Understanding parallel dialogs on page 1199.
Window `TYPE` attribute in `OPEN WINDOW` instruction.	See Window types on page 777.
`DISPLAY ARRAY` attributes for list views handling: `ACCESSORYTYPE`, `DETAILACTION`, `DOUBLECLICK`.	See Using tables on mobile devices on page 1362.
The `DISCLOSUREINDICATOR` action attribute.	See DISCLOSUREINDICATOR action attribute on page 1328

Overview	Reference
The `ROWBOUND` action attribute.	See ROWBOUND action attribute on page 1329
The `KEYBOARDHINT` form field attribute.	See KEYBOARDHINT attribute on page 973.
List filter with `DISPLAY ARRAY` dialog.	See Reduce filter on page 1358.
Method `ui.Interface.getFrontEndName()` can now return `GMI` or `GMA`	See ui.Interface.getFrontEndName on page 1761.
Front-end functions for Genero Mobile (GMA / GMI)	See Genero Mobile common front calls on page 1925, Genero Mobile Android front calls on page 1940, Genero Mobile iOS front calls on page 1945.
Toolbar style attribute `iosStretchSeparator`, to stretch item separators on iOS device toolbars.	See Toolbar style attributes on page 838.
Navigation bar button colors and background colors for iOS device (`iosTintColor` , `iosNavigationBarTintColor`, `iosToolBarTintColor`, `iosTabBarTintColor`) - provided as Window class style attributes.	See Window style attributes on page 839.

Table 20: SQL databases

Overview	Reference
Simplified database driver specification	See New database driver name specification on page 102.
Support for SQL Server 2014	See Database driver specification (driver) on page 462.
Support for Oracle Database 12c	See Database driver specification (driver) on page 462.
Support for PostgreSQL 9.3	See Database driver specification (driver) on page 462.
Better support for DATETIME types with SQLite	See DATETIME types with SQLite on page 103.
`STRING` typed variables can be used in SQL statements.	See STRING on page 206.

Genero Mobile V 1.1 (FGL 2.51.07)

Table 21: Core language (mobile apps)

Overview	Reference
Implementing C-Extensions on iOS / GMI.	See Implementing C-Extensions for GMI on page 1613.
Using Java interface for Android / GMA.	See Executing Java code with GMA on page 1587.
Implementing customer front calls for GMA.	See Implement front call modules for GMA on page 1620.

Overview	Reference
Presentation styles are now supported by mobile front-ends.	See Style attributes reference on page 818.
GMA bundles zxing for Android.	See scanBarCode on page 1937.

Table 22: Web Services (mobile apps)

Overview	Reference
Complete support of Web Services on mobile devices. (WS were partially supported in GM v1.0)	See Web services on page 2400.

Table 23: User interface (mobile apps)

Overview	Reference
Presentation styles are now supported by mobile front-ends.	See Style attributes reference on page 818.
GMA bundles zxing for Android.	See scanBarCode on page 1937.

What's new in Genero Business Development Language, v 2.50

This topic lists features added for the 2.50 release of the Genero Business Development Language.

Table 24: Core language

Overview	Reference
Support for character length semantics to simplify UTF-8 programming.	See Length semantics settings on page 314.
The UTF-8 character set can be used on Microsoft™ Windows™ platforms by setting the LANG environment variable to `.fglutf8`.	See Language and character set settings on page 313.
JSON (JavaScript™ Object Notation) utility classes.	See The util.JSON class on page 1966, The util.JSONObject class on page 1970, The util.JSONArray class on page 1979.
String to `DATETIME` conversion now accepts ISO 8601 format sub-set.	See Data type conversion reference on page 212.
The `base.Channel` method `dataAvailable()`, to check for channel readability.	See base.Channel.dataAvailable on page 1709.
With `IMPORT FGL`, fglcomp now automatically compiles imported modules when needed. To avoid implicit compilation, use the `--implicit=none` option of fglcomp.	See IMPORT FGL module on page 372.
The `--resolve-calls` or `-W implicit` fglcomp compiler options can be used to detected unresolved symbols.	See IMPORT FGL module on page 372.
The fglrun option `--print-imports` can be used to find modules dependencies and use `IMPORT FGL` instead of traditional linking.	See IMPORT FGL module on page 372.

Table 25: User interface

Overview	Reference
Dialog modularization. Declarative `DIALOG` blocks can be defined as module elements and reused with the `SUBDIALOG` keyword of procedural `DIALOG` blocks.	See Structure of a procedural DIALOG block on page 1153.
Form modularization. Use the new `FORM` layout keyword to include a sub-form in the current form specification file.	See Form file structure on page 901.
`CLEAR SCREEN ARRAY` instruction clears the values of all the rows of a form list (`TABLE`, `TREE`, `SCROLLGRID`).	See CLEAR SCREEN ARRAY.
`AUTONEXT` attribute is allowed in `DATEEDIT`, `SPINEDIT` and `TIMEEDIT` fields.	See DATEEDIT, SPINEDIT, TIMEEDIT.
`BUTTONEDIT` item type attribute `NOTEDITABLE`, to disable the field editor.	See NOTEDITABLE attribute on page 976.
`ON CHANGE` fired when selecting a date in `DATEEDIT` calendar or when changing the value of a `TIMEEDIT` widget.	See ON CHANGE block on page 1069.
Presentation style attributes `ringMenuButtonTextHidden` and `actionPanelButtonTextHidden` added to customize the default action view panels.	See actionPanelButtonTextHidden, ringMenuButtonTextHidden.
Presentation style attribute `thinScrollbarDisplayTime` to define the display time of the thin scrollbar when scrolling in fixed screen arrays.	See thinScrollbarDisplayTime
Presentation style attribute `customWidget` to define the widget to be used for a `TEXTEDIT` (and `CHECKBOX` - removed in V3.00).	See TEXTEDIT customWidget.
fglrun options `--start-guilog` and `--run-guilog`, to generate and replay a GUI protocol exchange.	See Front-end protocol logging on page 759.

Table 26: SQL databases

Overview	Reference
The SQLite driver `dbmsqt3xx` is now statically linked with the SQLite library, except on platforms where the SQLite library is usually present such as Linux™ and Mac OS-X™.	See the SQLite adaptation guide.
Database driver for PostgreSQL 9.2: `dbmpgs92x`. This driver is similar to the prior PGS 9.x drivers, it is supported for strict binary compatibility with the PostgreSQL 9.2 client library and is compiled with the 9.2 libpq headers.	See Database driver dbmpgs92x.
Database driver for IBM® DB2® UDB version 10: `dbmdb2Ax`. This driver is similar to the prior DB2® 9.x driver, it is supported for strict binary compatibility with the DB2® 10.x client library and is compiled with the 10.x CLI headers.	See Database driver dbmdb2Ax.
Support for the Oracle `RAW` data type, in order to use the `SYS_GUID()` values generator.	See The RAW data type on page 662.
`FGLPROFILE` entry for MySQL to specify the `my.cnf` client configuration file: `dbi.database.`*`dbname`*`.mys.config`.	See Oracle MySQL / MariaDB specific FGLPROFILE parameters on page 471.

Table 27: Web Services

Overview	Reference
New security library provides classes and methods to support basic cryptographic features. Although added for Genero Web Services, can be used for any Genero application.	See The security package on page 2278.
New signature methods in `xml.Signature` class: `signString()` and `verifyString()`.	See xml.Signature methods on page 2235.
New methods in `xml.CryptoKey`: `loadPublicFromString()` and `savePublicToString()`.	See xml.CryptoKey methods on page 2209.
Support of Diffie-Hellman key-agreement algorithm. It allows two peers to agree on the same symmetric key, the shared secret, without exchanging confidential data.	See The Diffie-Hellman key agreement algorithm on page 2447, Supported kind of keys on page 2221 and Computing the shared secret with Diffie-Hellman on page 2227
HTTP compression support has been added for Genero Web Services.	See HTTP compression on page 2432.
The `com.HTTPRequest.setAutoReply()` method now works for HTTP HEAD method as well as the GET method.	See com.HTTPRequest methods on page 2053.
DOM features: The Genero XML DOM library has been enhanced with new features that can be set with the setFeature() method or retrieved with the getFeature() method. • `load-save-base64-string` - loads and saves an XML document from/to a base64 string • `auto-id-attribute` - sets at document loading all unqualified attributes named ID, id, Id or iD of type ID • `auto-id-qualified-attribute` - sets at document loading all qualified attributes named ID, id, Id or iD of type ID • `enable-html-compliancy` - allows HTML document parsing and modification using the xml.DomDocument API.	See The DomDocument class on page 2104.
Binary support on HTTP layer: The Genero COM library has been enhanced to support transport of binary data via the Genero BYTE data type. On the client side, it is now possible to send and read binary data to/from a server with the following two methods: • `doRequest()` - sends binary data from a BYTE to a HTTP server • `getDataResponse()` - reads binary data from a HTTP server into a BYTE On the server side, it is possible to read and write binary data to a client with following two methods: • `readDataRequest()` - reads binary data from a HTTP client into a BYTE • `sendDataResponse()` - sends binary data from a BYTE to a HTTP client	See The com package on page 2009.

Overview	Reference
Access the HTTP headers request and response in high level web services.	See how to modify your server or use fglwsdl generated global end point at runtime.
The standard API is enhanced with few new methods and a new class called `HTTPPart` to handle the different part in a HTTP request or response at client and server side.	See The HTTPPart class on page 2077, The HTTPRequest class on page 2053, The HTTPResponse class on page 2070, and The HTTPServiceRequest class on page 2036.
The client side is able to generate stubs to support multiple part with Genero Web Services. Support for the server side is not yet provided. **Note:** Starting with version 2.50.25, when generating client stubs managing multipart, you will get extra input and/or output variables called `AnyInputParts` and `AnyOutputParts`, defined as a `DYNAMIC ARRAY` of `com.HTTPPart` objects. These arrays may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program, to handle those dynamic arrays in any functions calling such stubs. See Client stubs managing multipart changes on page 109.	See Multipart in the client stub on page 2460 and SOAP multipart style requests in GWS on page 2434.
FGLPROFILE HTTPS configuration details no longer needed to perform HTTPS communication. A default SSL configuration is now generated automatically.	See HTTPS configuration on page 2440.
Creating URL base that applies to multiple server applications by using a wildcard in the URL, allowing for a shared server configuration (such as authentication and HTTPS).	See Wildcards in the URL base on page 2517.

What's new in Genero Business Development Language, v 2.41

This topic lists features added for the 2.41 release of the Genero Business Development Language.

Table 28: User interface

Overview	Reference
The `datatypeHint` style attribute (for Edit item types) and `nativeLook` style attribute (for CheckBox item types) have been added for use by the GWC for HTML5 front end. **Important:** In 2.50, the `nativeLook` attribute is renamed `customWidget`.	See Edit style attributes on page 826 and CheckBox style attributes on page 822.

What's new in Genero Business Development Language, v 2.40

This topic lists features added for the 2.40 release of the Genero Business Development Language.

Table 29: Core language

Overview	Reference
The NVL() operator allows you to write the equivalent of an IF *expr* IS NOT NULL THEN RETURN *expr* ELSE RETURN *default* END IF statement in a single scalar expression.	See NVL() on page 242.

Overview	Reference
The IIF() allows you to write the equivalent of an IF bool-expr THEN RETURN *true-value* ELSE RETURN *false-value* END IF statement in a single scalar expression.	See IIF() on page 243.
A new global program option has been added, OPTIONS SHORT CIRCUIT, to instruct the runtime system to evaluate Boolean expressions by using the *short-circuit evaluation* (also called *minimal evaluation*) method.	See OPTIONS (Compilation) on page 378 and Controlling semantics of AND / OR operators on page 379.

Table 30: User interface

Overview	Reference
New ON INSERT, ON APPEND, ON UPDATE and ON DELETE interaction blocks are now allowed in DISPLAY ARRAY dialogs to implement list modification, as an alternative to the traditional INPUT ARRAY dialog. These new triggers simplify the programming of modifiable record lists.	See DISPLAY ARRAY modification triggers on page 1380.
The new find and findnext actions of DISPLAY ARRAY and INPUT ARRAY can be used by the user to search rows where a field value matches the value entered in the find dialog box.	See Find function on page 1357.
The DISPLAY ARRAY dialog now supports a built-in seek feature to quickly find rows where a field value starts with the character typed by the user.	See Keyboard seek on page 1357.
It is now possible to define a summary line for TABLEs by using AGGREGATE form fields. Values can be automatically computed or can be calculated and displayed by program	See AGGREGATE item definition on page 933.
You can now use the terminfo database for text terminal mode (FGLGUI=0) by setting INFORMIXTERM=terminfo.	See Configuring a text terminal on page 762.

Table 31: SQL databases

Overview	Reference
New database drivers are provided.	List of new database drivers: • **dbmntz6x** for IBM® Netezza® ODBC client • **dbmsncB0** for SQL Server 2012 Native client • **dbmesmB0** for SQL Server 2012, with Easysoft ODBC driver • **dbmpgs91x** for PostgreSQL 9.1.x client
The fglcomp compiler now supports SQL ... END SQL blocks for compliance with IBM® Informix® 4GL.	See SQL ... END SQL on page 495.
The Static SQL syntax has been extended to allow the FIRST, LIMIT, SKIP and MIDDLE SELECT projection clause options.	See Static SQL statements on page 486.
The CASE operator is now allowed in Static SQL statements.	See Static SQL statements on page 486.

Overview	Reference
The syntax of DDL (Data Definition Language) statements in Static SQL now allows the IF NOT EXISTS and IF EXISTS clauses.	See Static SQL statements on page 486.
The transaction instruction set has been completed with SAVEPOINT and ROLLBACK WORK TO SAVEPOINT.	See SAVEPOINT on page 483 and ROLLBACK WORK on page 484.
Control shadow column extraction with fgldbsch.	See fgldbsch on page 1502.
A new FGLPROFILE entry parameter has been added to control the ORACLE DATE fetch into CHAR/VARCHAR variables.	See DATE and DATETIME data types on page 657.
Support for the ROWVERSION data type of SQL Server (2008 and +) has been added.	See SQL Server ROWVERSION data type on page 611.

Table 32: Web Services

Overview	Reference
The Genero Web Service engine has been enhanced to support a part of SOAP 1.2 protocol, restricted to the SOAP POST feature only. It does not support the SOAP 1.2 encoding feature, as it is prohibited by the WS-I Basic Profile 2.0. To allow the SOAP 1.2 protocol in your Genero Web service application, call the `setFeature()` method of your web service to enable SOAP 1.2 support. The same Web service can provide both the SOAP 1.1 and SOAP 1.2 protocol. You can also specify the SOAP role of your Genero application if you pass the new `SoapModuleURI` option to the WebServiceEngine `setOption()` method in order to identify the headers the SOAP engine has to understand.	See com.WebService.setFeature on page 2017, com.WebServiceEngine.SetOption on page 2030, and WebServiceEngine options on page 2032.
The Genero Web Service engine has been enhanced to support the WS-Addressing 1.0 specification. To enable WS-Addressing 1.0 specification in your Genero Web service application, call the `setFeature()` method of your web service with "`TRUE`" or "`REQUIRED`" as a parameter.	See com.WebService.setFeature on page 2017.
The Genero Web Service engine has been enhanced to support stateful services. There are two kinds of stateful services: • Based on WS-Addressing: independent from the transport protocol used to to convey the state between the client and the server. • Based on HTTP cookies: depends on the transport protocol to convey the state between the client and the server. To create a stateful web service, call `com.WebService.createStatefulWebService()` with a simple BDL variable or a dedicated W3CEndpointReference record to handle the service state. You can also take a look at WS-Addressing and at the following links for additional information: JAX-WS, Oracle and Stateful based on cookies.	See com.WebService.CreateStatefulWebService on page 2012 and Stateful web services on page 2422.
The Genero Web Service engine has been enhanced to support SOAP faults in RPC and Document style services.	See The com package on page 2009 (com.WebService.createFault

Overview	Reference
On the server side, you can define BDL variables that will be thrown as SOAP faults to a web service client using the SOAP 1.1 or SOAP 1.2 protocol. The `fglwsdl` tool has also been enhanced to generate client and server stubs according to the SOAP fault described in the WSDL. • Method `createFault()` • Method `addFault()` • Method `SetFaultDetail()` • Tool `fglwsdl`	on page 2011, com.WebOperation.addFault on page 2020, com.WebServiceEngine.SetFaultDetail on page 2030) and fglwsdl on page 1503.
The Genero fglwsdl tool generates a new Endpoint record per service in the client stub to configure the client behavior at runtime without the need to modify the generated code. This feature requires regeneration of the client stub and modification of the server location assignment if used in your application (See migration note).	See Change WS client behavior at runtime on page 2453.
The Genero fglwsdl tool has been enhanced to support WS-Addressing 1.0, the SOAP 1.2 protocol and to handle operation faults in SOAP 1.1 and SOAP 1.2. The generated client and server stub will handle WS-Addressing 1.0, SOAP 1.2 protocol and manage soap faults as defined in the WSDL. The following options have been added: Options related to SOAP: • `-soap11` : Generate only client and server stubs supporting the SOAP 1.1 protocol. • `-soap12` : Generate only client and server stubs supporting the SOAP 1.2 protocol. • `-ignoreFaults` : Do not generate soap faults. Options related to WS-Addressing: • `-wsa <yes|no>` : Force support of WS-Addressing 1.0. if `yes`, disable support of WS-Addressing 1.0, if `no`, otherwise support WS-Addressing 1.0 according to the definition in the WSDL. Other options: • `-alias` : Generate FGLPROFILE Logical names in place of URLs for all client stubs. • `-extDir` : Add all schema files located in a directory and ending with .xsd as external schemas. • `-CA` : Validate HTTPS certificate against a certificate authority list.	See fglwsdl on page 1503.
The XML-Signature and XML Encryption API of the XML library have been enhanced with new built-in methods to ease compatibility with the WS-Security specification: • Method `getSignatureMethod()` • Method `getThumbprintSHA1()` • Method `getSHA1()`	See XML security classes on page 2208.

Overview	Reference
The XML library has been enhanced to support XML parsing from PIPE and saving to PIPE: • Method `loadFromPipe()` • Method `saveToPipe()` • Method `readFromPipe()` • Method `writeToPipe()`	See The xml package on page 2103 (xml.DomDocument.loadFromPipe on page 2124, xml.DomDocument.saveToPipe on page 2126, xml.StaxReader.readFromPipe on page 2198, xml.StaxWriter.writeToPipe on page 2182)
The Genero Web Services service library has been enhanced to support global SSL security configuration in `FGLPROFILE` for HTTPS communication. You can now define the SSL certificate and private key to be used for all secured connections with the following entries and still use a dedicated SSL configuration if needed for a particular server. • Entry `security.global.certificate` • Entry `security.global.privatekey` • Entry `security.global.keysubject` (Windows™ only) • Entry `security.global.protocol`	See Web services configuration on page 2509.
A universal unique identifier function, `CreateUUIDString()`, has been added to the COM library. This funciton generates a universal unique identifier in BDL.	This method is desupported since 3.00, use security.RandomGenerator.CreateUUIDString on page 2280 as replacement.
The Genero Web services library has been enhanced with two new serializers: • `xml.Serializer.DomToStax()` converts a Dom node to a Stax writer • `xml.Serializer.StaxToDom()` converts a Stax reader to a Dom node	See xml.Serializer.DomToStax on page 2204 and xml.Serializer.StaxToDom on page 2206.

What's new in Genero Business Development Language, v 2.32

This topic lists features added for the 2.32 release of the Genero Business Development Language.

Table 33: Web Services

Overview	Reference
The COM library enables to intercept high-level web services operation on server side. You can now define three BDL functions via methods of the web service class. They will be executed at different steps of a web service request processing in order to modify the SOAP request, response or the generated WSDL document before or after the SOAP engine has processed it. This helps handle **WS-*** specifications not supported in the web service API. • Method `registerWSDLHandler()` • Method `registerInputRequestHandler()` • Method `registerOutputRequestHandler()`	See The WebService class on page 2009.

Overview	Reference

All three kinds of BDL callback functions must conform to the following prototype:
`FUNCTION CallbackHandler( doc xml.DomDocument )`
`  RETURNING xml.DomDocument`	

What's new in Genero Business Development Language, v 2.30

This topic lists features added for the 2.30 release of the Genero Business Development Language.

Table 34: Core language

Overview	Reference
Genero is now available on Mac OS-X™. You need at least Mac OS X version 10.5. The Operating System code for Mac OS X 10.5 64-bit is m64x105.	See Supported operating systems on page 33.
Platform identifier is now displayed when using the -V option with command-line tools.	See fglrun on page 1493.
The FGLPROFILE environment variable now accepts multiple file specification with an operating-system-specific path separator.	See The FGLPROFILE file on page 164.
The LOAD, UNLOAD and base.Channel class support the "CSV" delimiter specification to read/write files in Comma Separated Value format.	See LOAD on page 524, UNLOAD on page 527 and The Channel class on page 1707
Version **2.30.04** supports now the `fglrun.arrayIgnoreRangeError` entry which can be set to true to force the runtime system to return the first element of an array when the array index is out of bounds.	See Arrays on page 296.
The version **2.30.04** introduces the new `fglrun.mapAnyErrorToError` FGLPROFILE entry. This configuration parameter can be set to true to map the default action of the WHENEVER ANY ERROR exceptions to the action defined for the WHENEVER ERROR exception type.	See Exceptions on page 340.

Table 35: User interface

Overview	Reference
Drag & Drop support in DISPLAY ARRAY for tables or tree views.	See The DragDrop class on page 1827.
A new form item type called WEBCOMPONENT is provided to integrate external Java-Script-based widgets in your forms.	See WEBCOMPONENT item type on page 900.
New ui.Form class method to make a specific form field visible, showing the parent containers automatically. This method can also be used to bring a given folder page to the front, even if the field is not active (i.e. not driven by a dialog).	See ui.Form.ensureFieldVisible on page 1777 and ui.Form.ensureElementVisible on page 1776.
The ERROR and MESSAGE instructions get an additional STYLE attribute, to reference a presentation style and define the rendering with font, color, and position.	See MESSAGE on page 1035.

Overview	Reference
New style for TOOLBAR and TOPMENU elements. See Front-End documentation for more details about possible decoration attributes.	See Toolbars on page 1021 and Topmenus on page 1027.
As with COMBOBOX, the items of a RADIOGROUP are now filled with the values of the INCLUDE attribute, if specified.	See RADIOGROUP item definition on page 943
Identify the last clicked CANVAS item with the drawGetClickedItemId() function of fgldraw.4gl.	See Step by step canvas example on page 1452
The FIELD_TOUCHED() operator and ui.Dialog.getFieldTouched() method accept now a simple star as parameter, in order to check all fields used by the dialog.	See FIELD_TOUCHED() on page 266 and ui.Dialog.getFieldTouched on page 1800.
The JUSTIFY attribute is now supported for all form item types, in order to let you specify both the data justification in the field/cell and the alignment of the table column header.	See JUSTIFY attribute on page 972.
The ui.Dialog.setFieldActive() method takes now a list of fields as parameter, with the "dot-asterisk" notation, like the setFieldTouched() method.	See ui.Dialog.setFieldActive on page 1812.
This new feature is part of the fix for bug **#18224**. When modifying a tree during the dialog execution (for example, when implementing dynamic trees with ON EXPAND / ON COLLAPSE triggers), if you use the ui.Dialog.insertRow(), ui.Dialog.deleteRow() or ui.Dialog.deleteAllRows() methods to modify the node list, the internal tree structure was corrupted. You could safely modify directly the program array with array methods, but multi-range selection flags and cell attributes are not synchronized when doing this. Starting with **2.30.02**, you can now use the ui.Dialog.insertNode(), ui.Dialog.appendNode() and ui.Dialog.deleteNode() methods to manipulate the node list and get additional data like row selection flags and cell attributes synchronized.	See The Dialog class on page 1784.

Table 36: SQL databases

Overview	Reference
New database drivers	List of new database drivers: • **dbmase0Fx** for Sybase ASE 15.x (2.30.01) • **dbmmys55x** for a Mysql 5.5.x client (2.30.01) • **dbmpgs90x** for a PostgreSQL 9.0.x client (2.30.02)
Informix® SMALLFLOAT and FLOAT can now be stored in Oracle native BINARY_FLOAT / BINARY_DOUBLE types.	See SQL adaptation guide for Oracle Database 11, 12 on page 643.
The LOAD, UNLOAD and base.Channel class support the "CSV" delimiter specification to read/write files in Comma Separated Value format.	See LOAD on page 524, UNLOAD on page 527 and The Channel class on page 1707
Use the fgl_db_driver_type() built-in function to identify the target database type.	See fgl_db_driver_type() on page 1646.

Overview	Reference
In order to identify the reason why a database driver cannot be loaded, when setting FGLSQLDEBUG you now get an additional debug message that contains the operating system error message (dlerror())	See .
The fgldbsch tool can now extract database schema from SQLite. However, pay attention to the data types used in SQLite (V 3.6): This database supports some standard type names in the SQL syntax but in reality the types used to store data are very limited. For example, a DATE will be stored as an integer or string (i.e. there is no native DATE type). See SQLite documentation for more details. The fgldbsch tool will extract the schema according to the original type names used to create the table.	See fgldbsch on page 1502.

What's new in Genero Business Development Language, v 2.21

This topic lists features added for the 2.21 release of the Genero Business Development Language.

Table 37: Core language

Overview	Reference
Program module dependency specification with IMPORT FGL instruction.	See The IMPORT FGL instruction

Support for C1 Ming Guo date format modifier: Enable the digit-based Ming Guo date format by adding the C1 modifier at the end of the value set for the DBDATE environment variable:
`$ DBDATE="Y3MD/C1"`
`$ export DBDATE`
Note:
• When using C1, the possible values for the Yn specifier are Y4, Y3, Y2.
• The MDY() function is sensitive to the C1 modifier usage in DBDATE.
• The USING operator supports the c1 modifier as well.
• The C2 modifier to use Era names is not supported.
• Unlike Informix® 4gl, when using negative years, the minus sign is placed over the left-most zero of the year.
• Front-ends may not support the Ming Guo calendar for widgets like DATEEDIT.
	See DBDATE on page 174

Table 38: User interface

Overview	Reference
VALUEMIN/VALUEMAX attributes for the SPINEDIT widget.	See SPINEDIT
New presentation styles attributes for `Window` nodes.	See actionPanelButtonTextAlign, ringMenuButtonTextAlign
New presentation styles attributes for `Image` nodes.	See alignment

Overview	Reference
Numeric keypad decimal separator: The decimal separator defined by DBMONEY or DBFORMAT will be used when pressing the dot key of the numeric keypad.	See DBMONEY and DBFORMAT.
Automatic display of BYTE images: Image data contained in a BYTE variable are now displayed automatically when using a simple DISPLAY BY NAME, DISPLAY TO or when the BYTE variable is used by a dialog instruction. The BYTE data must be located in a file (LOCATE IN FILE "path") or temp file (LOCATE IN FILE).	See IMAGE item definition on page 941.
Paged DISPLAY ARRAY supports undefined initial row count: With this feature, when using a Paged DISPLAY ARRAY, it was mandatory to provide the total number of rows in the result set, which required a `SELECT COUNT(*)` before executing the dialog instruction. The dialog now supports an undefined number of rows, with value -1 in the COUNT dialog attribute.	See Read-only record list (DISPLAY ARRAY) on page 1075.
New ui.Interface.setSize() method to to let you define the initial size of the WCI container window.	See The Interface class on page 1755.
New `formScroll` presentation style attribute for windows.	See Window style attributes on page 839.

Table 39: SQL databases

Overview	Reference
New database drivers	List of new database drivers: • **dbmesmA0** for an EasySoft 1.2.3 client • **dbmpgs84x** for a PostgreSQL 8.4.x client • **dbmoraB2x** for Oracle 11g release 2 (11.2)
New EasySoft driver to connect from UNIX™ to SQL Server. This driver is based on the EasySoft SQL Server ODBC client.	See SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592.
New PostgreSQL 8.4 driver with INTERVAL support: **dbmpgs84x**. This driver converts Informix-style INTERVALs to native PostgreSQL INTERVALs.	See SQL adaptation guide for PostgreSQL 9.x on page 683.

Static SQL column definition supports DEFAULT clause: The syntax of the `CREATE TABLE` and `ALTER TABLE` Static SQL statements allows the `DEFAULT` clause in column definitions.
`CREATE TABLE item (`
`num SERIAL,`
`name VARCHAR(50)`
`DEFAULT '<undefined>'`
`NOT NULL )`
	See Static SQL statements on page 486.

PostgreSQL database driver supports now TEXT/BYTE.	See Large OBject (LOB) types on page 696.

Overview	Reference

New Static SQL syntax for the INSERT statement, which removes the record member defined as SERIAL, SERIAL8 or BIGSERIAL in the schema file:
`SCHEMA mydb`
`...`
`DEFINE record RECORD LIKE table.*`
`...`
`INSERT INTO table VALUES record.*`
	See INSERT on page 489.

The LOAD can now raise error -846 when the input file has a corrupted line (missing or invalid field separator, invalid character set, UNIX/DOS line terminators). You can now easily find the invalid line by setting the FGLSQLDEBUG on page 185 environment variable. The runtime system will display such debug messages with the line number:
`| DBI: LOAD: Corrupted data file,`
`  check line #12345.`
	See LOAD on page 524.

ODBC Character type control with SNC driver is now possible by using simple char or wide-char character strings for ODBC, with the following FGLPROFILE entry:
`dbi.database.<dbname>.snc.widechar =`
`true/false`
	See SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592.

Table 40: Web Services

Overview	Reference
The `fglwsdl` tool supports HTTPS request to retrieve WSDL or XSD on the network. You must specify the X509 certificate and private key using these options: • `-cert` *`filename`* : The *filename* of the X509 PEM-encoded certificate. • `-key` *`filename`* : The *filename* of the X509 PEM-encoded private key associatedto the above certificate. • `-wCert` *`name`* : The *name* of the X509 certificate and its associated private key in the Windows™ key store (Windows™ Only)	See fglwsdl on page 1503.
The `fglwsdl` tool allows http authentication and proxy authentication when requesting a WSDL or an XSD on the network, and supports basic and digest authentication. Two options have been added for authentication. • `-pAuth` *`login password`* : The *login* and the *password* to be used for proxy authentication. • `-hAuth` *`login password`* : The *login* and the *password* to be used for http or https authentication.	See fglwsdl on page 1503.
The `fglwsdl` tool provides a new option that generates: • a client stub entirely based on the DOM API • calls to a request, response and fault callback function per service	See WS client stubs and handlers on page 2456.

Overview	Reference
This option is especially useful when you have to communicate with another web service that requires additional information on the XML request, or when it returns additional information that was not specified in the WSDL. For instance, this is the case if you have to communicate with web services using WS-Security. You can manipulate the XML document in the generated client stub using the XML-Signature or XML-Encryption API to perform the security part by hand before it is sent on the network. The following option has been added for that purpose: • `-domHandler` : Generate function calls to a request, response and fault callback handler, and force the use of DOM in the client stub.	
The COM library is enhanced by a new function called `HandleRequest` to allow low-level and high-level web services on the same server.	See com.WebServiceEngine.HandleRequest on page 2028
The COM library is enhanced to perform automatic reply on HTTP GET request when the server requires HTTP authentication, proxy authentication, or returns an HTTP redirect.	See com.HTTPRequest.setAutoReply on page 2064.
The XML library supports a new option, `xml_useutctime`, to serialize any BDL `DATE` and `DATETIME` using the UTC format requested in most WS-Security exchanges.	See Serialization option flags on page 2207.
The XML library has been enhanced with two APIs in the `CryptoKey` class. Due to security issues, the usage of a direct shared symmetric or HMAC key is not recommended; most secured operations should use a key derived from a common shared key instead. The XML library has been enhanced with two APIs in the CryptoKey class: • Constructor `CreateDerivedKey()` • Method `deriveKey()`	See Derived keys on page 2224.
The COM library has been enhanced with two helper APIs in a new `Util` class. In most Web Service security exchanges, the application must be able to compute digest passwords and use random binary data to detect reply attacks (for instance). The COM library has therefore been enhanced with two helper APIs in a new `Util` class: • Static method `CreateDigestString()` • Static method `CreateRandomString()`	These methods are desupported since 3.00, use security.Digest.CreateDigestString on page 2294 and security.RandomGenerator.CreateRandomString on page 2279
The StAX reader and writer classes have been enhanced with two new methods to set up the XML stream on a TEXT lob. It enables parsing of an XML document in StAX directly from a TEXT with the `readFromText()` method, and creating a new XML document saved directly as TEXT with the `writeToText()` method.	See The StaxWriter class on page 2170 and The StaxReader class on page 2183.
The Genero Web Services library has been enhanced to support XML wildcard attributes. Such wildcard attribute can be set in a XML schema or in a WSDL via the `anyAttribute` tag. It allows additional attributes belonging to other XML schemas in a main XML schema. The additional attributes are not necessarily known by the main schema. The `fglwsdl` tool has been enhanced to recognize the additional attribute and to generate a one-dimensional dynamic array with a	See Attributes to customize XML serialization on page 2517 and The Serializer class on page 2202.

Overview	Reference
new `XMLAnyAttribute` attribute, and the XML Serializer has been enhanced to handle the new `XMLAnyAttribute` during the serialization and deserialization process. A new option called `xs_processcontents` is supported by the XML Serializer to generate the XML schema of such wildcard attributes with a `processContents` tag that defines the way a validator will handle them.	
The package contains a new demo called SimplePKI that demonstrates the usage of XML-Encryption in Genero. It allows several clients to register to a centralized PKI (Public Key Infrastructure) service that generates a unique RSA key-pair per user. The private key is returned to the user during the registration or login, using a derived symmetric key based on the user's password to make it secure. Then any client is able to retrieve the public key of the registered users, and to encrypt XML data only readable by that user. **Note:** This demo could easily be adapted in a real-world application if (for instance) all key-pair are stored in a database for persistence. You can find the demo in the demo/WebServices/simplepki subdirectory or by running the demo application in your installation directory.	N/A.

What's new in Genero Business Development Language, v 2.20

This topic lists features added for the 2.20 release of the Genero Business Development Language.

Table 41: Core language

Overview	Reference
The Java™ Interface allows your programs to use the Java™ library.	See Java™ Interface.
New TINYINT, BIGINT and BOOLEAN data types.	See TINYINT on page 207, BIGINT on page 192, BOOLEAN on page 195.
Private functions: It is now possible to hide a function (or report) to the other modules with the new PRIVATE keyword.	See Understanding functions on page 278.
Automatic source documentation generator.	See Source documentation on page 1517.
The fglcomp compiler has been extended with a new option (`--timestamp`) to write the compilation timestamp to the generated 42m p-code module. If present, the timestamp will be printed when using `fglrun -b`. Use compilation timestamps only if really needed; every new compiled .42m module will be different, even if the source code has not changed.	See fglcomp on page 1497.
The FGLRESOURCEPATH environment variable to define search paths for program resource files like forms.	See FGLRESOURCEPATH on page 184.
New precision math built-in functions for DECIMAL data.	See fgl_decimal_truncate() on page 1647, fgl_decimal_sqrt() on page 1647, fgl_decimal_exp() on page 1647, fgl_decimal_logn() on page

Overview	Reference
	1647, fgl_decimal_power() on page 1648.
Automatic Code Completion with VIM: If you have Vim 7 installed, you can now use .per and .4gl code completion.	See Source code edition on page 1516.

Table 42: Reports

Overview	Reference
The START REPORT instruction now allows to specify the XML SAX Document Handler to process XML output with the TO XML HANDLER clause.	See TO XML HANDLER syntax.
Report definition file generation with fglcomp --build-rdd option.	See See fglcomp on page 1497.

Table 43: User interface

Overview	Reference
Support for typical Tree-View widgets with the new TREE container.	See Tree views on page 1384.
The traditional user interface mode: To simplify migration from Informix® 4GL or Four Js BDS, you can now run applications in traditional mode to render windows as simple boxes, as in the WTK front-end.	See Traditional GUI mode on page 753.
Phantom form fields can be used to define the screen-record or screen-array, but are not used in the LAYOUT section of the form. Phantom fields are especially useful when implementing a TREE container.	See Phantom fields on page 861.
Multi-row selection allows end users to highlight several rows in a list of records.	See Syntax of DISPLAY ARRAY instruction on page 1076.
Built-in sort works now in INPUT ARRAY.	See List ordering on page 1356.
New `contextMenu` action default attribute to allow you to specify whether the menu option is visible in the default context menu. The default value is "yes" - the option is visible whenever the action is visible.	See Action defaults files on page 796.
New `integratedSearch` presentation style attribute for TEXTEDIT fields to enable text search.	See TextEdit style attributes on page 834.
FOLDER elements can now use a "`position`" style attribute to define the position (top, left, right, bottom) of folder tabs.	See Folder style attributes on page 827.
BUTTON form items get a new "`buttonType`" attribute to define the rendering of the button.	See Button style attributes on page 821.
MENU object created with the popup option can be placed with the "`position`" style attribute.	See Menu style attributes on page 829.
Window Menu and Action panel decoration can be customized using the new "`ringMenuDecoration`", "`actionPanelDecoration`" style attributes.	See Window style attributes on page 839.
The new "`tabbedContainer`", "`tabbedContainerCloseMethod`" style attributes can be used to turn on and customize tabbed WCI containers.	See Window style attributes on page 839.
TABLE elements can use the new "`tableType`" attribute to render data in different ways. The new "`resizeFillsEmptySpace`" attribute can be used to define how the last column is resized when the table is resized.	See Table style attributes on page 831.

Overview	Reference
All items with an IMAGE attribute can use the new "`imageCache`" attribute to define if the picture can be cached locally on the front-end.	See Common style attributes on page 818.
New Front-End Functions "`getWindowId`", "`feInfo`", "`launchURL`".	See Standard front calls on page 1889.
Front-End protocol compression can now be disabled with a new FGLPROFILE entry. This is especially useful in fast networks to save processor time.	See GUI protocol compression on page 758.
New built-in functions are now available to control the part of the text that is selected in the current field.	See fgl_dialog_getselectionend() on page 1652, fgl_dialog_setselection() on page 1653.
New IMAGE attribute in form LAYOUT element: The LAYOUT section of a form definition can now use the IMAGE attribute to define the icon to be used for the parent Window. This is especially useful in a Container-based application, to distinguish child programs inside the WCI container.	See LAYOUT section on page 907.
Use the new INFIELD clause in ON ACTION interactive block to automatically enable/disable the action when entering/leaving the specified field.	See Field-specific actions (INFIELD clause) on page 1335.
Getting the current active dialog with ui.Dialog.getCurrent().	See ui.Dialog.getCurrent on page 1792.

Table 44: SQL databases

Overview	Reference
New database drivers.	List of new database drivers: • **dbmsqt3xx** for an SQLite 3 library (2.20.01)
MySQL Driver supports TEXT/BYTE data types.	See SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x on page 625.
To work around conflicts with the Informix® database path specification in DBPATH, use the FGLRESOURCEPATH environment variable.	See FGLRESOURCEPATH on page 184.
Database user authentication callback function can be used to specify a database user and password when the DATABASE instruction cannot be replaced by CONNECT TO.	See User authentication callback function on page 474.
FGLSQLDEBUG output is improved to display and SQL command header with SQL command name and source/line information before executing the underlying ODI driver code. If the driver code crashes or stops the process with an assertion, you can easily identify the last SQL instruction that was executed.	See FGLSQLDEBUG on page 185.

Table 45: Web Services

Overview	Reference
The Genero Web Services XML Library has been improved to support the *XML-Signature* and *XML-Encryption* specifications defined by the W3C (also known as *XML-Security*).	See XML security classes on page 2208.

Overview	Reference
The library enables BDL applications to handle public, private, symmetric or hmac keys and X509 certificates in order to sign XML documents or document fragments, and verify a XML signature against a certificate or key. It also enables the applications to encrypt XML nodes using symmetric keys, and decrypt them back using DOM manipulation. Combined with the COM library, any BDL application can now exchange any XML documents over the Internet in a completely secured manner. The library provides classes for: • Manipulating cryptography keys • Handling X509 certificates for identification • Encrypting and decrypting XML documents, document fragments, or symmetric keys • Signing XML documents, document fragments, or any kind of data, and validating them againstXML signatures	
The Genero Web Services XML library provides APIs to encrypt and decrypt strings with symmetric or RSA public/private keys. These APIs can be used to encrypt/decrypt passwords directly in BDL applications.	See The Encryption class on page 2262 and fglpass on page 1506.
The Genero Web Services provides support for the new `BOOLEAN`, `TINYINT` and `BIGINT` data types. You can use these data types when writing your web service or to customize your BDL RECORDs for XML serialization. The `fglwsdl` tool has been enhanced to generate these new data types automatically when encountered in WSDL files or XML schemas. **Note:** For compatibility issues, the `fglwsdl` tool allows code generation without these new data types by using the option '`-legacyTypes`'.	See Attributes to customize XML serialization on page 2517 and fglwsdl on page 1503.

What's new in Genero Business Development Language, v 2.11

This topic lists features added for the 2.11 release of the Genero Business Development Language.

Table 46: Core language

Overview	Reference
New `-p noln` preprocessor option to remove line number information to get a readable output: `fglcomp -E -p noln mymodule.4gl`	See The preprocessor on page 1522
The `-b` option of `fglrun` has been extended to recognize headers of p-code modules compiled with older versions of Genero.	See Module build information on page 1515
The `fglform` compiler now writes build information in the `.42f` files, to identify on the production site what version was used to compile forms.	See Compiling form files on page 1508

Table 47: User interface

Overview	Reference
The `ui.ComboBox` class has been extended with new methods: `getTextOf()` and `getIndexOf()`.	See The ComboBox class on page 1820
A new FGLPROFILE entry has been added to force the current row to be shown automatically after a sort in a table: `Dialog.currentRowVisibleAfterSort = 1` By default, the offset does not change and the current row may disappear from the window. When this new parameter is used, the current row will always be visible.	See Dialog configuration with FGLPROFILE on page 1251

Table 48: SQL databases

Overview	Reference

Static SQL syntax now supports derived tables and derived column lists in the FROM clause. For example:
`SELECT * FROM`
`(SELECT * FROM customer`
`ORDER BY cust_num)`
`AS t(c1,c2,c3,...)`
See database server documentation for more details about this SQL feature.
Informix® 11 does not support the full ANSI SQL 92 specification for derived columns, while other databases like DB2® do. For this reason, fglcomp allows the ANSI standard syntax.
	See SELECT on page 493

The `SET ISOLATION` statement now supports the newInformix® 11 clauses for the `COMMITTED READ` option:
`SET ISOLATION TO COMMITTED READ`
`[LAST COMMITTED]`
`[RETAIN UPDATE LOCKS]`
When connecting to a non-Informix database, the `LAST COMMITTED` and `RETAIN UPDATE LOCKS` are ignored; other databases do not support these options, and have the same behavior as when these options are used with Informix® 11.
	See SET ISOLATION on page 485

The `CAST` operator can now be used in static SQL statements: `CAST ( expression AS sql-data-type )` Only Informix® data types are supported after the AS keyword.	See Static SQL statements on page 486

In order to execute database administration tasks, you can now connect to Oracle as SYSDBA or SYSOPER with the `CONNECT` instruction:
`CONNECT TO "dbname"`
`USER "scott/SYSDBA"`
	See CONNECT TO on page 477

Overview	Reference
`USING "tiger"`	

Table 49: Web Services - Version 2.11.00

Overview	Reference
The Genero Web Services com library provides the HTTPServiceRequest class to perform low-level XML and TEXT over HTTP communication on the server side. This allows communication at a very low-level layer, to write your own type of web services.	See The HTTPServiceRequest class on page 2036.
XML facet constraints attributes: the Genero Web Services XML library provides 12 new XML attributes to map to simple BDL variables. These attributes restrict the acceptable value-space for each variable in different ways such as: • a minimum or a maximum number of XML characters or bytes. • a strict number of XML characters or bytes. • a minimum inclusive or exclusive value depending on the data type. • a maximum inclusive or exclusive value depending on the data type, • a enumeration of authorized values. • a number of digits and fraction digits. • how white spaces have to be handled. • a regular expression to match. (See Section F of XML Schema Part 2)	See Attributes to customize XML serialization on page 2517.
The fglwsdl tool has been enhanced with the following three new options : • `-disk` : to retrieve locally a WSDL or an XSD with all its dependencies from an URL on the disk • `-noFacets` : to avoid the generation of the new facet constrain attributes (for compatibility) • `-regex` : to validate a value against a regular expression as described in the XML Schema specification	See fglwsdl on page 1503.

Table 50: Web Services - Version 2.11.04

Overview	Reference
The Genero Web Services library provides two new methods in the `WebOperation` class to create One-Way operations in services. A One-Way operation means that the server accepts an incoming request, but doesn't return any response back to the client. There is one method called `CreateOneWayRPCStyle` to create an RPC Style operation, and another one called `CreateOneWayDOCStyle` to create a Document Style operation. For instance, a One-Way operation can be used as a logger service, where a client sends a message to the server, but doesn't care about what the server is doing with it.	See The WebOperation class on page 2018.
The `fglwsdl` tool has been enhanced with the following new options: • `-b`: Generate code from a WSDL using the binding section instead of the service section	See fglwsdl on page 1503.

Overview	Reference
• `-autoNsPrefix`: Determine the prefix for variables and types according to the XML namespace they belong to • `-nsPrefix`: Set the prefix for a variable or a type belonging to the given XML namespace The following options have been changed: • `-o`: If there are several services in one WSDL, they will be generated in the same file with the given base name instead of returning an error • `-disk`: Retrieves and displays all dependencies to the current directory but there are no sub directories any longer. • `-prefix`: Accepts patterns %s, %f and %p	
The Genero Web Services library has been enhanced to support WSDL with circular references. The Genero language doesn't provide a way to define variables or types that refer to themselves. However, to provide better interoperability and a way to handle such circular data, the `fglwsdl` tool now generates variables or types of `xml.DomDocument` type when circular references are detected during the processing of WSDL files. This gives the user the ability to manipulate the circular data by hand, using the XML DOM API.	See The xml package on page 2103.

What's new in Genero Business Development Language, v 2.10

This topic lists features added for the 2.10 release of the Genero Business Development Language.

Table 51: Core language

Overview	Reference
The `TRY/CATCH` block can handle exceptions raised by the runtime system.	See TRY - CATCH block on page 344
`WHENEVER ... RAISE` instructs the runtime system that an uncaught exception will be handled by the caller of the function.	See WHENEVER instruction on page 342

NULL point exceptions can now be trapped as other exceptions: Error -8083 will be raised if you try to call an object method with a variable that does not reference an object (that contains NULL):
`DEFINE x ui.Dialog`
`-- x is NULL`
`CALL x.setFieldActive("fieldname",FALSE)`
`  -- raises -8083`
In previous versions, the above code raised a fatal NULL pointer error.
	See OOP support on page 349

The `base.Channel` class now provides a method to establish a client socket connection to a server, with the new `openClientSocket()` method.	See base.Channel.openClientSocket on page 1710
For debugging purpose, get the stack trace of the program with the `base.Application.getStackTrace()` method.	See base.Application.getStackTrace on page 1706
Before version 2.10, it was only possible to assign a `TEXT` to a `TEXT` variable. It is now possible to assign `STRING`, `CHAR` and `VARCHAR` values to a `TEXT` variable.	See Type conversions on page 211

Overview	Reference
The fglrun `-e` option now supports a comma-separated list of extensions, and `-e` can be specified multiple times: `fglrun -e ext1,ext2,ext3 -e ext4,ext5 myprogram`	See Loading C-Extensions at runtime on page 1601
Get an action event when the user modifies the value of a field, with the predefined `dialogtouched` action, to detect first user modifications.	See Immediate detection of user changes on page 1267
The `parse()` and `toString()` methods are now available for a `om.DomNode` object.	See The DomNode class on page 1839
A `om.DomDocument` object can be created with `createFromString()`.	See The DomDocument class on page 1833
The `TEXT` and `BYTE` data types now support the methods `readFile(fileName)` and `writeFile(fileName)`.	See BYTE on page 193, TEXT on page 208

Table 52: User interface

Overview	Reference
The new `DIALOG` instruction handles different parts of a form simultaneously.	See Multiple dialogs (DIALOG) on page 1144
`HBox` and `VBox` containers can now have a splitter.	See SPLITTER attribute on page 985
The new `DOUBLECLICK` table allows to configure the action to be sent when the user double-clicks on a row.	See DOUBLECLICK attribute on page 962
Define a timeout delay for front-end connections with the following FGLPROFILE entry: `gui.connection.timeout = seconds`	See Configure the GUI connection timeout on page 757
Before version 2.10, it was only possible to assign a `TEXT` to a `TEXT` variable. It is now possible to assign `STRING`, `CHAR` and `VARCHAR` values to a `TEXT` variable.	See Type conversions on page 211
Presentation styles have been extended: • The style attribute "`position`" for Windows™ can be set to "`previous`". • `TEXTEDIT` now has the "`textSyntaxHighlight`" attribute (value can be "`per`", more to come...). • All widgets can now use the "`localAccelerators`" global style attribute to interpret standard navigation and editor keys (like Home/ End) without firing an action that uses the same keys as accelerators.	See Presentation styles on page 799
Get an action event when the user modifies the value of a field, with the predefined `dialogtouched` action, to detect first user modifications.	See Immediate detection of user changes on page 1267
Use the `validate="no"` action default attribute to prevent data validation when executing an action.	See Data validation at action invocation on page 1331

Overview	Reference
Define a minimum width and height for forms with the `MINWIDTH`, `MINHEIGHT` attributes.	See MINHEIGHT attribute on page 975, MINWIDTH attribute on page 975
In `INPUT ARRAY`, avoid the automatic creation of a temporary row with the new `AUTO APPEND = FALSE` dialog attribute.	See INPUT ARRAY temporary rows on page 1378

Table 53: SQL databases

Overview	Reference
Support for SQL Server 2005 Native Client is now provided.	See SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592
The `fgldbsch` tool now supports the `X` conversion code to ignore table columns of a specific type. This is useful for ROWID-like columns such as SQL Server's *uniqueidentifier* columns.	See Data type conversion control on page 365
Before version 2.10, SQL interruption was not supported well for some databases. SQL interruption is now available with all databases providing an API to cancel a long-running query.	See SQL interruption on page 405

Table 54: Web Services

Overview	Reference
The Genero Web Services XML library (`xml`) has been added. This library provides classes and methods to perform: • XML manipulation with a W3C Document Object Model (DOM) API • XML manipulation with a Streaming API for XML (StAX) • Validation of DOM documents against XML Schemas • Serialization of BDL variables in XML • Creation of XML Schemas corresponding to BDL variables	See The xml package on page 2103.
New classes have been added to the Genero Web Services COM library to facilitate low-level XML and TEXT over HTTP and TCP Client communication (`com`). The Genero Web Services `com` library provides two classes, `HTTPRequest` and `HTTPResponse`, to perform low-level XML and TEXT over HTTP communications on the client side. Two more classes, `TCPRequest` and `TCPResponse`, are also provided to perform low-level XML and TEXT over TCP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP or TCP, as well as SOAP over HTTP. Specific streaming methods are also available to improve the communication by sending XML to the network even if the serialization process is not yet finished, as well as for the deserialization process. It is also possible to prevent asynchronous requests from being blocked when waiting for a response, and to perform specific HTTP form encoded requests as specified in HTML4 or XForms1.0.	See The HTTPRequest class on page 2053, The HTTPResponse class on page 2070, The TCPResponse class on page 2092 and The TCPResponse class on page 2092.

Overview	Reference
The `fglwsdl` tool now generates low-level and asynchronous client stubs from the WSDL. The `fglwsdl` tool generates all client stubs with the low-level `HTTPRequest` and `HTTPResponse` classes of the `com` library to perform HTTP communications. The low-level generated stub also takes advantage of the streaming methods, if Document Style or RPC-Literal web services are performed. Streaming is not possible with RPC-Encoded web services, as nodes can have references to other nodes in the XML document, requiring the entire document in memory to perform serialization or deserialization. The `fglwsdl` tool also generates two new BDL functions for each operation of a Web service. These two functions enable you to perform asynchronous web service operation calls by first sending the request, and retrieving the corresponding response later in the application. This allows you to prevent a BDL application from being blocked if the response of a web service operation takes a certain amount of time.	See The HTTPRequest class on page 2053, The HTTPResponse class on page 2070, and fglwsdl on page 1503.
Genero Web Services provides an enhanced `fglwsdl` tool that is able to generate Genero data types from a XML schema. The data types can then be used in your application to be serialized or deserialized in XML. The resulting XML is a valid instance of that XML schema, and validation with a XML validator will succeed.	See fglwsdl on page 1503.

What's new in Genero Business Development Language, v 2.02

This topic lists features added for the 2.02 release of the Genero Business Development Language.

Table 55: Core language

Overview	Reference
Share global variables between the Genero source and the C Extension, by using the `-G` option of `fglcomp`.	See Sharing global variables on page 1611
Customize the runtime system error messages according to the current locale.	See Runtime system messages on page 321
New debugger commands (`ptype`). Avoid switching into debug mode with SIGTRAP (Unix) or CTRL-Break (Windows™) with the new `fglrun.ignoreDebuggerEvent` FGLPROFILE entry.	See The debugger on page 1531

Table 56: User interface

Overview	Reference
Specify a `TABINDEX` of zero to exclude the form item from the tagging list.	See TABINDEX attribute on page 986

Table 57: SQL databases

Overview	Reference
Some common SQL statements have been added to the static SQL syntax, such as `TRUNCATE TABLE`, `RENAME INDEX`, `CREATE` / `ALTER` / `DROP` / `RENAME SEQUENCE`.	See Static SQL statements on page 486
With Oracle, specify the `SELECT` statement producing the unique session identifier which is used for temporary table names.	See Oracle DB specific FGLPROFILE parameters on page 470
To emulate Informix® temporary tables in Oracle, set the `temptables.emulation` parameter to use `GLOBAL TEMPORARY TABLES` instead of permanent tables..	See Using the global temporary table emulation on page 672

What's new in Genero Business Development Language, v 2.01

This topic lists features added for the 2.01 release of the Genero Business Development Language.

Table 58: Core language

Overview	Reference
The `fglcomp` compiler now supports a negative form for `-W` warning arguments.	See Compiling source code on page 1510
When using the `RUN` command, the `ComSpec` environment variable is now used under Windows™ platforms.	See RUN on page 391

Table 59: User interface

Overview	Reference
The layout tag syntax in grids has been extended to support an ending tag to get better control of form layout.	See Layout tags on page 868

Table 60: SQL databases

Overview	Reference
Support for IBM® DB2® V9.x.	See SQL adaptation guide for IBM DB2 UDB 10.x on page 540
Support for PostgreSQL 8.2.x.	See SQL adaptation guide for PostgreSQL 9.x on page 683

What's new in Genero Business Development Language, v 2.00

This topic lists features added for the 2.00 release of the Genero Business Development Language.

Table 61: Core language

Overview	Reference
The runtime system (`fglrun`) now uses shared libraries for database drivers; there is no need to link anymore.	See Database driver specification (driver) on page 462.
The `TYPE` instruction allows to define your own data type structures.	See Types on page 303.

Overview	Reference
File management function library provided as loadable extension.	See The os.Path class on page 1990.
Mathematical function library provided as loadable extension.	See The util.Math class on page 1960.
C extension support has been extended with Informix-like C API functions.	No longer applicable as of Genero 2.51
The runtime system now shares several static elements among all processes, reducing the memory usage. The shared elements are: Data type definitions, string constants and debug information. For example, when a program defines a string containing a long SQL statement, all fglrun processes will share the same string, which is allocated only once.	See Runtime system basics on page 1560.
The `IMPORT` instruction allows to declare a C extension module.	See IMPORT C-Extension on page 371.
New debugger commands (`call`, `ignore`).	See Debugger commands on page 1537.
The `base.Channel` class now has an `isEof()` method to detect end of file.	See Read and write simple lines on page 1720.
Ignoring the CTRL_LOGOFF_EVENT events on Microsoft™ Windows™ platforms.	See Responding to CTRL_LOGOFF_EVENT on page 386.
New built-in function to set an environment variable: `FGL_SETENV()`.	See fgl_setenv() on page 1662.
The XML reader and writer classes have been extended to properly support markup language entities (like HTML's ` `).	See The XmlReader class on page 1871, The XmlWriter class on page 1876.

Table 62: User interface

Overview	Reference
New form item types (i.e. widgets): `SLIDER`, `SPINEDIT`, `TIMEEDIT`.	See ATTRIBUTES section on page 932.
The `WIDTH` and `HEIGHT` attributes can be used for `IMAGE` form items, as a replacement for `PIXELWIDTH`/`PIXELHEIGHT`.	See HEIGHT attribute on page 965, WIDTH attribute on page 999.
New debugger commands (`call`, `ignore`).	See Debugger commands on page 1537.
Presentation styles support now pseudo selectors such as `focus`, `active`, `inactive`, `input`, `display` for fields and `odd` / `even` states for table rows.	See Pseudo selectors on page 802.
New presentation style attributes were added: • `'errorMessagePosition'` can be used for windows to define how the ERROR message must be displayed; • `'highlightTextColor'` for tables allows you to change the color of the selected line; • `'border'` allows you to remove the border of some widgets like button, images;	See Style attributes reference on page 818.

Overview	Reference
• 'firstDayOfWeek' can be used for DateEdit widget to specify the first day of the week in the calendar; • The auto-selection behavior for ComboBoxes and RadioGroup can be changed using 'autoSelectionStart'.	
With X11 or Windows™ TSE environments, you can now automatically start up the front-end with FGLPROFILE entries.	See Automatic front end startup on page 761.
Up to fourth accelerators can now be defined for an action in actions defaults files or in the ACTION DEFAULTS section of form files.	See Defining keyboard accelerators on page 1323.
Specify TTY attributes (COLOR, REVERSE) and conditional TTY attributes (COLOR WHERE) for all type of fields.	See COLOR attribute on page 957, REVERSE attribute on page 981, COLOR WHERE Attribute on page 958.

Table 63: SQL databases

Overview	Reference
Database schema files have been extended to centralize form field definition with the new FIELD item type. **Important:** This feature is deprecated in 2.51 and +.	See FIELD item type.
Call database stored procedures with output parameters with the new IN/OUT keywords.	See EXECUTE (SQL statement) on page 502, Stored procedures on page 441.

Primary key, foreign key and check constraints can be specified in static SQL CREATE TABLE statements:
`CREATE TABLE t1 (`
`col1 INTEGER PRIMARY KEY,`
`col2 CHAR(2),`
`col3 DATE,`
`FOREIGN KEY (col2)`
`REFERENCES t2(col1)`
`)`
	See CREATE TABLE on page 497.

The fgldbsch tool can now extract database tables with LVARCHAR columns. The LVARCHAR type is converted to VARCHAR2(n>255) in the .sch file.	See Data type conversion control on page 365.

Table 64: Web Services

Overview	Reference
You can now choose to use Document Style Service (Doc/Literal) or RPC Literal Style Service (RPC/Literal) with Genero Web Services (GWS), for .NET compatibility and WS-I compatibility (standards defined by the Web Services Interoperability organization). • Document Style Service allows you to exchange complex data structures, such as database tables or word processing documents (MS.Net default)	See Choosing a web services style on page 2483 and Writing a Web server application on page 2473.

Overview	Reference
• RPC Literal Style Service is usually used to execute a function, such as a service that returns a stock option **Note:** RPC/Encoded Style Service (Traditional SOAP section 5) is available for backwards compatibility.	
Genero Web Services now provides a tool, `fglwsdl`, to allow a Genero application that is accessing a Web Service to obtain the WSDL information for the service. It does not matter what language the Web Service is written in. The `fglwsdl` tool is installed in Genero as part of the Genero Web Services package.	See fglwsdl on page 1503.
You no longer need to create a runner that includes the Genero Web Services package. Instead, your applications import the Genero Web Services library named `com`. This library provides classes and methods that allow you to perform tasks associated with creating GWS Servers and Clients, and managing the Web Services.	See The com package on page 2009.
GWS now supports SOAP header management through the `CreateHeader` method in the Web Service class that is part of the Web Services library (`com`).	See The WebService class on page 2009.
HTTPS support has been added on the client side. GWS supports secure communications through the use of encryption and standard X.509 certificates. Based on the OpenSSL engine, new security features allow a Web Services client to communicate with any secured server over HTTP or HTTPS. A new tool is provided, `fglpass`, allowing you to encrypt a password from a standard X.509 certificate, and to decrypt a password you previously encrypted with a certificate. Entries in the `FGLPROFILE` file are used to define the configuration for client security.	See fglpass on page 1506, Encryption, base64 and password agent with fglpass tool on page 2429, and The FGLPROFILE file on page 164.
You can configure a GWS Client to connect via an HTTP proxy by adding an entry in the `FGLPROFILE` file.	See Configure a WS client to connect via an HTTP Proxy on page 2463.
You can define multiple Web Services in a single Genero DVM. When you start the Web Services engine, all registered Web Services are started.	See The WebServiceEngine class on page 2025.
You can remap the location of Genero Web Services using entries in the `FGLPROFILE` file, depending on the network configuration and the access rights management of the deployment site.	See Using logical names for service locations on page 2462.
Serializing Genero data types: you can add optional attributes to the definition of data types. You can use these attributes to map the BDL data types in a Genero Web Services Client or Server application to their corresponding XML data types.	See Attributes to customize XML serialization on page 2517.
The `WSHelper.42m` library file contains internal BDL functions to handle SOAP requests and errors. The file is provided in the `$FGLDIR/lib` directory of the Genero Web Services package, and should be linked into every Genero Web Services Server or Client program.	See Compiling the client application on page 2453 and Compiling GWS server applications on page 2480.

What's new in Genero Business Development Language, v 1.33

This topic lists features added for the 1.33 release of the Genero Business Development Language.

Table 65: Core language

Overview	Reference
New `base.TypeInfo` built-in class to serialize program variables.	See The TypeInfo class on page 1752
The `base.Channel` class now supports a binary mode with the `'b'` option, to control CR/LF translation when using DOS files.	See Line terminators on Windows and UNIX on page 1721

Table 66: User interface

Overview	Reference
Up to three accelerators can now be defined for an action in actions defaults files or in the `ACTION DEFAULTS` section of form files.	See Defining keyboard accelerators on page 1323

Table 67: SQL databases

Overview	Reference
Generic ODBC database driver is now available (code is generic ODBC database driver is now available (code is `odc`).	See Database driver specification (driver) on page 462
MySQL version 5.0.x is now supported.	See SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x on page 625
PostgreSQL version 8.1.x is now supported.	See SQL adaptation guide for PostgreSQL 9.x on page 683
Microsoft™ SQL Server 2005 is now supported.	See SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592
Pre-fetch rows by block with SQL Server to get better performance. Use the following FGLPROFILE entry to specify the maximum number of rows the driver can pre-fetch: `dbi.database.`*`dbname`*`.msv.prefetch.rows = `*`count`* See "Database vendor specific parameters" in Connections for more details.	See SQL Server (Native Client driver) specific FGLPROFILE parameters on page 471

What's new in Genero Business Development Language, v 1.32

This topic lists features added for the 1.32 release of the Genero Business Development Language.

Table 68: Core language

Overview	Reference
New debugger commands (`watch` with condition, `whatis`).	See Debugger commands on page 1537
The preprocessor is now part of the compilers and is always enabled. Preprocessing directives start with an ampersand character (`&`).	See The preprocessor on page 1522

Table 69: User interface

Overview	Reference
New built-in functions to transfer files from/to the front-end.	See fgl_getfile() on page 1656, fgl_putfile() on page 1660

Table 70: SQL databases

Overview	Reference
PostgreSQL version 8.0 is now supported (8.0.2 and higher).	See SQL adaptation guide for PostgreSQL 9.x on page 683

What's new in Genero Business Development Language, v 1.31

This topic lists features added for the 1.31 release of the Genero Business Development Language.

Table 71: Core language

Overview	Reference
C extensions can be loaded dynamically, no need to re-link runner.	See C-Extensions on page 1597
The `FGL_WIDTH()` built-in function computes the number of print columns needed to represent a single or multi-byte character.	See fgl_width() on page 1663

Table 72: User interface

Overview	Reference
GUI protocol compression for slow networks.	See GUI protocol compression on page 758
Interruption handling with SSH port forwarding - only supported with GDC 1.31!	See User interruption handling on page 1252
New method `ui.Form.setFieldStyle()` to set a style for a field.	See ui.Form.setFieldStyle on page 1782
Improved front-end identification when connecting to GUI client.	See Establish a GUI front-end connection on page 755

Table 73: SQL databases

Overview	Reference
MySQL version 4.1.x is now supported, 3.23 is desupported.	See SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x on page 625
Oracle version 10g is now supported.	See SQL adaptation guide for Oracle Database 11, 12 on page 643

What's new in Genero Business Development Language, v 1.30

This topic lists features added for the 1.30 release of the Genero Business Development Language.

Table 74: Core language

Overview	Reference
First version of integrated preprocessor using # sharp syntax for macros. Version 1.32 uses & instead	See The preprocessor on page 1522
Localization support (multi-byte character sets).	See Localization on page 307

The `fglcomp` compiler now adds build information in 42m modules. Compiler version of a 42m module can be checked on site by using the `fglrun` with the `-b` option (line break added for documentation only):
`$ fglrun -b module.42m`
`2004-05-17 10:42:05 1.30.2a-620.10 /devel/tests/module.4gl`
	See Module build information on page 1515

The `fglmkmsg` tool now has the same behavior as other tools like `fglcomp` and `fglform`: If you give only the source file, the message compiler uses the same file name for the compiled output file, adding the `.iem` extension.	See Compiling message files on page 795
New `BREAKPOINT` instruction to stop a program at a given position when using the debugger. It is ignored when not running in debug mode.	See Setting a breakpoint programmatically on page 1536
New assignment operator `:=` has been added to the language. Assign variables directly within expressions: `IF (i:=(j+1))==2 THEN`	See Assignment (:=) on page 259
New `fglcomp` compiler option to detect non-standard SQL syntax: `fglcomp -W stdsql module.4gl`	See SQL portability on page 412
New method `base.StringBuffer.replace()`, to replace a sub-string in a string: `CALL s.replace("old","new",2)` Replaces two occurrences of "old" with "new"...	See base.StringBuffer.replace on page 1745
New methods to read/write complete lines in `base.Channel` built-in class: `readLine()` and `writeLine()`.	See Read and write simple lines on page 1720
The FGLLDPATH variable is now used during program linking.	See Compiling source files on page 1508
The linker option `-O` (optimize) is de-supported (was ignored before). You now get a warning if you use this option.	See Linking programs on page 1512

The `[]` array sub-script operator now returns the sub-array:
`DEFINE a2 DYNAMIC ARRAY`
`  WITH DIMENSION 2 OF INTEGER`
`LET a2[5,10] = 123`
`DISPLAY a2.getLength() -- displays 5`
`DISPLAY a2[5].getLength() -- displays 10`
	See Arrays on page 296

Table 75: User interface

Overview	Reference
New layout rules and form item attributes provide better control of form design.	See Form rendering on page 1002
Decoration attribute can be defined in a presentation style file to set fonts and colors.	See Presentation styles on page 799
Action defaults can be specified in forms in the `ACTION DEFAULTS` section.	See ACTION DEFAULTS section on page 903
New `ui.Dialog` built-in class to provide better control over interactive instructions.	See The Dialog class on page 1784
`COMBOBOX` fields now support `UPSHIFT` and `DOWNSHIFT` attributes, to force character case when `QUERYEDITABLE` is used.	See QUERYEDITABLE attribute on page 979
New presentation style attribute `highlightCurrentRow` for Tables, to indicate if the current row must be highlighted in a specific mode. By default, the current row is highlighted during a `DISPLAY ARRAY`.	See Table style attributes on page 831
New method `appendElement()` for `ARRAYs`, to append an element at the end of a dynamic array.	See Array methods on page 302
New assignment operator `:=` has been added to the language. Assign variables directly within expressions: `IF (i:=(j+1))==2 THEN`	See Assignment (:=) on page 259
The new method `ui.Dialog.setCellAttributes()` lets you define colors for each cell of a table.	See Cell color attributes on page 1380
The `ui.Window` class provides new methods to create or get a form object.	See ui.Window methods on page 1769
When using a dynamic array in `INPUT ARRAY` or `DISPLAY ARRAY`, the number of rows is defined by the size of the dynamic array. The `SET_COUNT()` or `COUNT` attributes are ignored.	See Controlling the total number of rows on page 1350
The new form field attribute `TITLE` can be used to specify a table column label with a localized string.	See TITLE attribute on page 988
New class method `ui.Dialog.setDefaultUnbuffered()` to set the default for the `UNBUFFERED` mode.	See The buffered and unbuffered modes on page 1262
Action defaults are now applied at element creation by the runtime system. In previous versions this was done dynamically by the front-end. Now, changing an action default node at runtime has no effect on existing elements.	See Configuring actions on page 1318
The `DATEEDIT` field type now supports DBDATE/CENTURY settings and the `FORMAT` attribute.	See FORMAT attribute on page 963
New default action 'close' to control window closing: `ON ACTION close`	See Implementing the close action on page 1337
`INPUT ARRAY` using `TABLE` container now needs `FIELD ORDER FORM` attribute to keep tabbing order consistent with visual order of columns.	See Defining the tabbing order on page 1271
New instructions `ACCEPT INPUT` / `ACCEPT CONSTRUCT` / `ACCEPT DISPLAY` to validate a dialog by program. `ON ACTION doit`	See ACCEPT INPUT instruction on page 1072, ACCEPT DISPLAY instruction on page 1095, ACCEPT

Overview	Reference
`ACCEPT INPUT`	CONSTRUCT instruction on page 1139
New dialog attribute `ACCEPT` / `CANCEL` to avoid creation of default actions 'accept' and 'cancel'.	See INPUT instruction configuration on page 1065
New default action 'append' in `INPUT ARRAY`. Allows you to add a row at the end of the list.	See Default actions in INPUT ARRAY on page 1105
New method `ui.Window.createForm()` to create an empty form object in order to build forms from scratch at runtime.	See ui.Window.createForm on page 1770
`TOPMENU` definition in forms now allows attributes in parenthesis.	See TOPMENU section on page 903
The form layout syntax now allows you to specify the real width of form items by using a dash '-' in the layout tag.	See Widget size within hbox tags on page 1016
Important remark: Before build 530 the `MENU` has attached the window when returning from the `BEFORE MENU` actions. Since build 530 the `WINDOW` must exist before the `MENU` statement. So now the `Menu` AUI tree node is available in the `BEFORE MENU` block, but a window opened or made current in the `BEFORE MENU` block will NOT be used.	
Layout `GRID` now accepts HBox tags to group items horizontally.	See Hbox tags on page 875
Form `VERSION` attribute to distinguish form revisions.	See VERSION attribute on page 994
Form layout `SPACING` attribute to define space between widgets.	See SPACING attribute on page 984
Form `DEFAULT SAMPLE` instruction to define a default sample attribute for all form fields.	See INSTRUCTIONS section on page 950
New form item attributes: `SAMPLE`, `JUSTIFY`, `SIZEPOLICY` ...	See SAMPLE attribute on page 981, JUSTIFY attribute on page 972, SIZEPOLICY attribute on page 982
To hide form elements by default, that can be shown by the end user by option, use `HIDDEN=USER` as 'hidden to the user by default'.	See HIDDEN attribute on page 965
Individual table columns now have new attribute `UNMOVABLE` to avoid moving.	See UNMOVABLE attribute on page 990
`WANTCOLUMNSANCHORED` replaced by `UNMOVABLECOLUMN` and `WANTCOLUMNSVISIBLE` replaced by `UNHIDABLECOLUMNS`.	See UNMOVABLECOLUMNS attribute on page 990, UNHIDABLECOLUMNS attribute on page 990
Tables now accept a `WIDTH` and `HEIGHT` attribute to specify a size.	See WIDTH attribute on page 999, HEIGHT attribute on page 965
New `RADIOGROUP` attribute to define the orientation of the radio buttons: `ORIENTATION`.	See ORIENTATION attribute on page 977
The `MENU COMMAND` clause now generates action names in lowercase. This means, when you define `COMMAND "Open"`, it will bind to all actions views defined with the name 'open'.	See COMMAND [KEY()] "option" block on page 1054

Overview	Reference
New `ui.Interface.loadTopMenu()` method to load a global `TOPMENU`.	See ui.Interface.loadTopMenu on page 1765
The `ON CHANGE` block is now invoked when the user clicks on a `CHECKBOX`, `RADIOGROUP`, or changes the item in a `COMBOBOX`.	See ON CHANGE block on page 1069
New `DIALOG` keyword to reference the current dialog as a `ui.Dialog` object. This can be used for example to enable/disable fields durint the dialog execution.	See The Dialog class on page 1784

The `ui.Form` built-in class has new methods to handle form elements. The hidden attribute is now also managed at the model level, this allows you to hide form fields by name, instead of using the decoration node.
`CALL myform.setElementHidden("formonly.field1",2)`
`CALL myform.setFieldHidden("field1",2)`
`-- prefix is optional`
	See The Form class on page 1774

New methods are provided in `ui.Interface` to control the MDI children.	See Window containers (WCI) on page 1458
In `INPUT ARRAY`, `CANCEL INSERT` now supported in `AFTER INSERT`, to remove the new added line when needed.	See CANCEL INSERT instruction on page 1120
`TOOLBAR` and `TOPMENU` elements now have the hidden attribute so you can create them and hide the options the user is not supposed to see. **Important:** Hiding a toolbar or topmenu option does not prevent the use of the accelerator of the action. Use `ui.Dialog.setActionActive()` to disable an action.	See ui.Form.setElementHidden on page 1779
New option `NEXT FIELD CURRENT` to gives control back to the dialog instruction without moving to another field.	See Giving the focus to a form element on page 1272

Table 76: SQL databases

Overview	Reference
Support for PostgreSQL 7.4 with parameterized queries.	See SQL adaptation guide for PostgreSQL 9.x on page 683
A MySQL 3.23 driver is now provided for Windows™ platforms (was previously only provided on Linux™).	See SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x on page 625

The `fglcomp` compiler now converts static SQL updates like:
`UPDATE tab SET (c1,c2)=(v1,c2) ...`
to a standard syntax:
`UPDATE tab SET c1=v1, c2=v2 ...`
	See UPDATE on page 490

On Windows™ platforms only, the ix drivers automatically set standard Informix® environment variables with ifx_putenv(). Values are taken	See

Overview	Reference

from the console environment with getenv(). Additional variables can be specified with:
`dbi.stdifx.environment.count = n`
`dbi.stdifx.environment.xx = "variable"`	

What's new in Genero Business Development Language, v 1.20

This topic lists features added for the 1.20 release of the Genero Business Development Language.

Table 77: Core language

Overview	Reference
Integrated debugger with gdb syntax to interface with graphical tools like ddd.	See The debugger on page 1531.
The program profiler can be used to generate statistics of program execution, to find the bottlenecks in the source code.	See The profiler on page 1556.
Internationalize your application in different languages with localized strings, by using the %"string" notation.	See Localized strings on page 327.
The `TERMINATE REPORT` and `EXIT REPORT` can be used in reports to respectively stop a report from outside of the `REPORT` routine, or stop the report from inside the `REPORT` routine.	See TERMINATE REPORT on page 1468, EXIT REPORT on page 1480.
The `fgl_getversion()` function returns the version number of the runtime system.	See fgl_getversion() on page 1657.
Static arrays can be passed as parameters: all elements are expanded.	See Static arrays on page 298.
New methods for `StringBuffer` class: `base.StringBuffer.replaceAt()` and `base.StringBuffer.insertAt()`.	See The StringBuffer class on page 1738.
Operators equal (= or ==) and not equal (<> or !=) now can be used with records: All record members will be compared. If two members are `NULL` the result of this member comparison results in `TRUE`.	See DEFINE ... RECORD on page 294.
New `-W` option for fglform to show warnings.	See fglform on page 1495.
`LSTR()` operator, to get a localized string by name. Useful when the localized string identifier is known at runtime only.	See LSTR() on page 253.
`SFMT()` operator, to format strings with parameter placeholders. Useful to localize application messages with parameters.	See SFMT() on page 253.
The `base.StringTokenizer` class can be used to parse strings for tokens.	See The StringTokenizer class on page 1749.
`CONSTANT` language elements can now be defined as `GLOBALS`.	See Constants on page 291.
The `base.Application` class provides an interface to the program properties.	See The Application class on page 1703.
Review of the definition of `base.Channel` class, now based on objects.	See The Channel class on page 1707.

Table 78: User interface

Overview	Reference
Interactive instructions support the UNBUFFERED mode, to synchronise data model and view automatically: When you set a variable, the value is automatically displayed to the field, and when the user fires and action, the field value is automatically assigned to the corresponding program variable.	See The buffered and unbuffered modes on page 1262.
DISPLAY ARRAY can now work in paged mode, to avoid loading a large array of rows, with the ON FILL BUFFER clause.	See Paged mode of DISPLAY ARRAY on page 1374.
Centralize default attributes for actions in ACTION DEFAULTS.	See Configuring actions on page 1318.
Client side settings can now be saved by application name, with a specific API. By default it is the the name of the program.	See ui.Interface.setName on page 1766.
New attribute APPEND ROW = TRUE/FALSE attribute for the INPUT ARRAY instruction, to control the creation of the default append action.	See INPUT ARRAY row modifications on page 1377.
New attribute KEEP CURRENT ROW = TRUE/FALSE for the DISPLAY ARRAY and INPUT ARRAY instructions, to defines if the current row must remain highlighted when leaving the dialog. The default is FALSE.	See Handling the current row on page 1352
You can now define a TOOLBAR in form specification files.	See TOOLBAR section on page 905.
You can now define a TOPMENU in form specification files.	See TOPMENU section on page 903.
The fgl_gethelp() function returns the help text for the given help number.	See fgl_gethelp() on page 1655.
The fgl_set_arr_curr() function changes the current row in DISPLAY ARRAY or INPUT ARRAY.	See Handling the current row on page 1352.
Users can now send an interruption event to the program,to stop long running SQL queries, processing loops and reports.	See User interruption handling on page 1252.
The statusBarType window style attribute to define the statusbar layout.	See Window style attributes on page 839.
The new FIELD ORDER FORM option can be used to follow the new TABINDEX attribute, to define the field tabbing order. FIELD ORDER FORM can also be used at the dialog level as dialog attribute.	See Defining the tabbing order on page 1271.
For COMBOBOX form items, a default ITEMS list is created by fglform when an INCLUDE attribute is used.	See COMBOBOX item type on page 881.
The ON IDLE clause can be used to execute a block of instructions after a timeout.	See Get program control if user inactivity on page 1254.
New logical order of execution for INPUT ARRAY triggers: **1.** BEFORE INPUT **2.** BEFORE ROW **3.** BEFORE INSERT **4.** BEFORE FIELD	See Editable record list (INPUT ARRAY) on page 1098.
New ui.ComboBox class to configure COMBOBOX fields at runtime.	See The ComboBox class on page 1820.

Overview	Reference
`DISPLAY ARRAY` and `INPUT ARRAY` instructions now automatically use two predefined actions `nextrow` and `prevrow`, which allow binding action views for navigation.	See Predefined actions on page 1338.
`ON CHANGE` field trigger can be used to detect field modification. Useful for fields such as `CHECKBOX` and `COMBOBOX`.	See Reacting to field value changes on page 1267.
Program icon definition with `ui.Interface.setImage()`.	See ui.Interface.setImage on page 1766.
`LABEL` fields can now have a `FORMAT` attribute.	See LABEL item type on page 890.
Front-end function calls allow to execut code on the front-end side with the `ui.Interface.frontCall()` method.	See Front calls on page 395.
New ui.Form built-in class to handle forms.	See The Form class on page 1774.
New `ON ROW CHANGE` clause in `INPUT ARRAY`, executed when if at least one value in the row has been modified, and the user moves to another row or validates the dialog. The `ON ROW CHANGE` block is executed before the `AFTER ROW` block.	See ON ROW CHANGE block on page 1110.
`MENU` instruction now supports `ON ACTION` clause, to write abstract menus as simple action handlers.	See Ring menus (MENU) on page 1048.
New 'help' predefined action, to start help viewer for `HELP` clauses in dialog instructions.	See Predefined actions on page 1338.

Table 79: SQL databases

Overview	Reference
SQL Server driver now supports the TINYINT data type.	See NUMERIC data types on page 602.
The fglcomp compiler supports now ANSI outer join syntax in SQL statements (`LEFT OUTER JOIN`), to replace the Informix specific `OUTER()` syntax.	See SELECT on page 493.
`FOREACH` that raises an error no longer loops infinitely.	See FOREACH (result set cursor) on page 512.
New `SQLSTATE` and `SQLERRMESSAGE` registers, to give SQL execution information.	See SQL error identification on page 402.

What's new in Genero Business Development Language, v 1.10

This topic lists features added for the 1.10 release of the Genero Business Development Language.

Table 80: Core language

Overview	Reference
The language supports now built-in classes, a new object-oriented way to program in BDL.	See OOP support on page 349.
`CONSTANT` keyword to define constants in your programs.	See Constants on page 291.

Overview	Reference
The language now supports dynamic arrays with automatic memory allocation.	See Dynamic arrays on page 300.
A set of XML Utilities are provided in the runtime library as built-in classes.	See The om package on page 1833.
The `STRING` data type can be used to manipulate character strings without a length limit as with `CHAR`/`VARCHAR`.	See STRING on page 206.

Table 81: User interface

Overview	Reference
The Dynamic User Interface is the major new concept in Genero. It is the basement for the new graphical user interface.	See User interface basics on page 747.
Compared to classic IBM Informix 4gl, interactive instructions such as `INPUT`, `DISPLAY ARRAY`, have been extended with new control blocks and control instructions.	See Dialog instructions on page 1034.
Form specification files (.per) support now extended layout definition with the `LAYOUT` section.	See Form definitions on page 769.
Defining Window Containers (a.k.a. MDI) is a simple way to group programs.	See Window containers (WCI) on page 1458.

Table 82: SQL databases

Overview	Reference
The new `SCHEMA` instruction allows you to specific a database schema, without having an implicit connection, when the program executes.	See Database schema on page 355.

Frequently asked questions

The FAQ lists those questions frequently asked when migrating an existing 4GL application to Genero.

- FAQ001: Why do I have a different display with Genero than with BDS V3? on page 85
- FAQ002: Why does an empty window always appear? on page 86
- FAQ003: Why do some COMMAND KEY buttons no longer appear? on page 86
- FAQ004: Why aren't the elements of my forms aligned properly? on page 87
- FAQ005: Why doesn't the ESC key validate my input? on page 88
- FAQ006: Why doesn't the Ctrl-C key cancel my input? on page 88
- FAQ007: Why do the gui.* FGLPROFILE entries have no effect? on page 89
- FAQ008: Why do I get invalid characters in my form? on page 89
- FAQ009: Why do large static arrays raise a stack overflow? on page 89
- FAQ010: Why do I get error -6366 "Could not load database driver drivername"? on page 90

FAQ001: Why do I have a different display with Genero than with BDS V3?

Explanation

Genero Business Development Language (BDL) introduces major graphical user interface enhancements that sometimes require code modification. With BDS V3, application windows created with the `OPEN`

WINDOW instruction were displayed as static boxes in the main graphical window. In the GUI mode of Genero, application windows are displayed as independent, re-sizeable graphical windows.

Solution:
Review the program logic to reduce the number of windows created by the programs. Replace MENU created in specific windows by TOPMENU elements in your forms.

FAQ002: Why does an empty window always appear?

Description

An additional empty window appears when I explicitly create a window with the OPEN WINDOW instruction.

```
MAIN
  OPEN WINDOW w1 AT 1,1 WITH FORM "form1"
  MENU "Example"
    COMMAND "Exit"
      EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

Explanation

In the new standard GUI mode, all windows are displayed as real front-end windows, including the default SCREEN window. When an application starts, the runtime system creates this default SCREEN window, as in version 3. This is required because some applications use the SCREEN window to display forms (they do not use the OPEN WINDOW instruction to create new windows). To facilitate BDS V3 to Genero migration, the runtime system must keep the default SCREEN window creation; otherwise, existing applications would fail if their code was not modified.

Solution

You can either execute a CLOSE WINDOW SCREEN at the beginning of the program, to close the default window created by the runtime system, or use the OPEN FORM + DISPLAY FORM instructions, to display the main form in the default SCREEN window.

Example

```
MAIN
  OPEN FORM f FORM "form1"
  DISPLAY FORM f
  MENU "Example"
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

FAQ003: Why do some COMMAND KEY buttons no longer appear?

Description

When creating a MENU with COMMAND KEY(*keyname*) "*option*" clause, the button for *keyname* is no longer displayed:

```
MAIN
  MENU "Example"
```

```
    COMMAND "First"
       EXIT PROGRAM
    COMMAND KEY (F5) "Second"
       EXIT PROGRAM
    COMMAND KEY (F6) -- Third is a hidden option
       EXIT PROGRAM
  END MENU
END MAIN
```

Explanation

In BDS Version 3, when using the `MENU` instruction, several buttons are displayed for each clause of the type `COMMANDKEY(`*`keyname`*`) "`*`option`*`"`: one for the menu option, and others for each associated key.

When using Genero, for a named `MENU` option defined with `COMMAND KEY`, the buttons of associated keys are no longer displayed (F5 in our example), because there is already a button created for the named menu option. The so called "hidden menu options" created by a `COMMAND KEY(`*`keyname`*`)` clause (F6 in our example) are not displayed as long as you do not associate a label, for example with the `FGL_SETKEYLABEL()` function.

FAQ004: Why aren't the elements of my forms aligned properly?

Description

In my forms, I used to align labels and fields by character, for typical terminal display. But now, when using the new `LAYOUT` section, some elements are not aligned as expected. In this example, the beginning of the field `f001` is expected in the column near the end of the digit-based text of the first line, but the field is actually displayed just after the label "`Name:`":

```
DATABASE FORMONLY

LAYOUT
  GRID {
  01234567890123456789
   Name:             [f001       ]
  }
  END
END

ATTRIBUTES
  f001 = formonly.field1 TYPE CHAR;
END
```

Explanation

By default, Genero displays form elements with proportional fonts, using layout managers to align these elements inside the window. In some cases, this requires a review of the content of form screens when using the new layout management, because the layout is based on new alignment rules which are more abstract and automatic than the character-based grids in Version 3.

In most cases, the fglform compiler is able to analyze the layout section of .per form specification file in order to produce an acceptable presentation, but sometimes you will have to touch the form files to give hints for the alignment of elements.

Solution

In this example, the field `f001` is aligned according to the label appearing on the same line. By adding one space before the field position, the form compiler will understand that the field must be aligned to the text in the first line:

```
DATABASE FORMONLY

LAYOUT
 GRID {
 01234567890123456789
  Name:              [f001       ]
 }
 END
END

ATTRIBUTES
  f001 = formonly.field1 TYPE CHAR;
END
```

In the next example, the fields are automatically aligned to the text in the first line:

```
DATABASE FORMONLY

LAYOUT
 GRID {
                First         Last
   Name:        [f001      ]  [f002       ]
 }
 END
END

ATTRIBUTES
  f001 = formonly.field1 TYPE CHAR;
  f002 = formonly.field2 TYPE CHAR;
END
```

FAQ005: Why doesn't the ESC key validate my input?

Description

The traditional ESC (escape) key does not validate an `INPUT`, it cancels the dialog instead.

Explanation

To follow platform standards (like Microsoft™ Windows™ for example), the ESC key as the standard key to cancel the current interactive statement.

Solution

You can change the accelerator keys for the 'accept' action with action defaults. However, is not recommended to change the defaults, because ESC is the standard key to be used to cancel a dialog in GUI applications.

FAQ006: Why doesn't the Ctrl-C key cancel my input?

Description

The traditional Ctrl-C key does not cancel an `INPUT` statement.

Explanation

To follow platform standards (like Microsoft™ Windows™ for example), the Ctrl-C key is used as the standard key to copy the current selected text to the clipboard, for cut and paste.

Solution

You can change the accelerator keys for the 'cancel' action with action defaults. However, is not recommended to change the defaults, because ESC is the standard key to be used to cancel a dialog in GUI applications.

FAQ007: Why do the gui.* FGLPROFILE entries have no effect?

Description

The `gui.*` and some other FGLPROFILE entries related to graphics no longer have effect.

Explanation

These entries are related to the old user interface. They are no longer supported. In BDS version 3, the `gui.*` entries were interpreted by the front end. As the user interface has completely been redesigned in Genero, some `gui.*` entries have been removed.

Solution:

Review all FGLPROFILE entries used in your current application and verify if there is a replacement.

FAQ008: Why do I get invalid characters in my form?

Description

The application starts, connects to the database and seams to work properly, but strange symbols (rectangles, question marks) are displayed in the forms for non-ASCII characters. The ASCII characters display properly.

Explanation

The is certainly a character set configuration mistake.

Solution

You have probably defined a wrong runtime system locale or the database client locale.

FAQ009: Why do large static arrays raise a stack overflow?

Description

When using very large static arrays (DEFINE a1 ARRAY[10000] OF ...), I get a stack overflow on Windows™ platforms.

Explanation

The runtime system uses the default stack size defined by the C compiler. Because function static arrays are allocated on the C stack, using very large static arrays in functions can result in a stack overflow error.

Solution

Review the program and use dynamic array instead of static arrays.

FAQ010: Why do I get error -6366 "Could not load database driver *drivername*"?

Description

Error **-6366** occurs when the runtime system fails to load the specified database driver.

Explanation

The database driver shared object (.so or . DLL) or a dependent library could not be found.

Solution

Make sure that the specified driver name does not have a spelling mistake. If the driver name is correct, there is probably an environment problem. Make sure that the database client software is installed on the system (Genero does not communicate directly with the database server, you need the client library). Check the UNIX™ LD_LIBRARY_PATH environment variable or the PATH variable on Windows™. These must point to the database client libraries. Another common error is the installation of a database client software of a different object type as the Genero runtime system. For example, if you install a 32 bit Genero version, you must install a 32 bit version of the database client software, the 64 bit version will not work.

Upgrade Guides for Genero BDL

Each upgrade guide is an incremental upgrade guide that covers only topics related to a specific version of Genero. It is important that you read all of the upgrade guides that sit between your existing version and the desired version.

- General upgrade guide on page 90
- 3.00 upgrade guide on page 91
- 2.51 upgrade guide on page 101
- 2.50 upgrade guide on page 106
- 2.40 upgrade guide on page 109
- 2.32 upgrade guide on page 112
- 2.30 upgrade guide on page 113
- 2.21 upgrade guide on page 116
- 2.20 upgrade guide on page 117
- 2.11 upgrade guide on page 122
- 2.10 upgrade guide on page 123
- 2.02 upgrade guide on page 123
- 2.01 upgrade guide on page 123
- 2.00 upgrade guide on page 123
- 1.33 upgrade guide on page 129
- 1.32 upgrade guide on page 129
- 1.31 upgrade guide on page 130
- 1.30 upgrade guide on page 130

General upgrade guide

These topics describe general considerations when upgrading to a new version of Genero BDL.

1. Runtime system and front-end compatibility on page 91
2. P-Code compatibility accross versions on page 91
3. Genero Web Services migration notes on page 91

Runtime system and front-end compatibility
For better compatibility and GUI related bug fixes, use front-end and runtime system with the equivalent version number.

Graphical User Interface new features and bug fixes usually require modifications inside the runtime system (`fglrun`) and front-ends (GDC, GWC, GMA, GMI).

When upgrading the runtime system to the latest version, we strongly recommend that you upgrade to the latest front-end version as well. For example, when upgrading to a runtime system 2.50.xx, upgrade front-ends to the latest available 2.50.xx version.

P-Code compatibility accross versions
P-Code incompatibility (within .42m files) may be introduced from version to version.

Recompilation is only needed when the p-code becomes incompatible. When executing a program with and older p-code version as expected, `fglrun` will raise the error -6201.

Recompile your .4gl sources when upgrading to a new features release. Recompilation is not required when upgrading to a bug-fix release.

Feature and bug-fix releases are distinguished by the product version number. The product version number can be found by executing the `fglrun` command with the `-V` option.

The product version number has the following format: `M.FF.BB`, where `M` stands for the major release number, `FF` is a feature number, and `BB` is the bug-fix number. For example: `2.31.14`.

- A new feature release is identified by the `M.FF` part of the product version number.
- A bug-fix release is idenfitied by the `BB` part of the product version number.

For example, you must recompile your sources when upgrading from 2.50 to 3.00, from 2.40 to 2.50, or from 2.51. to 2.52.

Genero Web Services migration notes
Upgrade notes for Genero Web Services are available in the chapter dedicated to web services programming.

For more details see Migration notes for Genero Web Services.

3.00 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 3.00.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Form definitions for mobile applications on page 92
2. Desupported database drivers on page 92
3. Web Services changes on page 93
4. Oracle DB NUMBER type on page 95
5. Oracle DB scroll cursor emulation removal on page 95
6. MySQL VARCHAR size limit on page 95
7. MySQL DATETIME fractional seconds on page 96

18. Structured ARRAYs in list dialogs on page 100

Form definitions for mobile applications
Genero version 3 supports grid-based layout with all front-ends, and introduces STACK layout.

Support for grid-based and stack-based layout

Before Genero version 3.00 (i.e., with Genero Mobile version 1.1), the GMI front-end could only support a stack-based layout and it was required to create different forms for iOS apps and other front-ends supporting grid-based layout. In fact, to get a stack-based layout, grid-based `.per` forms were automatically transformed on the fly when displayed on the GMI front-end.

Starting with Genero 3.00, all mobile front-end supports now grid-based layout and stack-based layout, and a new STACK layout container was introduced to define stack-based layout forms explicitely. Therefore, you can now use the same form definition for all mobile front-ends, by implementing the layout type of your choice. It is even possible to mix grid-based or stack-based forms in the same app.

Loading different forms according to front-end type

If you want to use a grid-based or stack-based form according to the front-end, you can load the form with `OPEN FORM` (or `OPEN WINDOW`) based on the front-end name returned by the `feInfo.feName` front call:

```
-- util module
DEFINE fe_name STRING

FUNCTION get_fe_name()
   IF fe_name IS NULL THEN
      CALL ui.Interface.frontCall("standard", "feInfo", "feName", [fe_name])
   END IF
   RETURN fe_name
END FUNCTION

FUNCTION is_gmi()
   RETURN (get_fe_name() == "GMI")
END FUNCTION

-- main module
MAIN
   ...
   OPEN FORM f1 FROM IIF( is_gmi(), "myform_stack", "myform_grid" )

   ...
END MAIN
```

Desupported database drivers
Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in version 3.00:

- SAP Sybase ASE 15.x (`dbmase_15`): New SAP Sybase ASE 16.x version is now supported.
- Oracle Database 10.1 and 10.2 (`dbmora_10`)

  Note that no more driver is available for Linux PowerPC 32/64 platforms, because Oracle has desupported this platform.
- IBM DB2 UDB 9.x (`dbmdb2_9`)

Web Services changes

There are changes in support of web services in Genero 3.00.

Default SSL protocol

The default for the FGLPROFILE entry `security.global.protocol` is now `SSLv23`, enabling all supported SSL protocols, including `TLSv1.2` as required by the Federal Law of USA. In prior versions, the default was TLSv1 (v1.0). It is up to the web server administrator to restrict the SSL protocol to TLSv1.2.

For more details, see HTTPS and password encryption on page 2510

Server socket read/write timeout

Before version 3.00, when a WS client did not send all the HTTP body (for instance, after connection has been accepted), by default the WS server was waiting indefinitely, and this could end up in a deny of service.

The `com.WebServiceEngine` class supports now a new option called `server_readwritetimeout`, to define the server socket read/write timeout: If a timeout occurs, the WS server program will raise the BDL exception -15553. By default this timeout is defined as 5 seconds.

For more details, see WebServiceEngine options on page 2032.

HTTPPart header default settings with com.HTTPPart.CreateAttachment()

The `com.HTTPPart.CreateAttachment()` method now by default headers fields according to the filename and file extension.

For more details, see com.HTTPPart.CreateAttachment on page 2080.

File path returned by com.HTTPPart.getAttachment()

Before version 3.00, the `com.HTTPPart.getAttachment()` method returned the path to a temporary file. Starting with Version 3.00, this method will now return the absolute path location of the received part filename, according to the "Content-Disposition" header.

For more details, see com.HTTPPart.getAttachment on page 2080.

XForms characters in com.HTTPServiceRequest.readFormEncodedRequest()

Starting with version 3.00, if the result string of the HTTP request contains & or = XForms special characters, these are escaped by doubling it.

For more details, see com.HTTPServiceRequest.readFormEncodedRequest on page 2046.

> **Note:** This behavior change is related to the bug fix FGL-401.

Specific exception -15575 when GAS disconnects web service server

The GWS methods listed below will raise an exception with a specific error code -15575, when the GAS disconnects properly the web service server. Before version 3.00, the generic error -15565 was raised. A specific error code allows you to distinguish properly a normal disconnection from other errors, in a `TRY/CATCH` block. See code examples in method reference pages:

- com.WebServiceEngine.GetHTTPServiceRequest on page 2027
- com.WebServiceEngine.HandleRequest on page 2028

SOAP fault handling in client stub

Web Services client stub generation has been changed to support fault response with HTTP error code of 200.

The generated code supports SOAP fault with HTTP error code of 200 and 500. To enable this new feature in your client stub code, re-generate the stubs with the `fglwsdl` tool.

For more details, see Client side SOAP fault handling.

Optional multipart handling in client stub

In the generated client stub code, all functions handling the SOAP request with multipart get an additional input parameter and/or return parameter as a `DYNAMIC ARRAY OF com.HTTPPart`, to pass and return optional parts.

When generating client stubs managing multipart, you get an extra input and/or output variable called "`AnyInputParts`" and "`AnyOutputParts`" that is a `DYNAMIC ARRAY` of `com.HTTPPart` objects. Those variables may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program by handling those dynamic arrays in any Genero functions calling such stubs.

Request example prior to 3.00:

```
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  ...
  RETURN wsstatus
END FUNCTION
```

Request example 3.00 and greater, with extra input variable `AnyInputParts`:

```
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus
END FUNCTION
```

> **Note:** This change has also been backported in 2.50.25.

For more details, see Multipart in the client stub on page 2460.

Removal of FGLWSNOINFO environment variable

Before version 3.00, the GWS library was displaying by default a message about certificates used by the program:

```
—
WS-INFO (Certificate authority) | Loading from Windows keystore
—
```

To avoid this message, it was possible to set the FGLWSNOINFO environment variable to TRUE.

Starting with version 3.00, this message is no longer displayed by the GWS library, and the FGLWSNOINFO is no longer required.

Desupported Web Services APIs

The methods listed in the following table are de-supported in Genero 3.00.

Table 83: Table of de-supported methods (with their alternative)

Method de-supported as of 3.00	Alternative method to use
`com.Util.CreateDigestString`	`security.Digest.CreateDigestString` on page 2294
`com.Util.CreateRandomString`	`security.RandomGenerator.CreateRandomString` on page 2279
`com.Util.CreateUUIDString`	`security.RandomGenerator.CreateUUIDString` on page 2280

Oracle DB NUMBER type
The NUMBER/FLOAT Oracle data type can now be extracted by fgldbsch to create .sch files.

Before Genero 3.00, columns using the native Oracle NUMBER/NUMBER(p>32) type (with up to 38 significant digits), or the FLOAT(b) type (when (b/3)>32), were denied by the fgldbsch schema extractor. This restriction was applied to avoid potential overflow errors, if the Oracle NUMBER/FLOAT column contains values that do not fit into a BDL DECIMAL(32,s) type.

Starting with Genero 3.00, fgldbsch can map NUMBER/FLOAT native Oracle types to BDL DECIMAL(32) or DECIMAL(32,s) types, according to the `-cv` option:

- NUMBER (floating point number) is extracted as DECIMAL(32)
- NUMBER(p>32) (scale defaults to 0) is extracted as DECIMAL(32,0)
- NUMBER(p>32,s) or NUMBER(*,s) is extracted as DECIMAL(32,s)
- FLOAT(b) is extracted as DECIMAL(b/3) or FLOAT

For more details about Oracle type conversion rules and `-cv` type positions, run fgldbsch with the `-cx ora` option.

> **Note:** This new behavior has been introduced to simplify integration with existing Oracle databases, to extract .sch schema from databases using column types that have no exact equivalent BDL type. When designing new database tables, you should only use DECIMAL(p,s), with p<=32 to achieve maximum portability. When fetching numeric values with more than 32 significant digits into BDL decimals, values will be rounded for DECIMAL(32), or raise an overflow error -1226 for DECIMAL(32,s).

Oracle DB scroll cursor emulation removal
The scroll cursor emulation has been removed in the Oracle DB driver.

Before Genero 3.00, it was possible to enable scrollable cursor emulation (with temporary files) by defining the following FGLPROFILE entry:

```
dbi.database.mydbname.ora.cursor.scroll.emul = true
```

This feature was supported to workaround an Oracle DB bug in versions 8 and 9i. The Oracle bug does no longer exist in recent Oracle DB versions and the default native scrollable cursor feature can be safely used.

If this FGLPROFILE entry is set, the runtime system will print a warning to stderr.

MySQL VARCHAR size limit
MySQL 5 VARCHAR columns can be used to store VARCHAR(N>255) values.

Before Genero 3.00, the MySQL driver converted a VARCHAR(N>255) type to a MySQL TEXT type, because MySQL versions before 5.0.3 only allowed up to 255 characters for a VARCHAR column. MySQL TEXT type is a large object type with specific semantics and constraints, but it was the only available type to store character data above the 255 character limit. As a result, data type information was lost when extracting the database schema with fgldbsch from a MySQL database: When creating a table in a Genero BDL program, the original VARCHAR(N>255) type was converted to TEXT (with a fixed size of 65535

characters), and then converted by fgldbsch back to a VARCHAR2(65535) type in the .sch file. The original size of the VARCHAR type was lost.

Starting with Genero 3.00, when creating a table in a BDL program with CREATE TABLE, the MySQL driver leaves any VARCHAR(N) as-is, even if the size is greater as 255.

> **Note:** The MySQL driver does not distinguish MySQL server 5.0.x (5.0.2 / 5.0.3) versions. It assumes that we are connected to a server version 5.0.3 or above, supporting large VARCHAR types.

If your application is using VARCHAR(N) types with N>255 and your MySQL server version is 5.0.3 or above, you should review your database creation scripts to use VARCHAR(N) instead of TEXT.

> **Note:** The CHAR(N>255) types are still mapped to a MySQL TEXT type, because MySQL CHAR type has a limit of 255 characters. When designing a database, consider using CHAR only for short character string data storage (less than 50 characters), and use VARCHAR for larger character string data storage (name, address, comments).

MySQL DATETIME fractional seconds

MySQL 5.6.4 TIME and DATETIME types support fractions of seconds that can be used to store DATETIME HOUR TO FRACTION(N) or DATETIME YEAR TO FRACTION(N).

Before Genero 3.00, the MySQL driver converted DATETIME types as follows:

- DATETIME HOUR TO SECOND was converted to MySQL TIME.
- Other DATETIME types were converted to MySQL DATETIME.

Starting with Genero 3.00, when creating a table in a BDL program with the CREATE TABLE statement, if the MySQL server version is greater or equal to 5.6.4, the types are converted differently, as follows:

The SQL Translator of the MySQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to MySQL TIME (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to MySQL TIME.
- DATETIME HOUR TO FRACTION(N) is converted to MySQL TIME(N).
- DATETIME YEAR TO MINUTE is converted to MySQL DATETIME (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to MySQL DATETIME.
- DATETIME YEAR TO FRACTION(N) is converted to MySQL DATETIME(N).

This change has no impact if your application is using DATETIME HOUR TO SECOND or DATETIME YEAR TO SECOND. However, it is now possible to store DATETIME HOUR TO FRACTION(N) and DATETIME YEAR TO FRACTION(N) data. The DATETIME YEAR TO FRACTION(N) is typically used to implement data modification timestamps to track user changes.

PostgreSQL DATETIME type mapping change

Conversion of DATETIME type with fractional seconds to PostgreSQL TIME(N)/TIMESTAMP(N) was invalid and has been reviewed.

Before Genero 3.00, the PostgreSQL driver converted DATETIME types as follows:

- DATETIME HOUR TO MINUTE was converted to TIMESTAMP(3) WITHOUT TIME ZONE
- DATETIME HOUR TO SECOND was converted to TIME(0) WITHOUT TIME ZONE
- DATETIME HOUR TO FRACTION(N) was converted to TIME(N+1) WITHOUT TIME ZONE
- DATETIME YEAR TO MINUTE was converted to TIMESTAMP(3) WITHOUT TIME ZONE
- DATETIME YEAR TO SECOND was converted to TIMESTAMP(3) WITHOUT TIME ZONE
- DATETIME YEAR TO FRACTION(N) was converted to TIMESTAMP(N+1) WITHOUT TIME ZONE

Starting with Genero 3.00, when creating a table in a BDL program with CREATE TABLE, the types are converted in a different way.

The SQL Translator of the PostgreSQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to PostgreSQL TIME(0) WITHOUT TIME ZONE (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to PostgreSQL TIME(0) WITHOUT TIME ZONE.
- DATETIME HOUR TO FRACTION(N) is converted to PostgreSQL TIME(N) WITHOUT TIME ZONE.
- DATETIME YEAR TO MINUTE is converted to PostgreSQL TIMSTAMP(0) WITHOUT TIME ZONE (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to PostgreSQL TIMESTAMP(0) WITHOUT TIME ZONE.
- DATETIME YEAR TO FRACTION(N) is converted to PostgreSQL TIMESTAMP(N) WITHOUT TIME ZONE.

> **Note:** This behavior change is related to the bug fix FGL-3893.

This bug fix introduces a incompatibility and can have an impact on applications using DATETIME HOUR TO MINUTE, DATETIME HOUR TO FRACTION(N) or DATETIME YEAR TO FRACTION(N). If you are using one of these types, consider reviewing your database schema, to modify the column types accord to the new SQL type conversion rules.

MariaDB support
The MariaDB database is now supported by Genero 3.00.

MariaDB is the open source brand of Oracle's MySQL and has been adopted by several major organizations.

The purpose of the MariaDB project is to be a drop-in replacement for MySQL.

MariaDB supported versions are 10.0 and higher.

To connect to MariaDB, use the MySQL database driver (dbmmys), and follow MySQL adaptation guide for configuration and SQL portability issues.

According to the libmysqlclient library compatibility, you might need to configure Genero to use a version-stamped driver. As of Genero version 3.00, the generic driver name "dbmmys" can be used to connect to MariaDB 10.0. See Database driver specification (driver) on page 462 for more details.

FreeTDS driver supports SQL Server 2008, 2012, 2014
The FreeTDS driver can now be used for SQL Server versions > 2005.

Before Genero version 3.00, the FreeTDS driver could only be used to connect to SQL Server 2005. Starting with Genero 3.00 the `dbmftm` driver can connect to SQL Server 2008, 2012 and 2014.

With SQL Server version >= 2008, date/time types used to store DATE and DATETIME values is different as with SQL Server version 2005. See DATE and DATETIME data types on page 604 for more details.

> **Important:** For SQL Server version 2008, 2012 and 2014, you must set `TDS_Version=7.3` in odbc.ini. Using TDS version 8.0 introduces problems (tested with FreeTDS 0.95.5 to 0.95.19)

FGL_GETVERSION() built-in function
The `FGL_GETVERSION()` function now returns the product version number (for ex: 3.00.00).

Prior to Genero 3.00, the `FGL_GETVERSION()` built-in function was returning the internal build number.

Starting with Genero 3.00, the function returns the product version number as a string, such as 3.00.00.

Built-in front-end icons desupport
Images resources included in front-ends are desupported with Genero 3.00.

Starting with Genero 3.00, the icon files distributed in front-end packages are no longer provided (former `GDC-installation-dir/pics` for example)

Common icons for buttons, toolbars, topmenus, and other items using icons can be centralized on the application side where the program executes. This feature should be used to get the same icons on different type of front-ends, or use specific icons, but from the same central icon directory. For more details, see Providing the image resource on page 784.

Note however that mobile front-ends will display default icons, for default action views, if no `IMAGE` attribute is specified for the action. See Rendering default action views on mobile on page 1279 for more details.

Presentation style attribute changes
Deprecated and renamed presentation style attributes.

Starting with version 3.00:

The following presentation style attributes are desupported:

- `CheckBox: customWidget`

The following presentation style attributes are deprecated:

- `Image: imageContainerType ( = "browser")`

  Note: Replace `IMAGE` fields using this style attribute by URL-based `WEBCOMPONENT` fields.

Modifications in front calls
Describes changes done in front calls.

Front call modifications in BDL version 3.00:

- Before version 3.00, the `connectivity` front call was accepting a hostname as parameter. Starting with version 3.00, this front call no longer use a hostname: It will only check the available network type. For more details, see the mobile.connectivity front call.

SERIAL emulation with SQL Server
The SERIAL and BIGSERIAL types can be emulated with triggers and sequences when using SQL Server 2012 and higher.

By default when using SQL Server, the SERIAL and BIGSERIAL types are emulated with IDENTITY columns. This native sequence generator is the fastest and prefered solution. However, it requires to remove the serial column in all INSERT statements, which can lead to a large change in your legacy code.

Until version 3.00, you could workaround this limitation by using the "regtable" serial emulation. But this solution is using a dedicated SERIALREG table that must be updated for each INSERT statement. This can result in bad performances, when concurrent programs create rows in the same tables (locking issues in SERIALREG).

Starting with Genero 3.00, it is now possible to use a serial emulation based on triggers and sequences. Sequences where introduced in SQL Server version 2012, so you need at least a 2012 server in order to use this emulation:

```
dbi.database.mydb.ifxemul.datatype.serial.emulation = "trigseq"
```

Improved compilation time
The `fglcomp` and `fglform` compilers have been reviewed to achieve faster compilation.

A Genero project can be very large, with thousands of `.4gl` source files to compile. Compilation time can be an issue when the whole set of sources needs to be compiled every day, or several times a day.

In Genero 3.00, the `fglcomp` compiler has been improved to deliver better performances. Depending on the content of the source file, the compiler can be over twice as fast.

Loading `.sch` database schema files has also been improved. Using huge schema files with several thousands of lines is no longer an issue. This is especially useful when compiling forms that define fields based on database columns in a schema file.

Preprocessor changes
Several bugs have been fixed in the preprocessor, that can now result in a compilation error.

String token expansion

Before version 3.00, the following preprocessor syntax could be used to expand a string macro parameter:

```
&define T(x) DISPLAY "head_"#x"_tail"
-- macro usage:
T(body)
```

This was producing following result (after preprocessing):

```
"head_""body""_tail"
```

And was accepted by the compiler, because it was interpreted as a single string literal.

The new preprocessor now produces (as expected):

```
"head_" "body" "_tail"
```

However, this will now result in a compiler error, because this is not a valid string literal.

To solve such issue and get the same result string as before version 3.00, use the `||` concatenation operator in the preprocessor macro and add (escaped) double quotes before and after the *`#ident`* placeholder:

```
&define T(x) DISPLAY "head_""" || #x || """_tail"
```

or, by using single quotes as border strings delimiters:

```
&define T(x) DISPLAY 'head_"' || #x || '"_tail'
```

Identifier concatenation

Before version 3.00, the following type of macro:

```
&define FOO() foo
-- macro usage:
FOO()bar
```

was producing a single identifier token (accepted by the compiler):

```
foobar
```

But it will now produce two distinct identifier tokens (as expected):

```
foo bar
```

And this will result in a compilation error.

Backslash in macro parameters

Before version 3.00.00 is was possible to use the backslash to escape a comma in preprocessor macro parameters. This syntax is no longer allowed by the preprocessor, it is not a valid usage. To solve such issue, replace parameters by real string literals in the macro:

```
-- bad coding
&define FOO(p1) DISPLAY #p1
FOO(hello world)       -- expands to: DISPLAY "hello world"
FOO(hello \, world)    -- error

-- good coding
&define FOO(p1) DISPLAY p1
FOO("hello world")     -- expands to: DISPLAY "hello world"
FOO("hello , world")   -- expands to: DISPLAY "hello , world"
```

The ## paste operator

Before version 3.00.00, the ## paste operator could be used to construct code with two elements that did not result in a valid token, for example:

```
&define FOO(name) rec_ ## [ x ]
FOO(x)
```

was producing:

```
rec_[ x ]
```

This kind of preprocessor macro is no longer allowed in version 3.00.00 and will result in a compiler error:

```
x.4gl:2:1:2:1:error:(-8042) The operator '##' formed 'rec_[', an invalid
 preprocessing token.
```

The ## paste operator must be used to join two identifiers, to create a new identifier:

```
&define REC_PREFIX(name) rec_ ## name
LET REC_PREFIX(customer) = NULL
```

will produce:

```
LET rec_customer = NULL
```

Current system time in UTC

Use the util.Datetime.getCurrentAsUTC() method to get the current system date/time in UTC.

Starting with Genero version 3.00, you can use the util.Datetime.getCurrentAsUTC() method to get the current system time in UTC (Coordinated Universal Time).

This method has been added to solve the issue when using `util.Datetime.toUTC(CURRENT)` during the daylight saving time transition period in the fall, as described in util.Datetime.toUTC on page 1953.

Structured ARRAYs in list dialogs

ARRAYs with sub-records can be used in list dialogs, to simplify array definition based on database tables, requiring additional information at runtime.

Starting with Genero version 3.00, ARRAY variables defined with a sub-records can be bound to `DISPLAY ARRAY` and `INPUT ARRAY` screen records.

This is especially useful when you need to define arrays from database tables, and handle additional row information at runtime, for example, to hold image resource for each row, to be displayed with the `IMAGECOLUMN` attribute.

An array is usually defined with a flat list of members:

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD LIKE items.*
...
```

With version 3.00, arrays structured with sub-records can now be used within a `DISPLAY ARRAY` or `INPUT ARRAY` dialog. The array members and the form fields used by the screen array are bound by position:

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
                    item_data RECORD LIKE items.*,
                    it_image STRING,
                    it_count INTEGER
                END RECORD
...
DISPLAY ARRAY a_items TO sr.*
   ...
```

For more details about program variable to form field binding in dialogs, see Variable binding in DISPLAY ARRAY on page 1078, Variable binding in INPUT ARRAY on page 1101, Binding variables to form fields on page 1264, Example 4: DISPLAY ARRAY with structured array.

2.51 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.51.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Desupported database drivers on page 101
2. New database driver name specification on page 102
3. The FIELD form item type and .val schema file on page 102
4. TRY/CATCH and ERROR LOG on page 103
5. DATETIME types with SQLite on page 103
6. Desupport of C-Extension API functions on page 103

Desupported database drivers

Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in version 2.51:

- Genero DB is no longer supported (`dbmads*`).
- Oracle MySQL 5.0, 5.1 (`dbmmys50x`, `dbmmys51x`).
- PostgreSQL 8.3, 8.4 (`dbmora83x`, `dbmpgs84x`)
- Oracle MySQL 4.1 (`dbmmys41x`)
- Oracle Database 9.2 (`dbmora92x`)
- IBM DB2 UDB version 7.x and 8.x (`dbmdb27x`, `dbmdb28x`)

Note also that database driver naming convention has changed in 2.51, for more details see New database driver name specification on page 102.

New database driver name specification
Allows database driver specification without target database version information.

Starting with version 2.51, the database drivers are following a new file name convention, to let you specify a generic name according to the target database type, without any database version information.

> **Important:** Most database driver names have changed. You need to re-configure the `"driver"` entry in your FGLPROFILE settings (or database connection string parameters), to match the new driver names. If you are using the default driver (`dbmdefault`), there is no configuration change needed. To simplify upgrading, the runtime system identifies old driver names and converts them to new names. However, you should consider using the generic driver name corresponding to the type of database your applications connect to. The error -6366 occurs if the runtime system is not able to load the specified database driver, or cannot identify an old driver name.

Before version 2.51, it was required to specify the exact database type and version, that had to match both the database client and the server version. For example, when using Oracle 11.2 (server and client):

```
dbi.database.stores.driver = "dbmoraB2x"
```

Starting with 2.51, you can now for example specify a generic driver name without version, which can connect to any database server version supported by the DB vendor client/server protocol. The generic name defines a database driver for the latest database client version that is available on the platform:

```
dbi.database.stores.driver = "dbmora"
```

Each generic database driver name has also a human-readable alias, such as "informix" or "oracle".

```
dbi.database.stores.driver = "oracle"
```

To simplify driver specification, install the latest database client software that corresponds to the generic driver name, especially if it does not require a database server upgrade.

For some type of database client software, additional database drivers are still provided for older database client versions (if available on the platform). In such case, the driver file name gets a version identifier.

For example:

- `dbmora_11` (Oracle 11g client)
- `dbmmys_5_1` (Oracle MySQL 5.1.x)
- `dbmsnc_10` (SQL Native Client 10 (SQLNCLI10.DLL))
- `dbmsnc_9` (SQL Native Client 9 (SQLNCLI.DLL))

Such database drivers with version info are provided to follow db client library dependency rules, as defined by the database vendors. For example, on a Linux platform, Oracle MySQL version 5.1.x provides the db client library named `libmysqlclient.so.16`. In this file name, "16" is the version number that defines the shared library compatibility. The database driver that was compiled and linked in a compatible db client environment is `dbmmys_5_1`: This database driver is linked to `libmysqlclient.so.16`. Starting with Oracle MySQL version 5.5.x, the db client library version number has incremented to 18 (i.e. `libmysqlclient.so.18`). The driver to be used with that library version is `dbmmys_5_5`, which was compiled and linked with a 5.5.x environment.

The FIELD form item type and .val schema file
Form files using the FIELD item type and/or .val attribute definitions must be reviewed.

Starting with version 2.51, the `FIELD` item type defining abstract fields in forms, based on .val schema file attributes is deprecated.

Further, any non-I4GL attribute defined in the .val schema file must be avoided: Reading attributes in the .val is now only supported for compatibility with I4GL projects.

With Genero, it is recommended to define all form item attributes in the form definition file.

TRY/CATCH and ERROR LOG
Errors are no longer logged when raised in a TRY/CATCH block.

Before version 2.51, exceptions occuring in a TRY/CATCH block were logged if the error log is initiated with the startlog() function. With version 2.51, if an exception is raised in a TRY/CATCH block, it will no longer be logged in the error log file. In other words, the TRY/CATCH block will behave like WHENEVER ERROR CONTINUE, regarding error logging.

> **Note:** This behavior change is related to the bug fix FGL-3091.

Example:

```
CALL startlog("errors.txt")
...
TRY
    INSERT INTO customer ...
CATCH
    -- Handle errors and write to error log with errorlog() if needed.
    IF SQLCA.SQLCODE == -8634 THEN
       ...
    END IF
END TRY
```

> **Important:** In order to get this new behavior, the pcode is no longer compatible with older versions (<=2.50): All programs must be recompiled.

DATETIME types with SQLite
Better support for Informix DATETIME types emulation within SQLite.

Before version 2.51, DATETIME SQL types where converted to SQLite types as follows:

- DATETIME HOUR TO SECOND type was translated to TIME (hh:mm:ss).
- DATETIME YEAR TO FRACTION and all other combinations (except HOUR TO SECOND) were translated to TIMESTAMP (YYYY-MM-DD hh:mm:ss.fff).

Since most DATETIME types were converted to TIMESTAMP, it was not possible to distinguish common date/time types such as DATETIME HOUR TO MINUTE or DATETIME YEAR TO MINUTE, especially when extracting the database schema with fgldbsch: Type information was lost and this prevented schema-base variable definitions with DEFINE LIKE.

Starting with version 2.51, common DATETIME SQL types are now mapped to different types in SQLite, for a better support of these types. In fact, SQLite allows to define table columns with custom types (you can use any type name), however the number of tokens in the syntax is limited so it's not possible to use for ex the tokens DATETIME YEAR TO SECOND directly. The Genero database driver uses this SQLite SQL language feature to map Informix-style DATETIME types to specific custom types. For example, a DATETIME HOUR TO MINUTE becomes a SMALLTIME, a DATETIME YEAR TO FRACTION(2) becomes a DATETIME(2), etc. Further, the data values inserted in the database do now match exactly the precision of the original DATETIME type. For more details about date/time mapping and emulation, see DATE and DATETIME data types on page 714.

Desupport of C-Extension API functions
BIGINT and BOOLEAN stack functions and C API functions for C-Extensions are no longer supported.

Since version 2.51:

The C-Extension stack functions to handle BIGINT and BOOLEAN types have been removed:

Table 84: Desupported FGL stack functions

popboolean()
popbigint()

pushboolean()
pushbigint()

The C API functions such as `decadd()`, `risnull()`, `rsetnull()`, have been removed. These functions are part of the IBM® Informix® ESQL/C product and cannot be part of the Genero BDL product. The Genero runtime system provides only the C functions to push and pop data on the Genero BDL stack.

Below is the list of C API functions that have been removed, check your C extension code for the usage of these functions. If such functions are required, link your C-Extensions with the IBM® Informix® ESQL/C libraries.

Table 85: Desupported C API functions

bycmpr()

2.50 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.50.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Desupported database drivers on page 106
2. TEXT/BYTE support with FTM/ESM database drivers on page 106
3. Presentation style attribute changes on page 107
4. Floating point to string conversion on page 107
5. Web Services changes on page 108
6. Implicit creation of certificates for HTTPS on page 108
7. PostgreSQL schema extraction needs namespace on page 108
8. Client stubs managing multipart changes on page 109

Desupported database drivers

Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in versions 2.50:

- SQL Server MDAC drivers (Code MSV, name: `dbmmsv*`):

  On a Microsoft™ Windows™ platform, use the SQL Native Client driver instead (Code SNC).

  With the SNC drivers, set the **dbi.database.*dbname*.snc.widechar** FGLPROFILE entry to **false** when using CHAR/VARCHAR/TEXT in the SQL Server database.
- Oracle MySQL 5.4 (`dbmmys54x`)
- Oracle Database 8.1 (`dbmora81x`)
- Oracle Database 9.0 (`dbmora90x`)

TEXT/BYTE support with FTM/ESM database drivers

FTM and ESM database drivers TEXT/BYTE type mapping has changed.

Since version 2.50, the TEXT and BYTE data types are now converted respectively to VARCHAR(MAX) and VARBINARY(MAX) data types, the recommended LOB types introduced in SQL Server 2005. Before version 2.50, the TEXT and BYTE data types were converted to TEXT and IMAGE data types, respectively, in SQL Server.

Note: This behavior change is related to the bug fix FGL-2534.

It is still possible to use SQL Server TEXT and IMAGE types, but if you create or alter tables in an FGL program, the VARCHAR(MAX) and VARBINARY(MAX) types will be used instead.

Presentation style attribute changes
Deprecated and renamed presentation style attributes.

Starting with version 2.50:

The following presentation style attributes are deprecated (still implemented, but not to be used):

- `Window: backgroundImage`
- `TextEdit: textSyntaxHighlight`

The next presentation style attributes have been replaced by a new style attribute, or have been renamed:

- `CheckBox: nativeLook => customWidget` (with same possible values)

Important: In 3.00, the `customWidget` attribute is desupported.

Floating point to string conversion
The default formatting of a `DECIMAL(P)`, `SMALLFLOAT` and `FLOAT` adapts to the significant digits of the value.

Floating point decimal types (like `DECIMAL(5)`) can store a large range of values, with a variable number of digits after the decimal point: For example, a `DECIMAL(5)` can store 12345 as well as 0.12345. See DECIMAL(p,s) on page 200 for more details about floating point decimal types.

With Genero 2.50, the conversion to string from a `DECIMAL(P)`, `FLOAT` and `SMALLFLOAT` has been revised, to keep all significant digits and avoid data loss.

Note: This behavior change is related to the bug fix FGL-3915.

Before Genero 2.50, floating point decimals converted to strings were formatted with 2 decimal digits by default, which could lead to data loss. See following example using a `DECIMAL(12)`:

```
MAIN
   DEFINE str STRING, dec12, dec12_bis DECIMAL(12)
   LET dec12 = 10.12999
   LET str = dec12
   DISPLAY str
   LET dec12_bis = str
   DISPLAY (dec12 == dec12_bis)
END MAIN
```

Prior to Genero 2.50, the above code would display:

```
10.13
     0
```

Starting with Genero 2.50, all significant digits are kept, which allows proper decimal data serialization:

```
10.12999
     1
```

Prior to Genero 2.50, floating point decimal values conversion of huge values could also lose digits in the whole part of the number; the width of the result was never longer than p + 2. Starting with Genero 2.50, all significant digits of a floating point decimal are kept in the result string:

```
   Values            Vers<2.50       Vers>=2.50
-----------------------------------------------
```

```
    1.23456e123       1.23456e123     1.23456e123
    1.23456e40        1.235e40        1.23456e40
    123.456           123.46          123.456
    123456.0          123456.0        123456.0
    0.123456          0.12            0.123456
    0.0123456         0.01            0.0123456
    0.00123456        0.00            0.00123456
    1.23456e-08       0.00            1.23456e-08
```

If you expect that any `DECIMAL(P)` to string conversion rounds to 2 digits, define the following FGLPROFILE entry:

```
fglrun.decToCharScale2 = true
```

> **Note:** Do not use this configuration parameter unless you have migration issues. This configuration parameter applies only to `DECIMAL(P)` types, `FLOAT` and `SMALLFLOAT` conversions to string is not impacted.

Web Services changes
Several methods of built-in and extension classes are de-supported.

The methods listed in the following table are deprecated in version 2.50.

Table 86: Table of deprecated methods (with their alternative)

Method deprecated as of 2.50	Alternative method to use
`com.Util.CreateDigestString`	`security.Digest.CreateDigestString` on page 2294
`com.Util.CreateRandomString`	`security.RandomGenerator.CreateRandomString` on page 2279
`com.Util.CreateUUIDString`	`security.RandomGenerator.CreateUUIDString` on page 2280

Implicit creation of certificates for HTTPS
Certificates for HTTPS are now created implicitly, when nothing is specified in FGLPROFILE.

Before version 2.50, certificates for HTTPS had to be specified explicitly in FGLPROFILE.

Starting with 2.50, in no HTTPS certificate is defined in FGLPROFILE, when a web services program starts, the creation is implicit.

PostgreSQL schema extraction needs namespace
To extract a database schema from PostgreSQL, the fgldbsch tool now requires db namespace specification.

In version 2.50, the fgldbsch database schema extractor can only extract the schema from a PostgreSQL database if you specify the `-ow` option.

> **Note:** This behavior change is related to the bug fix FGL-2647.

PostgreSQL distinguishes table owners from table schemas (i.e. table namespaces). The real table namespace is defined by the `pg_class.relnamespace` column: it contains the `oid` of a namespace defined in `pg_namespace`. For PostgreSQL, the fgldbsch `-ow` option will specify the namespace, instead of the owner of the table, because an db user can create several schemas/namespaces and use the same table name in those different namespaces. As result, filtering on user name can mix table definitions from different schemas/namespaces.

When extracting a database schema from a PostgreSQL database, you must specify the namespace of tables with the `-ow` option. If no `-ow` option is specified and the `-un` option is specified, fgldbsch will use

the login name of the `-un` option as namespace. If neither `-ow`, nor `-up` options are specified, fgldbsch will use the PostgreSQL "public" namespace/schema by default.

Since database tables are usually created in the "public" namespace, you typically specify this namespace with the `-ow` option:

```
fgldbsch -db test1 -dv dbmpgs -un pgsuser -up fourjs -v -ow public
```

Client stubs managing multipart changes
You must update client programs that call client stubs managing multipart.

> **Important:** This change has been backported from V 3.00

Starting with version 2.50.25, when generating client stubs managing multipart, you get an extra input and/or output variable called "`AnyInputParts`" and "`AnyOutputParts`" that is a `DYNAMIC ARRAY` of `com.HTTPPart` objects. Those variables may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program by handling those dynamic arrays in any Genero functions calling such stubs.

Request example prior to 2.50.25:

```
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  ...
  RETURN wsstatus
END FUNCTION
```

Request example 2.50.25 and greater, with extra input variable `AnyInputParts`:

```
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus
END FUNCTION
```

2.40 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.40.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Desupported database drivers on page 110
2. Program size option removal (fglrun -s) on page 110
3. Informix SERIAL emulation with SQL Server on page 110
4. SIZEPOLICY attribute removal for containers on page 110
5. The LVARCHAR type in IBM Informix databases on page 110
6. Right-trim collation for character types in SQLite on page 111
7. Message files support now 4-bytes integer message numbers on page 111
8. MySQL client library version change in MySQL 5.5.11 on page 111
9. New compiler warning to avoid action shadowing on page 111
10. Runtime error raised when report dimensions are invalid on page 112
11. Linker checks all referenced functions on page 112

Desupported database drivers
Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in versions 2.40:

- PostgreSQL versions 8.0, 8.1 and 8.2 (dbmpgs80x, dbmpgs81x, dbmpgs82x).
- Sybase Adaptive Server Anywhere (ASA) version 8 driver (dbmasa8x)

  The dbmasa8x driver was provided for the Sybase ASA desktop database engine (renamed Sybase SQL Anywhere when writing these lines). Since version 2.30, Genero Business Development Language supports a new driver to connect to Sybase Adaptive Server Enterprise (ASE): dbmase*.

Program size option removal (fglrun -s)
The -s option of fglrun is no longer available.

Before version 2.30 the -s option of fglrun could be used to compute the size of program elements such as global and module variables, p-code and structured data types. Starting with version 2.30, this option reported a size of zero. With version 2.40 the -s option is now fully desupported.

The -s option was mainly implemented for internal use. Regarding the amount of memory used by a program, you should consider the memory allocated dynamically at runtime: If you fill large dynamic arrays, or leave a lot of SQL cursors open without freeing them, the memory footprint of a program can be much larger as the actual size of static elements that could be reported by the -s option.

Informix® SERIAL emulation with SQL Server
SERIAL type emulation has been enhanced for SQL Server.

Using SCOPE_IDENTITY() to get the last sequence

Before version 2.40, the SQL Server drivers (SNC, MSV, ESM, FTM) were using the @@IDENTITY expression to retrieve the last generated identity column, if the native serial emulation is configured. But @@IDENTITY is not recommended, because it can return an identity value generated for another table in a trigger of the main table.

Starting with 2.40, the SQL Server drivers use the SCOPE_IDENTITY() function, which returns the last number generated in the current scope (ignoring identity numbers generated in triggers).

Regtable serial emulation trigger code change

When using the "regtable" serial emulation, the code of the triggers has changed in version 2.40, using now the SET NOCOUNT ON instruction. Existing serial triggers created by prior versions must be reviewed, to have the same trigger body in all tables, otherwise an SQL error is raised when executing INSERT statements.

SIZEPOLICY attribute removal for containers
The SIZEPOLICY attribute is no longer availabel for layout containers like TABLE / GRID.

Before version 2.40 it was possible to specify a SIZEPOLICY attribute for several sort of form elements, including containers such as TABLE, GRID. The SIZEPOLICY attribute make no sense in containers and is only meaningful for leaf nodes (i.e. widgets such as EDIT, COMBOBOX). The form compiler will now report a syntax error if the SIZEPOLICY attribute is used in the definition of elements that are not widgets.

The LVARCHAR type in IBM® Informix® databases
Native LVARCHAR type of Informix is now mapped by default to a large VARCHAR in schema file.

Starting with version 2.40, the fgldbsch database schema extractor converts now by default IBM® Informix® LVARCHAR(N) types to VARCHAR2(N) with type code 201. Before 2.40, you had to pass -cv AAAB... option to avoid a conversion error when generating the schema file.

The static SQL syntax has been enhanced, to support the LVARCHAR type name in DDL statements such as CREATE TABLE. The non-Informix ODI drivers have been adapted to convert LVARCHAR type names to VARCHAR.

Two-Pass reports can now use VARCHAR types with a size greater as 255 bytes (the temporary table will be created with an LVARCHAR column). Note however that and index is created as well, and IBM® Informix® IDS (version 11 when writing these lines) has a size limitation for indexes. You may get an SQL error -517 if the VARCHAR variable used to group / order rows in the report routine exceeds ~350 bytes (see IDS SQL error -517 for details).

Right-trim collation for character types in SQLite
CHAR and VARCHAR columns in SQLite need to be defined with a TRIM collation to ignore trailing spaces in comparisons.

Since version 2.40, the SQLite database driver adds the COLLATE RTRIM keywords after the CHAR(N) and VARCHAR(N) types in CREATE TABLE statements, when Informix® emulation is enabled (the default). This collation clause forces SQLite to use right-trim comparison rules instead of the default binary mode. The binary mode requires to have the same number of trailing spaces in both character values to be equal. By using COLLATE RTRIM clause, the trailing blanks are trimmed and thus ignored. You should also use [VAR]CHAR(N) COLLATE RTRIM in database creation scripts.

Message files support now 4-bytes integer message numbers
2-byte .msg message number limitation was removed.

Before version 2.40, message files entries could only be defined with numbers in the range -32767 to 32767 (i.e. SMALLINT). This limitation is not longer true in 2.40: Message numbers can now be in the range -2147483648 to 2147483647 (i.e. INTEGER).

> **Note:** This behavior change is related to the bug fix FGL-1670.

MySQL client library version change in MySQL 5.5.11
Shared library version number of the MySQL client library must match the library used to link the ODI driver.

Starting with MySQL 5.5.11, the client library version number was changed from 16 to 18. In fact the `libmysqlclient.so.16` file was renamed to `libmysqlclient.so.18`. From a cross-5.5.x compatibility point of view, this was maybe not the best thing to do: Since the major shared library version has changed, client applications using the C API (such as Genero ODI MySQL drivers) need to be recompiled and re-linked in order to use le latest library.

In Genero version 2.40, the dbmmys55x ODI driver is linked with libmysqlclient.so.18 on the platforms where MySQL 5.5.11+ is available. That is: Linux™, Solaris and Mac OS X® platforms, when writing these lines. On other UNIX™ platforms such as HP, the client library is still `libmysqlclient.so.16`. This may change in the future Genero versions, following the availability of MySQL 5.5.11+ versions.

Therefore, you must pay attention to the MySQL 5.5 version you have installed: You need to upgrade your MySQL 5.5 client software to match le client library that was used to build the `dbmmys55x.so` shared library. On Linux™, you can run the ldd command to check what `libmysqlclient.so` version is required. If it's not possible to upgrade your MySQL client software, please contact the support channel.

New compiler warning to avoid action shadowing
Prevent the same action name at different levels of ON ACTION handlers in a dialog.

The fglcomp compiler of version 2.40 will now print warning -8409, if a dialog block defines ON ACTION handlers at different levels with the same action name.

It is not good practice to use the same action names at different levels of a dialog. For example, you can define several ON ACTION INFIELD handlers using the action name "zoom", but you should not define and ON ACTION zoom at the sub-dialog or dialog level.

If the warning occurs during compilation, modify your code in order to use specific action names at each level, and do not forget to rename the actions of the corresponding action views in the forms.

Runtime error raised when report dimensions are invalid
Report page length checking error -4375 might occur at compile time or runtime.

Starting with version 2.40, a START REPORT instruction raises the runtime error -4375, when the top/bottom margin sizes do not fit the page length.

In version 2.40, the error is not returned at compile time, because report dimensions can be specified with variables in START REPORT.

But since version 2.50.00 (build 2155) fixing bug FGL-3711, the compiler will also raise error -4375 when using constants.

Further change is done in version 2.51.07 (build 2506), by fixing the bug FGL-651, to relax the page length test and allow FIRST PAGE HEADER blocks with the same number of rows as the page length.

> **Note:** This behavior change is related to the bug fix FGL-3035, FGL-3711 and FGL-651.

Linker checks all referenced functions
The linker checks definition of all functions referenced in all modules provided in the link command.

Starting with version 2.40, any reference to a function has to be resolved by the linker: When linking a 42r program, if an unused module references an undefined function, the linker (`fglrun -l` or `fgllink`) will stop with the error -1338. Before version 2.40, the undefined function was ignored.

> **Note:** Complete function reference is only checked by the linker when creation a 42r program file. When creating a 42x library, there can be references to undefined functions.

In the next example, the `main.4gl` module does not call any function, but the module used in the link line (`module.4gl`) defines an unused function (`f1`) calling an undefined function (`f2`):

`main.4gl`:

```
MAIN
    DISPLAY "In main..."
END MAIN
```

`module.4gl`:

```
FUNCTION f1() -- Unused in program
    DISPLAY "In f1..."
    CALL f2() -- Undefined
END FUNCTION
```

Compiling and linking:

```
$ fglcomp main.4gl
$ fglcomp module.4gl
$ fgllink -o prog.42r main.42m module.42m
ERROR(-1338):The function 'f2' has not been defined in any module in the
 program.
```

2.32 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.32.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Front-end protocol compression disabled on page 113
2. SQLite driver does no longer need libiconv on Windows on page 113

3. Need for Informix CSDK to compile C extensions on page 113
4. FESQLC tool removal on page 113

Front-end protocol compression disabled
GUI communication does not require protocol compression on LAN networks.

Until version 2.32.00, front-end protocol compression was enabled by default, to speed GUI communication on slow networks. However, on regular networks, compression is useless and can be disabled to save processing resources. With version 2.32.00, the compression is now disabled by default. If needed, compression can be enabled with this FGLPROFILE entry:

```
gui.protocol.format = "zlib"
```

Note also that compression needs the zlib library to be present on the computer where fglrun executes. Starting with 2.32.00, the product package does no longer include the fallback zlib library ($FGLDIR/lib/libzfgl.so or %FGLDIR%\bin\libzfgl.dll). If no standard zlib is installed on your system, compression will not be possible.

SQLite driver does no longer need libiconv on Windows™
UTF-8 string data storage in SQLite requires conversion when the application is not UTF-8.

Starting with version 2.32, the SQLite driver (dbmsqt3xx) does no longer need the LIBICONV.DLL library on Windows™ platforms to do charset conversion, when the application locale is not UTF-8.

Need for Informix® CSDK to compile C extensions
Compiling C Extensions requires now the Informix CSDK.

> **Note:** This upgrade note is related to C Extensions or ESQL/C Extensions, and can be ignored if your application does not use such extensions.

To compile C or ESQL/C extensions manipulating data types like DECIMAL, you need IBM® Informix® data type structure definitions such as dec_t, dtime_t, intrvl_t, as well as macros like DECLEN() or TU_ENCODE(). Before version 2.32, these C structure and macros where provided in the files of the FGLDIR/include/f2c directory.

Genero BDL version 2.32 does no longer provide the IBM® Informix® ESQL/C structure definitions in FGLDIR/include/f2c files, because we have identified that some of the definitions are platform specific. However, to compile your C extensions, you need these definitions if your extensions use complex data types such as DECIMAL, DATETIME/INTERVAL, BYTE/TEXT. The definitions are not required if you use standard C types such as int or char[].

Starting with version 2.32, you need to install an IBM® Informix® CSDK on your development machine in order to get the structure and macro definitions to compile your C extensions. Understand that the IBM® Informix® CSDK is only required on the development platform. It is not required to install the CSDK on the production machines, except of course if you want to connect to an IBM® Informix® database server.

FESQLC tool removal
The ESQL/C compiler (fesql) has been removed from the Genero BDL product.

Starting with version 2.32, the `fesqlc` compiler and linker is no longer part of the Genero BDL package.

Contact you support channel for more details.

2.30 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.30.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. GUI server auto start on page 114
2. Form compiler is more strict on page 114

3. ORACLE and INTERVAL columns on page 114
4. DIALOG.setCurrentRow() changes row selection flags on page 115
5. Schema extractor needs table owner on page 115
6. Windows installation for all users only on page 115
7. MenuAction close no longer created by default on page 115
8. Emulated scrollable cursor temp files in DBTEMP on page 115
9. Modifying tree view data during dialog execution on page 115
10. FPI tool removal on page 115

GUI server auto start
FGLSERVER defaults the server defined by wsmap settings, when starting GUI server

Before version 2.30, the runtime system was trying to connect to `localhost:0` when FGLSERVER was not set, even if `gui.server.autostart` FGLPROFILE entries are defined.

This behavior has been identified as a bug (FGL-1583) and has been fixed, changing the way fglrun proceeds with the GUI connection when autostart settings are defined; with 2.30, the `wsmap` workstation mappings are now taken into account, so that FGLSERVER defaults to `locahost:`*n*, where *n* is the GUI server number found from the wsmap settings.

> **Note:** This behavior change is related to the bug fix FGL-1583.

Form compiler is more strict
The .per grammar parser has been reviewed to deny invalid code.

In version 2.30, the internals of fglform have been reviewed to simplify the extension of the form syntax with new item types and attributes. This code review has removed some inconsistencies in the grammar parser; as a result, the form compiler is more strict regarding invalid syntaxes. Thus, you may experience compilation errors with forms that compiled with prior versions. Simply fix the invalid syntax in your forms and recompile.

ORACLE and INTERVAL columns
INTERVAL storage bug fix needs a review of existing databases in production.

Before 2.30.00 (build 1566), negative (and only negative) INTERVAL values were inserted incorrectly. This a critical bug.

For example, it was not possible to compare an INTERVAL value inserted by a program with an INTERVAL literal:

```
SELECT ... FROM table
  WHERE interval_col = INTERVAL '-55555-11' YEAR(9) TO MONTH
```

The problem concerns database columns with the following interval types:

```
INTERVAL YEAR(p) TO MONTH
INTERVAL DAY(p) TO FRACTION(n)
```

(Other INTERVAL types are stored in a CHAR(50))

A simple INTERVAL to CHAR to INTERVAL conversion will fix the values:

```
UPDATE table SET interval_col = TO_CHAR(interval_col)
```

> **Note:** This behavior change is related to the bug fix FGL-95.

DIALOG.setCurrentRow() changes row selection flags
Row selection flags are reset by a call to setCurrentRow().

Before version , the DIALOG.setCurrentRow() method was not modifying the row selection flags.

Starting with version 2.30, the method resets row selection flags to false and marks the new current row as selected.

Schema extractor needs table owner
The fgldbsch schema extractor requires a -ow option to distinguish different database users/shemas.

Starting with version 2.30, the fgldbsch schema extractor will always use a table owner / schema to select tables from databases where several schemas can hold tables with the same name.

> **Note:** This behavior change is related to the bug fix FGL-2072.

The table owner can be specified with the `-ow` option, and defaults to the user name passed with the `-un` option, or to the current database user if no `-up` option was given. The last case can occur when the database connection information is taken from the FGLPROFILE configuration file, or when the OS user authentication is used.

Windows™ installation for all users only
Installation on Windows platforms is for all users.

Starting with version 2.30, the Windows™ installer forces you to install the product for all users.

MenuAction close no longer created by default
The close action is no longer created by default in MENU dialog.

Before version 2.30, a `close` MenuAction was created by default for MENU dialogs. This action node is no longer created, except if you have a COMMAND KEY(INTERRUPT) in the MENU, or if you have your own user action handler ON ACTION close, of course. You must take this change into account if you are manipulating the AUI tree with om classes in MENUs.

Emulated scrollable cursor temp files in DBTEMP
Directory of scrollable cursor data storage can be defined with DBTEMP.

On UNIX™ platforms, starting with 2.30, the temporary files for emulated scrollable cursors will be created in the directory defined by the DBTEMP environment variable when defined, otherwise TMPDIR, TEMP or TMP will be used. Using DBTEMP for database files conforms to DBTEMP usage for temporary files of TEXT and BYTE data storage.

Modifying tree view data during dialog execution
Use ui.Dialog methods to insert/append/delete treeview nodes.

Before version 2.30, it was possible to use the `insertRow()` / `appendRow()` / `deleteRow()` / `deleteAllRows()` dialog class methods to modify the tree array during the dialog execution. But these methods were not prepared to handle tree data properly. You could use program array methods instead, but when modifying the program array directly, multi-range selection flags or cell attributes were not synchronized.

Starting with 2.30.02, you can now use the `insertNode()`, `appendNode()` and `deleteNode()` methods of the `ui.Dialog` class. You can still directly fill the program array before the dialog execution, but you should use dialog methods during the dialog execution.

FPI tool removal
The fgi tool to show version information is no longer available, use fglrun -V.

Up to version 2.30, the fpi tool was provided to print version information of the different components of Genero BDL.

Starting with 2.32.00, this tool is no longer distributed.

To print version information, you must use the -V option of fglrun.

2.21 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.21.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. PostgreSQL 8.4 and INTERVAL type on page 116
2. fglcomp --build-rdd compiles the module on page 116
3. Unique and primary key constraint violation on page 116
4. IMPORT with list of C-Extensions on page 117
5. Initializing dynamic arrays to null on page 117
6. Strict screen record definition for tables on page 117

PostgreSQL 8.4 and INTERVAL type

The `dbmpgs84x` database driver requires your database schema use the INTERVAL type, rather than a CHAR(50) type.

Version 2.21 introduced support for PostgreSQL 8.4 with the new database driver `dbmpgs84x`. This version of PostgreSQL implements a native INTERVAL data type that is similar to the Genero Business Development Language INTERVAL type.

When using the `dbmpgs84x` (and higher) driver, Informix-style INTERVAL types will be mapped / translated to native PostgreSQL INTERVALs. Prior drivers will keep using the CHAR(50) replacement. If your application is storing INTERVAL in a PostgreSQL database, you will have to modify you database schema to replace the existing CHAR(50) column with the native INTERVAL data type of PostgreSQL 8.4. If you cannot migrate the database, you can still use the older dbmpgs83x driver using CHAR(50) for INTERVALs, but that driver requires a PostgreSQL client version 8.3.

fglcomp --build-rdd compiles the module

`fglcomp --build-rdd` now creates both the `.42m` and `.rdd` files.

Before version 2.21, `fglcomp --build-rdd` only produced the `.rdd` data definition file.

This option is now a compilation option. Both `.42m` and `.rdd` files are created at the same time.

Unique and primary key constraint violation

Unique and primary key constraint violations mostly return error -268, however you might also need to check for error -269 in some instances.

When a unique or primary key constraint is violated, the IBM® Informix® driver returns the error -268 in SQLCA.SQLCODE if the database uses transaction logging, and error -239 if the database uses no logging.

Regarding non-Informix drivers, all 2.21 drivers now return -268 when a unique constraint or primary key constraint is violated. Before 2.21, the Oracle and SQL Server / Sybase drivers returned error -239, which is only returned by IBM® Informix® databases without transaction logging. Returning error -268 for all drivers is the best choice in a context of transactional databases.

Check your code for -239 error code usage and replace by -268. If you still need to test error -239 (for example because you have IBM® Informix® databases without transactions), we recommend that you write a function testing different error codes to check unique constraint violation:

```
FUNCTION isUniqueConstraintError()
  IF (SQLCA.SQLCODE==-239 OR SQLCA.SQLCODE==-268)
  OR (SQLCA.SQLCODE==-346 AND SQLCA.SQLERRD[2]==-100)
  THEN
    RETURN TRUE
  ELSE
    RETURN FALSE
```

```
  END IF
END FUNCTION
```

IMPORT with list of C-Extensions
The `IMPORT` instruction for C extensions denies a comma-separated syntax.

Before version 2.21.00, the `IMPORT` instruction for C extensions was documented as allowing a comma-separated list of libraries:

```
IMPORT lib1, lib2
```

This compiled, but at runtime only the first library was found. Using elements of the other libraries raised a runtime error.

With 2.21.00 and the new .42m module importation support, the compiler is now more strict and denies the comma-separated syntax. You must specify every library, Java™ class or .4gl module in separate lines:

```
IMPORT lib1
IMPORT JAVA myclass
IMPORT FGL mymodule
```

Initializing dynamic arrays to null
The INITIALIZE TO NULL instruction clears the dynamic array.

(This issue was actually registered as a bug/enhancement #15128)

Starting with version 2.21.00, the INITIALIZE TO NULL instruction clears the dynamic arrays (i.e. array.getLength() returns 0). Before this version, all elements of the dynamic array were kept, and set to null. Since the old behavior was documented, this behavior change required a migration note. The new behavior is expected by most programmers.

Strict screen record definition for tables
The fglform compiler of version 2.21.00 now makes a strict checking of the fields used in the screen record definition for table containers.

It generates error -6819 if the screen record do not use all columns used in the table. The order can be different, however.

> **Note:** This behavior change is related to the bug fix FGL-2701 and FGL-3174.

2.20 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.20.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Sort is now possible during INPUT ARRAY on page 118
2. Cell attributes and buffered mode on page 118
3. Field methods are more strict on page 118
4. Strict variable identification in SQL statements on page 118
5. SQL Warnings with non-Informix databases on page 119
6. SERIALREG table for 64-bit serial emulation on page 119
7. Extracting the database schema with fgldbsch on page 120
8. Database driver internal error changed from -768 to -6319 on page 120
9. Searching for image files on the application server on page 120
10. Strict action identification in dialog methods on page 120
11. Strict field identification in dialog methods on page 120
12. Form compiler checking invalid layout definition on page 121

13. Database schema compatibility on page 121
14. Predefined actions get automatically disabled according to context on page 122
15.BEFORE ROW no longer executed when array is empty on page 122
16. Controlling INPUT ARRAY temporary row creation on page 122

Sort is now possible during INPUT ARRAY
Starting with version 2.20, the built-in sort is now available during `INPUT ARRAY`. If you want to avoid sorts in a Table, use the `UNSORTABLECOLUMNS` attribute.

Cell attributes and buffered mode
Use the UNBUFFERED mode when setting cell attributes.

Before version 2.20, array cell attributes were synchronized quite often by the runtime system, and this was not very efficient. As a result, there was not much difference between using buffered or unbuffered mode; when changing cell attributes, the result was immediate even in buffered mode.

Starting with version 2.20, it is recommended that you use the UNBUFFERED mode when setting cell attributes; otherwise, the colors will not be synchronized on the front-end.

Field methods are more strict
Starting with Genero 2.20 (or when using multiple dialogs in 2.11.08 and higher), DIALOG class methods such as `setFieldActive()` need the correct field specification with the screen-record name prefix, if the field was explicitly bound with the `FROM` clause of `INPUT` or `INPUT ARRAY`.

In prior versions, the field was found by these methods even if the prefix was invalid. (Actually, the prefix was just ignored and only the fieldname was used.)

Strict variable identification in SQL statements
Program variable identification in static SQL statements is more strict in version 2.20 than older versions.

If you define a variable with the same name as a SQL object (i.e. table name, table alias), the fglcomp compiler will raise an error because it will consider the program variable first. For example, if the variable name matches the table or alias identifier, using *table.column* in the SQL statement will be resolved as *variable.member*, which does not exist.

The next code example will not compile because the program defines a variable using the same name as the table alias *c*:

```
MAIN
   DEFINE c INTEGER
   DATABASE stores
   SELECT COUNT(*) INTO cFROM customer c
          WHERE c.fnameIS NULL
END MAIN
```

The code also fails to compile with IBM® Informix® 4gl 7.32, but it did compile with version of Genero Business Development Language.

To work around this, you must either rename the program variable, or explicitly identify SQL objects with the @ prefix in the SQL statement:

```
MAIN
   DEFINE c INTEGER
   DATABASE stores
   SELECT COUNT(*) INTO cFROM customer c
          WHERE @c.fnameIS NULL
END MAIN
```

Recompile all your programs to find the conflicts.

SQL Warnings with non-Informix databases
SQL Warnings are now propagated for all database drivers, and can set the SQLCA.SQLAWARN, SQLSTATE and SQLERRMESSAGE registers.

Before version 2.20, is was impossible for a non-Informix driver to return SQL Warning information in SQLCA, SQLSTATE and SQLERRMESSAGE.

This new behavior will have no impact if you test SQL Errors with STATUS or SQLCA.SQLCODE, as these registers remain zero if an SQL Warning is raised. However, if you are using SQLSTATE to check for SQL Errors, you must now distinguish SQLSTATE of class 01: These are SQL Warnings, not SQL errors.

In this example, when connected to IBM® DB2®, the SQLSTATE register will get the value 01504 indicating that all rows of the table have been deleted. As a result, testing SQLSTATE against 00000 will evaluate to false, and run into the error handling block, which is unexpected:

```
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   DELETE FROM customer
   IF SQLSTATE <> "00000" THEN
      -- handle error
   END IF
END MAIN
```

To check for successful SQL execution with or without warning, you can, for example, code:

```
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   DELETE FROM customer
   IF NOT (SQLSTATE=="00000" OR SQLSTATE MATCHES "01*") THEN
      -- handle error
   END IF
END MAIN
```

SERIALREG table for 64-bit serial emulation
You must alter the `SERIALREG` table to do serial emulation on a `BIGINT` column.

The SERIALREG based serial emulation is defined by the following FGLPROFILE entry:

```
dbi.database.<dbname>.ifxemul.datatype.serial.emulation = "regtable"
```

Version 2.20 introduces the `BIGINT` data type, which is a 64-bit signed integer. You can use `BIGSERIAL` or `SERIAL8` columns with IBM® Informix®, and ODI drivers can emulate 64-bit serials in other database servers. However, if you are using serial emulation based on the `SERIALREG` table, you must redefine this table to change the `LASTSERIAL` column data type to a `BIGINT`. If the `BIGINT` data type is not supported by the database server, you can use a `DECIMAL(20,0)` instead:

```
CREATE TABLE serialreg (
  tablename   VARCHAR2(50) NOT NULL,
  lastserial  BIGINT       NOT NULL,
  PRIMARY KEY ( tablename )
)
```

> **Important:** If you need to migrate an installed database using `SERIALREG`-based triggers, you will have to keep the current registered serials and use `ALTER TABLE` instead of `CREATE TABLE`. This example shows the `ALTER TABLE` syntax for SQL Server. Check the database server manuals for the exact syntax of the `ALTER TABLE` statement.
>
> ```
> ALTER TABLE serialreg ALTER COLUMN lastserial BIGINT NOT NULL
> ```

Additionally, all existing `SERIALREG`-based triggers must be modified, in order to use `BIGINT` instead of `INTEGER` variables, otherwise you will get `BIGINT` to `INTEGER` overflow errors. For example, to modify existing triggers with SQL Server, you can use the `ALTER TRIGGER` statement, which can be easily generated from the database browser tool (there is a *modify* option in the contextual menu of triggers). After the existing trigger code was generated, you must edit the code to replace the `INTEGER` data type by `BIGINT` in the variable declarations, and execute the `ALTER TRIGGER` statement.

Extracting the database schema with fgldbsch
The fgldbsch database schema extraction tool has been updated to map native database types to newly-added types.

Version 2.20 implements new data types such as BIGINT and BOOLEAN. The fgldbsch database schema extraction tool has been reviewed to map native database types to these new types when possible. Pay attention to these changes, when extracting a schema from your database.

For example, before version 2.20, fgldbsch converted an Oracle NUMBER(20,0) to a DECIMAL(20,0) by default. Now, since 2.20 provides the BIGINT native FGL type, it can be used to store a NUMBER(20,0) from Oracle.

You can get the previous behavior by using a conversion directive with the `-cv` option of fgldbsch.

To see the new conversion rules, run the fgldbsch tool with the `-ct` option.

Database driver internal error changed from -768 to -6319
The internal error raised was changed to avoid conflicts with an IBM® Informix® SQL error code.

Prior to version 2.20, if an unexpected error occurred in a database driver, the driver could return error -768, which is a real IBM® Informix® SQL error that instructs the user to call the IBM® support center.

To avoid any mistake, 2.20 database drivers return now the error -6319 if an internal error occurs, which is a Genero Business Development Language specific error message that suggests you to set the FGLSQLDEBUG environment variable to get detailed debug messages.

Searching for image files on the application server
For security reasons, the image file transfer mechanism has been slightly modified in version 2.20.

(This modification has also been back-ported in 2.11.14):

If FGLIMAGEPATH is set, the current working directory is no longer searched as in previous versions. You must explicitly add "." to the list of directories. By default, if FGLIMAGEPATH is not defined, the runtime system still searches the current directory.

If FGLIMAGEPATH is defined, the image files used in IMAGE form fields or in the IMAGE attribute must be located below one of the directories listed in the environment variable. This constraint does not exist if FGLIMAGEPATH is not set and has been relaxed in 2.21.00 for image fields displayed by program.

Starting with 2.21.00, images displayed by program to IMAGE fields are considered as valid files to be transferred to the clients without risk and do not follow the FGLIMAGEPATH security restrictions. Images are however searched according to the path list defined in FGLIMAGEPATH.

Strict action identification in dialog methods
Actions referenced in methods of the dialog class must exist in the current dialog, or an error is raised.

Starting with version 2.20.00, dialog class methods like `ui.Dialog.setActionActive()` can now raise a runtime error -8089 if the action name is invalid. Before version 2.20, the method ignored the invalid action name, and it could take a while for the programmer to find the mistake.

Strict field identification in dialog methods
Fields referenced in methods of the dialog class must exist in the current dialog, or an error is raised.

Starting with version 2.20.05, dialog class methods like `ui.Dialog.setFieldTouched()` can now raise a runtime error -1373 if the field specified does not match a field in the current dialog. Before version

2.20.05, these methods previously ignored the invalid field specification, and it could take a while for the programmer to find the mistake.

Form compiler checking invalid layout definition
It is better to identify form layout mistakes when the form is compiled, rather than at runtime.

Starting with version 2.20.05, the fglform compiler performs more layout checking than before. Thus, existing (invalid) forms that compiled with prior versions of Genero may no longer compile with 2.20.05. This strict checking is done to detect layout mistakes during form design, instead of having the front-ends render invalid forms in a unknown manner at run time.

For example, the following form definitions are invalid and will raise a compilation error with fglform:

```
SCHEMA FORMONLY
LAYOUT
GRID
{
  [f01:  |f02    ]     -- HBox layout tags in lists are denied
  [f01:  |f02    ]
  [f01:  |f02    ]
  [f01:  |f02    ]
}
END
END
```

```
SCHEMA FORMONLY
LAYOUT
GRID
{
  [f01    ]  [f02    ]
  [f01    ]       [f02    ]   -- Misaligned field tags (vertical)
  [f01    ]  [f02    ]
  [f01    ]       [f02    ]
}
END
END
```

```
SCHEMA FORMONLY
LAYOUT
GRID
{
  [f01][f01][f01]  [f01]   -- Misaligned field tags (horizontal)
}
END
END
```

Database schema compatibility
Version 2.20.06 database schema extraction now generates a different type code for BOOLEAN, that introduces a compatibility issue with older versions of fglcomp and fglform.

> **Note:** This behavior change is related to the bug fix FGL-2048.

If database tables use data types that are equivalent to the BOOLEAN Informix® type, such as the BIT type in SQL Server, you must regenerate the .sch database schema file with the fgldbsch tool. If you keep using the schema generated by an older version such as 2.20.04, fglcomp or fglform will raise the error -6634.

This problem will only occur if your database tables use the BOOLEAN (or native equivalent type). See ODI Adaptation Guides for more details about database specific boolean types.

Predefined actions get automatically disabled according to context
Dialogs will automatically disable some predefined actions, if it makes no sense to trigger the action in the current context.

Starting with version 2.20, (or with version 2.10 when `FGL_USENDIALOG=1`), the dialogs will automatically disable some predefined actions if it makes no sense to trigger the action in the current context. For example, during an `INPUT ARRAY`, if there are no rows to remove, the predefined delete action will be disabled automatically. Similarly, the insert and append actions get disabled when the array is full (this can happen with static arrays or when using the `MAXCOUNT` attribute). The predefined actions will also be disabled if you overwrite them with your own `ON ACTION` handler.

BEFORE ROW no longer executed when array is empty
In order to trigger the BEFORE ROW block when entering an array, the array must not be empty.

Before version 2.20, the `BEFORE ROW` block was always executed when entering a `DISPLAY ARRAY` or `INPUT ARRAY` dialog, even if the number of real data rows was zero. Starting with 2.20, when using an empty dynamic array or when using a static array and specifying zero data rows with a `SET_COUNT(0)` call or with the `COUNT=0` attribute, the `BEFORE ROW` control block is no longer executed when the dialog starts.

The `BEFORE ROW` block will be executed when a new row is created in `INPUT ARRAY`. When entering an `INPUT ARRAY` with an empty array, a new temporary row is created by default, except if you use the `AUTO APPEND = FALSE` attribute.

Controlling INPUT ARRAY temporary row creation
The INPUT ARRAY dialog and sub-dialog provides the APPEND ROW and AUTO APPEND attributes to control row creation at the end of a list (known as *temporary row creation*).

`APPEND ROW` controls explicit temporary row creation, while `AUTO APPEND` controls automatic temporary row creation.

Starting with version 2.20, moving down after the last row (with the mouse or keyboard) or leaving the last column of the last row with a TAB key are considered events that trigger automatic temporary row creation.

Before version 2.20, these cases were considered as events for an explicit temporary row creation. In other words, if you want to deny temporary row creation in such case, it is now done with `AUTO APPEND = FALSE` while in older versions it was controlled by `APPEND ROW = FALSE`.

2.11 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.11.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check previous upgrade guides if you migrate from an earlier version.

1. Writing timestamp information in p-code modules on page 122

Writing timestamp information in p-code modules
A compilation timestamp is no longer automatically written to p-code files, when the source code is not modified.

Before release 2.10, the 42m p-code files were stamped with a compilation timestamp. This information changed after every compilation, even if the source code was not modified.

Since 2.10, the timestamp information is no longer written to p-code files by default, allowing 42m file comparison, checksum creation, or storage of 42m file in versioning tools. Version 2.11.05, provides the --timestamp fglcomp option to force a timestamp in p-code modules:

```
$ fglcomp --timestamp mymodule.4gl
$ fglrun -b mymodule.42m
2008-12-24 11:22:33 2.11.05-1169.84 /home/devel/stores/mymodule.4gl 15
```

2.10 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.10.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check previous upgrade guides if you migrate from an earlier version.

1. XML declaration added automatically on page 123

XML declaration added automatically

The XML declaration is added automatically when writing XML files.

An XML file must start with a "Prolog" or "XML Declaration" defining the XML version and character set used by the file:

```
<?xml version='1.0' encoding='ISO-8859-1' ?>
<root ...>
...
</root>
```

Starting with Genero version 2.10.05, the XML declaration is now added automatically when writing XML files.

> **Note:** This behavior change is related to the bug fix FGL-285.

Before 2.10.05, you could workaround this by writing this header yourself as a processing instruction, but this solution was subject to mistakes: The non-ASCII characters written to the XML file must match the encoding specification in the XML Declaration.

To avoid invalid character set definitions, the Genero BDL built-in classes now add the XML Declaration with the `encoding` attribute defined according to the current locale used by the runtime system. The value written in the `encoding` attribute is defined by the charmap.alias file.

2.02 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.02.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Automatic HBox/VBox on page 123

Automatic HBox/VBox

Starting with version 2.02.01, the form compiler automatically adds HBox and VBox containers with splitter around stretchable form elements that are placed side-by-side.

When recompiling your forms with this new version of fglform, the generated .42f can get additional HBox/VBox nodes even if you did not touch the .per source file.

2.01 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.01.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

There is no upgrade note with this version.

2.00 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 2.00.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Runner creation is no longer needed on page 124
2. Desupported Informix client environments on page 124
3. Desupported database drivers on page 124
4. fglmkrtm tool removed on page 125
5. fglinstall tool removed on page 125
6. Linking the utility functions library on page 125
7. Dynamic C extensions on page 125
8. WANTCOLUMNSANCHORED is desupported on page 125
9. PIXELWIDTH / PIXELHEIGHT are desupported on page 125
10. Pre-fetch parameters with Oracle on page 126
11. Preprocessor directive syntax changed on page 126
12. Static SQL cache is removed on page 126
13. Connection database schema specification on page 127
14. Changes in the schema extraction tools on page 127
15. Global and module variables using the same name on page 128
16. Connection parameters in FGLPROFILE when using Informix on page 128
17. Inconsistent USING clauses on page 128
18. Usage of RUN IN FORM MODE on page 129
19. TTY and COLOR WHERE attribute on page 129

Runner creation is no longer needed

Starting with version 2.00, you no longer need to recompile/build a runner.

The runtime system architecture is now based on shared libraries (or DLLs on Windows™), and the database drivers are automatically loaded according to FGLPROFILE configuration parameters.

If you have C extensions, you must rebuild them as shared libraries.

> **Important:** Database vendor client libraries (libclntsh, libcli, libpq, libaodbc) must be provided as shared objects (or DLL on Windows™).

Desupported Informix® client environments

We strongly recommend you to upgrade the IBM® Informix® Client Software Development Kit (CSDK) to the most recent version supported by Genero BDL.

The database interface of Genero Business Development Language (BDL) version 2.00 was redesigned to allow dynamic loading of database drivers. The following IBM® Informix® drivers and environments have been desupported with this redesign:

- ix210: Informix® ESQL/C 2.10
- ix410: Informix® ESQL/C 4.10
- ix501: Informix® ESQL/C 5.01
- ix711: Informix® ESQL/C 7.11
- ix720: Informix® ESQL/C 7.20

If required, old IBM® Informix® drivers can be re-enabled in a next Genero BDL version. However, we strongly recommend you to upgrade the IBM® Informix® Client Software Development Kit (CSDK) to the most recent version supported by Genero BDL.

Desupported database drivers

Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in versions 2.00:

- Adabas D 12 (dbmabd12)
- PostgreSQL 7 (dbmpgs7x)

- SQL Server 7 (dbmmsv7x)

fglmkrtm tool removed
The fglmkrtm tool has been removed, as database drivers are loaded dynamically.

Starting with version 2.00, database drivers are now always loaded dynamically. Thus the fglmkrtm tool has been removed from the distribution. This tool was provided in previous versions to create a fglrun runner with the correct database driver.

Refer to Database connections on page 457 for more details about database driver configuration.

fglinstall tool removed
The fglinstall tool has been removed from the distribution.

This tool was provided in previous versions to compile product message files, form files, and program modules provided in the distribution. The compiled versions of all these files are now included in the package.

Linking the utility functions library
All utility functions are in the libfgl4js.42x library, up until 2.21.

Prior to version 2.00, some utility functions (canvas draw* and database db_* functions) were linked automatically to the 42r program when using fglrun -l or fgllink. These functions are implemented in the fgldraw.4gl and fgldbutl.4gl modules, which were linked in the libfgl.42x library and loaded automatically at runtime by fglrun.

Starting with version 2.00, all utility functions are now in the libfgl4js.42x library. So, if you use the draw* or db_* utility functions, you must now add the libfgl4js.42x library explicitly when using fglrun -l or fgllink, or you can use the fgl2p tool to link .42r programs. The fgl2p tool links the program with the libfgl4js.42x library by default.

Starting with version 2.21, the libfgl.42x library is no longer provided.

Dynamic C extensions
Dynamic C extensions are automatically loaded according to `IMPORT` instructions.

Prior to version 2.00, you must use FGLPROFILE entries to specify Dynamic C extensions to be loaded at runtime.

Starting with version 2.00, Dynamic C extensions are automatically loaded according to `IMPORT` instructions. The FGLPROFILE entries are no longer used.

> **Important:** Global variables (userData) can no longer be shared between the runtime system and the C extensions. You must use functions to pass global variable values.

There is no longer a need to define the FGL_API_MAIN macro in the extension interface file.

All C data type definitions are now centralized in the fglExt.h header file, header files like Date.h, MyDecimal.h have been removed from the distribution.

WANTCOLUMNSANCHORED is desupported
Use `UNMOVABLECOLUMNS` to specify that table columns cannot be moved around by the user.

Before version 2.00, the `WANTCOLUMNSANCHORED` attribute was undocumented but still supported by the language, to simplify migration from 1.20.

Starting with version 2.00, the `WANTCOLUMNSANCHORED` attribute is de-supported; you must use `UNMOVABLECOLUMNS` to specify that table columns cannot be moved around by the user.

PIXELWIDTH / PIXELHEIGHT are desupported
Use the `WIDTH` and `HEIGHT` attributes to specify the size of an image.

Before version 2.00, the `PIXELWIDTH` and `PIXELHEIGHT` attributes were used to specify the real size of an `IMAGE` form item.

Starting with version 2.00, you must use the `WIDTH` and `HEIGHT` attributes to specify the size of an image:

In the .per form file:

```
IMAGE img1 = FORMONLY.image1,
      HEIGHT = 100 PIXELS,
      WIDTH = 100 PIXELS;
```

The `PIXELWIDTH` and `PIXELHEIGHT` attributes are still supported by the form compiler, but are deprecated and will be removed in a future version.

Pre-fetch parameters with Oracle
Pre-fetch parameters allow an application to automatically fetch rows from the Oracle database when opening a cursor.

Before version 2.00, the default pre-fetch parameters are 50 rows and 65535 bytes for the pre-fetch buffer. Some customers experienced a huge memory usage with those default values, when using a lot of cursors: It appears that the Oracle client is allocating a buffer of pre-fetch.memory (i.e. 64 Kbytes) for each cursor.

Starting with version 2.00, the default is 10 rows and 0 (zero) bytes for the pre-fetch buffer (memory), meaning that memory is not included in computing the number of rows to pre-fetch.

Preprocessor directive syntax changed
The preprocessor directives use an ampersand character (&) instead of a sharp (#) character.

Before version 2.00, the preprocessor directives start with a (#) sharp character, to be compliant with standard preprocessors (like **cpp**). This caused too many conflicts with standard language comments that use the same character:

```
#include "myheader.4gl"
# This is a comment
```

Starting with version 2.00, the preprocessor directives use an ampersand character (&):

```
&include "myheader.4gl"
FUNCTION debug( msg )
  DEFINE msg STRING
&ifdef DEBUG
  DISPLAY msg
&endif
END FUNCTION
```

The preprocessor is now integrated in the compiler, to achieve faster compilation.

> **Important:** To simplify the migration, the # sharp character is still supported when using the -p fglpp option of compiler. However, you should review your source code and use the & character instead; # sharp will be desupported in a future version.

Static SQL cache is removed
The Static SQL Cache has been removed.

Before version 2.00, the size of the static SQL cache is defined by a FGLPROFILE entry:

```
dbi.sql.static.optimization.cache.size = max
```

This entry was provided to optimize SQL execution without touching code using a lot of static SQL statements, especially when using non-Informix databases where the execution of static SQL statements is slower than with Informix®. This is useful for fast migrations, but there were a lot of side effects and unexpected errors.

Starting with version 2.00, the Static SQL Cache has been removed for the reasons described. Programs continue to run without changing the code, but if you want to optimize program execution, you must use dynamic SQL (PREPARE + EXECUTE).

Connection database schema specification
Oracle- and DB2-specific FGLPROFILE entries can be specified to define the database schema at runtime.

Before version 2.00, an FGLPROFILE entry can be specified to define the database schema at runtime:

```
dbi.database.dbname.schema = "schema-name"
```

This entry could be used to select the native database schema after connecting to the server, for Oracle and DB2 only.

Starting with version 2.00, this entry is now specific to the Oracle and DB2 database driver configuration parameters:

```
dbi.database.dbname.ora.schema = "schema-name"
dbi.database.dbname.db2.schema = "schema-name"
```

For other database servers, this configuration parameter is not defined.

> **Important:** It is no longer possible to specify the "schema" parameter in the connection string (dbname+schema='name').

Changes in the schema extraction tools
The fgldbsch schema extractor is recommended, and has been enhanced.

Unique tool

Version prior to 2.00 provide two schema extractors: fglschema and fgldbsch. The first can only extract schemas from Informix® databases, while the second one can extract schemas from all supported databases.

Starting with version 2.00, the fgldbsch tool has been extended to support the old fglschema options, and fglschema has been replaced by a simple script calling fgldbsch. When you call fglschema, you actually call fgldbsch. We recommend that you use fgldbsch with its specific command line options.

System tables

In 2.0x, fgldbsch does not extract system tables by default. You must specify the -st option to get the system tables description in the schema files.

Remote synonyms

The original fglschema tool was searching for *remote synonyms* with Informix® databases. The fgldbsch tool of version 2.00 does not search for remote synonyms.

Public and private synonyms

Since version 1.32.1b (build 620.313), fgldbsch does not extract *private synonyms* anymore. Only *public synonyms* are extracted. The **.sch** schema files do not contain table owners, and if two *private synonyms* have the same names, there is no way to distinguish them in the schema files. Therefore, to avoid any mistakes, *private synonyms* are not extracted anymore.

> **Note:** This behavior change is related to the bug fix FGL-1033.

Global and module variables using the same name
Since version 2.00, when you declare a module variable with the same name as a global variable, a compilation error must be thrown.

> **Note:** This behavior change is related to the bug fix FGL-114.

This is critical to avoid confusion with the variable usage:

```
GLOBALS
  DEFINE level INTEGER
END GLOBALS
```

```
GLOBALS "globals.4gl"
DEFINE level INTEGER
FUNCTION func1()
  LET level = 123  -- is this the global or the module variable?
END FUNCTION
```

Before version 2.00, the compiler did not detect this and the module variable was used, but one might want to use the global variable instead!

If you have module variables defined with the same name as global variables, the compiler now raises the following error:

```
-4319: The symbol 'variable-name' has been defined more than once.
```

You can easily fix this by renaming the module variable. There is no risk to do this modification, because in versions before 2.00, the module variable was used, not the global variable.

Remark: The compiler now also detects duplicate global variable declaration. Just remove the duplicated lines in your source.

Connection parameters in FGLPROFILE when using Informix®
The dbi.database.* connection parameters defined in FGLPROFILE are used by the Informix® driver

Before version 2.00, the dbi.database.* connection parameters defined in FGLPROFILE are ignored by the Informix® drivers.

Starting with version 2.00, the dbi.database.* connection parameters defined in FGLPROFILE are used by the Informix® driver, as well as other database vendor drivers. For example, if you connect to the database "stores", and you have the following entries defined, the driver tries to connect as "user1" with password "alpha":

```
dbi.database.stores.username = "user1"
dbi.database.stores.password = "alpha"
```

You typically get SQL errors -387 or -329 when the wrong database login or the wrong database name is used.

Inconsistent USING clauses
Having data types changing at each execute is no longer supported.

> **Important: This issue applies to non-Informix databases only.**

Before version 2.00, it was possible to execute a prepared statement with the variable list changing at each EXECUTE statement:

```
DEFINE var1 DECIMAL(6,2)
DEFINE var2 CHAR(10)
DEFINE var3 DATE
```

```
PREPARE st1 FROM "INSERT INTO tab1 VALUES ( ?. ?, ? )"
EXECUTE st1 USING var1, var2, var3
EXECUTE st1 USING var2, var3, var1   -- different order = different data
 types
```

The database interface of version 2.00 has been rewritten for better performance. Having data types changing at each execute is no longer supported.

Error -254 will be raised if different data types are used in subsequent EXECUTE statements (with the same statement name).

Usage of RUN IN FORM MODE
RUN ... IN LINE MODE is recommended to run interactive applications.

Before version 2.00, RUN...IN FORM MODE was recommended to run interactive applications.

Starting with version 2.00, RUN ... IN LINE MODE is recommended to run interactive applications. The RUN command should be used as follows (in both GUI and TUI mode):

1. When starting an interactive program, either use RUN ... IN LINE MODE or, if the default mode is LINE MODE, use the RUN instruction without any option.
2. When starting a batch program that does not display any message, you should use RUN ... IN FORM MODE.

For more details about the RUN options, see the RUN instruction.

TTY and COLOR WHERE attribute
All type of fields now allow TTY attributes and the conditional COLOR WHERE attribute.

Before version 2.00, only some field types like EDIT or TEXTEDIT could support TTY attributes (COLOR, REVERSE), and the conditional COLOR WHERE attribute.

Starting with version 2.00, all type of fields now allow TTY attributes and the conditional COLOR WHERE attribute. So when using any ATTRIBUTES(*tty-attribute*) in programs, all fields will now be affected.

For example, CHECKBOX and RADIOGROUP fields will now get a colored background, this was not the case in prior versions.

1.33 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 1.33.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Desupported database drivers on page 129

Desupported database drivers
Database drivers for old database client versions are removed according to the vendor de-support plans.

Database drivers desupported in versions 1.33:

- MySQL 3.23.x (dbmmys32x)

1.32 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 1.32.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

There is no upgrade note with this version.

1.31 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 1.31.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

There is no upgrade note with this version.

1.30 upgrade guide

These topics describe product changes you must be aware of when upgrading to version 1.30.

> **Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Also check prior upgrade guides if you migrate from an earlier version.

1. Action and field activation on page 130
2. Using HBox tags in forms on page 130
3. Width of ButtonEdit/DateEdit/ComboBox on page 133
4. Form fields default sample on page 135
5. Size policy for ComboBoxes on page 136
6. Action defaults at form level on page 139
7. Compiled string files have now .42s extension on page 139

Action and field activation

Dialog methods can be used to control action and field activation.

Version 1.30 provides dialog methods to control action and field activation:

- ui.Dialog.setActionActive(action-name, TRUE/FALSE)
- ui.Dialog.setFieldActive(field-name, TRUE/FALSE)

Previous versions allowed to modify directly the 'active' attribute of the underlying DOM node in the AUI tree; This is now forbidden: It is mandatory to use the methods to enable/disable action or fields. The dialog will synchronize the 'active' attribute in the AUI tree according to the value passed to the methods and according to the context (some actions or fields can be automatically disabled).

Using HBox tags in forms

You can use HBox tags to stack form items horizontally, without being influenced by elements above or below.

Version 1.30 supports now HBox tags to stack form items horizontally without being influenced by elements above or below.

In an HBox there is a free mix of Form Fields, labels, and Spacer Items possible.

A typical usage of an HBox Tag is to have zipcode/city form fields side by side with predictable spacing in-between.

The "classic" layout would look like the following form definition:

```
<G "User Data(version 1.20)"                                        >
 Last Name     [l_name           ]First Name[f_name          ]
 Street        [street                                       ]
 City          [city          ]Zip Code[zip  ]
 Phone(private)[phone           ] At work [                 ]
 Code          [aa]-[ab]-[ac]
```

In Figure 7: HBox tag example screenshot on page 131 you will notice that the distance between "`l_name`" and "`First Name`" is smaller than between "`First Name`" and "`f_name`". How can this be? Two lines under, there is the "zip" field which affects this distance.

If we put HBox Tags around the fields we want to group horizontally together, we get the predictable spacing between "l_name","First Name" and "f_name".

```
<G "User Data in HBoxes stacked"                                    >
Last Name     [l_nameh         :"First Name":f_nameh         ]
Street        [streeth                                      :]
City          [cityh        :"Zip Code":ziph :              ]
Phone(private)[phoneh          :"At work":phonewh          : ]
Code          [ba:"-":bb:"-":bc:                             ]
```

Here "l_nameh", "First Name" and "f_nameh" are together in one HBox; the ":" colon acts as a separator between the 3 elements.

The width of an element is calculated from the space between "[" and ":" (width of cityh is 14), or from the space between ":" and ":" (width of "bb" is 2), or from the space between ":" and "]" (width of "f_nameh" is 16). The "zip" field in the version 1.20 example has a width of five and the "ziph" field has also a width of five.

In the second Groupbox in Figure 7: HBox tag example screenshot on page 131 you will notice that the HBox is smaller than the first one, even though it uses two characters more in the screen definition. The reason is that each HBox occupies only ONE cell in the parent grid, and the content in one HBox is independent of the content in another HBox. This relaxes the parent grid; it has to align only the edges of the HBoxes and the labels left of the HBoxes. The two extra characters in the Form file for the second Group come from the fact that the labels need quoting to distinguish them from field definitions. Of course, you could use a Label field if the two extra characters are unwanted (which is done in the third Groupbox).

The third Groupbox shows how the alignment in an HBox can be affected by putting empty elements (: :) inside the HBox Tag:

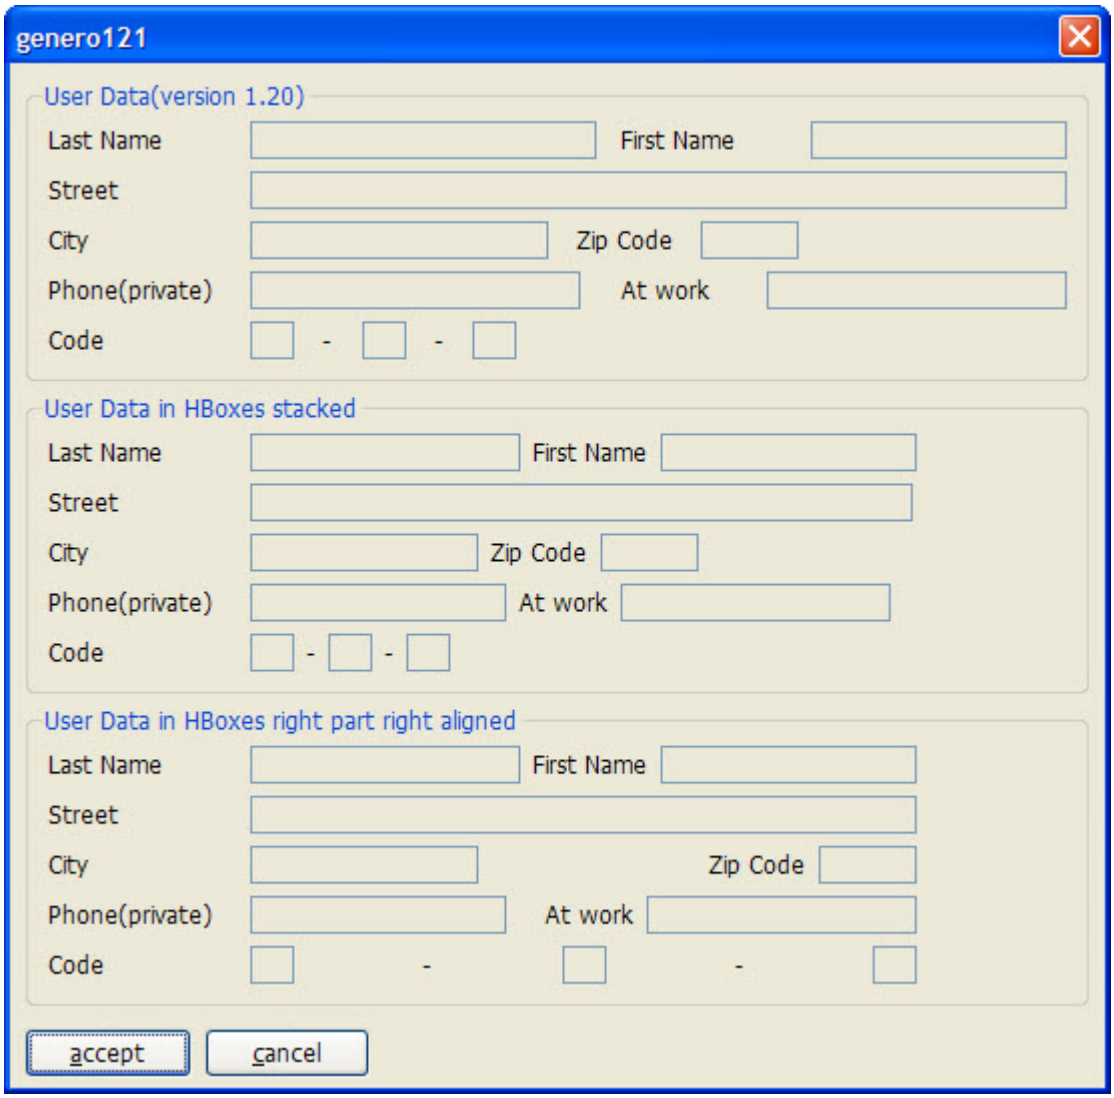
```
<G "User Data in HBoxes right part right aligned"                   >
Last Name     [l_nameh2        : :lfirsth2:f_nameh2          ]
Street        [streeth2                                      ]
City          [cityh2          :                  :lzip:ziph2]
Phone(private)[phoneh2        :      :latw:phonewh2          ]
Code          [ca:   "-"        :cb:        "-"           :cc]
```

Between "l_nameh2" and "lfirsth2" there are two ":" signs with a white space between them. This means: put a Spacer Item between l_nameh2 and lfirsth2, which gets all the additional space if the HBox is bigger than the sum of l_nameh2, lfirsth2 and f_nameh2. The number of spaces, however, has no effect. The spacer item between cityh2 and lzip has the same force as the spacer between l_nameh2 and lfirsth2.

You can treat a spacer item like a spring. The spacer item between cityh2 and lzip presses cityh2 to the left-hand side, and the rest of the fields to the right-hand side. In the "Code" line there is more than one spacer item; they share the additional space among them. (The "Code" HBox sample in the third line is only to show how spacer items work; we always advise using "Code" as in the second Groupbox, or to use a picture)

In general we advise using the approach shown in the second Groupbox: stack the items horizontally by replacing field ends with ":". This is the easy way to remove unwanted horizontal spacing.

Figure 7: HBox tag example screenshot



A big advantage in using elements in an HBox tag is that the fields get their real sizes according to the .per definition.

```
LAYOUT
GRID
{
<G g1 >
[a    ] single Edit Field

<G g2 >
 MMMMM
[b    ] The large label expands the Edit Field

<G g3 >
 MMMMM
[c   :]The large label has no influence on the Edit width

}

END
END
ATTRIBUTES
```

```
EDIT a = formonly.a, sample="0", default="12345";
EDIT b = formonly.b, sample="0", default="12345";
EDIT c = formonly.c, sample="0", default="12345";
END
```

In the second Groupbox, the edit field is expanded to be as large as the label above; using an HBox prevents this.

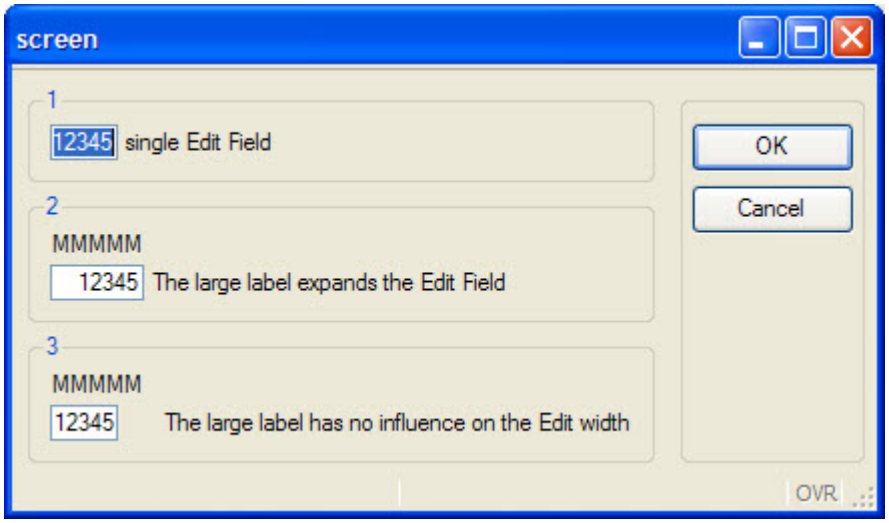


Figure 8: Use of HBox

> **Note:** in this example, we use a sample of "0" to display *exactly* five numbers.

HBox Tags limitations

HBox Tags don't work for fields of Screen Arrays or Tables; you will get a form compiler error. The reason is that the current AUI structure does not allow this. The front end needs a `Matrix` element directly in a `Grid` or a `ScrollGrid` to perform the necessary positioning calculations for the individual fields.

Width of ButtonEdit/DateEdit/ComboBox

When using `BUTTONEDIT`/`COMBOBOX`/`DATEEDIT` fields, you should account for the width of the widget button in addition to the input area.

The problem with BUTTONEDIT, DATEEDIT and COMBOBOX in versions prior to 1.30 is that a field `[b ]` got the width 3, the same width as an edit field with the same layout.

For example:

```
LAYOUT
GRID
{
  [e  ]
  [b  ]
}
END
END
ATTRIBUTES
EDIT e=formonly.e;
BUTTONEDIT b=formonly.b;
END
```

In this example, the outer (visual) width of both elements was the same, but the edit portion of "b" was much smaller, because the button did not count at all. (In practice this meant that on average only one and

a half characters of "b" was visible). However, you could input 3 characters! This made a BUTTONEDIT where you could see only one character and input only one character without tricks impossible.

Starting with version 1.30, for the Button, the Form Compiler subtracts two character positions from the width of BUTTONEDIT/COMBOBOX/DATEEDIT. This is possible because now the form compiler differentiates the width of the widget from the width of the entry part.

In fact, there is no *visual* difference between version 1.20 and 1.30 regarding this example, but in version 1.30 you can only enter one character, which is visually more correct.

In the example the BUTTONEDIT aligns with the Edit; that's why the Edit part of the BUTTONEDIT is usually still a bit bigger than one character (this depends on the button size, but if a button edit is contained by an HBox, it will get the exact size of "width" multiplied by the average character pixel width.

To express the BUTTONEDIT/COMBOBOX/DATEEDIT layout more visually, it is possible to specify:

```
[e  ]
[b- ]
```

the "-" sign marks the end of the edit portion and the beginning of the button portion (edit width ="1", widget width ="3").

The two characters are also subtracted for a BUTTONEDIT which is child of an HBox.

```
 [b  :]
```

gets also width="1" , but no widget width, because the HBox stacks the elements horizontally without needing widget width definition.

The two extra characters are only used to show the real size relations more WYSIWYG, and to have the same calculation as in a field without an HBox parent.

```
[e1:e2:e3:     ]
[b1  :b2  :b3  ]
```

shows that three BUTTONEDIT fields are much larger than three EDIT fields with the same width.

You can even write:

```
[e1:e2:e3:     ]
[b1- :b2- :b3- ]
```

or:

```
[e1:e2:e3:  ]
[b1-:b2-:b3-]
```

to use slim buttons and

```
[e1:e2:e3:        ]
[b1-  :b2-  :b3-  ]
```

if one uses large buttons to get the maximum WYSIWYG effect.

Please note that buttons do not grow if two characters "- " is expanded to three characters "- "; the button always computes its size from the image used, it's just to reserve more space in the form to match the real size.

Form fields default sample

An algorithm is used to compute the field width when no SAMPLE attribute is specified.

Starting with version 1.30, if no SAMPLE attribute is specified in the form files, the client uses an algorithm to compute the field width. In this case, a very pessimistic algorithm is used to compute the field widths: The client assumes a default SAMPLE of "M" for the first six characters and then "0" for the subsequent characters and applies this algorithm to all fields, with some exceptions like DATEEDIT fields.

The default algorithm tends to produce larger forms compared to forms used in BDS V3 and very first versions of Genero. Do not hesitate to modify the SAMPLE attribute in the form file, to make your fields shorter.

If you do not want to touch all your forms, a more tailored automatic solution would be to specify a ui.form.setDefaultInitializer() function, to set the SAMPLE depending on the AUI tag. In this example small UPSHIFT fields get a sample of "M"; all other fields get a sample of "0". This will preserve the original width for UPSHIFT fields, however numeric and normal String fields will get the sample of "0" and make the overall width of the form smaller.

Program:

```
# this demo program shows how to affect the "sample" attribute in a
#  ui.form.setDefaultInitializer function
# the main concern is to set a default sample of "0" and to
# correct the sample attribute for small UPSHIFT fields to "M"
# to be able to display full uppercase letter for fields with a small width

MAIN
  DEFINE three_char_upshift CHAR(3)
  DEFINE three_digit_number Integer
  DEFINE longstring CHAR(100)
  CALL ui.form.setDefaultInitializer("myinit")
  OPEN form f from "sampletest2"
  DISPLAY form f
  INPUT BY NAME three_char_upshift,three_digit_number,longstring
END MAIN

FUNCTION myInit(f)
  DEFINE f ui.Form
  CALL checkSampleRecursive(f.getNode())
END FUNCTION

FUNCTION checkSampleRecursive(node)
  DEFINE node,child om.DomNode
  LET child= node.getFirstChild()
  WHILE child IS NOT NULL
    CALL checkSampleRecursive(child)
    CALL setSample(child)
    LET child=child.getNext()
  END WHILE
END FUNCTION

FUNCTION setSample(node)
  DEFINE node,parent om.DomNode
  LET parent=node.getParent()
  -- only set the "sample" for FormFields in this example
  IF parent.getTagName()<>"FormField" THEN
    RETURN
  END IF
  IF node.getAttribute("shift")="up"
    AND node.getAttribute("width")<=6 THEN
    CALL node.setAttribute("sample","M")
  ELSE
    CALL node.setAttribute("sample","0")
```

```
  END IF
  DISPLAY "set sample attribute of ",node.getId()," to \"",
    node.getAttribute("sample"),"\""
END FUNCTION
```

Form File:

```
LAYOUT(text="sampletest2")
GRID
{
 <G sampletest
   >
  3 Letter Code: [a  ] 3 digit code:[b  ]  Description:[longstring ]

 <G "What can be seen"
   >
  There is no default sample set in this form, but due to a
  ui.form.setDefaultInitializer function, small UPSHIFT fields
  are adjusted to a sample of "M", all other fields get the sample "0"

 ------------------------------------------------------------------------------
  1. The 3 letter code should show up exactly "MMM" because of the applied
     sample="M"
  2. The 3 letter digit code should show up exactly "123" without additional

     spacing
}
END
END
ATTRIBUTES
EDIT a=formonly.three_char_upshift,UPSHIFT,default="MMM";
EDIT b=formonly.three_digit_number,default="123";
EDIT longstring=formonly.longstring,UPSHIFT,
     default="DESCRIPTION OF THE ITEM",SCROLL;
END
```

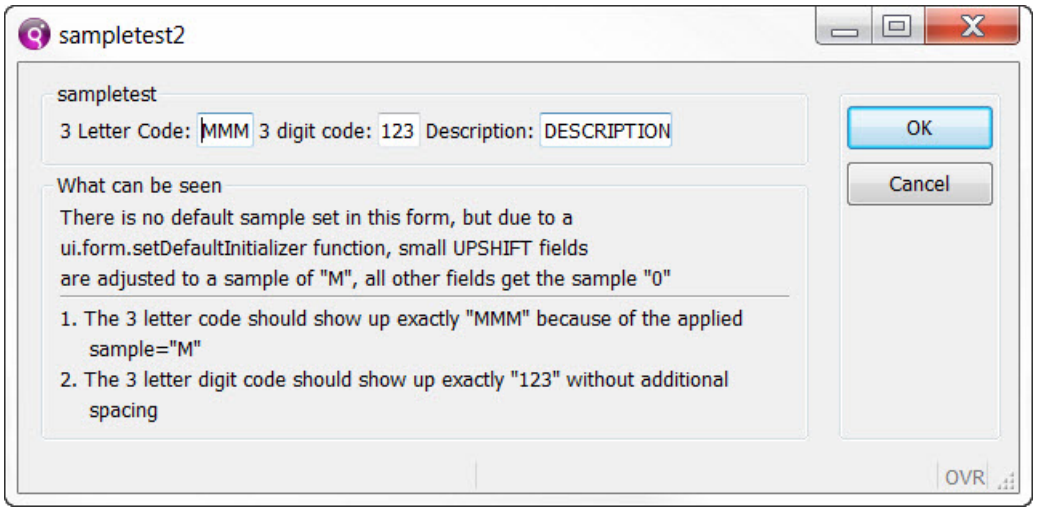

Figure 9: Sample usage in form

Size policy for ComboBoxes
You can use the SIZEPOLICY attribute for a COMBOBOX.

Starting with version 1.30 you can use the SIZEPOLICY attribute for COMBOBOXes.

COMBOBOX form items had a special behavior in versions prior to 1.30, because they adapted their size to the maximum item of the value list. On one hand, this is very convenient because the programmer doesn't have to find the biggest string in the value list, and to estimate how large it will be on the screen (with proportional fonts the string with the highest number of characters is not automatically the largest string). On the other hand, this behavior often led to an unpredictable layout if the programmer didn't reserve enough space for the COMBOBOX.

The SIZEPOLICY attribute gives better control of the result.

```
<G "Combo makes edit2 too big"                    >
 [edit1]
 [combo   ]
 [edit2   ]
...
ATTRIBUTES
EDIT edit1=formonly.edit1;
COMBOBOX combo=formonly.combo,
   ITEMS=((0,"Veeeeeeeery Looooooooooooooooong Item"),(1,"hallo")),
   DEFAULT=0;
EDIT edit2=formonly.edit2;
END
```

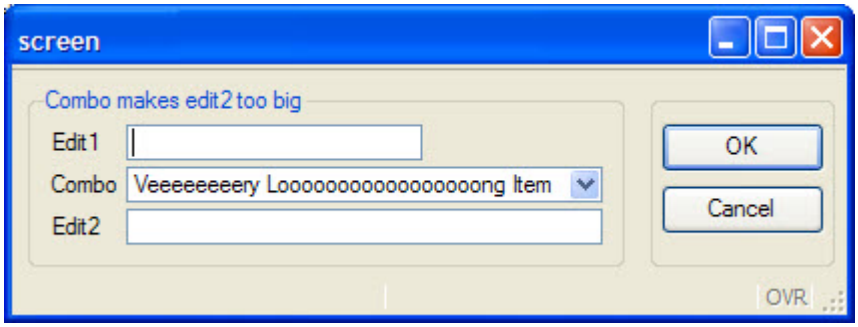

Figure 10: Use of SIZEPOLICY

In this case, the "combo" field gets very large as does "edit2", because it ends in the same grid column. It will confuse the end user if he can input only eight characters and the field is apparently much bigger. Two possibilities exist to surround this:

Use an HBox to prevent the edit2 from growing, and use HBoxes for all fields which start together with combo and are as large or bigger than combo:

```
<G "Edit2 in HBox doesn't grow" >
[edit1]
[combo  :]
[edit2  :]
...
```

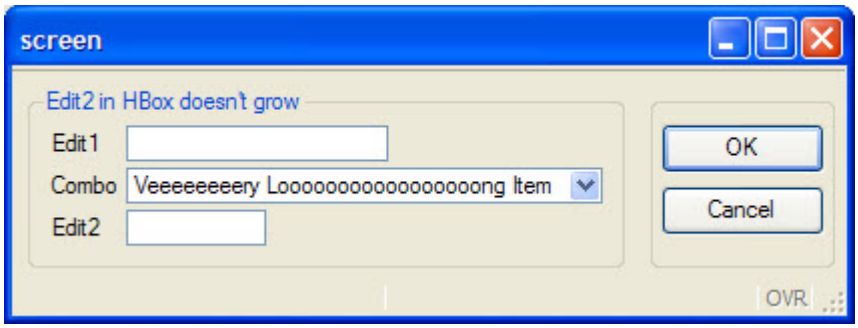

Figure 11: Use of HBox

Use the new `SIZEPOLICY` attribute, and set it to `fixed` to prevent `combo` from getting bigger than the initial six characters (6+Button):

```
 <G "Combo has a fixed size">
 ...
 [combo   ]
 [edit2   ]
 ...
 ATTRIBUTES
 ...
 COMBOBOX combo=formonly.combo,
    ITEMS = ((0,"Veeeeeeeery Looooooooooooooooong Item"),(1,"hallo")),
    DEFAULT=0, SIZEPOLOCY=FIXED ;
....
```

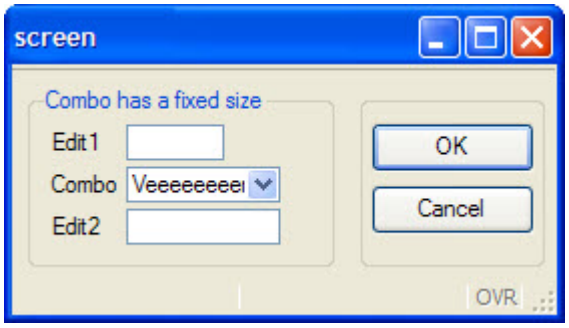

Figure 12: Use of SIZEPOLICY as fixed

In this example the `edit2` dictates the maximum size of `combo`, because even if the SIZEPOLICY is *fixed*, the elements are aligned by the Grid.

To prevent this and have *exactly* six characters (numbers) in the ComboBox, you need to de-couple `combo` from `edit2` by using an HBox.

```
<G "Combo has a fixed size,sample 0,in HBox"
...
Combo [combo  :]
Edit2 [edit2  :]
...
COMBOBOX combo=formonly.combo,
   ITEMS = ((0,"12345678 Looooooooooooooooong Item"),(1,"hallo")),
   DEFAULT=0, SIZEPOLICY=FIXED, SAMPLE="0";
```

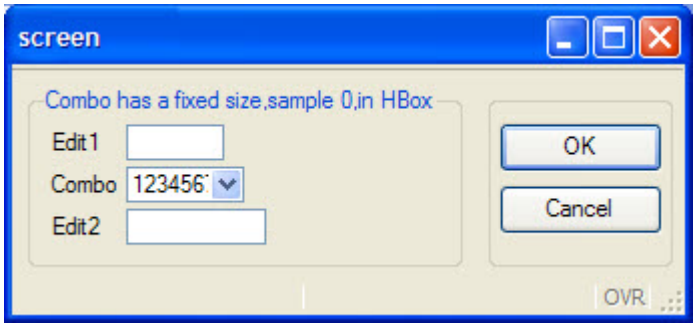

Figure 13: Use of HBox

Now the wanted six numbers are displayed and `combo` does not grow to the size of `edit2`.

Action defaults at form level
You can define action defaults in forms.

Starting with version 1.30 it is now possible to define action defaults in forms. In previous versions you had to define a global action default file; this works for defining common global action attributes, but there is a need to define specific action attributes in some forms. A typical zoom window may have search and navigation actions, while data input windows need to define add/delete/update actions instead.

It is now possible to define an action default section in the form file, and you can also load action defaults with ui.Form.loadActionDefaults().

Compiled string files have now .42s extension
Starting with version 1.30, compiled localized string files use now the file extension `.42s`.

Before version 1.30, the file extension was `.4ls`.

See Localized strings on page 327.

Planned desupport

The features described in this topic will be deprecated or de-supported in the next major release of the product.

Consider reviewing your code now, if you are using one of these features.

Features that will be deprecated in next versions

- Microsoft SQL Server 2005

Features that will be de-supported in next versions

- The `FIELD` form item type, that could be used to specify abstract form fields with attributes defined in the `.val` schema file.
- The GDC WinCOM, WinDDE and WinMail front-call modules.

Introduction to I4GL migration

IBM® Informix® 4GL and Genero BDL products

IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) are distinct development tools. The purpose of Genero BDL is to be as compatible as possible with I4GL, and it is very close. The success of Genero BDL depends on the ability to compile and run legacy 4gl code with minimum code changes. For text-mode applications, the migration steps are often reduced to recompile-and-run.

Genero BDL extends the I4GL language with advanced features, such as a Graphical User Interface and SQL access to non-Informix databases. This leads to some differences that you have to deal with, but these incompatibilities are minor compared to the added value.

In some rare cases, the Genero BDL team decided to take a different path to implement an I4GL feature, because we considered that the IBM® Informix® 4gl solution was not adaptable. For example, the dynamic arrays in I4GL and Genero BDL have different semantics.

This guide will help you identify the differences and find solutions to make the migration from IBM® Informix® 4gl easier.

IBM® Informix® 4GL reference version

Several versions of the IBM® Informix® 4GL language have been released. It started in the mid-80s with I4GL version 4.x; then came version 6.x in 1996. I4GL version 7.2 was released in 1998; then versions 7.31, 7.32, and finally the version: 7.50 came out.

There have been several bug fixes and enhancements over the life of I4GL, resulting in releases that slightly differ. Supporting strict compatibility with all versions of I4GL is not possible for Genero BDL.

The Genero BDL compatibility level with IBM® Informix® 4gl is achieved by comparing with the latest version of I4GL, which is version **7.50** at the time of this writing.

Installation and setup topics

Using C extensions

With IBM® Informix® 4GL, you can extend the **fglgo** runtime executable or link your binary programs with **c4gl** by adding your own C functions.

When migrating to Genero Business Development Language, the C-Extensions must be reviewed in order to provide them as shared libraries. Normally, C extensions modules must be specified in .4gl modules with the IMPORT instruction. To simplify migration, the runtime system loads the **userextension** shared library (or DLL) automatically, so you can group all your existing C functions in a unique shared library and use it without changing the source code of your programs.

Localization support in Genero

To support language-specific and country-specific locales, as well as multibyte character sets like BIG5, IBM® Informix® 4GL uses the Informix® GLS library.

For locale support, Genero Business Development Language (BDL) does not use the Informix® GLS library, to be independent from Informix® GLS libraries. Genero uses the standard C library functions for character data hanlding, based on the POSIX setlocale() function.

I4GL uses the CLIENT_LOCALE environment variable to define the locale for the application. With Genero BDL, you must use the LANG/LC_ALL environment variables to specify the locale of the application. Note, however, that CLIENT_LOCALE is still needed to define the locale for the IBM® Informix® database client.

Database schema extractor

Before compiling .4gl or .per files, you must extract the database schema with the **fgldbsch** tool. This will produce an .sch file, and optionally, .val and .att files. The fgldbsch tool can extract database schemas from Informix®, and from other databases such as Oracle and SQL Server, but you must be aware of data type conversion rules.

Compiling 4GL to C

The IBM® Informix® 4GL compilers include a p-code based runtime system called RDS as well as a C-compiled solution, the c4gl compiler. The RDS solution is typically used in a development environment, supporting a debugger, while the Informix® 4GL C compiler is traditionally used to maximize performance on production sites. However, the C compiled binaries need to be built on the same target platform as the production system.

Genero Business Development Language supports a p-code architecture, which is as fast as the C-compiled version of IBM® Informix® 4GL. Since p-code files are portable, you can develop your application on a platform that is different from the production platform, saving porting procedures and simplifying deployment tasks.

User interface topics

Easy user interface migration with traditional mode

IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) handle windows and form content rendering differently. I4GL is designed to write applications for for dumb terminals, while Genero BDL uses real GUI rendering, with resizeable windows and proportional fonts. To simplify migration from TUI-style products, Genero BDL supports the traditional GUI mode.

SCREEN versus LAYOUT

To design a form with IBM® Informix® 4GL, you organize labels and fields in the `SCREEN` section of a **.per** form file. Genero Business Development Language introduced a new `LAYOUT` section to place form elements. The new `LAYOUT` section allows more sophisticated form design than `SCREEN`.

When writing new programs for GUI applications, you should use a `LAYOUT` section instead of `SCREEN`. However, the `SCREEN` section is still supported to be used to design TUI mode forms.

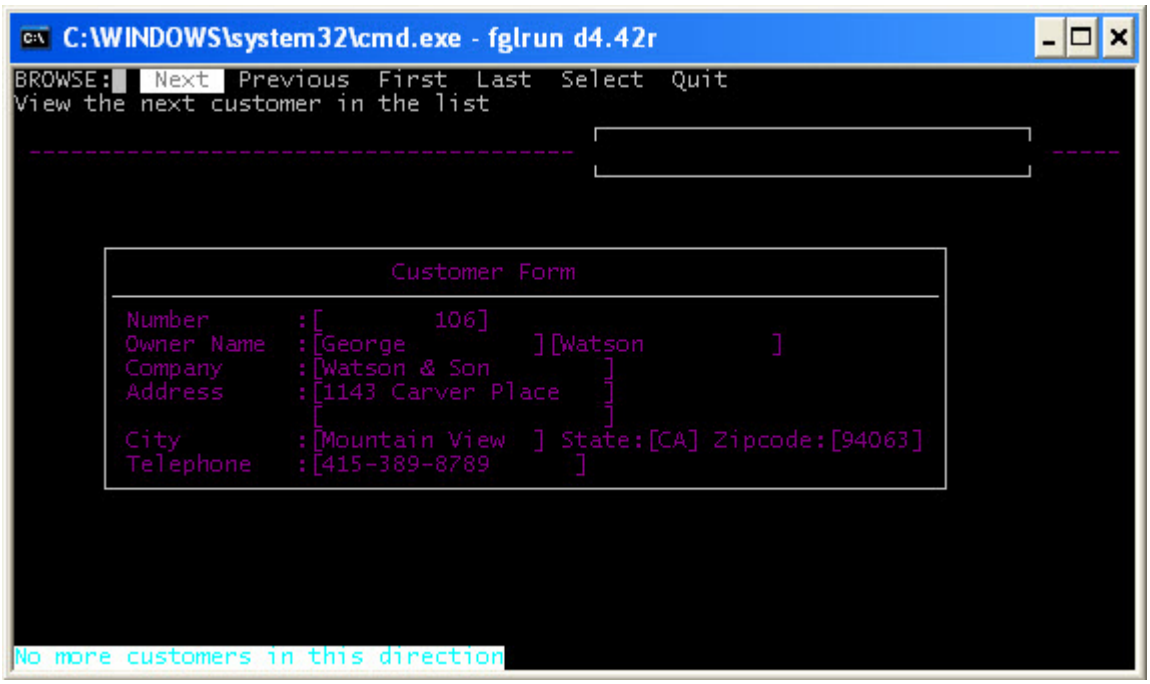

Figure 14: Form using a SCREEN section in TUI mode

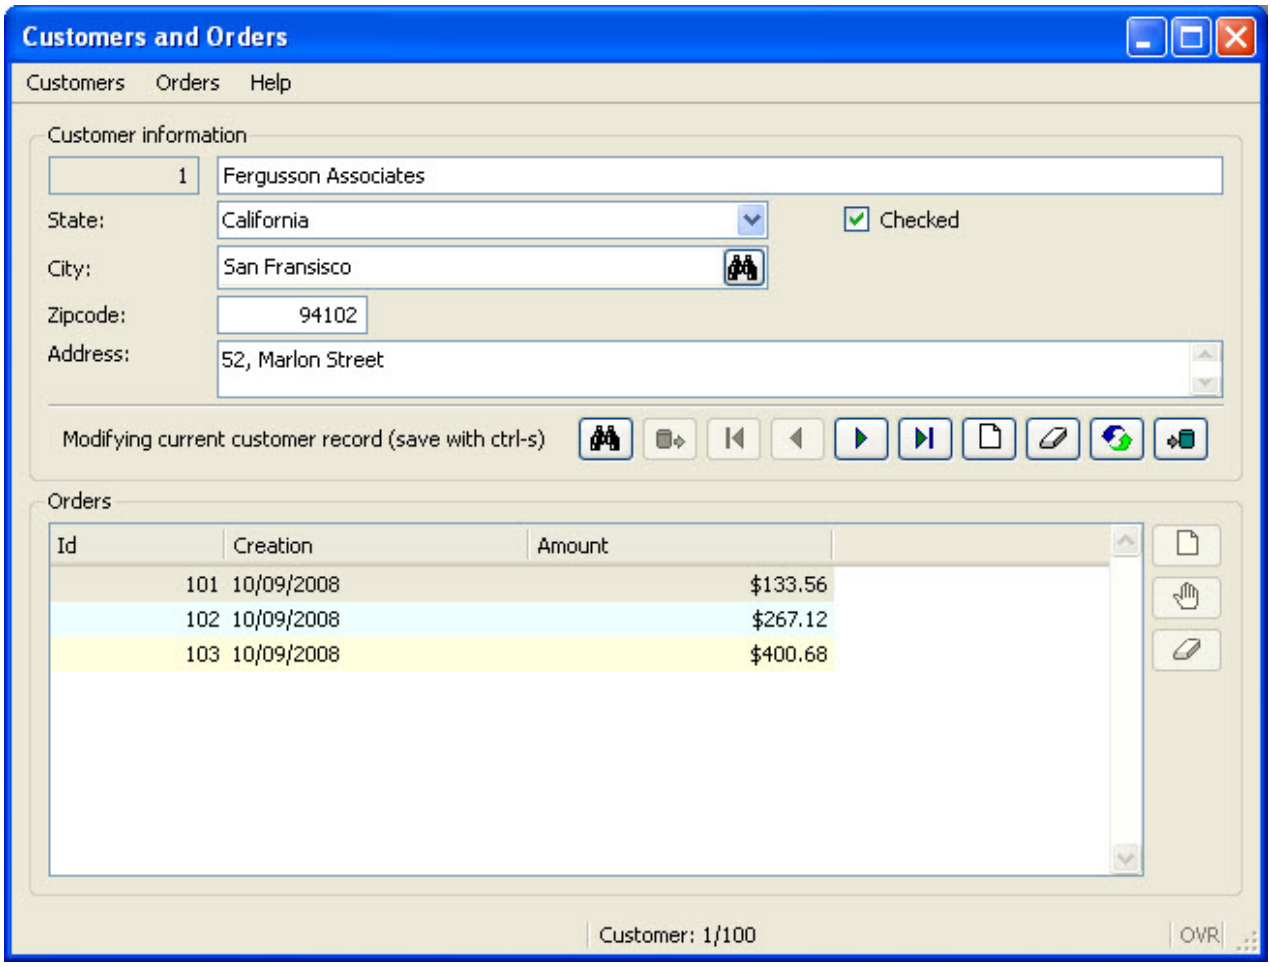

Figure 15: Form using a LAYOUT section in GUI mode

Migrating screen arrays to tables

With IBM® Informix® 4GL, a list of records can be displayed on the screen by using a static screen array in the SCREEN section of the form specification file, with a finite number of lines:

```
DATABASE stores
SCREEN
{
 Id       First name   Last name
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
}
END
TABLES
  customer
END
ATTRIBUTES
  f001 = customer.customer_num ;
  f002 = customer.fname ;
  f003 = customer.lname ;
END
INSTRUCTIONS
  SCREEN RECORD sr_cust[6]( customer.* );
END
```

The display of the form specification file in GUI mode:

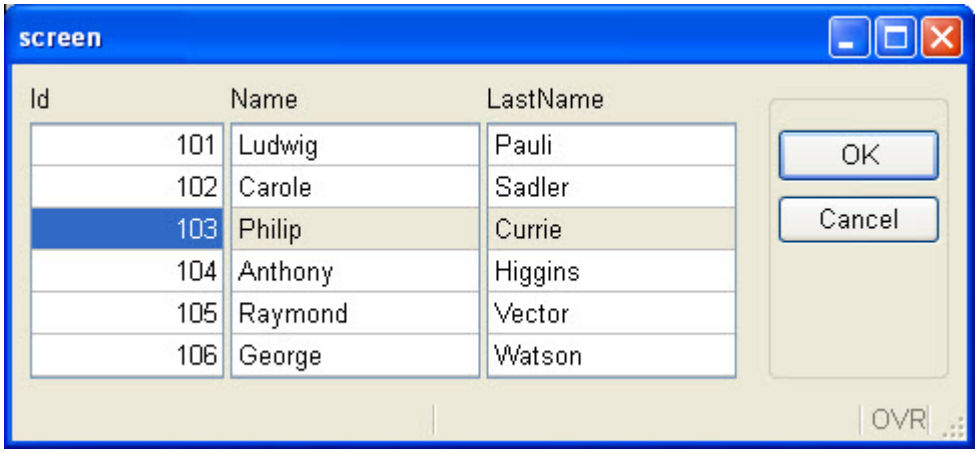

Figure 16: Form displayed not using table widget

With Genero Business Development Language, use a static screen array for applications displayed in dumb terminals, and for GUI applications you can for example use the TABLE container:

```
DATABASE stores
LAYOUT
TABLE
{
 Id       First name   Last name
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
```

```
[f001    |f002        |f003        ]
}
END
END
TABLES
 customer
END
ATTRIBUTES
 f001 = customer.customer_num ;
 f002 = customer.fname ;
 f003 = customer.lname ;
END
INSTRUCTIONS
 SCREEN RECORD sr_cust( customer.* );
END
```

The display of the form specification file is a real table widget, which is resizeable. The .4gl source is untouched.

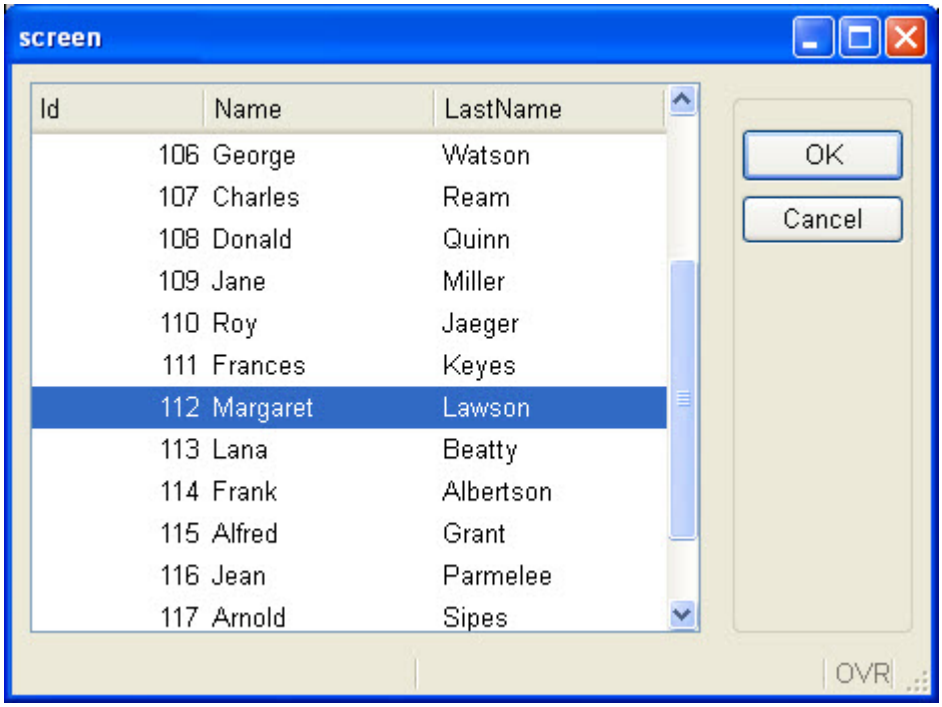

Figure 17: Form displayed as table widget

Review TUI specifics

Typical IBM® Informix® 4GL programs use the TUI mode and often exploit all the display possibilities of the language for dumb terminals. Some instructions are specific to TUI mode and should be reviewed when redesigning the application for GUI mode.

For example, data records can be displayed in a screen array with a `DISPLAY`*`array`*`[`*`array-index`*`].* TO `*`screen-array`*`[`*`screen-line`*`]` instruction, optionally with the `ATTRIBUTES()` clause to use some TTY attributes like colors, reverse and bold effects. When scrolling a list, I4GL actually uses the terminal scrolling capabilities to preserve the TTY attributes in each row. This applies only to the current rows visible on the screen, but it was a commonly used feature.

In order to display application screens on different types of front-ends, Genero Business Development Language (BDL) handles user interface elements in a more abstract way. Therefore, dumb terminal specifics as described above cannot be supported. A good replacement for `DISPLAY ... TO ... ATTRIBUTES()` in `DISPLAY ARRAY` or `INPUT ARRAY` is to use the DIALOG.setArrayAttributes() method.

Genero BDL supports TUI-specific instructions such as `DISPLAT AT`, `CLEAR SCREEN`, `CLEAR WINDOW`, as well as TTY attributes such as BLUE, RED, REVERSE, but you should use those instructions for TUI programs only. New GUI programs should use graphical user interface possibilities. For example, a good replacement for TTY attributes is to use presentation styles.

The default SCREEN window

When the first interactive instruction is reached in a Genero BDL program, a default window named `SCREEN` is created.

The default `SCREEN` window can be used to open one or more successive forms; it can also be closed, with the `CLOSE WINDOW SCREEN` instruction. If the default `SCREEN` window is not cloase, and a new window is created with the `OPEN WINDOW` command, an empty default `SCREEN` window will be displayed.

When writing a GUI application, you typically open the main form in the `SCREEN` window, and display other forms with the `OPEN WINDOW` name `WITH FORM` instruction:

```
MAIN
  DEFER INTERRUPT
  OPTIONS INPUT WRAP
   ...
  OPEN FORM f_main FROM "custfrm"
  DISPLAY FORM f_main
   ...
END MAIN
```

The `SCREEN` window is not visible in TUI mode because program windows are rendered as simple boxes and `SCREEN` is created without borders. The size of the `SCREEN` window is 80x25 in TUI mode.

Specifying WINDOW position and size

When writing a program for TUI mode, the windows can be created with the `OPEN WINDOW name AT x,y` instruction, specifying an position on the screen; sometimes even the width and height of the window is specified, for example when you don't use a form to create the window. Window position and size is allowed by Genero Business Development Language for TUI mode applications.

However, the window position and sizes are ignored in GUI mode. In GUI mode, the window position is defined by the window manager, and the size adapts to the form displayed. In this mode, the preferred way to display application forms is to use the `OPEN WINDOW` name `WITH FORM` instruction.

Right justified field labels

If the application forms define right-justified labels and use a proportional font in GUI mode, the text will no longer be aligned as on a dumb terminal. Form layout must be reviewed to replace any right-justified text with `LABEL` form items. Migration to GUI mode can also be easier achieved with the traditional mode, to leave TUI-style forms untouched.

Example of right-justified static form labels

```
DATABASE FORMONLY
SCREEN
{
     Customer id: [f01       ]
           Name: [f02                          ]
         Zipcode: [f03     ]
         Address: [f04                                 ]
}
END
ATTRIBUTES
EDIT f01 = FORMONLY.cust_id;
EDIT f02 = FORMONLY.cust_name;
EDIT f03 = FORMONLY.cust_zipcode;
```

```
EDIT f04 = FORMONLY.cust_address;
END
```

Example of form label items with localized text

```
LAYOUT
GRID
{
     [l01         |f01       ]
     [l02         |f02                          ]
     [l03         |f03     ]
     [l04         |f04                                  ]
}
END
END
ATTRIBUTES
LABEL l01: TEXT=%"customer.id";
LABEL l02: TEXT=%"customer.name";
LABEL l03: TEXT=%"customer.zipcode";
LABEL l04: TEXT=%"customer.address";
EDIT f01 = FORMONLY.cust_id;
EDIT f02 = FORMONLY.cust_name;
EDIT f03 = FORMONLY.cust_zipcode;
EDIT f04 = FORMONLY.cust_address;
END
```

Using widgets instead of multiple text screens

Applications designed for dumb terminals (TUI mode) use various techniques to ensure that all display fits in an 80x25 screen. This may mean iterating through a number of dialogs using different forms, only displaying certain columns in an record list, using abbreviations for labels, etc.

With a graphical user interface (GUI mode), windows are wider, re-sizable and can contain different sort of layout elements and widgets, displaying much more information as in a simple dumb terminal. For example, TABLE containers display record lists and have the ability to scroll horizontally so that you can show more than 78 characters of data.

Dump-terminal oriented programs should be reviewed to take advantage of the GUI possibilities. However, do not end up with over-crowded screens, that will be unreadable to the end user.

Review application ergonomics

With IBM® Informix® 4GL, programs can only execute a single `MENU`, `INPUT`, `CONSTRUCT`, `DISPLAY ARRAY` or `INPUT ARRAY` instruction at a time. This may be sufficient for dumb-terminal applications, but is not adapted for a graphical user interface.

Genero Business Development Language (BDL) introduces the concept of multi-dialog, where multiple interactive instructions control several form areas at the same time. Typical GUI concepts such as Drag and Drop and Tree Views are supported as well. You may wish to review your code to take advantage of these features.

Subscripted form fields are not supported

IBM® Informix® 4GL forms can define subscripted fields with multiple field definition entries in the `ATTRIBUTES` section, each defining a piece of the data displayed by the field, as in this example:

```
DATABASE stores
SCREEN
{
   1234567890
  [f01       ]
```

```
  [f02       ]
}
END
ATTRIBUTES
f01 = customer.cust_name[1,10];
f02 = customer.cust_name[11,20];
END
```

In the ATTRIBUTES section, the name of the field is immediately followed by a subscript specification defining the piece of sub-data the screen tag displays and allows to input.

This feature is not supported at all by Genero BDL, all fields must be defined as a whole.

4GL programming topics

Dynamic arrays

Both IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) implement static arrays with a fixed size. Static arrays cannot be extended:

```
DEFINE arr ARRAY[100] OF RECORD LIKE customer.*
```

I4GL introduced dynamic arrays in version **7.32**. Unlike Genero BDL, I4GL requires explicitly to associate memory storage with a dynamic array by using the ALLOCATE ARRAY statement, and memory must be freed with DEALLOCATE ARRAY. I4GL dynamica arrays can be resized with the RESIZE ARRAY statement. I4GL dynamic arrays cannot be used in a interactive instructions such as DISPLAY ARRAY.

```
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
ALLOCATE ARRAY arr[10]
RESIZE ARRAY arr[100]
LET arr[50].cust_name = "Smith"
DEALLOCATE ARRAY arr
```

Genero BDL supports dynamic arrays in a slightly different way than I4GL. There are no allocation, resizing, or deallocation instructions, because the memory for element storage is automatically allocated when needed. Further, you can use dynamic arrays with interactive instructions, making a DISPLAY ARRAY or INPUT ARRAY unlimited.

```
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
LET arr[50].cust_name = "Smith"
DISPLAY ARRAY arr TO sr.*
```

In Genero BDL, the main difference between static arrays and dynamic arrays is the memory usage; when you use dynamic arrays, elements are allocated on demand. With static arrays, memory is allocated for the complete array when the variable is created.

> **Important: The semantics of dynamic arrays is very similar to static arrays, but there are some small differences. Keep in mind that the runtime system automatically allocates a new element for a dynamic array when needed. For example, when a `DISPLAY arr[100].*` is executed with a dynamic array, the element at index 100 is automatically created if does not exist.**

Debugger command syntax

IBM® Informix® 4GL (I4GL) provides a program debugger. Genero Business Development Language provides a program debugger with a different set of commands as I4GL, compatible with the well-known gdb tool. This debugger can be used alone in command line mode, or with a graphical shell compatible with gdb, such as **ddd**:

```
ddd --debugger "fglrun -d myprog"
```

Mismatching global variable definitions

The c4gl C-code compiler of IBM® Informix® 4GL has a weakness that allows global variable declarations of the same variable with different data types. Each different declaration found by the c4gl compiler defines a distinct global variable, which can be used separately. This can actually be very confusing (the same global variable name can, for example, reference a `DATE` value in module A and an `INTEGER` value in module B).

IBM® Informix® 4GL RDS (fglpc / fglgo) does not allow multiple global variable declaration with different types. The fglgo runner raises error -1337 if this happens.

The next code example shows two .4gl modules defining the same global variable with different data types:

Main.4gl:

```
GLOBALS
  DEFINE v INTEGER
END GLOBALS
...
MAIN
  ...
  LET v = 123
  ...
END MAIN
```

Module.4gl:

```
GLOBALS
  DEFINE v DATE
END GLOBALS
...
FUNCTION test()
  ...
  LET v = TODAY
  ...
END FUNCTION
```

The fglcomp tool compiles both modules separately without problem, but when linking with fgllink, the linker raises error -1337.

You must review your code and use the same data type for all global variables having the same name.

Strict function signature checking

IBM® Informix® 4GL (I4GL) is not very strict regarding function signature. With I4GL, you can, for example, define a function in module A that returns three values, and call that function in module B with a returning clause specifying two variables:

Module A:

```
FUNCTION func()
   RETURN "abc", "def", "ghi"
END FUNCTION
```

Module B (main):

```
MAIN
   DEFINE v1, v2 VARCHAR(100)
   CALL func() RETURNING v1, v2
END MAIN
```

The c4gl compiler (7.32) compiles and links these modules without error, but at execution time you get the following runtime error:

```
Program stopped at  "main.4gl", line number 3.
FORMS statement error number -1320.
A function has not returned the correct number of values
expected by the calling function.
```

With Genero Business Development Language (BDL), the mistake will be detected at link time:

```
$ fgllink -o prog.42x main.42m module_a.42m
ERROR(-6200): Module 'main': The function module_a.func(0,3) will be
called as func(0,2).
```

Similarly, I4GL does not detect an invalid number of parameters passed to a function defined in a different module:

Module A:

```
FUNCTION func( p )
   DEFINE p INTEGER
   DISPLAY p
END FUNCTION
```

Module B (main):

```
MAIN
   CALL func(1,2)
END MAIN
```

The c4gl compiler (7.32) compiles and links these modules without error, but at execution time, you get the following runtime error:

```
Program stopped at  "main.4gl", line number 2.
FORMS statement error number -1318.
A parameter count mismatch has occurred between the calling
function and the called function.
```

When using Genero BDL, the error will be detected at link time:

```
$ fgllink -o prog.42x main.42m module_a.42m
ERROR(-6200): Module 'main': The function module_a.func(1,0) will be
called as func(2,0).
```

Note, however, that Genero BDL does not check function signatures when several RETURN instructions are found by the compiler. This is necessary in order to be compatible with I4GL. The next code example compiles and runs with both I4GL and BDL:

```
MAIN
   DEFINE v1, v2 VARCHAR(100)
   CALL func(1) RETURNING v1
   DISPLAY v1
   CALL func(2) RETURNING v1, v2
   DISPLAY v1, v2
END MAIN

FUNCTION func( n )
   DEFINE n INTEGER
   IF n == 1 THEN
      RETURN "abc"
   ELSE
```

```
      RETURN "abc", "def"
   END IF
END FUNCTION
```

However, this type of programming is not recommended.

STRING versus CHAR/VARCHAR

Genero Business Development Language (BDL) introduces a new data type named `STRING`, which is similar to `VARCHAR`, but without a size limit. The `STRING` data type does not exist in IBM® Informix® 4GL. The `STRING` data type implementation is optimized for memory usage; unlike `CHAR/VARCHAR`, BDL will only allocate the memory needed to hold the actual character string value in a `STRING` variable.

A `STRING` variable is typically used within utility functions (for example, to hold the path to a file). Another typical usage is with CONSTRUCT, to hold the SQL condition. The `STRING` variable can then be completed to build the SQL text and passed to the PREPARE or DECLARE instruction.

However, because of SQL assignment and comparison rules, the `STRING` variables cannot be used as SQL parameters in the `USING` clause of EXECUTE or OPEN/ FOREACH, not can it be used to receive fetched data with the FETCH instruction: For SQL statements, use CHAR or VARCHAR data types.

The `STRING` data type has a number of built-in methods e.g. getLength() that will are very useful and will reduce source code.

Review user-made C routines

IBM® Informix® 4GL (I4GL) applications often need additional utility C routines implemented in C-Extensions, for example to access the file system and read the content of a directory. Writing C-Extensions is an important cost in cross-platform portability and maintenance.

Genero Business Development Language (BDL) provides a set of utility libraries that include functions and classes which can probably replace some of the routines written for I4GL application. For example, BDL implements typical file management functions to search directories and files.

If portability is a concern (for example if you want to move from a UNIX™ platform to a Microsoft™ Windows™ or Mac OS-X™ platform), review your C routines and check whether there is a replacement built into the language or in one of the libraries provided.

Genero BDL even allows to use to the huge Java™ class library with the Java™ Interface .

Web Services support

Starting with IBM® Informix® 4GL version **7.50**, I4GL functions can be deployed as Web Services. The published functions can be subscribed from programs that run on a Web client in another programming language.

Web Services support was introduced in Genero Business Development Language before I4GL 7.50 was released. Each implementation is quite different, but the basic principles are the same: publishing 4gl functions as Web Services, by handling WS requests and supporting easy input and output parameter conversions between WS data formats and 4gl program variables.

File I/O statements and APIs

Enhancement reference: BZ#19156

IBM® Informix® 4GL version **7.50.xC4** introduced file manipulation instructions to access files on the operating system running the application. These instructions can be used to open, read, write, seek and close files:

```
MAIN
   DEFINE fd1, fd2 INTEGER, v1,v2 VARCHAR(10)
   OPEN FILE fd1 FROM "/tmp/file1" OPTIONS (READ, FORMAT="CVS")
```

```
   OPEN FILE fd2 FROM "/tmp/file2" OPTIONS (WRITE, APPEND, CREATE,
 FORMAT="CVS")
   READ FROM fd1INTO v1, v2
   SEEK ON fd2TO 0FROM LAST INTO v1
   WRITE TO fd2USING v1, v2
   CLOSE FILE fd1
   CLOSE FILE fd2
END MAIN
```

Genero Business Development Language (BDL) implements file I/O support with the *base.Channel* built-in class. This class implements file access, but it can also open streams to subprocesses (i.e. pipes) and sockets.

OPEN USING followed by FOREACH

In earlier versions of IBM® Informix® 4GL (I4GL), the `FOREACH` instruction had no a `USING` clause to pass SQL parameters to the prepared statement. SQL Parameters could be specified in a `OPEN USING` instruction, and were re-used by the next `FOREACH` instruction:

```
PREPARE st1 FROM "SELECT * FROM tab WHERE col>?"
DECLARE cu1 CURSOR FOR st1
OPEN cu1 USING var
FOREACH cu1 INTO rec.*
  DISPLAY rec.*
END FOREACH
```

This feature is supported by Genero Business Development Language, but can lead to defects with some versions of the Informix® database client. Review your code to avoid the `OPEN` statement by moving the `USING` clause to the `FOREACH` instruction.

Migrating from Four Js BDS to Genero BDL

These topics describe product changes you must be aware of when migrating from Four Js BDS 3.xx to the most recent Genero Business Development Language version.

- Installation and setup topics on page 152
  - License controller on page 152

Installation and setup topics

License controller

With Four Js Business Development Suite (BDS), you must license the product with the `licencef4gl` command line tool. Starting with Genero Business Development Language, the command line tool to license the product is `fglWrt`. Run fglWrt with the -h option for the possible options.

Runner linking is no longer needed

With Four Js Business Development Suite (BDS), you need to create the fglrun binary with the fglmkrun tool, by specifying the type of the database driver and C extensions libraries to be linked with the runtime system. Since Genero Business Development Language version 2.00, you do not more need to link the runtime system.

The database drivers are provided as shared libraries ready to use; you just need to specify the driver to be loaded.

However, C extensions must be provided shared libraries for Genero BDL. To easy migration, the runtime system loads automatically the `userextension` share library (or DLL).

Localization support

IBM® Informix® 4GL (I4GL) and Four Js Business Development Suite (BDS) use the Informix® GLS library for localization support (i.e. to support non-ASCII character sets such as BIG5). This implies a strong dependency to the proprietary GLS library.

Genero Business Development Language (BDL) does not use the GLS library; Genero BDL uses the standard C library functions for character set handling, based on the setlocale() POSIX conformant function.

While I4GL/BDS need the CLIENT_LOCALE environment variable to define the locale for the application, you must now use the LANG/LC_ALL environment variables to specify the locale of the Genero application. Note, however, that CLIENT_LOCALE is still needed when connecting to an Informix® database.

In Four Js BDS, you could select the locale library with the fglmode tool, to select either GLS or ASCII mode. This tool is no longer needed in Genero.

Database schema extractor

Before compiling .4gl or .per files with Four Js Business Development Suite (BDS) or with Genero Business Development Language (BDS), you need to extract the database schema as a .sch file.

In DBS, the name of the schema extraction tool fglschema, while Genero BDL provides the fgldbsch tool. The fglschema tool could only extract schemas from Informix® databases; fgldbsch can extract database schemas from Informix®, and from other databases like Oracle, SQL Server, DB2®, PostgreSQL, MySQL and Genero db. The fglschema tool is still supported in Genero BDL for backward compatibility, but fglschema actually calls fgldbsch.

Note that Genero BDL allows you to centralize new widget types and attributes in the .val file.

C-Code compilation is desupported

Four Js Business Development Suite (BDS) fglcomp could compile to P-Code or C-Code. The compiler of Genero Business Development Language does not support C-Code generation. Only P-Code generation is supported by Genero BDL.

If you experience performance problems when comparing Genero BDL to Four Js BDS, please contact your local support center.

Desupported environment variables

This table lists the Four Js Business Development Suite (BDS) environment variables that are no longer supported (or replaced) in Genero Business Development Language:

Table 87: Desupported environment variables

Entry	Description of the BDS environment variable	Genero equivalent
FGLDBS	FGLDBS defines the type and version of the database driver, used when linking fglrun with fglmkrun.	Database drivers are loaded dynamically by fglrun.
FGLCC	FGLCC defines the name of the C compiler.	The fglrun tool does not need to be created, it's fully dynamic.
FGLLIBSQL	FGLLIBSQL defines the list of database client software libraries to be used to link fglrun with fglmkrun.	Database drivers are loaded dynamically by fglrun.
FGLLIBSYS	FGLLIBSYS defines the list of system libraries to be used to link fglrun with fglmkrun.	The fglrun tool does not need to be created, it's fully dynamic.
FGLSHELL	FGLSHELL defined the name of the fglrun program, for example when using tools like fglschema.	The name of the runtime system tool is fglrun and does not need to be changed.

Desupported FGLPROFILE entries

Genero Business Development Language comes with redesigned software components and features. Some FGLPROFILE entries have been desupported. This section describes what configurations settings are no longer supported, and point to Genero equivalent features if they exist.

User interface topics

Easy user interface migration with traditional mode

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Front-end compatibility

When migrating to Genero Business Development Language (BDL), you must use one of the Genero Front Ends; the **WTK**, **WebFE** and **JavaFE** front-ends are not compatible with the Genero fglrun runtime system. Note also that the UNIX™ version of Genero does not include the **fglX11d** front-end any longer. You must use the GDC front-end on UNIX™.

FGLGUI is 1 by default

In Four Js Business Development Suite (BDS), when the FGLGUI environment variable is not set, the application starts in TUI mode (FGLGUI=0). With Genero BDL, the default is GUI mode (FGLGUI=1). Therefore, when migrating from Informix® 4GL, you should set FGLGUI=0 to run the application in text mode as a first step.

FGLPROFILE: GUI configuration

This table shows Four Js Business Development Suite (BDS) FGLPROFILE entries related to GUI configuration which are desupported in Genero Business Development Language.

Table 88: BDS/WTK FGLPROFILE entries related to GUI configuration which are desupported in Genero

Entry	Description of the BDS feature	Genero equivalent
`fglrun.interface`, `fglrun.scriptName`	These entries defined the TCL configuration and script to be send to the WTK front-end.	There is no equivalent in Genero.
`fglrun.guiProtocol.*`	These entries could be used to configure the communication protocol with WTK front-end.	In Genero you can control this with gui.protocol.* entries.
`fglrun.error.line.number`	This entry was used to define the number of lines to be displayed in the error message line.	You can control the aspect of the error line with the Window style attribute called `statusBarType`.
`gui.useOOB.interrupt` `fglrun.signalOOB`	These entries could be used to configure or disable Out Of Band signal on the GUI protocol socket to avoid problems on platforms not supporting that feature. OOB signal was used to send interruption events the program executed is processing.	Genero supports interruption event handling with a predefined action name called **interrupt**. You can bind any sort of action view (button in form, toolbar or topmenu item) with this name. Interrupt events are sent asynchronously with the new Genero GUI protocol and don't use OOB signals any longer. See User interruption handling on page 1252 for more details.
`Sleep.minTime`	This entry was used to define the number of seconds before the interrupt key button appeared on the screen window when the program is processing.	Genero supports interruption event handling with a predefined action name called **interrupt**. You can bind any sort of action view (button in form, toolbar or topmenu item) with this name. Interrupt events are sent asynchronously with the new

Entry	Description of the BDS feature	Genero equivalent
		Genero GUI protocol and don't use OOB signals any longer. See User interruption handling on page 1252 for more details.
`gui.watch.delay`	This entry was used to define the number of seconds before the mouse cursor displays as a wait cursor, when the program is processing.	Genero supports interruption event handling with a predefined action name called **interrupt**. You can bind any sort of action view (button in form, toolbar or topmenu item) with this name. Interrupt events are sent asynchronously with the new Genero GUI protocol and don't use OOB signals any longer. See User interruption handling on page 1252 for more details.
`gui.bubbleHelp.*`	These entries could be used to enable and configure tooltips displaying field COMMENT text.	Genero front-ends display bubble-help with field COMMENT text by default.
`gui.controlFrame.scroll.*`	These entries could be used to show and configure a scrollbar in the control frame displaying ON KEY or COMMAND buttons.	Genero front-ends display control frame scrolling buttons by default when needed. See also Window style attributes like `ringMenuScroll`.
`screen.scroll`	This entry could be used to get scrollbars in the main window when the form was too big for the screen resolution of the workstation.	With Genero, by default, each program window is rendered as a distinct GUI window by the front-end. Window aspect can be controlled with style attributes. See Window style attributes for more details.

`gui.screen.size.x`
`gui.screen.size.y`
`gui.screen.x`
`gui.screen.y`
`gui.screen.incrx`
`gui.screen.incry`
	These entries could be used to configure the size and position of the main screen window with the WTK front-end.	In Genero, each program window is rendered as a distinct GUI window by the front-end. There is no equivalent for these options. However, you can use the traditional mode to render program windows in a single parent screen window and with BDS/WTK.

`gui.screen.withvm`	This entry could be used to integrate with the X11 window manager (allowing move and resize actions).	There is no equivalent in Genero.
`gui.preventClose.message`	This entry could be used to display an error message to the user attempting to close the main GUI	In Genero, each program window is rendered as a distinct GUI window by the front-end. You can use the

Entry	Description of the BDS feature	Genero equivalent
	window with CTRL-F4 or the cross-button on the right of the GUI window title bar.	**close** action to control window close events. See Implementing the close action on page 1337 for more details. See also ON CLOSE APPLICATION program option.
`gui.key.doubleClick.left`	This entry could be used to define the key to be returned to the program when the user double-clicks on the left button of the mouse.	You can use the DOUBLECLICK attribute to define the action to be invoked when the user double-clicks on a Table container.
`gui.key.click.right`	This entry could be used to define the key to be returned to the program when the user clicks on the right button of the mouse.	You can configure contextual menus with the **CONTEXTMENU** attribute in action attributes.
`gui.key.add_function`	Could be used to define the offset to identify SHIFT+Fx keys.	There is no equivalent in Genero.
`gui.key.`*`x`*`.translate`	These entries could be used to map keys. For example, when the user pressed Control-U, it could be mapped to F5 for the program.	There is no equivalent in Genero.
`gui.key.radiocheck.invokeexit`	Could be used to define the key to select the RADIO or CHECK field and move to the next field.	There is no equivalent in Genero.
`gui.mswindow.button`	This entry defined the aspect of buttons on Windows™ platforms.	There is no equivalent in Genero: Front-ends will use the current platform theme when possible.
`gui.mswindow.scrollbar`	Could be used to get MS Windows™ scrollbar style.	There is no equivalent in Genero: Front-ends will use the current platform theme when possible.
`gui.scrollbar.expandwindow`	When set to true, the WTK front-end expanded the window automatically if scrollbars are needed in a screen array.	There is no equivalent in Genero.
`gui.fieldButton.style`	Could be used to define the style of BMP field buttons.	There is no equivalent in Genero.
`gui.BMPbutton.style`	Could be used to define the style of FIELD_BMP field buttons.	There is no equivalent in Genero.
`gui.entry.style`	This entry defines the underlying widgets to be used to manage form fields.	There is no equivalent in Genero.
`gui.user.font.choice`	This entry could be set to true to let the end user change the font of the application screen window.	Genero front-ends allow the user to change the font.

Entry	Description of the BDS feature	Genero equivalent
		See front-end specific documentation for option configuration.
`gui.interaction.inputarray.usehighlightcolor`	This entry could be used to highlight the current row during an INPUT ARRAY.	The current row highlighting can be controlled in Genero with the Table style attribute `highlightCurrentRow`.

`gui.form.foldertab.multiline`
`gui.folderTab.input.sendNextField`
`gui.folderTab.`*`x`*`.selection`
	These entries could be used to configure folder tabs and define the keys to be sent when a page is selected by the user.	Genero supports folder tabs with the FOLDER container in LAYOUT. An action can be defined for each folder PAGE.

`gui.keyButton.position`
`gui.keyButton.style`
`gui.button.width`
	These entries could be used to define the aspect of control frame buttons associated to ON KEY actions in dialogs like INPUT.	Default action views aspect and position can be controlled with Action Defaults attributes and with Window style attributes.

`Menu.style`
`gui.menu.timer`
`gui.menu.horizontal.*`
`gui.menu.showPagerArrows`
`gui.menuButton.position`
`gui.menuButton.style`
	These entries could be used to define the aspect of control frame buttons associated to COMMAND [KEY] actions in MENU.	Default action views aspect and position can be controlled with action attributes with window style attributes.

`gui.empty.button.visible`	This entry could be used to hide control frame buttons without text. By default, the empty buttons are visible but disabled.	Default action views aspect can be controlled with action attributes. Use for example the `defaultView` attribute to display a default button for an action.

`gui.containerType`
`gui.containerName`
`gui.mdi.*`
	These entries could be used to configure WCI windows in BDS.	To define WCI containers and children in Genero, use the ui.Interface methods.
		See Window containers (WCI) on page 1458 for more details.

`gui.toolBar.*`	These entries define the toolbar aspect in BDS.	Toolbar definition has been extended in Genero. See ToolBars for more details.
`gui.statusBar.*`	These entries define the status aspect in BDS.	The StatusBars are defined with Window presentation style attributes. See Presentation Styles for more details.
`gui.directory.images`	This entry defines the path to the directories where images (toolbar	See front-end documentation for image files located on the workstation. With Genero, image

Entry	Description of the BDS feature	Genero equivalent
	icons) are located, on the front-end workstation.	files can be located on the application server and automatically transmitted to the front-end according to the FGLIMAGEPATH environment variable.
`gui.display.<source>`	These entries could be used to redirect the ERROR / MESSAGE / COMMENT text to a specific place on the GUI screen.	The rendering of ERROR, MESSAGE or COMMENT can be configured with Window style attributes in Genero. However, it is not possible to customize keyboard NumLock / CapsLock status in Genero. See Presentation Styles for more details.

`gui.local.edit`
`gui.local.edit.error`
`gui.key.cut`
`gui.key.copy`
`gui.key.paste`
	These entry could be used to enable and configure cut/copy/ paste local keys in WTK.	Cut/Copy/Paste are defined as front-end local actions in Genero. You can bind action views with `editcut`, `editcopy`, `editpaste` predefined action names.
		See Dialog actions on page 1276 for more details.

`gui.key.*`	These entries were used to map physical key to a virtual key used in programs. For example: `gui.key.interrupt = "control-c"`	Cut/Copy/Paste are defined as front-end local actions in Genero. You can bind action views with editcut, editcopy, editpaste predefined action names. See Dialog actions on page 1276 for more details.
`gui.workSpaceFrame.nolist`	This entry could be used to define the aspect of fixed size screen arrays in forms, to render each array cell as an individual edit field.	*There is no equivalent in Genero.*

Key labels versus action defaults

In Four Js Business Development Suite (BDS), labels can be defined for keys such as **accept**, **F10** or **Control-Z**. With this feature, it is possible to easily decorate ON KEY or COMMAND KEY blocks with a button in the control frame.

With Genero Business Development Language (BDL), interaction statements can define actions with the ON ACTION blocks. These action handlers are more abstract than `ON KEY`: You identify an action by a name, while decoration is defined in form files (ACTION DEFAULTS section) or in global configuration files (.4ad file).

When adapting your code for Genero, you are free to use the traditional `ON KEY` blocks or the new `ON ACTION` blocks. Genero still supports the key label settings as in Four Js BDS. Note however that key label settings will overwrite Action Defaults settings. Additionally, if the name of the key specified in the `ON KEY` clause does not only contain alphanumeric characters (such as Control-Z), it will not be possible to define action defaults attributes for these action handlers, as action names must be simple identifiers. This is also true for Menu COMMAND labels, for example with `COMMAND"Exit program"`.

Migrating form field widgets

To get combo-boxes or check-boxes in Four Js Business Development Suite (BDS), **.per** forms could define fields with the WIDGET attribute. To ease migration, the `WIDGET` attribute and the corresponding form field widgets are still supported in Genero Business Development Language (BDL), but these are now deprecated: You should use new BDL form item types instead.

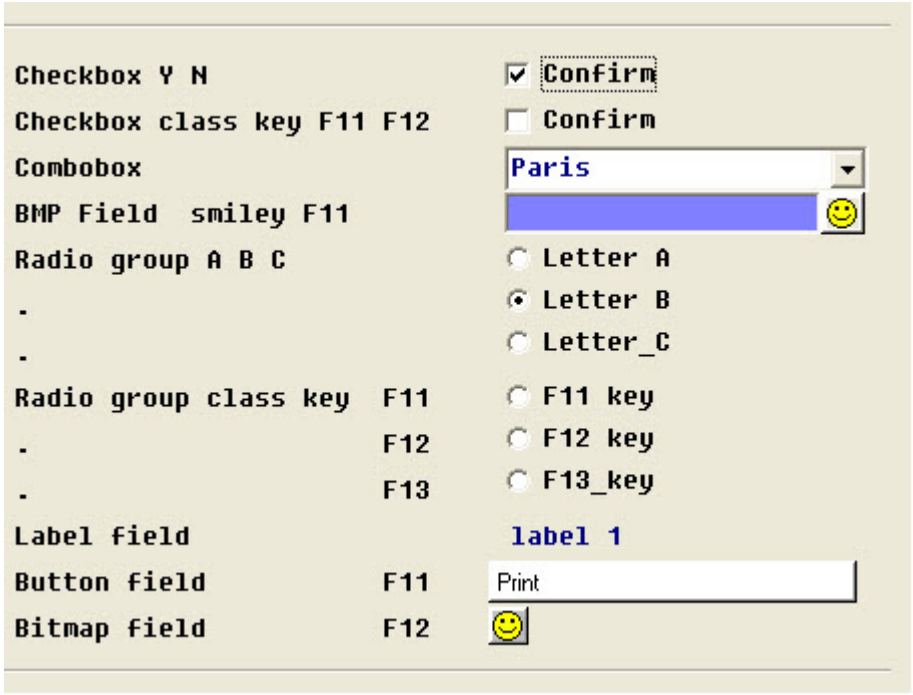

Figure 18: Four Js BDS-specific widgets

This table shows new Genero BDL form item types corresponding to old BDS WIDGET fields:

Table 89: Genero form item types corresponding to old BDS WIDGET fields

WIDGET=	Description	Genero equivalent
`WIDGET="Canvas"`	Drawing area for fgldraw functions	CANVAS item type
`WIDGET="BUTTON"`	Text push button firing key event	BUTTON item type
`WIDGET="BMP"`	Image push button firing key event	BUTTON item type
`WIDGET="CHECK"`	Checkbox field	CHECKBOX item type
`WIDGET="CHECK" + CLASS="KEY"`	Checkbox field firing key event	CHECKBOX item type + ON CHANGE trigger in program
`WIDGET="COMBO"`	Combobox field	COMBOBOX item type
`WIDGET="FIELD_BMP"`	Edit field with push button	BUTTONEDIT item type
`WIDGET="LABEL"`	Label field (no input)	LABEL item type
`WIDGET="RADIO"`	Radio group field	RADIOGROUP item type
`WIDGET="RADIO" + CLASS="KEY"`	Radio group field firing key event	RADIOGROUP item type + ON CHANGE trigger in program

Genero introduced more form item types like DATEEDIT, PROGRESSBAR.

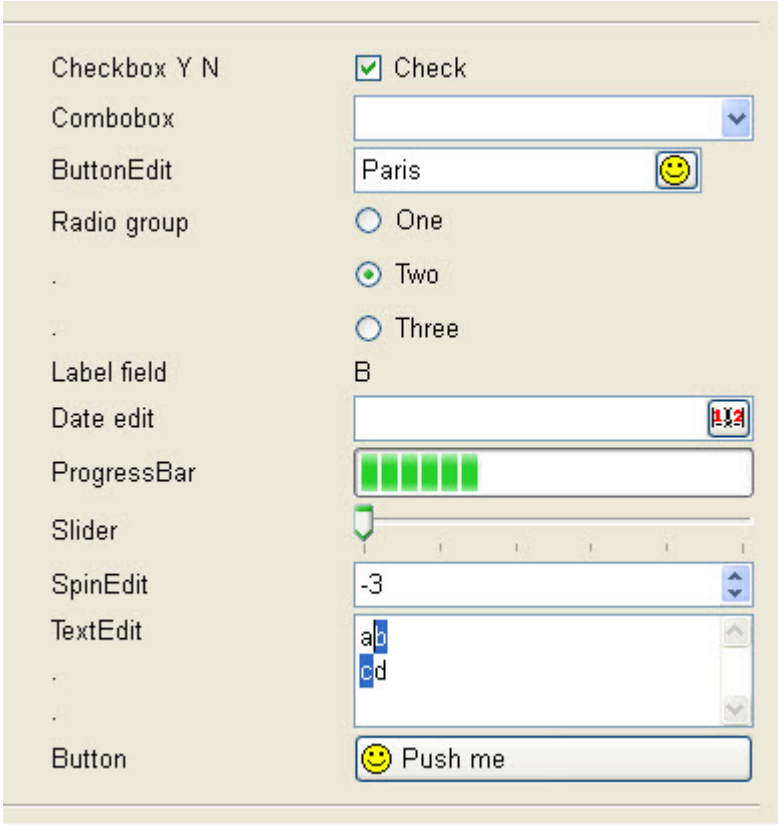

Figure 19: New form types in Genero

SCREEN versus LAYOUT

Review TUI specifics

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

The default SCREEN window

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Specifying WINDOW position and size

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Front-end configuration tools

Four Js Business Development Suite (BDS) provided WTK front-end and X11 front-end specific configuration tools called "Configuration Manager" / confdesi. These tools could be used to define widget aspect (color, borders, fonts).

In Genero Business Development Language, the form items can be decorated with presentation styles for all sorts of front-ends.

Function key mapping

With Four Js Business Development Suite (BDS), when the user pressed a key modifier plus a function key (like Shift-F4 or Ctrl-F6), the key combination was mapped to a regular function key F(n+offset), because *Shift* and *Control* key modifiers are not handled in the 4GL language. The number of function keys of the keyboard was defined by the gui.key.add_function FGLPROFILE entry. For example, when this entry is set to 12 (the default), a Shift-F4 was received as F16 (4 + 12) in the program.

This feature and FGLPROFILE entry is still supported when using the traditional mode.

4GL Programming topics

FGLPROFILE: VM configuration

Genero Business Development Language (BDL) comes with redesigned software components and features. Some Four Js Business Development Suite (BDS) specific FGLPROFILE entries have been desupported. This section describes what configurations settings are no longer supported, and point to Genero equivalent features if they exist.

This table shows BDS FGLPROFILE entries related to runtime system configuration which are desupported in Genero. See the FGLPROFILE description page for supported entries:

Table 90: BDS FGLPROFILE entries related to runtime system configuration which are desupported in Genero

Entry	Description of the BDS feature	Genero BDL equivalent
`fglrun.checkDecimalPrecision`	Controls decimal variable assignment when overflow occurs. For example, a value of 1000.0 does not fit in a DECIMAL(2,0). Is false by default = no overflow error, value assigned.	*There is no equivalent in Genero.* *By default Genero assigns NULL to a decimal when overflow occurs. Can be trapped by WHENEVER ANY ERROR.*
`fglrun.ix6`	Controls Informix® version 6.x compatibility. By default BDS is compatible with I4GL 4.x	*There is no equivalent in Genero.* *By default Genero is compatible to Informix® 4gl 7.32.*
`fglrun.cmd.winnt`, `fglrun.cmd.win95`	Defines the command line to be executed for a RUN WITHOUT WAITING on Windows™ platforms.	With Genero the command program can be defined with the COMSPEC environment variable.
`fglrun.database.listvar`, `fglrun.remote.envvar`	Was used by Informix® driver to set environment variables with the ifx_putenv() function on Windows™ platforms.	*There is no equivalent in Genero.*
`fglrun.setenv.*`, `fglrun.defaultenv.*`	These entries could be used to define environment variables for all programs.	*There is no equivalent in Genero.*
`fgllic.*`	License controller related entries	With Genero you configure license settings with the `flm.*` entries. See license manager documentation for more details.

Entry	Description of the BDS feature	Genero BDL equivalent
`fglrun.server.*`	These entries could be used to define X11 front-end automatic startup.	In Genero this can be configured with `gui.server.autostart.*` entries. See Automatic front end startup on page 761 for more details.

Calling fgl_init4gl() initialization function

Four Js Business Development Suite (BDS) provided a few utility functions in the libfgl4js.42x library. This library had to be initialized with a call to fgl_init4js():

```
MAIN
   ...
  CALL fgl_init4js()
   ...
END MAIN
```

Genero Business Development Language still supports the fgl_init4js() function, but only for backward compatibility. Calling this function has no effect in Genero.

Static versus Dynamic Arrays

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

Debugger syntax changed

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

fgl_system() function

The fgl_system() function is still supported in Genero Business Development Language, but it does not raise a terminal window on the front-end as with Four Js Business Development Suite (BDS). However, some front-ends implement a workaround for this feature, based on the detection of special strings displayed to stdout by fglrun. See front-end documentation for more details.

The Channel:: methods

Genero Business Development Language provides file, socket and process I/O with the Channel built-in class, while Four Js Business Development Suite (BDS) has the `Channel::` functions. You must review your code and replace `Channel::` calls with the new API.

STRING versus CHAR/VARCHAR

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Review user-made C routines

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Strict variable identification in SQL statements

This topic applies also to older Genero Business Development versions, see the Genero 2.20 Migration page for more details.

Default action of WHENEVER ANY ERROR

With old Four Js Business Development Suite (BDS) versions like 2.10, expression evaluation errors such as a division by zero stop the program with an error message. Genero Business Development Language behaves like IBM® Informix® 4GL and recent BDS versions like 3.55: By default, the WHENEVER ANY

ERROR action is to CONTINUE the program flow. You can change this behavior by setting the next FGLPROFILE entry to true:

```
fglrun.mapAnyErrorToError = true
```

Configuration

These topics cover configuration options of the Genero Business Development Language.

- The FGLPROFILE file on page 164
- Environment variables on page 169
- Configuring the database server connections on page 186
- Configuring the front-end connection on page 186

The FGLPROFILE file

- Understanding FGLPROFILE on page 164
- FGLPROFILE entry syntax on page 165
- List of FGLPROFILE entries on page 166

Understanding FGLPROFILE

The runtime system uses one or more configuration files in which you can define options and parameters to change the behavior of the programs.

Loading FGLPROFILE files

There are three different levels to specify a configuration file, and these files are loaded in the following order:

1. First, the runtime system reads the default configuration file provided in `FGLDIR/etc/fglprofile`. This file contains all supported entries, identifies the possible values for an entry, and documents default values. You should not modify this default configuration file.
2. Then, if the FGLPROFILE environment variable is set, the runtime system reads entries from the files specified by this environment variable. A list of files can be provided with FGLPROFILE. Files must be separated by the operating system specific path separator.

   Note: On mobile devices, it is not possible to define environment variables. To specify a custom fglprofile file for a mobile application, you must deploy a file with the name "`fglprofile`" in the *appdir* directory, along with the other application program files (`.42m`, `.42f`, and so on). Only one custom fglprofile file can be deployed for a given mobile application.
3. After loading and merging the two previous levels, the runtime system checks whether the `fglrun.defaults` entry is set. This entry defines the *program-specific profile directory*. If this directory contains a file with the same name as the current program (without a `.42r` extension), the runtime system reads the entries from that file.

The runtime system merges the different configuration files found at the three levels. If the same entry is defined in several files, the last loaded entry wins. This means that the order of precedence is:

1. Program-specific configuration file (if `fglrun.defaults` is defined in one of the other levels).
2. Configuration files defined by the FGLPROFILE environment variable, or *`appdir`*`/fglprofile`, for mobile applications.
3. The default configuration file `FGLDIR/etc/fglprofile`.

The default FGLPROFILE file

It is recommended that you NOT change the default configuration file in `FGLDIR/etc/fglprofile`. This file will be overwritten by a new installation and your changes will be lost. It is recommended that you make a copy and define your private configuration file using the FGLPROFILE environment variable.

FGLPROFILE file name

For non-mobile apps, there is no specific naming convention for FGLPROFILE configuration files. You can use a file name without an extension, or the `.txt` extension for simple text file.

On mobile devices, the name of the custom fglprofile file must be "`fglprofile`", and must be deployed under the *appdir* directory.

FGLPROFILE file encoding

The character encoding of FGLPROFILE files must match the application locale.

Defining your own FGLPROFILE entries

User-defined entries can be read with the `FGL_GETRESOURCE()` built-in function.

FGLPROFILE entry syntax

Description of the syntax of FGLPROFILE entries.

Syntax

```
  # comment
| entry-definition
```

where *entry-definition* is:

```
entry = value
```

where *entry* is:

```
ident [.ident [.ident] [...] ] ]
```

and *value* is:

```
  [-]{ digit [...] }[ . digit [...] ]
| " alphanum [...] "
| {true|false}
```

1. *comment* is a line of text that is started by a # sharp.
2. *entry* identifies the name of the entry. This can be a dot-separated list of identifiers.
3. *value* is the value of the entry; it might be a numeric value, a string literal, or a boolean value (true/false).

Usage

An FGLPROFILE entry is a line in the configuration file associating a parameter name to a value that can be specified as a numeric, string or boolean.

> **Important:** The encoding of FGLPROFILE files must match the application locale of the program. For more details about locale definition, see Application locale on page 307.

The entries are defined by a name composed of a list of identifiers separated by a dot character.

> **Note:** FGLPROFILE entry names are case insensitive. In order to avoid any confusion, it is recommended to write FGLPROFILE entry names in lower case.

If an entry is defined several times in the same file, the last entry found in the file is used. No error is raised.

The value can be a numeric literal, a string literal, or a boolean (true/false).

Numeric values are composed by an optional sign, followed by digits, followed by an optional decimal point and digits:

```
my.numeric.entry = -1566.57
```

String values must be delimited by single or double quotes. The escape character is backslash, `\t \n \r \f` are interpreted as TAB, NL, CR, FF. Double the backslash to write a backslash character (`\\`):

```
my.string.entry = "C:\\data\\test1.dbf"
```

Boolean values must be either the `true` or `false` keyword:

```
my.boolean.entry = true
```

Example

```
# Last modification: 2013-03-12/mike
report.aggregatezero = true
gui.connection.timeout = 100
dbi.database.stores.source = "C:\\data\\test1.dbf"
dbi.database.stores.prefetch.rows = 200
```

List of FGLPROFILE entries

This is a summary of supported FGLPROFILE entries.

Find more information for an FGLPROFILE entry by following the documentation link in the description of the entry.

Table 91: Partial list of supported FGLPROFILE entries

Entry	Values	Default	Description
`Dialog.currentRowVisibleAfterSort`	boolean	false	Forces current row to be shown after a sort in a table. See Dialog configuration with FGLPROFILE on page 1251.
`Dialog.fieldOrder`	boolean	false	Defines if the intermediate field triggers must be executed when a new field gets the focus with a mouse click. See Dialog configuration with FGLPROFILE on page 1251.
`dbi.default.driver`	string	NULL	Defines the default database driver. See Default database driver on page 464.
`dbi.database.`*`dbname`*`.driver`	string	NULL	Defines the database driver for a database name. See Database driver specification (driver) on page 462.

Entry	Values	Default	Description
`dbi.database.`*`dbname`*`.source`	string	NULL	Defines the data source for a database name. See Database source specification (source) on page 461.
`dbi.*`	N/A	N/A	Database interface configuration. See Connections.
`fglrun.arrayIgnoreRangeError`	boolean	false	Controls runtime behavior when array index is out of bounds. See Arrays on page 296 for more details.
`fglrun.decToCharScale2`	boolean	false	Formats DECIMAL(P) with 2 digits after the decimal point. See Floating point to string conversion on page 107.
`fglrun.defaults`	string	NULL	Defines the directory where program specific configuration files are located. See Understanding FGLPROFILE on page 164.
`fglrun.ignoreDebuggerEvent`	boolean	false	Defines whether the runtime system can swtich to debug mode. See The debugger on page 1531.
`fglrun.ignoreLogoffEvent`	boolean	false	Defines whether the runtime system ignores a CTRL_LOGOFF_EVENT on Windows™ platforms. See Responding to CTRL_LOGOFF_EVENT on page 386.
`fglrun.localization.*`	N/A	N/A	Defines load parameters for localized string resource files. See Localized strings on page 327.
`fglrun.mapAnyErrorToError`	boolean	false	Controls default action of `WHENEVER ANY ERROR`. See Exceptions on page 340.
`fglrun.mmapDisable` **Note:** This entry may be removed in a future version: It is only provided to solve file overwrite issues when doing live program files updates on Windows™ platforms.	boolean	false	Turns program files memory mapping off on Windows™ platforms. See Dynamic module loading on page 1560.
`flm.*`	N/A	N/A	License management related entries.

Entry	Values	Default	Description
			See licensing documentation.
`gui.connection.timeout`	integer	30	Defines the timeout delay (in seconds) the runtime system waits when it establishes a connection to the front-end. After this delay the program stops with an error. See Configure the GUI connection timeout on page 757.
`gui.key.add_function`	integer	none	If set, this entry defines the offset for function key mapping when using Shift-Fx and Control-Fx key modifiers. See Traditional GUI mode on page 753.
`gui.protocol.pingTimeout`	integer	600	Defines the timeout delay (in seconds) the runtime system waits for a front-end ping when there is no user activity. After this delay the program stops with an error. See Wait for front end ping timeout on page 757.
`gui.protocol.format`	string	default	Controls Front-End protocol format. Possible values are: "block", "zlib". Default is "block" (encapsulation only). See GUI protocol compression on page 758.
`gui.server.autostart.*`	N/A	N/A	Defines automatic front-end startup parameters. See Automatic front end startup on page 761.
`gui.uiMode`	string	NULL	Defines the user interface mode, to render windows in traditional I4GL mode. Possible values are: "default" or "traditional". Default is the new Genero GUI mode with real resizeable windows. See Traditional GUI mode on page 753.
`key.`*`key-name`*`.text`	string	N/A	Defines a label for an action defined with an ON KEY clause. *Provided for V3 compatibility only.* See Setting key labels on page 759.

Entry	Values	Default	Description
`mobile.environment.`*`name`* `= "`*`value`*`"`	N/A	N/A	Define environment variable values in FGLPROFILE for mobile applications. See Setting environment variables in FGLPROFILE (mobile) on page 170.
`Report.aggregateZero`	boolean	false	Defines if the report aggregate functions must return zero or NULL when all values are NULL. *Provided for V3 compatibility only.* See Report engine configuration on page 1492.
`authenticate.*`	N/A	N/A	Web services configuration. See Basic or digest HTTP authentication on page 2512
`proxy.*`	N/A	N/A	Web services configuration. See Proxy configuration on page 2512
`security.*`	N/A	N/A	Web services configuration. See HTTPS and password encryption on page 2510
`ws.*`	N/A	N/A	Web services configuration. See Server configuration on page 2513
`xml.*`	N/A	N/A	Web services configuration. See XML configuration on page 2514

Environment variables

- Setting environment variables on UNIX on page 169
- Setting environment variables on Windows on page 170
- Setting environment variables in FGLPROFILE (mobile) on page 170
- Operating system environment variables on page 171
- Database client environment variables on page 173
- Genero environment variables on page 173

Setting environment variables on UNIX™

On UNIX™ platforms, environment variables can be set through the following methods, depending on to the command interpreter used:

Bourne shell:

```
VAR=value; export VAR
```

Korn shell:

```
export VAR=value
```

C shell:

```
setenv VAR=value
```

For more details, refer to the documentation for your UNIX™ system.

Setting environment variables on Windows™

On Windows™ platforms, environment variables can be set by one of the following methods:

- In a command window, with the SET command.
- In the registry, for the current user in HKEY_CURRENT_USER or a global setting in HKEY_LOCAL_MACHINE.

For more details, refer to the documentation of your Windows™ system.

On Windows™, double quotes do not have the same meaning as on UNIX™ systems. For example, if you set a variable with the command SET VAR="abc", the value of the variable will be "abc" (with double quotes), and not abc.

When using Informix®, some variables related to the database engine must be set using the SETNET32 utility.

Setting environment variables in FGLPROFILE (mobile)

When executing applications on mobile devices, you can configure environment settings with FGLPROFILE entries. Setting an environment variable with an FGLPROFILE entry is equivalent to setting the environment variable before running the fglrun VM process on a server.

> **Note:** Environment variables set in an FGLPROFILE file are only read when the deployed application runs the mobile device. They are not read during development mode (i.e. when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

FGLPROFILE environment variables settings can be used to define DBDATE and DBFORMAT, if the default regional settings on the mobile must be ignored for date and numeric value formatting. Note that defining DBMONEY will have no effect, because DBFORMAT is defined automatically by the GMI or GMA front-end component before starting the VM component. Since DBFORMAT takes precedence over DBMONEY, setting DBMONEY in FGLPROFILE is useless.

> **Important:** C-runtime library variables such as LANG/LC_ALL cannot be set with FGLPROFILE entries, because the C-runtime library is (and must be) initialized before reading FGLPROFILE files.

The syntax is:

```
mobile.environment.env_name = "env_value"
```

where:

1. *env_name* is the name of the environment variable to be set.
2. *env_value* is the value for the *env_name* environment variable.

For example:

```
mobile.environment.MY_ENV_VAR = "my value"
```

The value specified in a mobile.environment entry can contain $*NAME* placeholders, that will be replaced by the actual value of the *NAME* environment variable. The *NAME* environment variable will typically be set by the front-end component, before starting the runtime system component, for example to define FGLDIR and FGLAPPDIR values.

If the environment variable contains directory or file pathes, use the UNIX path notation with `/` slashes as directory name separator, and the `:` colon as path separator.

The next example defines the FGLIMAGEPATH environment variable for the mobile app, using FGLAPPDIR and FGLDIR predefined environment variables:

```
mobile.environment.FGLIMAGEPATH = "$FGLAPPDIR/myimages:$FGLAPPDIR/icons/
myimage2font.txt:$FGLDIR/lib/image2font.txt"
```

> **Note:** During development (when executing programs on a server), consider defining environment variables such as FGLAPPDIR in the shell environment, along with the other environment variables that are defined with `mobile.environment` entries, as these are only read when executing on mobile devices.

Operating system environment variables

This section describes some well-known system environment variables that are used by Genero software components.

- LC_ALL (or LANG) on page 171
- LD_LIBRARY_PATH on page 171
- PATH on page 172
- TERM on page 172
- TERMCAP on page 172
- TERMINFO on page 172
- TMPDIR, TEMP, TMP on page 173

LC_ALL (or LANG)

Defines the current application locale on UNIX™ platforms.

The LC_ALL (or LANG) environment variable defines language, territory and codeset for programs running on UNIX™ platforms.

The codeset defined in LC_ALL is used by the runtime system to handle character strings.

It is important to set this variable properly according to the character set used by your application.

If LC_ALL is not defined, LANG is used instead.

Read the UNIX™ man page of the `setlocale()` C function for more details about this variable.

LD_LIBRARY_PATH

Defines search paths to find shared libraries on UNIX™ platforms.

The `LD_LIBRARY_PATH` environment variable defines the list of search paths for shared libraries loaded by the *dynamic linker* on UNIX™ platforms.

On some operating systems, the environment variable defining the shared library search path may have a different name.

- On a system where a 32-bit and a 64-bit environment coexist, you may need to set `LD_LIBRARY_PATH_64` to execute the 64-bit programs.
- On HP/UX, set `SHLIB_PATH`.
- On AIX®, set `LIBPATH`.
- On Mac OS X®, the usage of `DYLD_LIBRARY_PATH` is discouraged. Therefore, shared libraries that are not part of the Genero runtime system (such as database client libraries) must be found in the standard system directories (`/usr/lib`, `/usr/local/lib`)

PATH
Defines the list of search paths to find executable files.

The PATH environment variable defines the list of search paths for executable files.

On UNIX™ platforms, PATH defines the search path list for executable programs.

On Windows™ platforms, PATH defines the search path for programs and DLLs.

The path separator is a colon (`:`) on UNIX™ and a semicolon (`;`) on Windows™.

TERM
Defines the type of terminal on UNIX™ platforms.

The TERM variable is used by UNIX™ and Genero applications to identify the terminal type when running in TUI mode.

By default or when INFORMIXTERM equals *termcap*, Genero reads terminal capabilities from the file defined by the TERMCAP environment variable. When INFORMIXTERM is set to *terminfo*, Genero reads terminal capabilities from the terminfo database of the system.

TERMCAP is the older implementation of terminal capabilities database. you should set INFORMIXTERM=terminfo.

It is important to define this variable properly to match the text terminal hardware or the terminal emulation you are using.

TERMCAP
Defines the *termcap* terminal capabilities database on UNIX™ platforms.

Usage

For UNIX™ platforms, TERMCAP is an environment variable that defines to the terminal capabilities file. This variable must be used in conjunction with TERM, when INFORMIXTERM is set to *termcap*, or when INFORMIXTERM is not set.

If the TERMCAP variable is not defined, Genero tries to open `/etc/termap`. If no `/etc/termcap` file exists, the runtime system uses `$FGLDIR/etc/termcap`. You can add more terminal definitions in this file.

TERMCAP is the older implementation of terminal capabilities database. you should set INFORMIXTERM=terminfo.

It is important to define terminal capabilities properly according to the text terminal hardware or the terminal emulation you are using. Especially function keys (F1, F16) and display attributes (bold, reverse, colors) may not work if the escape sequences do not correspond to the terminal used.

For more details about the TERMCAP environment variable, please refer to your UNIX™ operating system manual.

TERMINFO
Defines the *terminfo* terminal capabilities database.

On UNIX™ platforms, the TERMINFO environment variable points to the terminal capabilities database. This variable must be used in conjunction with TERM, when INFORMIXTERM is set to *terminfo*.

You should not have to modify or set this environment variable. The default is defined by the UNIX™ system, it can be for example `/etc/terminfo`, `/usr/lib/terminfo`, or `/lib/terminfo`.

It is important to define terminal capabilities properly according to the text terminal hardware or the terminal emulation you are using. In particular, function keys (F1, F16) and display attributes (bold, reverse, colors) may not work if the escape sequences do not correspond to the terminal used.

For more details about the TERMINFO environment variable, please refer to your UNIX™ operating system manual.

TMPDIR, TEMP, TMP
Defines the directory for temporary files.

The TMPDIR, TEMP and TMP environment variables define the directory where temporary files are created by the operating system and by some other software (TMPDIR is typically used on UNIX™ platforms, TEMP and TMP are used on Windows™)

On desktop and server platforms, consider using DBTEMP to define the temp file directory for runtime system temporary files.

On mobile devices, there is no need to define the TMPDIR (or DBTEMP) environment variable: The runtime system will automatically use the appropriate temporary directory within the app sandbox file system.

Database client environment variables

Programs connecting to a database server use a database driver that in turn uses a database client library. The database client software usually needs configuration settings that are defined with environment variables. Database client environment variable define information such as installation directory of the client software, localization settings, temporary directory, and more.

Refer to the database client software documentation for the required environment variable settings.

Genero environment variables

This section lists and describes in detail all Genero specific environment variables.

DBCENTURY
Specifies the expansion for the century in DATE and DATETIME values.

The DBCENTURY environment variable specifies how to expand abbreviated one- and two-digit *year* specifications within DATE and DATETIME values, especially during field input.

> **Important:** The DBCENTURY environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

Default value is "R" (prefix the entered value with the first two digits of the current year).

Values are case sensitive; only the four uppercase letters are valid.

Table 92: DBCENTURY valid values

Symbol	Algorithm for Expanding Abbreviated Years
C	Use the past, future, or current year closest to the current date.
F	Use the nearest year in the future to expand the entered value.
P	Use the nearest year in the past to expand the entered value.
R	Prefix the entered value with the first two digits of the current year.

If a year is entered as a single digit, it is first expanded to two digits by prefixing it with a zero; DBCENTURY then expands this value to four digits.

Three-digit years are not expanded.

Years before 99 AD (or CE) require leading zeros (to avoid expansion).

If the database server and the client system have different settings for DBCENTURY, the client system setting takes precedence for abbreviations of years in dates entered through the application. Expansion is sensitive to the time of execution and to the accuracy of the system clock-calendar. You can avoid the need to rely on DBCENTURY by requiring the user to enter four-digit years or by setting the CENTURY attribute in the form specification of DATE and DATETIME fields.

DBDATE
Defines the default display and input format for DATE values.

The DBDATE environment variable defines the default display and input format for DATE values.

> **Important:** The DBDATE environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

DBDATE defines the order of the month, day, and year time units within a string representing a date with numeric month and day such as "24/04/2014".

Values of DBDATE must be a restricted combination of symbols representing the position of the year (Yn), month (M) and day (D), the separator and some optional configuration options. For example, DMY4/ defines a date format with the day unit at the first position, followed by the month and the year (on 4 digits): "dd/mm/yyyy".

The separator always goes at the end of the format string (for example, DMY2/). If no separator or an invalid character is specified, the slash (/) character is the default. Specifying a 0 (zero) as separator indicates that no separator is used.

The default value of DBDATE depends on the type of platform: On destkop/server platforms, the default setting for DBDATE is: `MDY4/`. On mobile platforms, DBDATE defaults to the regional settings defined on the device.

Table 93: Valid DBDATE symbols

Symbol	Meaning in DBDATE format string
`D`	Day of month as one or two digits
`M`	Month as one or two digits
`Y2`	Year as two digits
`Y3`	Year as three digits *(Ming Guo format only)*
`Y4`	Year as four digits
`/`	Default time-unit separator for the default locale
`C1`	Ming Guo format modifier (years as digits)
`-`	Hyphen time-unit separator
`.`	Period time-unit separator
`0`	Indicates no time-unit separator

The combinations must follow a specific order:

```
{ DM | MD } { Y2 | Y3 | Y4 } { / | - | . | 0 } [C1]
{ Y2 | Y3 | Y4 } { DM | MD } { / | - | . | 0 } [C1]
```

When a form field and its corresponding variable are defined with the `DATE` type, values will be displayed according to the DBDATE format, except if a `FORMAT` attribute is defined.

The DBDATE format is also used to automatically convert a character string to/from a DATE value in programs.

Note that DBDATE takes also effect when fetching DATE values from the database into `CHAR`/`VARCHAR` program variables. However, it is not recommended to fetch date information into string variables, you should use `DATE` or `DATETIME` variables instead.

The C1 modifier can be used at the end of the DBDATE value in order to use Ming Guo date format with digit-based years. When using C1, you can use one of the Y4, Y3 or Y2 symbols for the year.

A Gregorian date format can look like `"DMY4/"`, while a Ming Guo date format would look like `"Y3MD/C1"`.

Date formatting specified in a `USING` clause or `FORMAT` attribute overrides the formatting specified in DBDATE.

DBDELIMITER
Defines the value separator for unload data files.

The DBDELIMITER environment variable defines the value delimiter for `LOAD` and `UNLOAD` instructions.

If DBDELIMITER is not defined, the default delimiter is a (`|`) pipe.

Do not use backslash or hex digits (0-9, A-F, a-f).

DBEDIT
Defines the editor program for `TEXT` fields in TUI mode.

The DBEDIT environment variable defines the editor program to modify the values of form fields defined with the `TEXT` data type, when running programs on dumb terminals.

DBFORMAT
Defines currency symbol, decimal and thousands separator for input and display of numeric values.

The DBFORMAT environment variable defines the input and display format for numeric values.

Important:

- When defined, the DBFORMAT environment variable takes precedence over DBMONEY.
- The DBFORMAT environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

The value of a DBFORMAT variable must use the following syntax:

```
front:thousands:decimal:back
```

1. *front* is the leading currency symbol, can be an asterisk (*).
2. *thousands* is a character that you specify as a valid thousands separator, can be an asterisk (*).
3. *decimal* is a character that you specify as a valid decimal separator.
4. *back* is the trailing currency symbol, can be an asterisk (*).

DBFORMAT takes precedence over DBMONEY.

If neither DBMONEY, nor DBFORMAT are defined, the default numeric formatting depends on the type of platform where the runtime system executes:

- On destkop/server platforms, the default numeric format defines the (`,`) comma as thousands separator, the (`.`) dot as decimal separator, and the ($) dollar sign as front currency symbol for MONEY values. This corresponds to `DBMONEY="$."`, or `DBFORMAT="$:,:.:"`.
- On mobile platforms, the numeric format defaults to the regional settings defined on the device. Normally, there is no need to modify these defaults.

DBFORMAT can be set to define the input and display format for values of these types:

- `MONEY` (thousands separator, decimal separator and currency symbol)
- `DECIMAL` (thousands separator, decimal separator)
- `SMALLFLOAT` (thousands separator, decimal separator)
- `FLOAT` (thousands separator, decimal separator)
- `SMALLINT` (thousands separator)
- `INTEGER` (thousands separator)
- `BIGINT` (thousands separator)

DBFORMAT can specify the leading and trailing currency symbols (but not their default positions within a monetary value) and the decimal and thousands separators. The decimal and thousands separators defined by DBFORMAT apply to both monetary and other numeric data.

The instructions affected by the setting in DBFORMAT include (but are not restricted to) these items:

- `USING` operator.
- `FORMAT` field attribute.
- `DISPLAY` or `PRINT` statement (default formatting of numeric values).
- `LET` statement, where a `CHAR`, `VARCHAR` or `STRING` variable is assigned a monetary or number value.
- `LOAD` and `UNLOAD` statements that use ASCII files (or whatever the locale regards as a *flat* file) to pass data to or from the database.

The asterisk (*) specifies that a symbol or separator is not applicable; it is the default for any *front*, *thousand*s, or *back* term that you do not define.

If you specify more than one character for *decimal* or *thousand*s, the values in the *decimal* or *thousands* list cannot be separated by spaces (nor by any other symbols). However, only the first character will be used to display numeric or currency values, when converting strings to numbers and when entering values in form fields.

Any printable character that your locale supports is valid for the thousands separator or for the decimal separator, except:

- Digits (0, 1, 2, 3, 4, 5, 6, 7, 8, 9)
- <, >, |, ?, !, =, [,]

The same character cannot be both the thousands and decimal separator. A blank space (ASCII 32) can be the thousands separator (and is conventionally used for this purpose in some locales). The asterisk (*) symbol is valid as the decimal separator, but is not valid as the thousands separator.

Enclosing the DBFORMAT specification in a pair of single quotation marks is recommended to prevent the shell from attempting to interpret (or execute) any of the DBFORMAT characters.

The setting in DBFORMAT affects how formatting masks of the `FORMAT` attribute and `USING` operator are interpreted. In formatting masks of `FORMAT` and `USING`, these symbols are not literal characters but are placeholders for what DBFORMAT specifies:

- The dollar ($) sign is a placeholder for the *front* currency symbol.
- The comma (,) is a placeholder for the thousands separator.
- The period (.) is a placeholder for the decimal separator.
- The at (@) sign is a placeholder for the *back* currency symbol.

This table illustrates the results of different combinations of DBFORMAT setting and format string on the same value.

Table 94: Results of combinations of DBFORMAT setting and format string on the same value

Value	Format String	DBFORMAT	Result
`1234.56`	`$#,###.##`	`$:,:.:`	`$1,234.56`
`1234.56`	`$#,###.##`	`:.:,:DM`	`1.234,56`
`1234.56`	`#,###.##@`	`$:,:.:`	`1,234.56`
`1234.56`	`#,###.##@`	`:.:,:DM`	`1.234,56DM`

When the user enters numeric or currency values in fields, the runtime system behaves as follows:

- If a symbol is entered that was defined as a decimal separator in DBFORMAT, it is interpreted as the decimal separator.
- For `MONEY` fields, it disregards any *front* (leading) or *back* (trailing) currency symbol and any thousands separators that the user enters.
- For `DECIMAL` fields, the user must enter values without currency symbols.

When the runtime system displays or prints values:

- The DBFORMAT-defined leading or trailing currency symbol is displayed for `MONEY` values.
- If a leading or trailing currency symbol is specified by the `FORMAT` attribute for non-MONEY data types, the symbol is displayed.
- The thousands separator is not displayed unless it is included in a formatting mask of the `FORMAT` attribute or of the USING operator.

When `MONEY` values are converted to character strings by the `LET` statement, both automatic data type conversion and explicit conversion with a `USING` clause insert the DBFORMAT-defined separators and currency symbol into the converted strings.

For example, suppose DBFORMAT is set as follows:

```
*:.:,:SFr
```

The value 1234.56 will print or display as follows:

```
1234,56SFr
```

Here `SFr` stands for the Swiss Franc currency symbol. Values input by the user into a screen form are expected to contain commas, not periods, as their decimal separator because DBFORMAT has `*:.:,:SFr` as its setting in this example.

When using a graphical front-end, the decimal separator of the numeric keypad will produce the character defined by this environment variable.

DBMONEY
Defines currency symbol and decimal separator for input and display of numeric values, when DBFORMAT is not defined.

The DBMONEY environment variable defines the currency symbol and the decimal separator for numeric values.

Important:

- When defined, the DBFORMAT environment variable takes precedence over DBMONEY.
- The DBMONEY environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

The value of a DBMONEY variable must use the following syntax:

```
front{.|,}back
```

1. *front* is a character string representing a leading currency symbol that precedes the value.
2. *back* is a character string representing a trailing currency symbol that follows the value.

If neither DBMONEY, nor DBFORMAT are defined, the default numeric formatting depends on the type of platform where the runtime system executes:

- On destkop/server platforms, the default numeric format defines the (`,`) comma as thousands separator, the (`.`) dot as decimal separator, and the (`$`) dollar sign as front currency symbol for MONEY values. This corresponds to `DBMONEY="$."`, or `DBFORMAT="$:,:."`.
- On mobile platforms, the numeric format defaults to the regional settings defined on the device. Normally, there is no need to modify these defaults.

DBMONEY can only define the currency symbol and decimal separator characters must be specified in this environment variable. If you want to define the thousands separator, use the DBFORMAT environment variable instead. However, if only DBMONEY is used, an implicit thousands separator is selected.

The currency symbol in DBMONEY can be up to seven characters long and can contain any character except a comma or a period. It can be non-ASCII characters if the current locale supports a code set that defines the non-ASCII characters you use.

The DBMONEY environment variable can be set to define the input and display format for values of the following types:

- `MONEY` (thousands separator, decimal separator and currency symbol)
- `DECIMAL` (thousands separator, decimal separator)
- `SMALLFLOAT` (thousands separator, decimal separator)
- `FLOAT` (thousands separator, decimal separator)
- `SMALLINT` (thousands separator)
- `INTEGER` (thousands separator)

- `BIGINT` (thousands separator)

Numeric values will be displayed in forms and reports according to this environment variable.

DBMONEY will also be used for implicit data conversion between numeric values and character strings.

The position of the currency symbol (relative to the decimal separator) indicates whether the currency symbol appears before or after the `MONEY` value. When the currency symbol is positioned in DBMONEY before the decimal separator, it is displayed before the value ($1234.56). When it is positioned after the decimal separator, it is displayed after the value (1234.56F).

The runtime system recognizes the period (.) and the comma (,) as decimal separators. All other characters are considered to be part of the currency symbol. For example, ", FR" defines a MONEY format with the comma as decimal separator and the string " FR" (including the space) as the currency symbol.

Because only its position within a DBMONEY setting indicates whether a symbol is the *front* or *back* currency symbol, the decimal separator is required. If you use DBMONEY to specify a *back* symbol, for example, you must supply a decimal separator (a comma or period). Similarly, if you use DBMONEY to change the decimal separator from a period to a comma, you must also supply a currency symbol.

To avoid ambiguity in displayed numbers and currency values, do not use the thousands separator of DBFORMAT as the decimal separator of DBMONEY. For example, specifying comma as the DBFORMAT thousands separator dictates using the period as the DBMONEY decimal separator.

When using a graphical front-end, the decimal separator of the numeric keypad will produce the character defined by this environment variable.

DBPATH
Defines the paths to search for Genero program resource files.

For IBM® Informix® 4GL compatibility, DBPATH is used by the runtime system to find resource files such as form definitions.

> **Important:** The DBPATH environment variable is also used by the IBM® Informix® SE engine and SQLite, to define the path list to find database files. Genero has introduced the FGLRESOURCEPATH environment variable to not interfer with the database DBPATH settings. Consider dedicating DBPATH for database configurations, and use the FGLRESOURCEPATH to define program resource path list.

When FGLRESOURCEPATH is not defined, DBPATH environment variable is used to define the search paths for:

1. Form files loaded (.42f),
2. Message files (.iem),
3. Action defaults files (.4ad),
4. Presentation styles files (.4st),
5. Start menu files (.4sm),
6. Toolbar files (.4tb),
7. Topmenu files (.4tm),
8. Compiled localized strings files (.42s).

By the default, the runtime system looks for resource files is the current directory.

DBPATH must contain a list of paths, separated by the operating system specific path separator.

The path separator is platform specific (**":"** on UNIX™ platforms and **";"** on Windows™ platforms).

DBPRINT
Defines the print device to be used by reports.

The DBPRINT environment variable specifies the print device to be used by reports defined `TO PRINTER`.

On UNIX™ systems, the DBPRINT environment variable typically contains the printer queue command (such as **lp**).

To have the runtime system print to the printer on the client running the Genero Desktop Client (GDC), set `DBPRINT=FGLSERVER`.

DBSCREENDUMP
Defines the output file name for text screen shots.

The DBSCREENDUMP environment variable defines the output file name for text screen shots when pressing Ctrl-P.

When using the TUI mode, if the user pressed the Ctrl-P key, the runtime system will dump the current screen into the file defined by this variable.

Unlike DBSCREENOUT, the output of DBSCREENDUMP includes the escape sequences of TTY attributes, which makes it less readable.

DBSCREENOUT
Defines the output file name for text screen shots.

The DBSCREENOUT environment variable defines the output file name for text screen shots when pressing Ctrl-P.

When using the TUI mode, if the user pressed the Ctrl-P key, the runtime system will dump the current screen into the file defined by this variable.

Unlike DBSCREENDUMP, the output of DBSCREENOUT excludes the escape sequences of TTY attributes.

DBTEMP
Defines the directory for temporary files.

The DBTEMP environment variable defines the directory for temporary files created by the runtime system.

> **Important:** The DBTEMP environment variable is also used by the IBM® Informix® database client and server for temporary files.

This environment variable is use to create temporary files for:

1. `TEXT` or `BYTE` data located in a temporary file (`LOCATE IN FILE` without file name specification).
2. Temporary files of emulated scrollable cursors when the database engine does not support this feature.
3. Temporary file name generation with os.Path.makeTempName().
4. Temporary files created by the Web Services API, such as com.HTTPResponse.getFileResponse on page 2073.

On mobile devices, do not set DBTEMP environment variable: The runtime system will automatically use the appriopriate temporary directory withing the app sandbox file system.

FGL_LENGTH_SEMANTICS
Defines the length semantics to be used in programs.

Define the FGL_LENGTH_SEMANTICS environment variable to specify byte or character length semantics, by setting the value to BYTE or CHAR, respectively.

If the variable is not set, byte length semantics will be used by default.

When using a single-byte character set such as ISO-8859-1, use byte length semantics (the default). If the application character set is UTF-8, you should use char length semantics.

FGLAPPDIR
Contains the path to the application directory when executing on a mobile device.

When executing on mobile devices, the FGLAPPDIR environment variable is an automatic environment variable that contains the path to the *appdir* directory, containing application program files (`.42m`, `.42f`, and other resources).

This variable is typically used to define environment variables with `mobile.environment` FGLPROFILE entries, relative to the mobile appdir where application program files and resources are located.

> **Note:** During development (when executing programs on a server), consider defining the FGLAPPDIR in the shell environment, along with the other environment variables that are defined with `mobile.environment` entries, as these are only read when executing on mobile devices.

FGLAPPSERVER
Defines the listening port of the Web service in development context.

The FGLAPPSERVER environment variable defines the port on which the web service server will be started.

During development, define this environment variable before starting the web service server program, to let web service clients connect directly to the runtime system.

In production, Genero Application Server (GAS) is used to deploy web services servers. The GAS will automatically set FGLAPPSERVER. Do not manually set FGLAPPSERVER when GAS is involved.

FGLDBPATH
Defines the path to database schema files for compilers.

The fglcomp and fglform compilers need database schema files to compile source modules and forms. The path to the database schema files can be specified with FGLDBPATH.

If FGLDBPATH is not defined, the current directory is the default path for the database schema files. You can provide a list of paths, separated by the operating system specific path separator. FGLDBPATH is only used in development.

FGLDBPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is **":"** on UNIX™ platforms and **";"** on Windows™ platforms.

FGLDIR
Defines the installation directory of Genero Business Development Language.

The FGLDIR environment variable defines the installation directory of the runtime system and compilers of Genero.

When executing on a mobile device, the FGLDIR environment variable is automatically set by the front-end component, before starting the runtime system component. As result, it is possible to use the $FGLDIR keyword in FGLPROFILE environment variable settings when executing on mobile devices.

FGLGUI
Defines the user interface mode to be used by the program.

The FGLGUI environment variable indicates whether the applications are run in TUI or GUI mode.

When set to 0 (zero), the application executes in TUI mode.

When set to 1 (one, the default), the application executes in GUI mode and needs a front-end to display application windows.

FGLGUIDEBUG
Defines the debug level in GUI mode.

The FGLGUIDEBUG environment variable defines the debug level, when the GUI mode is used by the program.

By setting FGLGUIDEBUG to 1, the runtime system will display AUI protocol exchanges in the stderr output of the console running the program on the server.

The runtime system displays detailed information about user interface events that occur during program execution.

FGLIMAGEPATH
Defines the search paths for VM server image files.

FGLIMAGEPATH basics

The FGLIMAGEPATH environment variable is used by the runtime system, to find image resources on the server where the program executes, when the image name specified in the form element is not an URL that can be directly resolved and fetched by the front-end.

Image resources found through FGLIMAGEPATH will be transmitted to the front-end for display.

FGLIMAGEPATH defines a list of directories and/or image-to-font-glyph mapping files: If a path of FGLIMAGEPATH is a directory, it will be used for image file and font file lookup. If the element is a file name, it will be used as an image-to-font-glyph mapping file.

FGLIMAGEPATH setting on mobile devices

When executing on a mobile device, the environment variables must be defined with `mobile.environment` FGLPROFILE entries. The FGLAPPDIR and FGLDIR environment variables are automatically defined by the front-end component, and can be referenced with the $FGLAPPDIR and $FGLDIR placeholders, when defining FGLIMAGEPATH in FGLPROFILE:

```
mobile.environment.FGLIMAGEPATH = "$FGLAPPDIR/myimages:$FGLAPPDIR/icons/
myimage2font.txt:$FGLDIR/lib/image2font.txt"
```

For more details about environment variable settings for mobile apps, see Setting environment variables in FGLPROFILE (mobile) on page 170.

Default behavior when FGLIMAGEPATH is not defined

If the FGLIMAGEPATH environment variable is not defined, the runtime system will by default:

- Find image resource files in the current working directory where the BDL program executes.

  Note: When executing the app on an iOS device, instead of searching the current working directory, image resources are by default found in the *appdir* directory.
- Use `FGLDIR/lib/image2font.txt` along with `FGLDIR/lib/FontAwesome.ttf`, for image to font glyph mapping (to get default icons).

Order of precedence in FGLIMAGEPATH

It is possible to mix several image file directories with several image-to-font-glyph mapping files in FGLIMAGEPATH:

The list of mapping files and directories defines the order of precedence to resolve conflicts, when several image names can resolve to several image resources.

For example, if a form element defines an image as "smiley", and if FGLIMAGEPATH is defined as:

```
/opt/myapp/images:/opt/myapp/image2font.txt
```

If the `/opt/myapp/images` directory contains an image file `"smiley.png"`, and the `/opt/myapp/image2font.txt` file contains a mapping for `"smiley"`, the `"smiley.png"` file from `/opt/myapp/images` will be selected by the runtime system.

If FGLIMAGEPATH is defined as follows:

```
/opt/myapp/image2font.txt:/opt/myapp/images
```

The mapping for smiley to font glyph would take precedence.

FGLIMAGEPATH syntax

FGLIMAGEPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is **":"** on UNIX™ platforms and **";"** on Windows™ platforms.

For example, on UNIX:

```
$ export FGLIMAGEPATH="/var/myapp/myimages:$FGLDIR/lib/image2font.txt"
```

Image-to-font-glyph mapping

Image names can be mapped to font glyphs when at least one file path is specified in FGLIMAGEPATH. The runtime system distinguishes file paths (as image-to-font-glyph mapping files), from directory paths (as locations to file plain image files and font files).

> **Important:** The directory to the font file must be specified in FGLIMAGEPATH, except if the font file is located in the same directory as the mapping file.

A default mapping file ("`image2font.txt`") and its corresponding font file ("`FontAwesome.ttf`") are provided in `FGLDIR/lib`. If FGLIMAGEPATH is not defined, the runtime system will use these files to make the image to font glyph mapping.

> **Important:** When providing your own customized font file, it must be a valid TTF file. For example, changing the file name is not sufficient to turn it into another different font: In order to produce a valid TTF file, use font management tools such as FontForge (http://fontforge.github.io/en-US/) or Fontello (http://fontello.com). Further, to target Microsoft Internet Explorer (version 11), you will need to patch the generated TTF file to remove embedding limitations from TrueType fonts, by setting the `fsType` field in the OS/2 table to zero. This modification can be done with freeware tools like ttembed

The image-to-font-glyph mapping file must have the following syntax:

```
image-name=font-file:hexa-ordinal[:color-spec]
```

where:

1. *image-name* - is the name of the image to be mapped to a font character.
2. *font-file* - is the file name containing the font definitions.
3. *hexa-ordinal* - is the font glyph position in the font file, in hexadecimal notation.
4. *color-spec* - is the color to be used, in RGB hexadecimal format or as color alias as defined in presentation style colors. This field is optional: If not specified, the glyph will be displayed in a default color according to the front-end platform.

Lines starting with the # sharp character are considered as comment lines and ignored.

For example:

```
# Common icons
camera=FontAwesome.ttf:f030
file=FontAwesome.ttf:f0f6:#8B0000
smiley=FontAwesome.ttf:f118:yellow
# Traffic lights
circle-red=FontAwesome.ttf:f111:red
circle-orange=FontAwesome.ttf:f111:orange
```

```
circle-green=FontAwesome.ttf:f111:green
```

FGLIMAGEPATH and gICAPI web components

For applications executing on a server and displaying on GDC/GMA/GMI front-ends in client/server mode (not through the GAS), you can use the FGLIMAGEPATH environment variable to locate the HTML files of gICAPI web components on the server. Like image resources, the web component files will be automatically transferred to the front-end.

FGLLDPATH

Defines the search paths to load program modules.

The FGLLDPATH environment variable defines the search paths to load C extensions and modules, and by default to find sources with the debugger.

A program can be composed by several p-code modules (.42m) and can use C extensions. When linking and when executing the program, the runtime system must known where to search for these modules. You can use the FGLLDPATH environment variable to define the search paths to load C extensions and p-code modules.

FGLLDPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is **":"** on UNIX™ platforms and **";"** on Windows™ platforms.

The FGLLDPATH variable is used at link time and at run time.

The directories are searched for the modules in the following order:

1. The current directory.
2. The directory where the program (.42r) file resides.
3. A path defined in the FGLLDPATH environment variable.
4. The FGLDIR/lib directory.

If FGLSOURCEPATH is not defined, the debugger will use FGLLDPATH to find program sources.

FGLPROFILE

Defines the configuration files to be used by the runtime system.

Usage

The FGLPROFILE environment variable defines a list of configuration files to be used by the runtime system.

If FGLPROFILE is not set, the runtime system reads entries from the default configuration file located in FGLDIR/etc/fglprofile.

FGLPROFILE can define one unique configuration file, or a list of files to be loaded sequentially.

FGLPROFILE must contain a list of file paths, separated by the operating system specific path separator. The path separator is **":"** on UNIX™ platforms and **";"** on Windows™ platforms.

> **Note:** On mobile devices, it is not possible to define environment variables. To specify a custom fglprofile file for a mobile application, you must deploy a file with the name "`fglprofile`" in the *appdir* directory, along with the other application program files (`.42m`, `.42f`, and so on). Only one custom fglprofile file can be deployed for a given mobile application.

FGLRESOURCEPATH

Defines search path for resource files.

The FGLRESOURPATH environment variable is used to define the search paths for:

1. Form files loaded (.42f),
2. Message files (.iem),

3. Action defaults files (.4ad),
4. Presentation styles files (.4st),
5. Start menu files (.4sm),
6. Toolbar files (.4tb),
7. Topmenu files (.4tm),
8. Compiled localized strings files (.42s).

For compatibility with Informix® 4GL, DBPATH is used by default to search for resource files such as form files and XML files used by the program. However, DBPATH is also used by the Informix® database software to locate databases: Informix® Dynamic Server uses DBPATH to let you specify fallback servers if INFORMIXSERVER is not available, and former Informix® Standard Engine needs DBPATH to find **.dbs** database files. This can be a problem when connecting from a machine where path format is not the same as on the remote database server: It is not possible to mix UNIX™ and DOS path formats in DBPATH. To work around this Informix® limitation, FGLRESOURCEPATH can be used instead of DBPATH to specify the directories of program resource files. You are then free to define DBPATH as Informix® requires.

The path separator is platform specific (**":"** on UNIX™ platforms and **";"** on Windows™ platforms).

By the default, the runtime system looks for resource files is the current directory.

On mobile platforms, localize string files are searched by default in the language sub dirs of the app directory. For more details, see Using localized strings at runtime on page 331.

FGLSERVER
Defines the graphical front-end form the application.

In GUI mode, FGLSERVER defines the hostname and port of the graphical front end the runtime system will connect to in order to display application forms.

The values for the FGLSERVER environment variable must be specified with the following syntax:

```
{hostname|ipaddress}[:servnum]
```

1. *hostname* is the name of a machine on the network.
2. *ipaddress* is the IP V4 address (Ex: 10:0:0:105).
3. *servnum* identifies the front end.

The *servnum* parameter defines the front end server number (first is 0, second is 1, and so on). This defines implicitly the TCP port number the front end is listening to, as an offset for the base port 6400. For example, FGLSERVER=cobra:1 will use the TCP port 6401 (6400 + 1). This parameter is optional, when not specified, it defaults to zero (i.e. port 6400).

FGLSOURCEPATH
Defines the path to program source files.

The debugger needs to access the source files to display program code. By default, the current directory and the directories defined by FGLLDPATH are searched for the source files.

FGLSOURCEPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is **":"** on UNIX™ platforms and **";"** on Windows™ platforms.

FGLSQLDEBUG
Defines the debug level for tracing SQL instructions.

If FGLSQLDEBUG is set to a value greater than zero, you get a debug trace in the standard error channel for every SQL instruction executed by the program.

FGLSQLDEBUG should only be used in development, or on a production site in order to identify a problem related to SQL statements.

FGLWRTUMASK
Defines the umask to be used by the license manager.

The FGLWRTUMASK environment variable is used by the fglWrt license manager to create the `FGLDIR/lock` directory.

This variable defines the umask to create the `FGLDIR/lock` directory.

The default is 000, which creates a directory with **rwxrwxrwx** rights.

FGLWSDEBUG
The `FGLWSDEBUG` environment variable enables web services library debugging.

Set the FGLWSDEBUG environment variable to turn on debug information display in the web services library.

Table 95: FGLWSDEBUG variable values

Value	Definition
0	No data displayed; debug turned off.
1	Display socket errors.
2	Display HTTP bodies of incoming and outgoing requests (the XML content)
3	Display all information about incoming and outgoing requests (HTTP headers + HTTP bodies)

INFORMIXTERM
Defines terminal control library to be used.

The INFORMIXTERM environment variable indicates what terminal capabilities database must be used by the runtime system when running a program in TUI mode on a dumb terminal.

Possible values of INFORMIXTERM are *terminfo* and *termcap*. If the variable is not set, it defaults to *termcap*.

When set to *termcap* (the default), the runtime system reads terminal capabilities from the file defined by the TERMCAP environment variable.

When set to *terminfo*, the runtime system reads terminal capabilities from the terminfo database of the system (ncurses).

Configuring the front-end connection

In order to execute a Genero program with a graphical user interface, you need to specify the front-end (i.e. the graphical server) to the runtime system.

In development mode, the target front-end is defined with the FGLSERVER environment variable. However, there are various technologies to render a Genero application, according to the front-end platform (PC, mobile device, web browser).

Details about front-end configuration for the runtime system can be found the user interface basics chapter of this manual.

Configuring the database server connections

Before running a Genero program using a database, you must configure the connection parameters to access the database server.

There are different solutions to define database connection parameters, consider using and indirect database connection configuration, by using an abstract database name in programs, and define the real database source, driver with FGLPROFILE entries.

The database configuration details can be found the SQL support chapter of this manual.

Language basics

These topics cover the basics for the Genero Business Development Language

Syntax features

Genero BDL is an English-like programming language, easy to write and read.

- Lettercase insensitivity on page 188
- Whitespace separators on page 189
- Quotation marks on page 189
- Escape symbol on page 189
- Statement terminator on page 190
- Comments on page 190
- Identifiers on page 191
- Preprocessor directives on page 191

Lettercase insensitivity

Genero Business Development Language (BDL) is case insensitive, making no distinction between uppercase and lowercase letters, except within quoted strings.

Use pairs of double (") or single (') quotation marks in the code to preserve the lettercase of character literals, filenames, and names of database entities.

You can mix uppercase and lowercase letters in the identifiers that you assign to language entities, but any uppercase letters in identifiers are automatically shifted to lowercase during compilation.

It is strongly recommended that you define a naming convention for your projects. For example, you can use underscore notation (`get_user_name`). If you plan to use the Java™ notation (`getUserName`), do not forget that Genero BDL is case insensitive (`getusername` is the same identifier as `getUserName`).

With Genero BDL you can import and use Java™ classes and objects in BDL code. Genero BDL is case-sensitive regarding Java™ elements.

Whitespace separators

Genero Business Development Language (BDL) is free-form, like C or Pascal, and generally ignores TAB characters, LINEFEED characters, comments, and extra blank spaces between statements or statement elements. You can freely use these whitespace characters to enhance the readability of your source code.

Blank (ASCII 32) characters act as delimiters in some contexts. Blank spaces must separate successive keywords or identifiers, but cannot appear within a keyword or identifier. Pairs of double (") or single (') quotation marks must delimit any character string that contains a blank (ASCII 32) or other whitespace character, such as LINEFEED or RETURN.

Quotation marks

In the Genero BDL language, string literals are delimited by single (') or double (") quotation marks.

```
'Valid character string'
"Another valid character string"
```

Do not mix double and single quotation marks as delimiters of the same string. The following is not a valid character string:

```
'Not A valid character string"
```

To include literal quotation marks within a quoted string, precede each literal quotation mark with the backslash (\), or else enclose the string between a pair of the opposite type of quotation marks:

```
MAIN
   DISPLAY "Type 'Y' if you want to reformat your disk."
   DISPLAY 'Type "Y" if you want to reformat your disk.'
   DISPLAY 'Type \'Y\' if you want to reformat your disk.'
END MAIN
```

A string literal can be written on multiple lines. The compiler merges lines by removing the newline character.

In the SQL language, the standard specifications recommend that you use single quotes for string literals and double quotes for database object identifiers like table or column names. When accessing a non-Informix database, double quotation marks might not be recognized as database object name delimiters. As a general rule, use single quoted string literals in SQL statements, and use non-quoted, lowercase database object identifiers.

Escape symbol

The Genero Business Development Language (BDL) compiler treats a backslash (\ ) as the default escape symbol, and treats the immediately following symbol as a literal, except for special characters such as \r or \t.

See the string literals reference for the complete list.

To specify anything that includes a literal backslash, enter double (\\ ) backslashes wherever a single backslash is required. Similarly, use \\\\ to represent a literal double backslash.

```
MAIN
  DISPLAY "\a"   -- displays a
  DISPLAY "\r"   -- displays CR
  DISPLAY "\n"   -- displays NL
  DISPLAY "\ta"  -- displays <tab>a
  DISPLAY "\\"   -- displays \
  DISPLAY "\\\\" -- displays \\
END MAIN
```

Statement terminator

Genero Business Development Language (BDL) requires no statement terminators, but you can use the semicolon (;) as a statement terminator in some cases.

For example, you can add a semicolon statement terminator for PREPARE and PRINT statements.

```
MAIN
  DISPLAY "Hello, World"  DISPLAY "Hello, World"
  DISPLAY "Hello, World"; DISPLAY "Hello, World"
END MAIN
```

Comments

For clarity and to simplify program maintenance, it is recommended that you document your code by including comments in your source files.

A source comment is text in the source code to assist human readers, but which BDL ignores.

You can use comment indicators during development to disable instruction temporarily, without removing them from your source code modules.

A source comment can be specified by any of the following:

- A pair of minus signs (--) indicates a comment that terminates at the end of the current line. This comment indicator conforms to the ANSI standard for SQL.
- The sharp (#) symbol indicates a comment that terminates at the end of the current line.
- A starting left-brace ({) starts a comment. It can be followed by any character (including line breaks). The comment ends when the closing right-brace (}) symbol is found.

```
MAIN
  -- DISPLAY "This line will be ignored."
  # DISPLAY "This line will be ignored."
  {
  DISPLAY "This line will be ignored."
  DISPLAY "This line will be ignored."
  }
  DISPLAY "Hello, World"
END MAIN
```

Within a quoted string, the compiler interprets comment indicators as literal characters, rather than as comment indicators.

You cannot use braces ({ }) to nest comments within comments.

Comments cannot appear in the form section defining a layout grid, such as SCREEN, TABLE, TREE, or GRID.

The # symbol cannot indicate comments in an SQL statement block nor in the text of a prepared statement.

You cannot specify consecutive minus signs (--) in arithmetic expressions, as BDL interprets what follows as a comment. Instead, use a blank space or parentheses to separate consecutive arithmetic minus signs.

Do not follow the -- comment indicator with the sharp (#) symbol, unless you intend to compile the same source file with the Informix® 4GL product. The --# specific comment indicator is used to distinguish Informix® 4GL code from Genero BDL code. This conditional code compilation technique can be inverted by enclosing code blocks between --#{ and --#} comments:

```
MAIN
  --# DISPLAY "Ignored by I4GL, but compiled with BDL."
  --#{
```

```
      DISPLAY "Ignored by BDL, but compiled with I4GL."
  --#}
END MAIN
```

To summarize:

- Code lines starting with `--#` are compiled with Genero BDL, but ignored by Informix® 4GL.
- Code blocks surrounded with `--#{` and `--#}` are compiled with Informix® 4GL, but ignored by Genero BDL.

Identifiers

A Genero Business Development Language (BDL) identifier is a character string that is declared as the name of a program entity.

Identifiers must conform to the following rules:

- It must include at least one character, without any limitation in size.
- Only ASCII letters, digits, and underscore (_) symbols are valid.
- Blanks, hyphens, and other non-alphanumeric characters are not allowed.
- The initial character must be a letter or an underscore.
- Common identifiers are not case sensitive, so `my_Var` and `MY_vaR` both denote the same identifier. However, in some cases, identifiers are case sensitive (like action names in the AUI tree). It is recommended to always write identifiers in lower case to avoid mistakes.

Within non-English locales, BDL identifiers can include non-ASCII characters in identifiers, if those characters are defined in the code set of the current locale. In multibyte East Asian locales that support languages whose written form is not alphabet-based (such as Chinese, Japanese, or Korean), an identifier does not need to begin with a letter. It is however recommended to program in ASCII.

Preprocessor directives

Genero Business Development Language (BDL) supports preprocessing instructions, which allow you to write macros and conditional compilation rules.

```
&include "myheader.4gl"
FUNCTION debug( msg )
  DEFINE msg STRING
&ifdef DEBUG
  DISPLAY msg
&endif
END FUNCTION
```

> **Note:** Use the preprocessor with care, and only when there is no native language solution. Do not overcrowd your source code with preprocessing directive, that would make the code unreadable and unmaintainable.

Data types

Selecting the correct data type assists you in the input, storage, and display of your data.

Table 96: Genero Business Development Language data types

Data type	Description
BIGINT	8 byte signed integer
BOOLEAN	TRUE/FALSE boolean
BYTE	Large binary data (images)

Data type	Description
CHAR[(n)]	Fixed size character strings
DATE	Simple calendar dates
DATETIME q1 TO q2	High precision date and hour data
DECIMAL[(p[,s])]	High precision decimals
FLOAT[(p)]	8 byte floating point decimal
INTEGER	4 byte signed integer
INTERVAL q1 TO q2	High precision time intervals
MONEY[(p[,s])]	High precision decimals with currency formatting
SMALLFLOAT	4 byte floating point decimal
SMALLINT	2 byte signed integer
STRING	Dynamic size character strings
TINYINT	1 byte signed integer
TEXT	Large text data (plain text)
VARCHAR[(n[,r])]	Variable size character strings

BIGINT

The BIGINT data type is used for storing very large whole numbers.

Syntax

```
BIGINT
```

Usage

The storage of BIGINT variables is based on 8 bytes of signed data (= 64 bits).

The value range is from -9,223,372,036,854,775,807 to +9,223,372,036,854,775,807.

BIGINT variables can be initialized with integer literals:

```
MAIN
  DEFINE i BIGINT
  LET i = 9223372036854775600
  DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the BIGINT range, the overflow error -1284 will be raised.

BIGINT variables are initialized to zero in functions, modules and globals.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

BYTE

The BYTE data type stores any type of binary data, such as images or sounds.

Syntax

```
BYTE
```

Usage

A BYTE or TEXT variable is a handle for a large object (LOB), that is stored in a file or in memory. Such data type is a complex type that cannot be used like INTEGER or CHAR basic types: It is designed to handle a large amount of data and has different semantics as simple types. The main difference with simple data types, is the fact that you must specify the storage with the LOCATE instruction, before using BYTE and TEXT variables.

The maximum size of data that can be handled by BYTE and TEXT variable is theoretically 2^31 bytes (~2.14 Gigabytes), but the practical limit depends from the disk or memory resources available to the process.

BYTE and TEXT variable must be initialized with the LOCATE instruction before usage. The LOCATE instruction basically defines where the large data object has to be stored (in a named file, in a temporary file, or in memory). This instruction will actually allow you to fetch a LOB into memory or into a file, or insert a LOB from memory or from a file into the database. When located in a temporary file (IN FILE), the temp directory can be defined by the DBTEMP environment variable.

```
DEFINE t TEXT
LET t = "aaaa" -- invalid, t is not located
LOCATE t IN MEMORY
LET t = "aaaa" -- valid, now t is located in memory
```

With BYTE and TEXT types, you can insert/update/fetch large objects of the database. The native database type to be used depends from the type of database server. After defining the storage (LOCATE) of a large object handler, load / assign its value and use it directly in the SQL statements, or fetch data from LOB columns of the database, like simple data types:

```
DEFINE t1, t2 TEXT
...
CREATE TABLE mytable ( id INT, data TEXT )
...
LOCATE t1 IN MEMORY
CALL t1.readFile("lob.4gl")
INSERT INTO mytable VALUES ( 1, t1 )
LOCATE t2 IN FILE
SELECT data INTO t2 FROM mytable WHERE id=1
...
```

BYTE and TEXT types implement the readFile() and writeFile() methods to read/write the whole large object data from/to files. These methods can be used to easily interface with other software components:

```
DEFINE t TEXT
LOCATE t IN MEMORY
CALL t.readFile("orig.txt")
CALL t.writeFile("copy.txt")
```

When initializing a BYTE or TEXT variable to NULL (INITIALIZE *var* TO NULL), if the variable is located in a file, the file is truncated (file size will be zero). If the variable is located in memory, the data in memory

will be truncated. A subsequent usage of the variable (for example, FETCH INTO or LET assignment) is still possible:

```
DEFINE b BYTE
LOCATE b IN FILE "picture.png"
INITIALIZE b TO NULL
-- The file "picture.png" is now empty.
```

Resources allocated to a BYTE or TEXT variable can be deallocated with the FREE instruction. A FREE will remove the file if the LOB variable is located in a (named or temporary) file. When located in memory, the FREE instruction will de-allocate the memory. After freeing the resources of a LOB variable, it must be re-located with a LOCATE instruction:

```
DEFINE b BYTE
LOCATE b IN FILE
CALL t.readFile("picture.png") -- ok
FREE b
CALL t.readFile("picture.png") -- Invalid, b is not located.
LOCATE b IN MEMORY
CALL t.readFile("picture.png") -- ok
```

Important:

TEXT and BYTE are reference types. This implies that assigning two variables (LET, passing a variable as parameter to a function, returning a result from a function) does not copy the value (Only the handler is copied. As result, modifying the data with a TEXT/BYTE variable assigned from another TEXT/BYTE variable will in fact modify the same LOB data. Further, the storage resource (file or memory) that was used by the assigned variable becomes unreferenced and is lost:

```
DEFINE b1, b2 BYTE -- Could be TEXT: same behavior
LOCATE b1 IN FILE "mydata" -- reference file directly
LOCATE b2 IN MEMORY -- use memory instead of file
CALL b2.readFile("mydata") -- read file content into memory
# FREE b2 -- this should be done to free memory before LET
LET b2 = b1 -- Now b2 points directly to the file (like b1)
INITIALIZE b1 TO NULL -- truncates reference file
DISPLAY IIF( b2 IS NULL, "b2 is null", "b2 is not null")
-- Displays "b2 is null"
```

In the next (invalid) code example, we try to save the value of the `img BYTE` variable in a temporary variable (`tmp`), with the typical programming pattern to save the value before modification. In fact the `LET tmp=img` assignment does not copy the data of the LOB like for simple data types (STRING, VARCHAR, DECIMAL), only the reference (i.e. handle) to the data is copied:

```
-- WARNING: THIS IS AN INVALID CODE EXAMPLE
DEFINE img, tmp BYTE
LOCATE img IN MEMORY
CALL img.readFile("picture1.png")
LOCATE tmp IN MEMORY
LET tmp = img -- Expecting to save the current data, but now
              -- both variables reference the same data...
CALL img.readFile("picture2.png")
LET img = tmp -- Does not restore the old value: Same data.
```

If you need to clone a large object, use the `writeFile()` / `readFile()` methods.

BOOLEAN

The BOOLEAN data type stores a logical value, TRUE or FALSE.

Syntax

```
BOOLEAN
```

Usage

Boolean data types have two possible values: TRUE (integer 1) and FALSE (integer 0).

Variables of this type can be used to store the result of a boolean expression:

```
DEFINE result BOOLEAN
LET result = ( length("abcdef") > 0 )
```

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

Boolean variables are typically used to store the result of a boolean expression:

```
FUNCTION checkOrderStatus( cid )
  DEFINE oid INT, b BOOLEAN
  LET b = ( isValid(oid) AND isStored(oid) )
  IF NOT b THEN
    ERROR "The order is not ready."
  END IF
END FUNCTION
```

Note that the database vendor specific implementation of the boolean SQL type may not correspond exactly to the Genero BOOLEAN type. For example, IBM® Informix® SQL boolean type accepts the 't' and 'f' values, while the BOOLEAN Genero type expects 0/FALSE and 1/TRUE integer values only. You can however use a BOOLEAN variable in SQL statements: IBM® Informix® will handle the conversion, and for other databases, the db drivers handle the conversion. Note also that the TRUE/FALSE constants are Genero language constants: The SQL syntax of the database may not support these keywords, for example in an statement such as `INSERT INTO mytable (key,bcol) VALUES (455,TRUE)`. For more details, see SQL portability on page 412.

CHAR(size)

The CHAR data type is a fixed-length character string data type.

Syntax

```
CHAR[ACTER] [ (size) ]
```

1. *size* defines the maximum length of the character string, in byte or char units (depending on the character length semantics)
2. The maximum size of a CHAR type is 65534.
3. If no *size* is specified, it defaults to 1.

Usage

The CHAR type is typically used to store fixed-length character strings such as short codes (XB124), phone numbers (650-23-2345), vehicle identification numbers.

CHAR and CHARACTER are synonyms.

The *size* can be expressed in bytes or characters, depending on the length semantics used in programs. For more details about character length semantics, see Length semantics settings on page 314.

When *size* is not specified, the default length is 1.

CHAR variables are initialized to NULL in functions, modules and globals.

Text literals can be assigned to character string variables:

```
MAIN
  DEFINE c CHAR(10)
  LET c = "abcdef"
END MAIN
```

When assigning a non-NULL value, CHAR variables are always blank-padded:

```
MAIN
  DEFINE c CHAR(10)
  LET c = "abcdef"
  DISPLAY "[", c ,"]"   -- displays [abcdef    ]
END MAIN
```

Trailing blanks of a CHAR value are not significant in comparisons:

```
MAIN
  DEFINE c CHAR(5)
  LET c = "abc"
  IF c == "abc" THEN    -- evaluates to TRUE
     DISPLAY "equals"
  END IF
END MAIN
```

Numeric and date-time values can be directly assigned the character strings:

```
MAIN
  DEFINE c CHAR(50), da DATE, dec DECIMAL(10,2)
  LET da = TODAY
  LET dec = 345.12
  LET c = da, " : ", dec
END MAIN
```

When you insert character data from CHAR variables into CHAR columns in a database table, the column-value is blank-padded to the size of the column. Likewise, when you fetch CHAR column values into CHAR variables, the program variable is blank-padded to the size of the variable.

```
MAIN
  DEFINE c CHAR(10)
  DATABASE test1
  CREATE TABLE table1 ( k INT, x CHAR(10) )
  LET c = "abc"
  INSERT INTO table1 VALUES ( 1, c )
  SELECT x INTO c FROM table1 WHERE k = 1
  DISPLAY "[", vc ,"]"     -- displays [abc  ]
END MAIN
```

In SQL statements, the behavior of the comparison operators when using CHAR values may vary from one database to the other. However, most database engines ignore trailing blanks when compating CHAR values. For more details, see SQL portability on page 412.

DATE

The DATE data type stores calendar dates with a Year/Month/Day representation.

Syntax

```
DATE
```

Usage

Storage of DATE variables is based on a 4 byte integer representing the number of days since 1899/12/31.

The value range is from 0001-01-1 (-693594) to 9999-12-31 (2958464) .

DATE variables are initialized to zero (=1899/12/31) in functions, modules and globals.

Several built-in functions and operators specific to the DATE type are available, such as MDY( ) and TODAY. For more details, see Date and time operators on page 259.

Data type conversions, input and display of DATE values are ruled by environment settings, such as the DBDATE and DBCENTURY enviroment variables. Dates can be formatted with the USING operator. For more details, see Formatting DATE values on page 220.

> **Note:** As date-to-string conversion is based on an environment settings, it is not recommended that you hard code strings representing dates:
>
> ```
> LET date_var = "24/12/1998"      -- DBDATE dependant code
> LET date_var = MDY(12,24,1998)   -- Portable code
> ```

To add or substract a given number of days to a DATE, simply use a + or - arithmetic operator followed by an integer expression representing a number of days:

```
MAIN
  DEFINE d DATE
  LET d = TODAY
  LET d = d + 10   -- Add 10 days
  LET d = d - 20   -- Substract 20 days
  DISPLAY "d = ", d USING "yyyy-mm-dd"
END MAIN
```

The difference of two dates returns the number of days:

```
MAIN
  DEFINE d1, d2 DATE
  LET d1 = MDY(12,24,1998)
  LET d2 = MDY(5,11,2010)
  DISPLAY "d2 - d1 = ", (d2-d1)
END MAIN
```

DATE values can be converted directly from/to DATETIME values:

```
MAIN
  DEFINE d DATE,
         dt DATETIME YEAR TO FRACTION(3)
  LET d = TODAY
  LET dt = d;   DISPLAY "dt = ", dt
  LET dt = CURRENT
  LET d = dt;   DISPLAY "d = ", d
END MAIN
```

In order to add or substract a number of months to a DATE, use the UNITS operator:

```
MAIN
    DEFINE d0, d date
    LET d0 = MDY(01, 31, 2015)
    LET d = d0 + 1 UNITS MONTH; DISPLAY d
    LET d = d0 - 1 UNITS MONTH; DISPLAY d
    LET d = d0 - 2 UNITS MONTH; DISPLAY d
END MAIN
```

Note: In fact, the UNITS operator will produce an INTERVAL. Then the DATE value is converted to a DATETIME, to add or substract the INTERVAL value. Finally the DATETIME is converted to a DATE, in order to assign the result to the target variable.

DATETIME qual1 TO qual2

The DATETIME data type stores date and time data with time units from the year to fractions of a second.

Syntax

```
  DATETIME YEAR TO FRACTION [ ( scale ) ]
| DATETIME YEAR TO SECOND
| DATETIME YEAR TO MINUTE
| DATETIME YEAR TO HOUR
| DATETIME YEAR TO DAY
| DATETIME YEAR TO MONTH
| DATETIME YEAR TO YEAR
| DATETIME MONTH TO FRACTION [ ( scale ) ]
| DATETIME MONTH TO SECOND
| DATETIME MONTH TO MINUTE
| DATETIME MONTH TO HOUR
| DATETIME MONTH TO DAY
| DATETIME MONTH TO MONTH
| DATETIME DAY TO FRACTION [ ( scale ) ]
| DATETIME DAY TO SECOND
| DATETIME DAY TO MINUTE
| DATETIME DAY TO HOUR
| DATETIME DAY TO DAY
| DATETIME HOUR TO FRACTION [ ( scale ) ]
| DATETIME HOUR TO SECOND
| DATETIME HOUR TO MINUTE
| DATETIME HOUR TO HOUR
| DATETIME MINUTE TO FRACTION [ ( scale ) ]
| DATETIME MINUTE TO SECOND
| DATETIME MINUTE TO MINUTE
| DATETIME SECOND TO FRACTION [ ( scale ) ]
| DATETIME SECOND TO SECOND
| DATETIME FRACTION TO FRACTION [ ( scale ) ]
```

1. *scale* defines the scale of the fractional part, it can be 1, 2, 3, 4 or 5.

Usage

The DATETIME data type stores an instance in time, expressed as a calendar date and time-of-day.

The qualifiers following the DATETIME keyword define the precision of the DATETIME type. While many sort of datetime types can be defined with all possible qualifier combinations, only a limited set of DATETIME types are typical used in applications:

- DATETIME HOUR TO MINUTE, DATETIME HOUR TO SECOND, DATETIME HOUR TO FRACTION(scale): To hold a time value.

- `DATETIME YEAR TO MINUTE, DATETIME YEAR TO SECOND, DATETIME YEAR TO FRACTION(scale)`: To hold a date with time value.

`DATETIME YEAR TO DAY` is equivalent to `DATE`, consider used `DATE` instead.

When the `FRACTION` qualifier is specified without a precision, the precision defaults to 3.

`DATETIME` arithmetic is based on the `INTERVAL` data type, and can be combined with `DATE` values:

Table 97: Datetime Arithmetic operators

Left Operand Type	Operator	Right Operand Type	Result Type
DATETIME	-	DATETIME	INTERVAL
DATETIME	-	DATE	INTERVAL
DATETIME	-	INTERVAL	DATETIME
DATETIME	+	INTERVAL	DATETIME

`DATETIME` variables are initialized to `NULL` in functions, modules and globals.

The `CURRENT` operator provides current system date/time:

```
DEFINE dt DATETIME YEAR TO SECOND
LET dt = CURRENT
```

`DATETIME` variables can be assigned with datetime literals, by using the `DATETIME() q1 TO q2` notation:

```
DEFINE dt DATETIME YEAR TO SECOND
LET dt = DATETIME(2014-02-21 13:45:34) YEAR TO SECOND
```

`DATETIME` variables can be assigned from string literals, by using the format `YYYY-MM-DD hh:mm:ss.fffff`, or the ISO 8601 format sub-set (with the T separator between the date and time part, and with optional `+/-nn` UTC indicator or timezone offset):

```
DEFINE dt DATETIME YEAR TO FRACTION(5)
LET dt = "2012-10-05 11:34:56.99999"
LET dt = "2012-10-05T11:34:56.99999+02:00"
```

When converting a `DATETIME` to a string, the format `YYYY-MM-DD hh:mm:ss.fffff` is used.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

Datetime conversion functions are provided in the `util.Datetime` class, for example to convert local datetime to UTC datetime values:

```
IMPORT util
MAIN
    DEFINE dt DATETIME YEAR TO FRACTION(5)
    LET dt = "2012-10-05 11:34:56.99999"
    DISPLAY util.Datetime.toUTC( dt )
END MAIN
```

DECIMAL(p,s)

The `DECIMAL` data type is provided to handle large numeric values with exact decimal storage.

Syntax

```
DECIMAL [ ( precision[,scale]) ]
```

1. *precision* defines the number of significant digits (limit is 32, default is 16).
2. *scale* defines the number of digits to the right of the decimal point.
3. When no *scale* is specified, the data type defines a floating point number.
4. When no (*precision*, *scale*) is specified, it defaults to `DECIMAL(16)`.

Usage

Use the `DECIMAL` data type when you need to store values that have fixed number of digits on the right and left of the decimal point (`DECIMAL(p,s)`), or to store a floating point decimal with an exact number of significant digits (`DECIMAL(p)`).

`DEC`, `DECIMAL` and `NUMERIC` are synonyms.

`DECIMAL` variables are initialized to `NULL` in functions, modules and globals.

When using `DECIMAL(p,s)` with a precision and scale, you define a decimal for fixed point arithmetic, with p significant digits and s digits on the right of the decimal point. For example, `DECIMAL(8,2)` can hold the value 123456.78 (8 (p) = 6 digits on the left + 2 (s) digits of the right of the decimal point).

When using `DECIMAL(p)` with a precision but no scale, you define a floating-point number with p significant digits. For example, `DECIMAL(8)` can store 12345678, as well as 0.12345678.

> **Note:** In most database implementations, the decimal data type always has a fixed number of decimal digits. Use `DECIMAL` types with precision and scale to implement portable code, and avoid mistakes if default sizes apply when precisions and/or scale are omitted in SQL statements. For example, with Oracle, a `NUMBER(p)` is equivalent to a `DECIMAL(p,0)` in BDL, not `DECIMAL(p)`.

When using `DECIMAL` without a precision and scale, it defaults to `DECIMAL(16)`, a floating-point number with a precision of 16 digits.

```
MAIN
  DEFINE d1 DECIMAL(10,4)
  DEFINE d2 DECIMAL(10,3)
  LET d1 = 1234.4567
  LET d2 = d1 / 3 -- Rounds decimals to 3 digits
  DISPLAY d1, d2
END MAIN
```

`DECIMAL` values can be converted to strings according to the DBFORMAT (or DBMONEY) environment variable (defines the decimal separator).

Value ranges

The largest absolute value that a `DECIMAL(p,s)` can store without errors is $10^{p-s} - 10^{s}$. The stored value can have up to 30 significant decimal digits in its fractional part, or up to 32 digits to the left of the decimal point.

When using `DECIMAL(p,s)` the range of values is defined by the p, the number of significant digits. For example, a variable defined as `DECIMAL(5,3)` can store values in the range -99.999 to 99.999. The smallest positive non zero value is 0.001.

When using `DECIMAL(p)` the magnitude can range from -N*10^{-124} to N*10^{124}, where N can have up to p significant digits and be 0<N<10. For example, a variable defined as `DECIMAL(5)` can store values in the range -9.9999e-124 to 9.9999e+124. The smallest positive non zero value is 9.9999e-130.

Exceptions

When the default exception handler is used, if you try to assign a value larger than the decimal definition (for example, 12345.45 into `DECIMAL(4,2)`), no out of range error occurs, and the variable is assigned with `NULL`. If `WHENEVER ANY ERROR` is used, it raises error -1226. If you do not use `WHENEVER ANY ERROR`, the STATUS variable is not set to -1226.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

Computation and rounding rules

When computing or converting decimal values, the "round half away from zero" rule will apply: If the fraction of the value v is exactly 0.5, then r = v + 0.5 if v is positive, and r = v - 0.5 if v is negative. For example, when the result must be rounded to a whole number, 23.5 gets rounded to 24, and -23.5 gets rounded to -24.

In the next example, the division result of 11 / 3 gives the infinite decimal value 3.666666... (with an infinite decimal part). However, this value cannot be stored in a fixed point decimal type. When stored in a `DECIMAL(10,2)`, the value will be rounded to 3.67, and when multiplying 3.67 by 3, the result will be 11.01, instead of 11:

```
MAIN
    DEFINE v DECIMAL(10,2)
    LET v = 11 / 3
    DISPLAY "1. v = ", v USING "---&.&&&&&&&&"
    LET v = v * 3
    DISPLAY "2. v = ", v USING "---&.&&&&&&&&"
END MAIN
```

Output:

```
1. v =    3.67000000
2. v =   11.01000000
```

High-precision math functions

A couple of precision math functions are available, to be used with DECIMAL values. These functions have a higher precision as the standard C library functions based on C double data type, which is equivalent to `FLOAT`:

- FGL_DECIMAL_TRUNCATE()
- FGL_DECIMAL_SQRT()
- FGL_DECIMAL_EXP()
- FGL_DECIMAL_LOGN()
- FGL_DECIMAL_POWER()

FLOAT

The FLOAT data type stores values as double-precision floating-point binary numbers with up to 16 significant digits.

Syntax

```
FLOAT [(precision)]
```

1. FLOAT and DOUBLE PRECISION are synonyms.
2. The *precision* can be specified but it has no effect in programs.

Usage

The storage of FLOAT variables is based on 8 bytes of signed data (=64 bits), this type is equivalent to the double data type in C.

> **Note:** This data type it is not recommended for exact decimal storage; use the DECIMAL type instead.

FLOAT variables are initialized to zero in functions, modules and globals.

SMALLMONEY values can be converted to strings according to the DBFORMAT (or DBMONEY) environment variable.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

INTEGER

The INTEGER data type is used for storing large whole numbers.

Syntax

```
INTEGER
```

1. INT and INTEGER are synonyms.

Usage

The storage of INTEGER variables is based on 4 bytes of signed data (= 32 bits).

The value range is from -2,147,483,647 to +2,147,483,647.

INTEGER variables can be initialized with integer literals:

```
MAIN
  DEFINE i INTEGER
  LET i = 1234567
  DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the INTEGER range, the overflow error -1215 will be raised.

INTEGER variables are initialized to zero in functions, modules and globals.

The INTEGER type can be used to define variables storing values from SERIAL columns.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

INTERVAL qual1 TO qual2

The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

Syntax 1: *year-month* class interval

```
  INTERVAL YEAR[(precision)] TO MONTH
| INTERVAL YEAR[(precision)] TO YEAR
| INTERVAL MONTH[(precision)] TO MONTH
```

Syntax 2: *day-time* class interval

```
  INTERVAL DAY[(precision)] TO FRACTION[(scale)]
| INTERVAL DAY[(precision)] TO SECOND
| INTERVAL DAY[(precision)] TO MINUTE
| INTERVAL DAY[(precision)] TO HOUR
| INTERVAL DAY[(precision)] TO DAY

| INTERVAL HOUR[(precision)] TO FRACTION[(scale)]
| INTERVAL HOUR[(precision)] TO SECOND
| INTERVAL HOUR[(precision)] TO MINUTE
| INTERVAL HOUR[(precision)] TO HOUR

| INTERVAL MINUTE[(precision)] TO FRACTION[(scale)]
| INTERVAL MINUTE[(precision)] TO SECOND
| INTERVAL MINUTE[(precision)] TO MINUTE

| INTERVAL SECOND[(precision)] TO FRACTION[(scale)]
| INTERVAL SECOND[(precision)] TO SECOND

| INTERVAL FRACTION TO FRACTION[(scale)]
```

1. *precision* defines the number of significant digits of the first qualifier, it must be an integer from 1 to 9. For YEAR, the default is 4. For all other time units, the default is 2. For example, YEAR(5) indicates that the INTERVAL can store a number of years with up to 5 digits.
2. *scale* defines the scale of the fractional part, it can be 1, 2, 3, 4 or 5.

Usage

The INTERVAL data type stores a span of time, the difference between two points in time. It can also be used to store quantities that are measured in units of time, such as ages or times.

The INTERVAL data type falls in two classes, which are mutually exclusive:

- *Year-time* intervals store a span of years, months or both.
- *Day-time* intervals store a span of days, hours, minutes, seconds and fraction of seconds, or a contiguous subset of those units.

INTERVAL values can be negative.

INTERVAL variables are initialized to NULL in functions, modules and globals.

INTERVAL variables can be assigned from interval literals, by using the INTERVAL() q1 TO q2 notation:

```
DEFINE iv INTERVAL DAY(5) TO SECOND
LET iv = INTERVAL(-7634 14:23:55) DAY(5) TO SECOND
```

INTERVAL variables can be assigned from string literals, by using the format YYYY-MM or DD hh:mm:ss.fffff, according to the interval class:

```
DEFINE iv INTERVAL DAY(5) TO SECOND
```

```
LET iv = "-7634 14:23:55"
```

INTERVAL variables defined with a single time unit can be assigned from integer values, by using the UNITS operator:

```
DEFINE iv INTERVAL SECOND(5) TO SECOND
LET iv = 567 UNITS SECOND
```

Intervals are typically used for DATETIME computation. According to the arithmetic operator, DATETIME or DECIMAL operands are involved:

Table 98: Arithmetic operands for the INTERVAL, DATETIME, and DECIMAL data types

Left Operand Type	Operator	Right Operand Type	Result Type
INTERVAL	*	DECIMAL	INTERVAL
INTERVAL	/	DECIMAL	INTERVAL
INTERVAL	-	INTERVAL	INTERVAL
INTERVAL	+	INTERVAL	INTERVAL
DATETIME	-	INTERVAL	DATETIME
DATETIME	+	INTERVAL	DATETIME
DATETIME	-	DATETIME	INTERVAL

The next example shows how to use INTERVAL with DATETIME variables:

```
MAIN
  DEFINE iym1, iym2 INTERVAL YEAR TO MONTH,
         dt1, dt2 DATETIME YEAR TO MINUTE,
         diff INTERVAL DAY(5) TO MINUTE
  LET iym1 = "2342-4"
  LET iym2 = "-55-11"
  DISPLAY iym1 + iym2
  LET dt1 = CURRENT
  LET dt2 = "2010-12-24 00:00"
  LET diff = dt1 - dt2
  DISPLAY diff
  LET diff = INTERVAL(-7634 14:23) DAY(5) TO MINUTE
  DISPLAY diff
END MAIN
```

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

MONEY(p,s)

The MONEY data type is provided to store currency amounts with exact decimal storage.

Syntax

```
MONEY [ (precision[,scale]) ]
```

1. *precision* defines the number of significant digits (limit is 32, default is 16).
2. *scale* defines the number of digits to the right of the decimal point.
3. When no *scale* is specified, it defaults to 2.
4. When no (*precision*, *scale*) is specified, it defaults to MONEY(16,2).

Usage

The MONEY data type is provided to store currency amounts. Its behavior is similar to the DECIMAL data type, with some important differences:

A MONEY variable is displayed with the currency symbol defined in the DBFORMAT (or DBMONEY) environment variable.

You cannot define floating-point numbers with MONEY: If you do not specific the *scale* in the data type declaration, it defaults to 2. A MONEY without *precision* and *scale* defaults to MONEY(16,2), which is equivaltent to a DECIMAL(16,2).

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

See DECIMAL(p,s) on page 200 to learn other facts about the MONEY(p,s) data type.

SMALLFLOAT

The SMALLFLOAT data type stores values as single-precision floating-point binary numbers with up to 8 significant digits.

Syntax

```
SMALLFLOAT
```

1. SMALLFLOAT and REAL are synonyms.

Usage

The storage of SMALLFLOAT variables is based on 4 bytes of signed data (=32 bits), this type is equivalent to the `float` data type in C.SMALLFLOAT variables are initialized to zero in functions, modules and globals.

> **Note:** This data type it is not recommended for exact decimal storage; use the DECIMAL data type instead.

SMALLMONEY values can be converted to strings according to the DBFORMAT (or DBMONEY) environment variable.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

SMALLINT

The SMALLINT data type is used for storing small whole numbers.

Syntax

```
SMALLINT
```

Usage

The storage of SMALLINT variables is based on 2 bytes of signed data (= 16 bits).

The value range is from -32,767 to +32,767.

SMALLINT variables can be initialized with integer literals:

```
MAIN
  DEFINE i SMALLINT
  LET i = 1234
  DISPLAY i
```

```
END MAIN
```

When assigning a whole number that exceeds the SMALLINT range, the overflow error -1214 will be raised.

SMALLINT variables are initialized to zero in functions, modules and globals.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

STRING

The STRING data type is a variable-length, dynamically allocated character string data type, without limitation.

Syntax

```
STRING
```

Usage

The STRING data type is typically used to implement utility functions manipulating character string with unknown size, and in some special cases, in SQL statements.

STRING variables are initialized to NULL in functions, modules and globals.

The behavior of a STRING variable is similar to the VARCHAR data type, except that there is no theoretical size limit.

STRING variables can be initialized from string literals:

```
MAIN
    DEFINE s STRING
    LET s = "abcdef"
END MAIN
```

Variables declared with the STRING data type can be used to call STRING-type methods such as getLength() or toUpperCase(). For more details, see The STRING data type as class on page 1689:

```
MAIN
    DEFINE s STRING
    LET s = "abc"
    DISPLAY s.toUpperCase()
END MAIN
```

STRING variables have significant trailing blanks (i.e. "abc " is different from "abc"). However, in comparisons, trailing blancs do not matter:

```
MAIN
    DEFINE s STRING
    LET s = "abc  " -- a b c + 2 white spaces
    DISPLAY "1: s.length:", s.getLength()
    DISPLAY "[", s, "]" -- displays "[abc  ]"
    DISPLAY IIF(s=="abc","Equals",NULL)
END MAIN
```

Unlike CHAR and VARCHAR, a STRING can hold a value of zero length without being NULL. For example, if you trim a string variable with the trim() method and if the original value is a set of blank characters, the

result is an empty string. But testing the variable with the `IS NULL` operator will evaluate to `FALSE`. Using a `VARCHAR` with the `CLIPPED` operator would give a `NULL` string in this case:

```
MAIN
    DEFINE s STRING
    LET s = "     " -- 5 spaces
    LET s = s.trim()
    DISPLAY "s = [", s, "] len=", s.getLength()
    DISPLAY IIF(s IS NULL, "NULL", "not NULL")
END MAIN

outputs:

s = [] len=          0
not NULL
```

`STRING` typed variables can be used in some special cases to hold SQL character string data, when the size of the SQL data string is not known (string expressions, large strings like JSON documents). In order to store character string data stored in a database, consider using the `CHAR` or `VARCHAR` types instead of `STRING`.

In `STRING` methods, positions and length parameters (or return values) can be expressed in bytes or characters, depending on the length semantics used in programs. For more details, see Length semantics settings on page 314

TINYINT

The `TINYINT` data type is used for storing very small whole numbers.

Syntax

```
TINYINT
```

Usage

The storage of `TINYINT` variables is based on 1 byte of signed data (= 8 bits).

The value range is from -128 to +127.

`TINYINT` variables can be initialized with integer literals:

```
MAIN
  DEFINE i TINYINT
  LET i = 101
  DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the `TINYINT` range, the overflow error -8097 will be raised.

`TINYINT` variables are initialized to zero in functions, modules and globals.

The `TINYINT` variables cannot be `NULL`.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 216.

TEXT

The TEXT data type stores large text data.

Syntax

```
TEXT
```

Usage

A BYTE or TEXT variable is a handle for a large object (LOB), that is stored in a file or in memory. Such data type is a complex type that cannot be used like INTEGER or CHAR basic types: It is designed to handle a large amount of data and has different semantics as simple types. The main difference with simple data types, is the fact that you must specify the storage with the LOCATE instruction, before using BYTE and TEXT variables.

The maximum size of data that can be handled by BYTE and TEXT variable is theoretically 2^31 bytes (~2.14 Gigabytes), but the practical limit depends from the disk or memory resources available to the process.

BYTE and TEXT variable must be initialized with the LOCATE instruction before usage. The LOCATE instruction basically defines where the large data object has to be stored (in a named file, in a temporary file, or in memory). This instruction will actually allow you to fetch a LOB into memory or into a file, or insert a LOB from memory or from a file into the database. When located in a temporary file (IN FILE), the temp directory can be defined by the DBTEMP environment variable.

```
DEFINE t TEXT
LET t = "aaaa" -- invalid, t is not located
LOCATE t IN MEMORY
LET t = "aaaa" -- valid, now t is located in memory
```

With BYTE and TEXT types, you can insert/update/fetch large objects of the database. The native database type to be used depends from the type of database server. After defining the storage (LOCATE) of a large object handler, load / assign its value and use it directly in the SQL statements, or fetch data from LOB columns of the database, like simple data types:

```
DEFINE t1, t2 TEXT
...
CREATE TABLE mytable ( id INT, data TEXT )
...
LOCATE t1 IN MEMORY
CALL t1.readFile("lob.4gl")
INSERT INTO mytable VALUES ( 1, t1 )
LOCATE t2 IN FILE
SELECT data INTO t2 FROM mytable WHERE id=1
...
```

BYTE and TEXT types implement the readFile() and writeFile() methods to read/write the whole large object data from/to files. These methods can be used to easily interface with other software components:

```
DEFINE t TEXT
LOCATE t IN MEMORY
CALL t.readFile("orig.txt")
CALL t.writeFile("copy.txt")
```

When initializing a BYTE or TEXT variable to NULL (INITIALIZE *var* TO NULL), if the variable is located in a file, the file is truncated (file size will be zero). If the variable is located in memory, the data in memory

will be truncated. A subsequent usage of the variable (for example, FETCH INTO or LET assignment) is still possible:

```
DEFINE b BYTE
LOCATE b IN FILE "picture.png"
INITIALIZE b TO NULL
-- The file "picture.png" is now empty.
```

Resources allocated to a BYTE or TEXT variable can be deallocated with the FREE instruction. A FREE will remove the file if the LOB variable is located in a (named or temporary) file. When located in memory, the FREE instruction will de-allocate the memory. After freeing the resources of a LOB variable, it must be re-located with a LOCATE instruction:

```
DEFINE b BYTE
LOCATE b IN FILE
CALL t.readFile("picture.png") -- ok
FREE b
CALL t.readFile("picture.png") -- Invalid, b is not located.
LOCATE b IN MEMORY
CALL t.readFile("picture.png") -- ok
```

Important:

TEXT and BYTE are reference types. This implies that assigning two variables (LET, passing a variable as parameter to a function, returning a result from a function) does not copy the value (Only the handler is copied. As result, modifying the data with a TEXT/BYTE variable assigned from another TEXT/BYTE variable will in fact modify the same LOB data. Further, the storage resource (file or memory) that was used by the assigned variable becomes unreferenced and is lost:

```
DEFINE b1, b2 BYTE -- Could be TEXT: same behavior
LOCATE b1 IN FILE "mydata" -- reference file directly
LOCATE b2 IN MEMORY -- use memory instead of file
CALL b2.readFile("mydata") -- read file content into memory
# FREE b2 -- this should be done to free memory before LET
LET b2 = b1 -- Now b2 points directly to the file (like b1)
INITIALIZE b1 TO NULL -- truncates reference file
DISPLAY IIF( b2 IS NULL, "b2 is null", "b2 is not null")
-- Displays "b2 is null"
```

In the next (invalid) code example, we try to save the value of the `img BYTE` variable in a temporary variable (`tmp`), with the typical programming pattern to save the value before modification. In fact the `LET tmp=img` assignment does not copy the data of the LOB like for simple data types (STRING, VARCHAR, DECIMAL), only the reference (i.e. handle) to the data is copied:

```
-- WARNING: THIS IS AN INVALID CODE EXAMPLE
DEFINE img, tmp BYTE
LOCATE img IN MEMORY
CALL img.readFile("picture1.png")
LOCATE tmp IN MEMORY
LET tmp = img -- Expecting to save the current data, but now
              -- both variables reference the same data...
CALL img.readFile("picture2.png")
LET img = tmp -- Does not restore the old value: Same data.
```

If you need to clone a large object, use the `writeFile()` / `readFile()` methods.

It is possible to assign TEXT variables to/from VARCHAR, CHAR and STRING variables.

VARCHAR(size)

The VARCHAR data type is a variable-length character string data type, with a maximum size.

Syntax

```
VARCHAR [ ( size [,reserve] ) ]
```

1. *size* defines the maximum length of the character string, in byte or char units (depending on the character length semantics)
2. The maximum size of a VARCHAR type is 65534.
3. When no *size* is specified, it defaults to 1.
4. *reserve* is ignored; Its inclusion in the syntax is permitted for compatibility with the SQL data type.

Usage

The VARCHAR type is typically used to store variable-length character strings such as names, addresses and comments.

The *size* can be expressed in bytes or characters, depending on the length semantics used in programs. For more details about character length semantics, see Length semantics settings on page 314.

When *size* is not specified, the default length is 1.

VARCHAR variables are initialized to NULL in functions, modules and globals.

Text literals can be assigned to character string variables:

```
MAIN
  DEFINE c VARCHAR(10)
  LET c = "abcdef"
END MAIN
```

VARCHAR variables store trailing blanks (trailing blanks are displayed or printed in reports, and stored in database columns):

```
MAIN
  DEFINE vc VARCHAR(10)
  LET vc = "abc  "       -- a b c + 2 white spaces
  DISPLAY "[", vc ,"]"   -- displays [abc  ]
END MAIN
```

Trailing blanks of a VARCHAR value are not significant in comparisons:

```
MAIN
  DEFINE vc VARCHAR(10)
  LET vc = "abc  "        -- a b c + 2 white spaces
  IF vc == "abc " THEN    -- evaluates to TRUE
     DISPLAY "equals"
  END IF
END MAIN
```

Numeric and date-time values can be directly assigned the character strings:

```
MAIN
  DEFINE vc VARCHAR(50), da DATE, dec DECIMAL(10,2)
  LET da = TODAY
  LET dec = 345.12
  LET vc = da, " : ", dec
END MAIN
```

When you insert character data from VARCHAR variables into VARCHAR columns in a database table, the trailing blanks are kept. Likewise, when you fetch VARCHAR column values into VARCHAR variables, trailing blanks are kept.

```
MAIN
  DEFINE vc VARCHAR(10)
  DATABASE test1
  CREATE TABLE table1 ( k INT, x VARCHAR(10) )
  LET vc = "abc  "         -- two trailing blanks
  INSERT INTO table1 VALUES ( 1, vc )
  SELECT x INTO vc FROM table1 WHERE k = 1
  DISPLAY "[", vc ,"]"     -- displays [abc  ]
END MAIN
```

In SQL statements, the behavior of the comparison operators when using VARCHAR values differs from one database to the other. IBM® Informix® is ignoring trailing blanks, but most other databases take trailing blanks of VARCHAR values into account. For more details, see SQL portability on page 412.

Type conversions

Explains data type conversion rules of the language.

- When does type conversion occur? on page 211
- Data type conversion reference on page 212
- Handling type conversion errors on page 216
- Formatting numeric values on page 217
- Formatting DATE values on page 220
- Formatting DATETIME values on page 221
- Formatting INTERVAL values on page 223

When does type conversion occur?

The runtime system performs data conversion implicitly without objection, as long as the data conversion is valid. A date value can be converted to a character string, but a character string can only be converted to a date if the string represents a valid date in the current date format settings (DBDATE).

Implicit data type conversion can for example occur in the following cases:

- In a `LET` assignment,
- In an expression, when operands are not of the same data type,
- In `DISPLAY` instructions, or `PRINT` instructions in reports,
- In dialogs, when values must be converted to strings to be displayed in form fields,
- When passing and returning values to/from a function,
- When serializing numeric values in `UNLOAD`, JSON methods, etc.

In the next code example, implicit data type conversion occurs

1. When assiging the result of the decimal expression to the variable `v`,
2. When passing the decimal value `d` to function `func()`,
3. When returing the varchar value from the function `func()`,
4. In the `DISPLAY` instruction, to convert the decimal to a string.

```
MAIN
  DEFINE d DECIMAL(10,2), v VARCHAR(50)
  LET v = 1234.50 * 2   -- 1.
  LET d = func(d)       -- 2. and 3.
  DISPLAY d             -- 4.
END MAIN
```

```
FUNCTION func(v)
  DEFINE v VARCHAR(50)
  DISPLAY v
  RETURN v   -- 3.
END FUNCTION
```

Data type conversion reference

Boolean type conversions

A BOOLEAN value is an integer value 1 or 0 and thus can be converted to/from any other numeric type of the language.

When converting a numeric value to a BOOLEAN, any value different from 0 becomes TRUE, otherwise (zero) is FALSE.

```
DEFINE hasContent BOOLEAN, s STRING
LET s = "abc"
LET hasContent = s.getLength()
```

When converting a string (CHAR, VARCHAR or STRING) to BOOLEAN, the string will be converted to a number first, then the number-to-boolean conversion applies. If the string value cannot convert to a numeric value (for example, "abc"), the boolean value becomes NULL.

When converting a BOOLEAN to a string, the result will be "1" or "0" string values, according to the boolean value.

Large object type conversions

A TEXT value can be converted to/from CHAR, VARCHAR or STRING.

The BYTE type cannot be converted to/from any other type.

Integers to decimal types

TINYINT, SMALLINT, INTEGER and BIGINT values can be converted to SMALLFLOAT, FLOAT, DECIMAL or MONEY as long as the decimal type is defined with sufficient digits to hold the whole number.

If the integer value exceeds the range of the receiving data type, an overflow error occurs.

Decimal to integer types

When converting a SMALLFLOAT, FLOAT DECIMAL or MONEY to a TINYINT, SMALLINT, INTEGER or BIGINT, the fractional part of the decimal value is truncated.

```
MAIN
  DEFINE d DECIMAL(10,2),
         i INTEGER
  LET d = 123.45
  LET i = d
  DISPLAY i   -- displays 123
END MAIN
```

If the decimal value exceeds the range of the receiving integer data type, an overflow error occurs.

Decimal to decimal types

Converting between SMALLFLOAT, FLOAT DECIMAL or MONEY types is allowed as long as the receiving type is defined with sufficient digits to hold the whole part of the original value.

If the original value contains more fractional digits than the receiving data type supports, low-order digits are discarded.

```
MAIN
  DEFINE d1 DECIMAL(10,2),
         d2 DECIMAL(5,1)
  LET d1 = 123.45
  LET d2 = d1
  DISPLAY d2    -- displays 123.5
END MAIN
```

Decimal to character types

Converting `SMALLFLOAT`, `FLOAT` `DECIMAL` or `MONEY` values to `CHAR`, `VARCHAR` and `STRING` implies numeric formatting.

Numeric formatting is controlled by the DBMONEY and DBFORMAT environment variables.

According to the conversion context, the resulting string is left-aligned (for lossless conversions) or right-aligned (for visual conversions), and the decimal part is kept, according to the numeric type.

```
MAIN
  DEFINE m MONEY(8,2),
         s VARCHAR(10)
  LET m = 123.45
  LET s = m   -- Lossless conversion "$123.45"
  DISPLAY m   -- Visual conversion   "    $123.45"
END MAIN
```

Fixed point decimals (`DECIMAL(p,s)`) are converted to strings that can fit in a `CHAR(p+2)`: The string is build with up to p significant digits + 1 character for the sign + 1 character for the decimal point. The result of a `DECIMAL(p,s)` to string conversion is never longer than p + 2 characters. For example, a `DECIMAL(5,2)` can produce "-999.99" (5 + 2 = 7c).

Floating point decimals (`DECIMAL(p)`) are converted to strings that can fit in a `CHAR(p+7)`: The string is build with up to p significant digits + 1 character for the sign + 1 character for the decimal point + the length of the exponent of needed ("e+123"). The result of a `DECIMAL(p)` to string conversion is never longer than p + 7. For example, a `DECIMAL(5)` can produce "-1.2345e-123" (5 + 7 = 12c).

`DECIMAL` to string conversion depends on the context in which the conversion occurs:

1. *Visual conversion*: The result of this conversion will typically be presented to the end user. This conversion happens in `DISPLAY`, `MESSAGE`, `ERROR`, `PRINT`. The result of a visual conversion is right aligned (padded with leading blanks). This padding results in the same length for any value for a given decimal precision. The length of the result is the maximum possible length as described previously (p+2 for `DECIMAL(p,s)`, p+7 for `DECIMAL(p)`).

   Visual conversion examples for `DECIMAL(5,2)`:

   ```
      Values     1234567
   ----------------------
      0       |  "   0.00"
      -999.99 | "-999.99"
      12.3    |  "  12.30"
      12.34   |  "  12.34"
   ```

   Visual conversion examples for `DECIMAL(5)`:

   ```
      Values     123456789012
   ---------------------------
      0       |  "         0.0"
      -99999  |  "    -99999.0"
   ```

```
   12.3    | "        12.3"
   12.34   | "       12.34"
   12.345  | "      12.345"
   1.23e7  | "  12300000.0"
   1e100   | "       1e100"
```

2. *Form field conversion*: This conversion concerns decimal numbers presented in form-fields. The result of this conversion is in best case the same as (1). The result of the conversion depends on the width of the form-field. If the width of the form-field is smaller than the perfect length, automatic rounding and exponential notation might be used.
3. *Lossless conversion*: Such conversion happens when assigning numbers to string variables (`LET`), passing numbers as parameters to functions expecting strings, returning numbers from functions to strings, serializing numbers (`UNLOAD`, XML or JSON APIs). These conversions must avoid the loss of significant digits. When using floating point decimals, this leads to a variable length of the resulting string. A conversion must be reversible: decimal to string to decimal must give the original value. If the target variable is shorter then the maximum possible length, then automatic rounding will occur.

   Lossless conversion examples of `DECIMAL(5,2)`:

```
   Values     1234567
----------------------
   0       | "0.00"
   -999.99 | "-999.99"
   12.3    | "12.30"
   12.34   | "12.34"
```

   Lossless conversion examples of `DECIMAL(5)`:

```
   Values     123456789012
----------------------------
   0       | "0.0"
   -99999  | "-99999.0"
   12.3    | "12.3"
   12.34   | "12.34"
   12.345  | "12.345"
   1.23e7  | "12300000.0"
   1e100   | "1e100"
```

Automatic rounding occurs if the target string variable is shorter than the maximum possible length of the `DECIMAL` type. Such conversion might loose significant digits: The runtime system tries to round the value, to fit into the target variable.

```
  Values     Different target sizes
              123456   12345   1234
-----------------------------------
  0.98765  | "0.9877" "0.988" "0.99"
  123.45   | "123.45" "123.5" "123"
```

Automatic switch to the exponential notation will occur if the integer part of the decimal value does not fit into the target string variable. For example, if the source variable is a `DECIMAL(12)` and the target variable is a `CHAR(9)`:

```
  Values         123456789
----------------------------
  1234567     | "1234567.0"
  12345678    | "12345678"
  123456789   | "123456789"
  1234567890  | "1.2346e10"
  12345678901 | "1.2346e11"
```

The exponential notation will also be used if the absolute value of a floating point decimal is less than 1e-8 (0.00000001).

Default formatting of floating point decimals has been revised with Genero 2.50. If DECIMAL(P)-to-string conversion must round to 2 digits, use the fglrun.decToCharScale2 FGLPROFILE entry:

```
fglrun.decToCharScale2 = true
```

> **Note:** Do not use the decToCharScale2 configuration parameter, unless you have migration issues.

Formatting a FLOAT is the same as DECIMAL(16). Any FLOAT value with up to 15 digits is exact. There is no precision loss when converting an exact FLOAT back and forth to/form a string. Some FLOAT values require 16, in some rare cases 17 digits for an exact string representation. 16 and 17 digits are not always exact: "8.000000000000001" and "8.000000000000002" represent the same float value.

Formatting a SMALLFLOAT is the same as DECIMAL(7). Any SMALLFLOAT value with up to 6 digits is exact. There is no precision loss when converting an exact SMALLFLOAT back and forth to/form a string. Some SMALLFLOAT values require 7, in some rare cases 8 digits for an exact string representation. 7 and 8 digits SMALLFLOAT are not always exact: "0.0009999901" and "0.0009999902" represent the same SMALLFLOAT value.

Character to decimal types

A CHAR, VARCHAR and STRING value can be converted to a TINYINT, SMALLINT, INTEGER, BIGINT, SMALLFLOAT, FLOAT DECIMAL or MONEY value as long as the character string value represents a valid number.

If the original value contains more significant digits or more fractional digits than the receiving data type supports, low-order digits are discarded.

```
MAIN
  DEFINE d DECIMAL(10,2)
  LET d = "-123.45"
  DISPLAY d   -- displays -123.45
  LET d = "1234567890123.45"
  DISPLAY d   -- displays null
  LET d = "12345678.999"
  DISPLAY d   -- displays 12345679.00
END MAIN
```

Date time to character types

Converting DATE, DATETIME and INTERVAL values to CHAR, VARCHAR and STRING implies date time formatting.

DATE formatting is controlled by the DBDATE environment variable.

When converting a DATETIME to a string, the YYYY-MM-DD hh:mm:ss.fffff standard format is used.

When converting an INTERVAL to a string, either YYYY-MM or DD hh:mm:ss.fffff standard formats are used, according to the interval class.

If the resulting is longer than the receiving variable, the resulting character string is null.

```
MAIN
  DEFINE d DATE,
         s VARCHAR(20),
         v VARCHAR(5)
  LET d = MDY(12,24,2012)
  LET s = d
  DISPLAY s   -- displays 12/24/2012
```

```
  LET v = d
  DISPLAY v   -- displays null
END MAIN
```

Character to date time types

Converting a CHAR, VARCHAR or STRING value to a DATE, DATETIME or INTERVAL is possible as long as the character string defines a well formatted date time or interval value.

When converting a character string to a DATE, the string must follow the date format defined by the DBDATE environment variable.

When converting a string to a DATETIME, the format must be YYYY-MM-DD hh:mm:ss.fffff or follow the ISO 8601 format sub-set (with the T separator between the date and time part, and with optional UTC indicator or timezone offset)

```
MAIN
  DEFINE dt DATETIME YEAR TO SECOND
  LET dt = "2012-12-24 11:33:45"
  DISPLAY dt   -- displays 2012-12-24 11:33:45
  LET dt = "2012-12-24T11:33:45+01:00"
  DISPLAY dt   -- displays 2012-12-24 11:33:45 (if TZ=UTC+1h)
  LET dt = "2012-12-24T10:33:45Z"
  DISPLAY dt   -- displays 2012-12-24 11:33:45 (if TZ=UTC+1h)
END MAIN
```

Converting DATE to/from DATETIME types

When converting a DATETIME to another DATETIME with a different precision, truncation from the left or right can occur. When then target type has more fields as the source type, the year, month and day fields are filled with the current date.

When converting a DATE to a DATETIME, the datetime fields are filled with year, month and day from the date value and time fields are set to zero.

When converting a DATETIME to a DATE, an implicit EXTEND(*datetime-value,* YEAR TO DAY) is performed.

```
MAIN
  DEFINE da DATE,
         dt1 DATETIME YEAR TO SECOND,
         dt2 DATETIME HOUR TO MINUTE
  LET da = MDY(12,24,2012)
  LET dt1 = da
  DISPLAY dt1   -- displays 2012-12-24 00:00:00
  LET dt2 = "23:45"
  LET dt1 = dt2
  DISPLAY dt1   -- displays <current date> 00:00:00
END MAIN
```

Unsupported type conversions

Other data type conversions not mentioned in this topic are not allowed and will result in a runtime error.

Handling type conversion errors

By default, in case of type conversion error or overflow errors, the program continues, the target variable is set to NULL and the global STATUS variable is not set.

In order to detect data conversion and overflow errors, use the WHENEVER ANY ERROR statement.

The next code example:

```
MAIN  -- DBDATE set to Y4MD-
  DEFINE v VARCHAR(50), d DATE
  LET v = "2012-99-99"      -- invalid date string
  LET d = v
  DISPLAY status, "/", NVL(d,"NULL")  -- displays 0/NULL
  WHENEVER ANY ERROR CONTINUE
  LET d = v
  DISPLAY status, "/", NVL(d,"NULL")  -- displays -1205/NULL
  WHENEVER ANY ERROR STOP
  LET d = "2012-11-23"  -- valid date, ok
  DISPLAY status, "/", NVL(d,"NULL")  -- displays 0/2012-11-23
  LET d = v   -- program execution stopped with error -1205
END MAIN
```

Above code will produce the following output:

```
          0/NULL
      -1218/NULL
Program stopped at 'x.4gl', line number 10.
FORMS statement error number -1218.
String to date conversion error.
```

Conversion and overflow errors are implicitly trapped in TRY/CATCH blocks.

In the next example, the `INTERVAL` variable is not large enough to hold the result of `d2 - d1`:

```
MAIN
  DEFINE d1, d2 DATETIME YEAR TO FRACTION(5)
  DEFINE i INTERVAL SECOND(2) TO SECOND
  LET d1 = "2015-11-06 17:40:21.436"
  LET d2 = "2015-11-06 10:40:21.436"
  TRY
      LET i = d2 - d1
  CATCH
      DISPLAY STATUS, " / ", err_get(STATUS)
  END TRY
END MAIN
```

Above code will produce the following output:

```
      -1265 / Overflow occurred on a datetime or interval operation.
```

Formatting numeric values

When does numeric formatting take place?

Numeric formatting occurs when converting a number to a string with the `USING` operator, for example in a `LET`, `DISPLAY` or `PRINT` instruction, and when displaying numeric values in form fields defined with the `FORMAT` attribute.

Numeric values can be of type such as `INTEGER`, `FLOAT`, `DECIMAL`, `MONEY`, etc.

This example formats a `DECIMAL(10,2)` value with the `USING` operator:

```
MAIN
  DEFINE d DECIMAL(10,2)
  LET d = -123456.78
  DISPLAY d USING "-,---,--&.&& @"
END MAIN
```

Front currency symbol, thousands separator, decimal separator and back currency symbol are defined with the DBFORMAT (or DBMONEY) environment variable. For example, if DBFORMAT is defined as `":.:,:E"`, the previous code example will produce the following output:

```
-123,456.78 E
```

Default formatting occurs when `USING` or `FORMAT` are not used, and a numeric value has to be converted to a character string, for example when passing a `DECIMAL(p,s)` to a function expecting a `VARCHAR(n)`. For more details about default formatting, see Data type conversion reference on page 212.

This topic describes the syntax of the *format-string* in the `USING "format-string"` operator and `FORMAT = "format-string"` form field attribute.

Formatting symbols for numbers

When formatting numeric values, the *format-string* of the `USING` operator or `FORMAT` attribute consists of a set of place holders that represent digits, currency symbols, thousands and decimal separators. For example, `"###.##@"` defines three places to the left of the decimal point and exactly two to the right, plus a "back" currency symbol at the end of the string.

> **Note:** The `USING` operator or `FORMAT` attribute are required to display the thousands separator defined in DBFORMAT.

The *format-string* must use normalized placeholders described in Table 99: Format-string symbols for Numeric data types on page 218. The placeholders will be replaced by digits, blanks or by the elements defined in the DBFORMAT (or DBMONEY) environment variables. Any other character will be interpreted as a literal, and can be used at any place in the format string.

If the numeric value is too large to fit in the number of characters defined by the format, the result string is filled with a set of star characters (`********`), indicating an overflow.

The minus sign (-), plus sign (+), parentheses (( )), and dollar sign ($) float. This means that when you specify multiple leading occurrences of one of these characters, the result string gets only a single character immediately to the left of the first digit.

Table 99: Format-string symbols for Numeric data types

Placeholder	Description
*	The star placeholder fills with asterisks any position that would otherwise be blank.
&	The ampersand placeholder is used to define the position of a digit, and is replaced by a zero if that position would otherwise be blank.
#	The sharp placeholder is used to define the position of a digit, it is used to specify a maximum width for the resulting string. The # is replaced by a blank, if no digit is to be displayed at that position.
<	Consecutive "less than" characters cause left alignment and define digit positions.
-	Displays a minus sign if the value is negative, or a blank if the value is positive. When you group several minus signs in the format string, a single minus sign floats immediately to the left of the first digit.
+	Displays a minus sign if the value is negative, or a plus sign if the value is positive. When you group several plus signs in the format string, a single plus sign floats immediately to the left of the first digit.
(	Displayed as left parenthesis for negative numbers. It is used to display "accounting parentheses" instead of a minus sign for negative numbers. Consecutive left parentheses display a single left parenthesis to the left of the first digit.

Placeholder	Description
)	Displayed as right parenthesis for negative numbers. This wildcard character is used in conjunction with a open brace to display "accounting parentheses" for negative numbers.
, (comma)	The comma placeholder is used to define the position for the thousand separator defined in DBFORMAT. The thousand separator will only be displayed if there is a number on the left of it.
. (period)	The period placeholder is used to define the position for the decimal separator defined in DBFORMAT. You can only have one decimal separator in a number format string.
$	The dollar sign is the placeholder for the front currency symbol defined in DBFORMAT. When you group several consecutive dollar signs, a single front currency symbol floats immediately to the left of the first digit. The front currency symbol can be defined in DBFORMAT with more than one character (EUR, USD).
@	The "at" sign is the placeholder for the back currency symbol defined in DBFORMAT. Put several consecutive @ signs at the end of the format string to display a currency symbol defined in DBFORMAT with more than one character.

Table 100: Numeric formatting examples

Format String	Numeric value	DBFORMAT	Result string
[######.##]	0	:.:,:	[,]
[######.##]	-1234.56	:.:,:	[1234,56] (no sign!)
[######.##]	-1234567.89	:.:,:	[*********] (overflow)
[######.##]	+1234.56	:.:,:	[1234,56]
[#####&.&&]	0	:.:,:	[0,00]
[******.**]	0	:.:,:	[******,00]
[******.**]	-12.34	:.:,:	[****12,34] (no sign!)
[******.**]	+12.34	:.:,:	[****12,34]
[<<<<<<.<<]	-12.34	:.:,:	[12,34] (no sign!)
[<<<<<<.<<]	+12.34	:.:,:	[12,34]
[---,--&.&&]	-1234.56	:.:,:	[-1.234,56]
[+++,++&.&&]	-1234.56	:.:,:	[-1.234,56]
[+++,++&.&&]	+1234.56	:.:,:	[+1.234,56]
[$---,--&.&&]	-1234.56	E:.:,:	[E -1.234,56]
[$---,--&.&&]	+1234.56	E:.:,:	[E 1.234,56]
[$$$---,--&.&&]	+1234.56	E:.:,:	[E 1.234,56]
[$$$---,--&.&&]	+1234.56	EUR:.:,:	[EUR 1.234,56]
[-,---,-$&.&&]	-12.34	E:.:,:	[-E12,34]
[-,---,-$&.&&]	-1234.56	E:.:,:	[-E1.234,56]
[-,-$$,$$&.&&]	-12.34	E:.:,:	[- E12,34]

Format String	Numeric value	DBFORMAT	Result string
[-,-$$,$$&.&&]	-1234.56	E:.:,:	[-E1.234,56]
[---,--&.&&@]	-1234.56	:.:,:E	[-1.234,56E]
[---,--&.&&@]	+1234.56	:.:,:E	[1.234,56E]
[---,--&.&&@@@]	+1234.56	:.:,:EUR	[1.234,56EUR]
[($---,--&.&&)]	-1234.56	E:.:,:	[(E -1.234,56)]
[($###,##&.&&)]	-1234.56	E:.:,:	[(E 1.234,56)]
[(((((,(($.&&)]	0	E:.:,:	[E,00]
[(((((,(($.&&)]	-12.34	E:.:,:	[(E12,34)] (no sign!)
[(((((,(($.&&)]	+12.34	E:.:,:	[E12,34]
[(((((,(($.&&)]	-1234.56	E:.:,:	[(E1.234,56)] (no sign!)
[(((((,(($.&&)]	+1234.56	E:.:,:	[E1.234,56]

Formatting DATE values

When does DATE formatting take place?

Date formatting occurs when converting a DATE to a string with the USING operator, for example in a LET, DISPLAY or PRINT instruction, and when displaying date values in form fields defined with the FORMAT attribute.

This example formats a DATE value with the USING operator:

```
MAIN
  DEFINE d DATE
  LET d = MDY(12,24,2014)
  DISPLAY d USING "mmm ddd yyyy"
END MAIN
```

This code example produces the following output:

```
Dec Wed 2014
```

Default formatting occurs when USING or FORMAT are not used, and a date value has to be converted to a character string, for example when passing a DATE to a function expecting a VARCHAR(n). Default date formatting is based on the date format defined with the DBDATE environment variable. For more details about default formatting, see Data type conversion reference on page 212.

This topic describes the syntax of the *format-string* in the USING "*format-string*" operator and FORMAT = "*format-string*" form field attribute.

Formatting symbols for DATE values

When formatting DATE values, the *format-string* of the USING operator or FORMAT attribute consists of a set of place holders that represent the day of the month as digits or as abbreviated name of the month, the month of the year as digits or as abbreviated name of the month, and the year as 2, 3 or 4 digits.

Table 101: Format-string symbols for DATE values on page 221 shows the formatting symbols for DATE expressions. Any character different from the placeholders described in this table is interpreted as a literal and will appear as-is in the resulting string.

The calendar used for date formatting is the Gregorian calendar. The `c1` placeholder is a formatting symbol used to adapt the date to the Ming Guo calendar.

Table 101: Format-string symbols for DATE values

Placeholder	Description
`dd`	Day of the month as a 2-digit integer.
`ddd`	Three-letter English-language abbreviation of the day of the week. For example: Mon, Tue.
`mm`	Month as a 2-digit integer.
`mmm`	Three-letter English-language abbreviation of the month. For example: Jan, Feb.
`yy`	Year, as a 2-digits integer representing the 2 trailing digits.
`yyy`	Year as a 3-digit number (Ming Guo format only)
`yyyy`	Year as a 4-digit number.
`c1`	Ming Guo format modifier, see Using the Ming Guo date format on page 323.

Table 102: Date formatting examples

Format String	Date value	Result string
`dd/mm/yyyy`	`2011-10-24`	`24/10/2011`
`[dd/mm/yy]`	`2011-10-24`	`[24/10/11]`
`[ddd-mmm-yyyy]`	`0141-10-24`	`[Tue-Oct-0141]`
`(ddd.) mmm. dd, yyyy`	`1999-09-23`	`(Thu.) Sep. 23, 1999`

Formatting DATETIME values

When does DATETIME formatting take place?

Datetime formatting occurs when converting a `DATETIME` to a string, for example in a `LET`, `DISPLAY` or `PRINT` instruction, and when displaying datetime values in form fields.

By default, DATETIME values are formatted in the ISO format:

```
yyyy-mm-dd hh:mm:ss.fffff
```

The next example formats a `DATETIME` value by using the `util.Datetime.format()` method:

```
IMPORT util
MAIN
  DEFINE dt DATETIME YEAR TO SECOND
  LET dt = CURRENT
  DISPLAY util.Datetime.format(dt, "%Y-%m-%d %H:%M:%S")
END MAIN
```

This code example produces the following output:

```
2015-12-23 11:45:33
```

A datetime value can be formatted with the `util.Datetime.format()` method.

Converting strings to DATETIME values

When a string represents a datetime value is ISO format, it can be directly converted to a `DATETIME`:

```
DEFINE dt DATETIME YEAR TO FRACTION(5)
LET dt = "2015-12-24 11:34:56.82373"
```

If you need to convert a string that does not follow the ISO format, use the `util.Datetime.parse()` method, by specifying a format string:

```
DEFINE dt DATETIME YEAR TO MINUTE
LET dt = util.Datetime.parse( "2014-12-24 23:45", "%Y-%m-%d %H:%M" )
```

Formatting symbols for DATETIME values

When formatting `DATETIME` values, the *format-string* of the `util.Datetime.parse()` and `util.Datetime.format()` methods consists of a set of place holders that represent the different parts of a datetime value (year, month, day, hour, minute, second and fraction).

s shows the formatting symbols for `DATETIME` expressions. Any character different from the placeholders described in this table is interpreted as a literal and will appear as-is in the resulting string.

The calendar used for date formatting is the Gregorian calendar.

Table 103: Format-string symbols for DATETIME values

Placeholder	Description
%a	The abbreviated name of the day of the week. **Note:** When parsing a datetime string, %a and %A are equivalent to detect the name of the day of the week in abbreviated form or full day name.
%A	The full name of the day of the week.
%b or %h	The abbreviated month name. **Note:** When parsing a datetime string, %b/%h and %B are equivalent to detect the month name in abbreviated form or full month name.
%B	The full month name.
%c	The date and time representation.
%C	The century number (0-99)
%D	Equivalent to %m/%d/%y
%d	The day of month with 2 digits (01-31)
%e	The day of month with one or 2 digits (1-31)
%F	The fractional part of a second
%H	The hour with 2 digits (00-23).
%I	The hour on a 12-hour clock (1-12)

Placeholder	Description
%y	The year on 2 digits (91)
%Y	The year on 4 digits (1991)
%m	The month as 2 digits (01-12)
%M	The minutes (00-59)
%n	A newline character
%p	The locale's equivalent of AM or PM
%r	The 12-hour clock time. In the POSIX locale equivalent to %I:%M:%S %p
%R	Equivalent to %H:%M
%S	The seconds (00-59)
%t	A tab character
%T	Equivalent to %H:%M:%S
%x	The date, using the locale's date format.
%X	The time, using the locale's time format.
%w	The ordinal number of the day of the week (0-6), with Sunday = 0.
%y	The year within century (0-99)
%Y	The year, including the century (for example, 1991)

Table 104: Datetime formatting examples

Format String	Datetime value	Result string
%d/%m/%Y %H:%M	2011-10-24 11:23:45	24/10/2011 11:23
[%d %b %Y %H:%M:%S]	2011-10-24 11:23:45	[24 Oct 2011 11:23:45]
(%a.) %b. %d, %Y	1999-09-23	(Thu.) Sep. 23, 1999

Formatting INTERVAL values

When does INTERVAL formatting take place?

Interval formatting occurs when converting a INTERVAL to a string, for example in a LET, DISPLAY or PRINT instruction, and when displaying interval values in form fields.

By default, INTERVAL values are formatted in the ISO format:

```
[+|-]yyyy-mm
```

or:

```
[+|-]dddd hh:mm:ss.fffff
```

The next example formats a INTERVAL value by using the util.Interval.format() method:

```
IMPORT util
```

```
MAIN
  DEFINE iv INTERVAL DAY(6) TO MINUTE
  LET iv = "-157 11:23"
  DISPLAY util.Interval.format(iv, "%d %H:%M")
END MAIN
```

This code example produces the following output:

```
-157 11:23
```

And interval value can be formatted with the `util.Interval.format()` method.

Converting strings to INTERVAL values

When a string represents a interval value is ISO format, it can be directly converted to a `INTERVAL`:

```
DEFINE iv INTERVAL HOUR(6) TO FRACTION(5)
LET iv = "20234:34:56.82373"
```

If you need to convert a string that does not follow the ISO format, use the `util.Interval.parse()` method, by specifying a format string:

```
DEFINE iv INTERVAL DAY(6) TO FRACTION(5)
LET iv = util.Interval.parse( "-7467 + 23:45:34.12345", "%d + %H:%M:%S%F5" )
```

Formatting symbols for INTERVAL values

When formatting `INTERVAL` values, the *format-string* of the `util.Interval.parse()` and `util.Interval.format()` methods consists of a set of place holders that represent the different parts of a interval value (year, month, day, hour, minute, second and fraction).

Table 105: Format-string symbols for INTERVAL values on page 224 shows the formatting symbols for `INTERVAL` expressions. Any character different from the placeholders described in this table is interpreted as a literal and will appear as-is in the resulting string.

Table 105: Format-string symbols for INTERVAL values

Placeholder	Description
`%Y`	Years (0-999999999)
`%m`	Month (00-11) or (0-999999999)
`%d`	Days (0-999999999)
`%H`	Hours (00-23) or (0-999999999)
`%M`	Minutes (00-59) or (0-999999999)
`%S`	Secondes (00-59) or (0-999999999)
`%F[n]`	The fractional part of a second, where n specifies the number of digits in the fractional part (1 to 5)
`%t`	A tab character
`%n`	A newline character

Table 106: Interval formatting examples

Format String	Interval value	Result string
`%d days %H:%M`	`54561 11:23`	`54561 days 11:23`
`%d days %H:%M:%S%F5`	`54561 11:23:45.12345`	`54561 days 11:23:45.12345`
`[%Y years and %m months]`	`1023-03`	`[1023 years and 03 months]`

Literals

Describes the syntax of literals (constant values) to be used in sources.

- Integer literals on page 225
- Numeric literals on page 225
- Text literals on page 226
- Datetime literals on page 227
- Interval literals on page 228

Integer literals

Integer literals define a whole number in an expression.

Syntax

```
[+|-] digit[...]
```

1. *digit* is a digit character from '0' to '9'.

Usage

Integer literals are in base-10 notation, without blank spaces and commas and without a decimal point.

Integer literals can be used to specify values for `DECIMAL(P,0)`, `BIGINT`, `INTEGER`, `SMALLINT` and `TINYINT` data types.

Example

```
MAIN
  DEFINE n INTEGER
  LET n = 1234567
END MAIN
```

Numeric literals

Numeric literals define values with a decimal part in an expression.

Syntax

```
[+|-] digit[...] . digit[...] [ {e|E} [+|-] digit[...] ]
```

1. *digit* is a digit character from '0' to '9'.
2. Note that the decimal separator is always a dot, independently from DBMONEY.
3. The E notation can be used to specify the exponent.

Usage

Numeric/decimal literals in base-10 notation, without blank spaces and commas, with a decimal part after a dot.

Numeric literals can be used to specify values for `DECIMAL(P,S)`, `MONEY(P,S)`, `FLOAT` and `SMALLFLOAT` data types.

Example

```
MAIN
  DEFINE n DECIMAL(10,2)
  LET n = 12345.67
  LET n = -1.23456e-10
END MAIN
```

Text literals

Text literals define a character string in an expression.

Syntax 1 (using double quotes)

```
" char [...] "
```

Syntax 2 (using single quotes)

```
' char [...] '
```

1. *char* is any character supported in the current locale, or a `\` backslash escape character as described below:
   - `\\` : the backslash character.
   - `\"` : double-quote character.
   - `\'` : single-quote character.
   - `\n` : newline character.
   - `\r` : carriage-return character.
   - `\0` : null character.
   - `\f` : form-feed character.
   - `\t` : tab character.
   - `\x`*NN* : ASCII character defined by the hexadecimal code *NN*.

Usage

A text literal (or character string literal) defines a character string constant containing valid characters in the current application character set. The application character set is defined by the current locale.

A text literal can be written on multiple lines, the compiler merges lines by removing the newline character.

An empty string ("") is equivalent to `NULL`.

The escape character is the backslash character (\).

When using single quotes as delimiters, double quotes can be used as is inside the string, while single quotes must be doubled or escaped with a backslash:

```
DISPLAY '  2 double quotes: " "   2 single quotes: '' \' '
displays as:
  2 double quotes: " "   2 single quotes: ' '
```

When using double quotes as delimiters, single quotes can be used as is inside the string, while double quotes must be doubled or escaped with a backslash:

```
DISPLAY "  2 double quotes: "" \"   2 single quotes: ' ' "
displays as:
  2 double quotes: " "   2 single quotes: ' '
```

Special characters can be specified with backslash escape symbols. Use for example \n to insert a new-line character in a string literal:

```
DISPLAY "First line\nSecond line"
```

The \x*NN* hexadecimal notation allows you to specify control characters in a string literal. Only ASCII codes (<=0x7F) are allowed.

Example

```
MAIN
  DISPLAY "Some text in double quotes"
  DISPLAY 'Some text in single quotes'
  DISPLAY "Include double quotes:  \"  ""  "
  DISPLAY 'Include single quotes:  \'  ''  '
  DISPLAY 'Insert a newline character here: \n and continue with
 text.'
  DISPLAY "This is a text
     on multiple
     lines.\
     You can insert a newline with back-slash at the end of the
 line."
  IF "" IS NULL THEN
     DISPLAY 'Empty string is NULL'
  END IF
END MAIN
```

Datetime literals

Datetime literals define date/time value in an expression.

Syntax

```
DATETIME ( dtrep ) qual1 TO qual2[(scale)]
```

where *qual1* can be one of:

```
  YEAR
  MONTH
  DAY
  HOUR
  MINUTE
  SECOND
  FRACTION
```

and *qual2* can be one of:

```
  YEAR
  MONTH
  DAY
  HOUR
  MINUTE
```

```
  SECOND
  FRACTION
  FRACTION(1)
  FRACTION(2)
  FRACTION(3)
  FRACTION(4)
  FRACTION(5)
```

1. *dtrep* is the datetime value representation in normalized format (YYYY-MM-DD hh:mm:ss.fffff).
2. *scale* defines the number of significant digits of the fractions of a second.
3. *qual1* and *qual2* qualifiers define the precision of the `DATETIME` literal.

Usage

A datetime literal is specified with the `DATETIME( )` notation, and is typically used in interval or datetime expressions, or to assign a DATETIME variable. In order to get the current date and time, use the `CURRENT` operator.

Example

```
MAIN
  DEFINE d1 DATETIME YEAR TO SECOND
  DEFINE d2 DATETIME HOUR TO FRACTION(5)
  LET d1 = DATETIME( 2002-12-24 23:55:56 ) YEAR TO SECOND
  LET d2 = DATETIME( 23:44:55.34532 ) HOUR TO FRACTION(5)
END MAIN
```

Interval literals

Interval literals define an interval value in an expression.

Syntax 1: *year-month* class interval

```
 INTERVAL ( inrep ) YEAR[(precision)] TO MONTH
|INTERVAL ( inrep ) YEAR[(precision)] TO YEAR
|INTERVAL ( inrep ) MONTH[(precision)] TO MONTH
```

Syntax 2: *day-time* class interval

```
 INTERVAL ( inrep ) DAY[(precision)] TO FRACTION[(scale)]
|INTERVAL ( inrep ) DAY[(precision)] TO SECOND
|INTERVAL ( inrep ) DAY[(precision)] TO MINUTE
|INTERVAL ( inrep ) DAY[(precision)] TO HOUR
|INTERVAL ( inrep ) DAY[(precision)] TO DAY

|INTERVAL ( inrep ) HOUR[(precision)] TO FRACTION[(scale)]
|INTERVAL ( inrep ) HOUR[(precision)] TO SECOND
|INTERVAL ( inrep ) HOUR[(precision)] TO MINUTE
|INTERVAL ( inrep ) HOUR[(precision)] TO HOUR

|INTERVAL ( inrep ) MINUTE[(precision)] TO FRACTION[(scale)]
|INTERVAL ( inrep ) MINUTE[(precision)] TO SECOND
|INTERVAL ( inrep ) MINUTE[(precision)] TO MINUTE

|INTERVAL ( inrep ) SECOND[(precision)] TO FRACTION[(scale)]
|INTERVAL ( inrep ) SECOND[(precision)] TO SECOND

|INTERVAL ( inrep ) FRACTION TO FRACTION[(scale)]
```

1. *inrep* is the interval value representation in normalized format (YYYY-MM or DD hh:mm:ss.fffff, according to the interval class).

Usage

An interval literal is specified with the `INTERVAL( )` notation, and is typically used to assign in interval or datetime expressions, or to assign an interval variable.

Example

```
MAIN
  DEFINE i1 INTERVAL YEAR TO MONTH
  DEFINE i2 INTERVAL HOUR(5) TO SECOND
  LET i1 = INTERVAL( 345-5 ) YEAR TO MONTH
  LET i2 = INTERVAL( 34562:22:33 ) HOUR(5) TO SECOND
END MAIN
```

Expressions

Shows the possible expressions supported in the language.

- Understanding expressions on page 229
- Boolean expressions on page 230
- Integer expressions on page 231
- Numeric expressions on page 231
- String expressions on page 232
- Date expressions on page 232
- Datetime expressions on page 233
- Interval expressions on page 233

Understanding expressions

What is an expression ?

An expression is a sequence of operands, operators, and parentheses that the runtime system can evaluate as a single value. Operands are program variables, constants, functions returning a single value and literal values. Operators are used for arithmetic or string manipulation, and the parentheses are used to overwrite precedence of operators.

Language and SQL expressions

Expressions in SQL statements are evaluated by the database server, not by the runtime system. The set of operators that can appear in SQL expressions resembles the set of language operators, but they are not identical. A program can include SQL operators, but these are restricted to SQL statements. Similarly, most SQL operands are not valid in program expressions. The SQL identifiers of databases, tables, or columns can appear in a `LIKE` clause or field name in program instructions, provided that these SQL identifiers comply with the naming rules of language. Here are some examples of SQL operands and operators that cannot appear in other language expressions:

- SQL identifiers, such as column names
- The SQL keywords `USER` and `ROWID`
- Built-in or aggregate SQL functions that are not part of the language
- The `BETWEEN` and `IN` operators
- The `EXISTS`, `ALL`, `ANY`, or `SOME` keywords of SQL expressions

Conversely, you *cannot* include language-specific operators in SQL expressions. For example:

- Arithmetic operators for exponentiation (`**`) and modulus (`MOD`)
- String operators `ASCII`, `COLUMN`, `SPACE`, `SPACES`, and `WORDWRAP`
- Field operators `FIELD_TOUCHED()`, `GET_FLDBUF()`, and `INFIELD()`
- The report operators `LINENO` and `PAGENO`

Parentheses in expressions

Parentheses are used as in algebra, to override the default order of precedence of operators. In mathematics, this use of parentheses represents the "associative" operator. It is, however, a convention in computer languages to regard this use of parentheses as delimiters rather than as operators. (Do not confuse this use of parentheses to specify *operator precedence* with the use of parentheses to enclose arguments in function calls or to delimit other lists.)

In this example, the variable **y** is assigned the value of 2.

```
LET y = 15 MOD 3 + 2
```

In this example, **y** is assigned the value of 0 because the parentheses change the sequence of operations.

```
LET y = 15 MOD (3 + 2)
```

Boolean expressions

A boolean expressions evaluates to an `INTEGER` value that can be `TRUE`, `FALSE` and in some cases, `NULL`.

```
MAIN
  DEFINE r, c INTEGER
  LET c = 4
  LET r = ( c!=5 ) AND ( c==2 OR c==4 )
  IF ( r AND canReadFile("config.txt") ) THEN
     DISPLAY "OK"
  END IF
END MAIN
```

Boolean expressions are a combination of logical operators and boolean comparison operators such as `==`, `>=` or `!=`. The result type of a boolean expression is an `INTEGER`. Any integer value different from zero is defined as true, while zero is defined as false. You can use an `INTEGER` or a `BOOLEAN` variable to store the result of a boolean expression.

```
MAIN
  DEFINE b BOOLEAN
  LET b = ( "a" == "b" )  -- result is FALSE (0)
END MAIN
```

If an expression that returns `NULL` is the operand of the `IS NULL` operator, the value of the boolean expression is `TRUE`.

```
MAIN
  DEFINE r INTEGER
  LET r = NULL
  IF r IS NULL THEN
     DISPLAY "TRUE"
  END IF
END MAIN
```

If you include a boolean expression in a context where the runtime system expects a number, the expression is evaluated, and is then converted to an integer by the rules `TRUE=1` and `FALSE=0`.

```
MAIN
  DEFINE r INTEGER
  LET c = 4
  LET r = 4 + (1==0)    -- result is 4.
END MAIN
```

The boolean expression evaluates to `TRUE` if the value is a non-zero real number or any of the following items:

- Character string representing a non-zero number
- Non-zero `INTERVAL`
- Any `DATE` or `DATETIME` value
- A `TRUE` value returned by a boolean function like `INFIELD()`
- The built-in integer constant `TRUE`

If a boolean expression includes an operand whose value is not an integer data type, the runtime system attempts to convert the value to an integer according to the data conversion rules.

A boolean expression evaluates to `NULL` if the value is `NULL` and the expression does not appear in any of the following contexts:

- The `IS [NOT] NULL` test.
- Boolean Comparisons.
- Any conditional statement (`IF`, `CASE`, `WHILE`).

The syntax of boolean expressions in programs is not the same as *Boolean conditions* in SQL statements.

Boolean expressions in `CASE`, `IF`, or `WHILE` statements return `FALSE` if any element of the comparison is `NULL`, except for operands of the `IS NULL` and the `IS NOT NULL` operator.

Integer expressions

An integer expression evaluates to a whole number.

```
MAIN
  DEFINE r, c INTEGER
  LET c = 4
  LET r = c * ( 2 + c MOD 4 ) / getRowCount("customers")
END MAIN
```

The operands of an integer expression can be:

- An integer literal.
- A variable or constant of type `TINYINT`, `SMALLINT`, `INTEGER` or `BIGINT`.
- A function returning a single integer value.
- A boolean expression.
- The result of a DATE subtraction, as a number of days.

If an integer expression includes an operand whose value is not an integer data type, the runtime system attempts to convert the value to an integer according to the data conversion rules.

If an element of an integer expression is `NULL`, the expression is evaluated to `NULL`.

Numeric expressions

A numeric expression evaluates to a decimal value.

```
MAIN
```

```
  DEFINE r, c DECIMAL(10,2)
  LET c = 456.22
  LET r = c * 2 + ( c / 4.55 )
END MAIN
```

The operands of a numeric expression can be one of:

- An integer literal.
- A decimal literal.
- A variable or constant of numeric data type.
- A function returning a single numeric value.
- A boolean expression.
- The result of a DATE subtraction, as a number of days.

If a number expression includes an operand whose value is not a numeric data type, the runtime system attempts to convert the value to a number according to the data conversion rules.

If an element of a number expression is `NULL`, the expression is evaluated to `NULL`.

String expressions

A string expression includes at least one character string value and evaluates to a string data type value.

```
MAIN
  DEFINE r, c VARCHAR(100)
  LET c = "abcdef"
  LET r = c[1,3] || ": " || TODAY USING "YYYY-MM-DD" || " " || length(c)
END MAIN
```

The data type of string expression result is `STRING`.

At least one of the operands in a string expression must be one of:

- A string literal.
- A variable or constant of `CHAR`, `VARCHAR` or `STRING` data type.
- A function returning a single character value.

Other operands whose values are not character string data types are converted to strings according to the data conversion rules.

If an element of a string expression is `NULL`, the expression is evaluated to NULL.

An empty string ("") is equivalent to `NULL`.

Date expressions

A date expression evaluates to a `DATE` data type value.

```
MAIN
  DEFINE r, c DATE
  LET c = TODAY + 4
  LET r = ( c - 2 )
END MAIN
```

The operands of a date expression can be one of:

- A string literal that can be evaluated to a date according to DBDATE environment variable.
- A variable or constant of type `DATE`.
- A function returning a single Date value.
- A unary + or - associated to an integer expression representing a number of days.
- The `TODAY` constant.

- A CURRENT expression with YEAR TO DAY qualifiers.
- An EXTEND expression with YEAR TO DAY qualifiers.

If a date expression includes an operand whose value is not a date data type, the runtime system attempts to convert the value to a date value according to the data conversion rules.

If an element of an date expression is NULL, the expression is evaluated to NULL.

Datetime expressions

A datetime expression evaluates to a DATETIME data type.

```
MAIN
  DEFINE r, c DATETIME YEAR TO SECOND
  LET c = CURRENT YEAR TO SECOND
  LET r = c + INTERVAL( 234-02 ) YEAR TO MONTH
END MAIN
```

The operands of a datetime expression can be one of:

- A datetime literal.
- A string literal representing a datetime with the format YYYY-MM-DD hh:mm:ss.fffff.
- A variable or constant of DATETIME type.
- A function returning a single Datetime value.
- A unary + or - associated to an interval expression.
- A CURRENT expression.
- An EXTEND expression.

If a datetime expression includes an operand whose value is not a datetime data type, the runtime system attempts to convert the value to a datetime value according to the data conversion rules.

If an element of an integer expression is NULL, the expression is evaluated to NULL.

Interval expressions

An interval evaluates to an INTERVAL data type.

```
MAIN
  DEFINE r, c INTERVAL HOUR TO MINUTE
  LET c = "12:45"
  LET r = c + ( DATETIME(14:02) HOUR TO MINUTE - DATETIME(10:43) HOUR TO
 MINUTE )
END MAIN
```

The operands of an interval expression must be one of:

- An interval literal.
- A string literal representing an Interval with the format YYYY-MM-DD hh:mm:ss.fffff.
- An integer expression using the UNITS operator.
- A variable or constant of INTERVAL type.
- A function returning a single interval value.
- The result of a DATETIME subtraction.

If an interval expression includes an operand whose value is not an interval data type, the runtime system attempts to convert the value to an interval value according to the data conversion rules.

If an element of an integer expression is NULL, the expression is evaluated to NULL.

Operators

This section describes basic syntax elements that can appear in expressions.

There are different sort of basic syntax elements such as operators for arithmetics, string and comparison, predefined variables and registers like `SQLSTATE`, and utility operators like `SFMT()` or `TODAY`.

Elements of an expressions are evaluated according to their precedence, from highest to lowest, as described in the order of precedence list. Use `()` parentheses to instruct the runtime system to evaluate the expression in a different way than the default order of precedence.

- Order of precedence on page 234
- General warnings regarding expressions on page 236
- List of expression elements on page 236

Order of precedence

The following list describes the precedence order of expression elements. The order of precedence defines in which order the elements of an expression are evaluated.

For example, the `MOD` operator has a higher precedence as the `*` operator. When computing an expression like `( 33 MOD 2 * 5 )`, the runtime system first evaluates `(33 MOD 2) = 1` and then evaluates `(1 * 5) = 5`. The order of evaluation can be changed this by using parentheses: `( 33 MOD ( 2 * 5 ) ) = 3`.

Table 107: Order of precedence list

P	Syntax Element	A	Description	Example
14	`CAST(v AS type)`	N	Type casting	`CAST(var AS fgl.FglRecord)`
14	`INSTANCEOF`	L	Type checking	`var INSTANCEOF`

P	Syntax Element	A	Description	Example
				`java.lang.Boolean`
13	`UNITS`	L	Single-qualifier interval	`(integer) UNITS DAY`
12	`+`	R	Unary plus	`+ number`
12	`-`	R	Unary minus	`- number`
11	`**`	L	Exponentiation	`x ** 5`
11	`MOD`	L	Modulus	`x MOD 2`
10	`*`	L	Multiplication	`x * y`
10	`/`	L	Division	`x / y`
9	`+`	L	Addition	`x + y`
9	`-`	L	Subtraction	`x - y`
8	`||`	L	Concatenation	`"Amount:" || amount`
7	`LIKE`	R	String comparison	`mystring LIKE "A%"`
7	`MATCHES`	R	String comparison	`mystring MATCHES "A*"`
6	`<`	L	Less than	`var < 100`
6	`<=`	L	Less then or equal to	`var <= 100`
6	`>`	L	Greater than	`var > 100`
6	`>=`	L	Greater than or equal to	`var >= 100`
6	`==`	L	Equals	`var == 100`
6	`<> or !=`	L	Not equal to	`var <> 100`
5	`IS NULL`	L	Test for NULL	`var IS NULL`
5	`IS NOT NULL`	L	Test for NOT NULL	`var IS NOT NULL`

In this table, the **P** column defines the precedence, from highest (14) to lowest (1). Note that some operators have the same precedence (i.e. are equivalent in evaluation order). The **A** column defines the direction of association (L=Left, R=Right, N=None).

General warnings regarding expressions

Pure SQL Syntax Elements

The following are related to SQL syntax and not part of the language:

- `BETWEEN` *`expr`* `AND` *`expr`*
- `IN ( ` *`expr`* `[ , ..' ] )`

Report Routine Syntax Elements

The following are only available in the FORMAT section of report routines:

- `PAGENO`
- `WORDWRAP`

See Report Definition for more details.

List of expression elements

Comparison operators

Comparison operators allow you to compare two values, to include the greater than, less than and equal to functions.

Table 108: Comparison operators

Operator	Description
IS NULL on page 237	The `IS NULL` operator checks for `NULL` values.
LIKE on page 237	The `LIKE` operator returns `TRUE` if a string matches a given mask.
MATCHES on page 238	The `MATCHES` operator returns `TRUE` if a string matches a given mask.
Equal to (==) on page 239	The == operator checks for equality of two expressions or for two record variables.
Different from (!=) on page 240	The `!=` operator checks for non-equality of two expressions or for two record variables.
Lower (<) on page 241	The < operator is provided to test whether a value or expression is lower than another.
Lower or equal (<=) on page 241	The <= operator is provided to test whether a value or expression is lower than or equal to another.
Greater (>) on page 242	The > operator is provided to test whether a value or expression is greater than another.
Greater or equal (>=) on page 242	The >= operator is provided to test whether a value or expression is greater than or equal to another.
NVL() on page 242	The `NVL( )` operator returns the second parameter if the first argument evaluates to `NULL`.

Operator	Description
IIF() on page 243	The `IIF()` operator returns the second or third parameter according to the boolean expression given as first argument.

IS NULL
The `IS NULL` operator checks for `NULL` values.

Syntax

```
expr IS NULL
```

1. *expr* can be any expression supported by the language.

Usage

The `IS NULL` operator can be used to test whether the left-hand expression is `NULL`.

This operator applies to most data types, except complex types like `BYTE` and `TEXT`.

Example

```
MAIN
  DEFINE n INTEGER
  LET n = NULL
  IF n IS NULL THEN
     DISPLAY "The variable is NULL."
  END IF
END MAIN
```

LIKE
The `LIKE` operator returns `TRUE` if a string matches a given mask.

Syntax

```
expr [NOT] LIKE mask [ ESCAPE "char" ]
```

1. *expr* is any character string expression.
2. *mask* is a character string expression defining the filter.
3. *char* is a single char specifying the escape symbol.

Usage

The *mask* can be any combination of characters, including the % and _ wildcards:

- The % percent character matches any string of zero or more characters.
- The _ underscore character matches any single character.

The ESCAPE clause can be used to define an escape character different from the default backslash. It must be enclosed in single or double quotes.

A backslash (or the escape character specified by the ESCAPE clause) makes the operator treat the next character as a literal character, even if it is one of the special symbols in the *mask* list. This allows you to search for %,_ or \ characters.

Do not confuse with the `LIKE` clause of the `DEFINE` instruction .`LIKE` operators used in SQL statements are evaluated by the database server. This may have a different behavior than the `LIKE` operator of the language.

If you need to escape a wildcard character, keep in mind that a string constant must also escape the backslash character. As a result, if you want to pass a backslash to the `LIKE` operator (by using backslash as default escape character), you need to write four backslashes in the original string constant.

The next table shows some examples of string constants used in the source code and their equivalent `LIKE` pattern:

Table 109: Examples of string constants used in the source code and their equivalent `LIKE` pattern

Original String Constant	Equivalent MATCHES pattern	Description
`"%"`	`%`	Matches any character in a non-empty string.
`"_"`	`_`	Matches a single character.
`"abc%"`	`abc%`	Starts with abc.
`"*abc"`	`%abc`	Ends with abc.
`"%abc%"`	`%abc%`	Contains abc.
`"abc__"`	`abc__`	Strings equals abc followed by two additional characters.
`"\\%"`	`\%`	Contains a single star character (the % wildcard is escaped)
`"%abc\\\\def%"`	`%abc\\def%`	Contains abc followed by a backslash followed by def (the backslash is escaped)

Example

```
MAIN
  IF "abcdef" LIKE "a%e_" THEN
     DISPLAY "The value matches."
  END IF
END MAIN
```

MATCHES

The `MATCHES` operator returns `TRUE` if a string matches a given mask.

Syntax

```
expr [NOT] MATCHES mask [ ESCAPE "char" ]
```

1. *expr* is any character string expression.
2. *mask* is a character string expression defining the filter.
3. *char* is a single char specifying the escape symbol.

Usage

The *mask* can be any combination of characters, including the `*`, `?`, `[`, `]`, `-` and `^` wildcards:

- The `*` star character matches any string of zero or more characters.
- The `?` question mark matches any single character.
- The `[ ]` brackets match any enclosed character.
- Inside `[ ]`, the `-` (hyphen) between characters means a range of characters.

- Inside `[ ]`, the ^ An initial caret matches any character that is not listed.

The ESCAPE clause can be used to define an escape character different from the default backslash. It must be enclosed in single or double quotes.

A backslash (or the escape character specified by the ESCAPE clause) makes the operator treat the next character as a literal character, even if it is one of the special symbols in the *mask* list. This allows you to search for wildcard charachers such as `*`, `?`, `[`, `]` or `\`.

If you need to escape a wildcard character, keep in mind that a string constant must also escape the backslash character. As a result, if you want to pass a backslash to the MATCHES operator (by using backslash as default escape character), you need to write four backslashes in the original string constant.

The next table shows some examples of string constants used in the source code and their equivalent MATCHES pattern:

Table 110: String constants used in the source code and their equivalent `MATCHES` pattern

Original String Constant	Equivalent MATCHES pattern	Description
`"*"`	`*`	Matches any character in a non-empty string.
`"?"`	`?`	Matches a single character.
`"abc*"`	`abc*`	Starts with abc.
`"*abc"`	`*abc`	Ends with abc.
`"*abc*"`	`*abc*`	Contains abc.
`"abc??"`	`abc??`	Starts with abc, followed by two additional characters.
`"[a-z]*"`	`[a-z]*`	Starts with a letter in the range a to z.
`"[^0-9]*"`	`[^0-9]*`	Must not start with a digit.
`"\\*"`	`\*`	Contains a single star character (the * wildcard is escaped)
`"*abc\\\\def*"`	`*abc\\def*`	Contains abc followed by a backslash followed by def (the backslash is escaped)

Example

```
MAIN
  IF "55f-plot" MATCHES "55[a-z]-*" THEN
     DISPLAY "Item reference format is correct."
  END IF
END MAIN
```

Equal to (==)

The == operator checks for equality of two expressions or for two record variables.

Syntax 1: Expression comparison

```
expr == expr
```

Syntax 2: Record comparison

```
record1.* == record2.*
```

1. *expr* can be any expression supported by the language.
2. *record1* and *record2* are records with the same structure.

Usage

The == operator evaluates whether two expressions or two records are identical.

A single equal sign (=) can be used as an alias for the == operator.

When comparing expressions using the first syntax, the result of the operator is FALSE when one of the operands is NULL. This first syntax applies to most data types, except complex types like BYTE and TEXT.

When comparing two records using the second syntax, the runtime system compares all corresponding members of the records. If a pair of members are different, the result of the operator is FALSE. When two corresponding members are NULL, they are considered as equal. This second syntax allows you to compare all members of records, but records must have the same structure.

Example

```
MAIN
  DEFINE n INTEGER
  LET n=512
  IF n==512 THEN
     DISPLAY "The variable equals 512."
  END IF
END MAIN
```

Different from (!=)

The != operator checks for non-equality of two expressions or for two record variables.

Syntax 1: Expression comparison

```
expr != expr
```

Syntax 2: Record comparison

```
record1.* != record2.*
```

1. <> is a synonym for!=
2. *expr* can be any expression supported by the language.
3. *record1* and *record2* are records with the same structure.

Usage

The != operator evaluates whether two expressions or two records are different.

A less-than sign followed by a greater-than sign (<>) can be used as an alias for the != operator.

When comparing expressions with the first syntax, the result of the operator is FALSE when one of the operands is NULL. This syntax applies to most data types except complex types like BYTE and TEXT.

When comparing two records with the second syntax, the runtime system compares all corresponding members of the records. If one pair of members are different, the result of the operator is TRUE. When two corresponding members are NULL, they are considered as equal. This second syntax allows you to compare all members of records, but records must have the same structure.

Example

```
MAIN
  DEFINE n INTEGER
  LET n==512
  IF n!=32 THEN
     DISPLAY "The variable is not equal to 32."
  END IF
END MAIN
```

Lower (<)

The < operator is provided to test whether a value or expression is lower than another.

Syntax

```
expr < expr
```

Usage

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

```
MAIN
  DEFINE n INT
  LET n = 45
  IF n < 100 THEN
     DISPLAY "The variable is lower than 100."
  END IF
END MAIN
```

Lower or equal (<=)

The <= operator is provided to test whether a value or expression is lower than or equal to another.

Syntax

```
expr <= expr
```

Usage

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

```
MAIN
  DEFINE n INT
  LET n = 100
  IF n <= 100 THEN
     DISPLAY "The variable is lower than or equal to 100."
  END IF
END MAIN
```

Greater (>)
The > operator is provided to test whether a value or expression is greater than another.

Syntax

```
expr > expr
```

Usage

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

```
MAIN
  DEFINE n INT
  LET n = 200
  IF n > 100 THEN
     DISPLAY "The variable is greater than 100."
  END IF
END MAIN
```

Greater or equal (>=)
The >= operator is provided to test whether a value or expression is greater than or equal to another.

Syntax

```
expr >= expr
```

Usage

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

```
MAIN
  DEFINE n INT
  LET n = 100
  IF n >= 100 THEN
     DISPLAY "The variable is greater than or equal to 100."
  END IF
END MAIN
```

NVL()
The NVL( ) operator returns the second parameter if the first argument evaluates to NULL.

Syntax

```
NVL( main-expr, subst-expr )
```

1. *main-expr* and *subst-expr* are any expression supported by the language.

Usage

The `NVL()` operator evaluates the first argument, and returns the result if the value is not null, otherwise it returns the second argument. This allows you to write the equivalent of the following `IF` statement, in a simple scalar expression:

```
IF main-expr IS NOT NULL THEN
  RETURN main-expr
ELSE
  RETURN subst-expr
END IF
```

Example

```
MAIN
  DEFINE var VARCHAR(100)
  LET var = arg_val(1)
  DISPLAY "The argument value is: ", NVL(var, "NULL")
END MAIN
```

IIF()

The `IIF()` operator returns the second or third parameter according to the boolean expression given as first argument.

Syntax

```
IIF( bool-expr, true-expr, false-expr)
```

1. *bool-expr* is a boolean expression.
2. *true-expr* and *false-expr* are language expressions.

Usage:

The `IIF()` operator evaluates the first argument, the returns the second argument if the first argument is true, otherwise it returns the third argument. This allows you to write the equivalent of the following `IF` statement, in a simple scalar expression:

```
IF bool-expr THEN
   RETURN true-expr
ELSE
   RETURN false-expr
END IF
```

Example

```
MAIN
  DEFINE var VARCHAR(10)
  LET var = arg_val(1)
  DISPLAY IIF(var == "A", "Accepted", "Rejected")
END MAIN
```

Logical operators

Logical operators include NOT, AND and OR.

Table 111: Logical operators

Operator	Description
NOT on page 244	The NOT operator performs a logical negation to invert a boolean expression.
AND on page 244	The AND operator is the logical intersection operator.
OR on page 245	The OR operator is the logical union operator.

NOT

The NOT operator performs a logical negation to invert a boolean expression.

Syntax

```
NOT bool-expr
```

1. *bool-expr* is a boolean expression.

Usage

The NOT operator is typically used to invert the value of a boolean expression.

If the operand is NULL, the negation expression evaluates to NULL.

Example

```
MAIN
  IF NOT ( 256 == 257 ) THEN
     DISPLAY "This line should display"
  END IF
END MAIN
```

AND

The AND operator is the logical intersection operator.

Syntax

```
bool-expr AND bool-expr
```

1. *bool-expr* is a boolean expression.

Usage

If one of the operands is NULL, the logical expression evaluates to FALSE.

By default, the runtime system evaluates both operands on the left and right side of the AND keyword. This is the traditional behavior of the Genero language, but in fact the right operand does not need to be evaluated if the first operand evaluates to FALSE. This method is called *short-circuit evaluation*, and can be enabled by adding the OPTIONS SHORT CIRCUIT clause at the beginning of the module.

Example

```
MAIN
```

```
  IF 256!=257 AND 257==257 THEN
     DISPLAY "This line should display"
  END IF
END MAIN
```

OR

The OR operator is the logical union operator.

Syntax

```
bool-expr OR bool-expr
```

1. *bool-expr* is a boolean expression.

Usage

If one of the operands is NULL, the logical expression evaluates to FALSE.

By default, the runtime system evaluates both operands on the left and right side of the OR keyword. This is the traditional behavior of the Genero language, but in fact the right operand does not need to be evaluated if the first operand evaluates to TRUE. This method is called *short-circuit evaluation*, and can be enabled by adding the OPTIONS SHORT CIRCUIT clause at the beginning of the module.

Example

```
MAIN
  IF TRUE OR FALSE THEN
     DISPLAY "This line should display"
  END IF
END MAIN
```

Arithmetic operators

Arithmetic operators allow you to complete numeric operations, such as addition and subtraction.

Table 112: Arithmetic operators

Operator	Description
Addition (+) on page 245	The + operator adds a number to another.
Subtraction (-) on page 246	The - operator subtracts a number from another.
Multiplication (*) on page 246	The * operator multiplies a number with another.
Division (/) on page 247	The / operator divides a number by another.
Exponentiation (**) on page 247	The ** operator calculates an exponentiation.
MOD on page 247	The MOD operator calculates the modulus.

Addition (+)

The + operator adds a number to another.

Syntax

```
num-expr + num-expr
```

1. *num-expr* is a numeric expression.

Usage

Use the + operator to add two numeric values.

If one of the operands is `NULL`, the arithmetic expression evaluates to `NULL`.

Example

```
MAIN
  DISPLAY 100 + 200
END MAIN
```

Subtraction (-)

The - operator subtracts a number from another.

Syntax

```
num-expr - num-expr
```

1. *num-expr* is a numeric expression.

Usage

Use the - operator to subtract a numeric value from another numeric value.

If one of the operands is `NULL`, the arithmetic expression evaluates to `NULL`.

Example

```
MAIN
  DISPLAY 100 - 200
END MAIN
```

Multiplication (*)

The * operator multiplies a number with another.

Syntax

```
num-expr * num-expr
```

1. *num-expr* is a numeric expression.

Usage

Use the * operator to multiply a numeric value to another numeric value.

If one of the operands is `NULL`, the arithmetic expression evaluates to `NULL`.

Example

```
MAIN
  DISPLAY 100 * 200
END MAIN
```

Division (/)
The / operator divides a number by another.

Syntax

```
num-expr / num-expr
```

1. *num-expr* is a numeric expression.

Usage

Use the / operator to divide a numeric value by another numeric value.

If one of the operands is NULL, the arithmetic expression evaluates to NULL.

Example

```
MAIN
  DISPLAY 100 / 200
END MAIN
```

Exponentiation (**)
The ** operator calculates an exponentiation.

Syntax

```
num-expr ** int-expr
```

1. *num-expr* is a numeric expression.

Usage

The ** operator returns a value calculated by raising the left-hand operand to a power corresponding to the integer part of the right-hand operand.

If the right operand is a number with a decimal part, it is rounded to a whole integer before computing the exponentiation.

Example

```
MAIN
  DISPLAY 2 ** 8
  DISPLAY 10 ** 4
END MAIN
```

MOD
The MOD operator calculates the modulus.

Syntax

```
int-expr MOD int-expr
```

1. *int-expr* is an integer expression.

Usage

The MOD operator returns the remainder, as an integer, from the division of the integer part of two numbers.

If the right operand is a number with a decimal part, it is rounded to a whole integer before computing the modulus.

Example

```
MAIN
  DISPLAY 256 MOD 16
  DISPLAY 26 MOD 2
  DISPLAY 27 MOD 2
END MAIN
```

Character string operators

Character string operators allow you to work with and manipulate character strings.

Table 113: Character string operators

Operator	Description
ASCII() on page 248	The `ASCII()` operator produces an ASCII character.
COLUMN on page 249	The `COLUMN` operator generates blanks.
Concatenate (||) on page 250	The `||` operator makes a string concatenation.
Append (,) on page 250	The `,` (comma) appends an expression to a string.
Substring ([s,e]) on page 250	The `[]` (square braces) extract a substring.
USING on page 251	The `USING` operator converts date and numeric values to a string, according to a formatting mask.
CLIPPED on page 252	The `CLIPPED` operator removes trailing blanks of a string expression.
ORD() on page 252	The `ORD()` operator returns the code point of a character in the current locale.
SPACES on page 252	The `SPACES` operator returns a character string with blanks.
LSTR() on page 253	The `LSTR()` operator returns a localized string.
SFMT() on page 253	The `SFMT()` operator replaces place holders in a string with values.

ASCII()

The `ASCII()` operator produces an ASCII character.

Syntax

```
ASCII ( int-expr )
```

1. *int-expr* is an integer expression, in the range 0-255 or 0-127, according to the current locale.

Usage

The `ASCII()` operator returns the character corresponding to the ASCII code passed as a parameter.

`ASCII()` is typically used to generate a non-printable character such as newline or escape. You should avoid to use this function for other characters.

The possible values of the integer parameter passed to ASCII() depends on the locale settings:

- For single byte encodings (like ISO8859-1), the argument must be in the range of 0 to 255.
- For UTF-8, using char length semantics, the argument must be any valid 16bit code point.
- For any other locale setting (any multibyte character set, or UTF-8 with byte length semantics), the argument must be in the range 0 to 127.

When the argument is zero, ASCII() has a different behavior, according to the context:

- ASCII(0) only displays the NULL character within the PRINT statement.
- If you specify ASCII(0) in other contexts, it returns a blank space.

Example

```
MAIN
  DISPLAY ASCII(65), ASCII(66), ASCII(7)
END MAIN
```

COLUMN

The COLUMN operator generates blanks.

Syntax

```
COLUMN position
```

1. *position* is the column position (starts at 1).

Usage

The COLUMN operator is typically used in report routines to align data in PRINT statements and move the character position forward within the current line. This operator makes sense when used in an expression with the comma append operator: Spaces will be generated according to the number of characters that have been used in the expression, before the COLUMN operator.

The COLUMN operator can be used outside report routines, in order to align data to be displayed with a proportional font, typically in a TUI context. For example, the next lines will always display the content of the *lastname* variable starting from column 30 of the terminal, no matters the number of characters contained in the *firstname* variable. The example defines VARCHAR variables, since CHAR variables are blank-padded, we would need to use the CLIPPED operator:

```
DEFINE firstname, lastname VARCHAR(50)
DISPLAY firstname, COLUMN(30), lasttname
```

The *pos* operand must be a non-negative integer that specifies a character position offset (from the left margin) no greater than the line width (that is, no greater than the difference (right margin - left margin). This designation moves the character position to a left-offset, where 1 is the first position after the left margin. If current position is greater than the operand, the COLUMN specification is ignored.

Example

```
PAGE HEADER
  PRINT "Number", COLUMN 12,"Name", COLUMN 35,"Location"
ON EVERY ROW
  PRINT customer_num, COLUMN 12, fname, COLUMN 35,city
```

Concatenate (||)
The || operator makes a string concatenation.

Syntax

```
expr || expr
```

1. *expr* can be a character, numeric or date time expression.

Usage

The || operator is the concatenation operator that produces a string expression from the expression elements on both sides of the operator.

This operator has a high precedence; it can be used in parameters for function calls. The precedence of this operator is higher than LIKE and MATCHES, but less than arithmetic operators. For example, a || b + c is equivalent to (a||(b+c)).

If any of the members of a concatenation expression is NULL, the result string will be NULL.

Example

```
MAIN
  DISPLAY "Length: " || length( "ab" || "cdef" )
END MAIN
```

Append (,)
The , (comma) appends an expression to a string.

Syntax

```
char-expr, expr
```

Usage

The comma operator formats and concatenates expressions together.

This operator can only be used in some instructions such as LET, PRINT, MESSAGE, ERROR and DISPLAY instructions.

As an alternative, use the || concatenation operator.

Use the comma concatenation operator when data needs to be formatted for printing and display.

Example

```
MAIN
  DISPLAY "Today:", TODAY, " and a number: ", 12345.67
END MAIN
```

Substring ([s,e])
The [] (square braces) extract a substring.

Syntax

```
char-variable [ start  [, end  ] ]
```

1. *char-variable* must be a character data type variable.

2. *start* defines the position of the first character of the substring to be extracted.
3. *end* defines the position of the last character of the substring to be extracted.
4. If *end* is not specified, only one character is extracted.

Usage

The `[]` (square braces) notation following a `CHAR` or `VARCHAR` variable extracts a substring from that character variable.

The *start* and *end* arguments can be expressed in bytes or characters, depending on the length semantics used in your programs.

> **Important:** Substring expressions in SQL statements are evaluated by the database server. This may have a different behavior than the substring operator of the language.

Example

```
MAIN
  DEFINE s CHAR(10)
  LET s = "abcdef"
  DISPLAY s[3,4]
END MAIN
```

USING

The `USING` operator converts date and numeric values to a string, according to a formatting mask.

Syntax

```
expr USING format
```

1. *expr* is a language expression.
2. *format* is a string expression that defines the formatting mask to be used.

Usage

The `USING` operator applies a formatting string to the left operand.

The left operand must be a valid date, integer or decimal number. Note that `DATETIME` and `INTERVAL` expressions cannot be formatted with the USING operator.

The format string can be any valid string expression using formatting characters as described in Formatting numeric values on page 217 and Formatting DATE values on page 220.

The `USING` operator has a low order of precedence: if you use operators with a higher precedence, the resulting string might not be what you are expecting.

For example, the `||` concatenation operator is evaluated before `USING`. As a result:

```
LET x = a || b USING "format"
```

will first concatenate a and b, then apply the `USING` format.

To solve this issue, use braces around the `USING` expression:

```
LET x = a || (b USING "format")
```

Example

```
MAIN
  DEFINE d DECIMAL(12,2)
```

```
  LET d = -12345678.91
  DISPLAY d USING "$-##,###,##&.&&"
  DISPLAY TODAY USING "yyyy-mm-dd"
END MAIN
```

CLIPPED
The `CLIPPED` operator removes trailing blanks of a string expression.

Syntax

```
expr CLIPPED
```

1. *expr* is a language expression.

Usage

This operator removes all trailing spaces of a string expression.

The `CLIPPED` operator is typically used to remove the trailing blanks of a `CHAR` value, which would be printed otherwise.

Example

```
MAIN
  DISPLAY "Some text   " CLIPPED
END MAIN
```

ORD()
The `ORD()` operator returns the code point of a character in the current locale.

Syntax

```
ORD( source STRING )
```

1. *source* is a string expression.

Usage

The value returned by `ORD()` is the code point in the current locale of the character passed as argument.

Only the first character of the argument is evaluated.

When using UTF-8 with character length semantics, the `ORD()` operator returns the UNICODE code point of the character.

`ORD` returns `NULL` if the argument passed is not valid.

SPACES
The `SPACES` operator returns a character string with blanks.

Syntax

```
int-expr SPACES
```

1. *int-expr* is an integer expression.
2. `SPACE` (without S) is an alias for this operator.

Usage

The SPACE operator is typically used in reports to print spaces to align data in the report output.

Example

```
MAIN
  DISPLAY 20 SPACES || "xxx"
END MAIN
```

LSTR()
The LSTR( ) operator returns a localized string.

Syntax

```
LSTR(str-expr)
```

1. *str-expr* is a string expression.

Usage

The LSTR( ) operator returns a localized string corresponding to the identifier passed as parameter.

Normally localized strings are automatically replaced when using the %"ident" notation in the source code. When the localized string identifier is not known at compile time, use the LSTR( ) function.

Example

```
MAIN
  DISPLAY LSTR ("str"||123)  -- loads string 'str123'
END MAIN
```

SFMT()
The SFMT( ) operator replaces place holders in a string with values.

Syntax

```
SFMT( str-expr , param [ , param [...] ])
```

1. *str-expr* is a string expression.
2. *param* is any valid expression used to replace parameter place holders (%*n*).
3. At least one parameter is required.

Usage

The SFMT( ) operator can be used with parameters that will be automatically set in the string at the position defined by parameter placeholders. The parameters used with the SFMT( ) operator can be any valid expressions. Numeric and date/time expressions are evaluated to strings according to the current format settings (DBDATE, DBMONEY).

A placeholder a is special marker in the string, that is defined by the percent character followed by the parameter number. For example, %4 represents the parameter #4. You are allowed to use the same parameter placeholder several times in the string. If you want to use the percent sign in the string, you must escape it with %%.

Predefined placeholders can be used to insert information about last runtime system error that occurred. Note that these are only available in the context of a runtime error trapped with a WHENEVER ERROR GOTO / CALL handler:

Table 114: Predefined placeholders for runtime system error information

Predefined parameter	Description
%(ERRORFILE)	Name of the module where last runtime error occurred.
%(ERRORLINE)	Line number in the module where last runtime error occurred.
%(ERRNO)	Last operating system error number.
%(STRERROR)	Last operating system error text.

Example

```
MAIN
  DEFINE n INTEGER
  LET n = 234
  DISPLAY SFMT("Order #%1 has been %2.",n,"deleted")
END MAIN
```

In this example, %1 is replaced by the value of the variable *n*, while %2 is replaced by the string "deleted", resulting in: `Order #234 has been deleted.`

Associative syntax operators

Associative syntax operators allow you to group together objects.

Table 115: Associative syntax operators

Operator	Description
Parentheses (()) on page 254	Parentheses (( )) force the evaluation of an expression before other operators.
Membership (object.member) on page 255	Separator for object members.
Variable parameter list ([ ]) on page 255	Variable parameter list delimiters.

Parentheses (())

Parentheses (( )) force the evaluation of an expression before other operators.

Syntax

```
( expr  [...] )
```

1. *expr* is a language expression.

Usage

Parentheses can be used to change the order in which expression elements are evaluated, to bypass the precedence of operators.

Parentheses can also be used to ease the readability of the code in a complex expression.

Example

```
MAIN
  DEFINE n INTEGER
```

```
  LET n = ( ( 3 + 2 ) * 2 )
  IF n=10 AND ( n<=0 OR n>=20 ) THEN
    DISPLAY "OK"
  END IF
END MAIN
```

Membership (object.member)
Separator for object members.

Syntax

```
setname.element
```

Usage

The period expression element specifies that its right-hand operand is a member of the set whose name is its left-hand operand.

This notation is used to reference `RECORD` members, object and class methods, as well as module elements.

Example

```
IMPORT FGL customer_module
...
MAIN
  DEFINE rec RECORD
     n INTEGER,
     c CHAR(10)
  END RECORD
  DEFINE form ui.Form
  LET rec.n = 12345
  LET rec.c = "abcdef"
  ...
  CALL form.setElementHidden("page1")
  ...
  CALL customer_module.check(345)
  ...
END MAIN
```

Variable parameter list ([ ])
Variable parameter list delimiters.

Syntax

```
[ variable [,...] ]
```

Usage

The square brace notation in function parameters defines a variable list of arguments for a built-in function or a built-in class method.

The elements of a variable parameter list are program variables which are passed by reference. As result, the called function can modify the content of the passed variables, to return values in output parameters.

It is not possible to define user functions with variable parameter lists.

For real usage examples, see the read and write methods of the `base.Channel` class.

Example

```
MAIN
  DEFINE id INTEGER, name STRING,
           count INTEGER, stat INTEGER
  LET id = 12345
  LET name = "Forman"
  -- Warning: This is a fake call, the function does not exist!
  -- Here, id and name are passed as input values, while count
  -- and stat are used as output parameters...
  CALL built_in_function( [id,name], [count, stat] )
END MAIN
```

SQL related operators

SQL related operators allow you to retrieve the SQL state and the SQL error message.

Table 116: SQL related operators

Operator	Description
SQLSTATE on page 256	The SQLSTATE variable returns the code corresponding to the last SQL error.
SQLERRMESSAGE on page 257	The SQLERRMESSAGE variable holds the error message corresponding to the last SQL error.

SQLSTATE

The SQLSTATE variable returns the code corresponding to the last SQL error.

Syntax

```
SQLSTATE
```

Usage

The SQLSTATE predefined variable returns the ANSI/ISO SQLSTATE code when an SQL error occurred.

The SQLSTATE error code is a standard ANSI specification, but not all database engines support this feature. Check the database server documentation for more details.

The variable is NULL if the last SQL statement was successfull.

Example

```
MAIN
  DATABASE stores
  WHENEVER ERROR CONTINUE
  SELECT foo FROM bar
  DISPLAY SQLSTATE
END MAIN
```

SQLERRMESSAGE

The SQLERRMESSAGE variable holds the error message corresponding to the last SQL error.

Syntax

```
SQLERRMESSAGE
```

Usage

The SQLERRMESSAGE predefined variable returns the error message if an SQL error occurred.

The variable is NULL if the last SQL statement was successfull.

Example

```
MAIN
  DATABASE stores
  WHENEVER ERROR CONTINUE
  SELECT foo FROM bar
  DISPLAY SQLERRMESSAGE
END MAIN
```

Data type operators

Data type operators allow you cast a data type or create an instance of a data type.

Table 117: Data type operators

Operator	Description
CAST on page 257	The CAST operator converts a Java™ object to the user-defined type or Java class specified.
INSTANCEOF on page 258	The INSTANCEOF checks the class of an object.

CAST

The CAST operator converts a Java™ object to the user-defined type or Java class specified.

Syntax

```
CAST( obj AS type )
```

1. *obj* is a Java object.
2. *type* is a user-defined type or a Java class.

Usage

The CAST( ) operator is required when you want to assign an object reference to variable defined with a user-defined type or Java class which requires narrowing reference conversion.

Example

In this example, when assigning a `java.lang.StringBuffer` reference to a `java.lang.Object` variable, widening reference conversion occurs and no CAST( ) operator is needed, but when assigning an `java.lang.Object` reference to a `java.lang.StringBuffer` variable, you must cast the object reference to a `java.lang.StringBuffer`:

```
IMPORT JAVA java.lang.Object
```

```
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE sb1, sb2 java.lang.StringBuffer
  DEFINE o java.lang.Object
  LET sb1 = StringBuffer.create()
  LET o = sb1 -- Widening Reference Conversion does not need CAST()
  LET sb2 = CAST( o AS java.lang.StringBuffer ) -- Narrowing
                  -- Reference Conversion needs CAST()
END MAIN
```

In order to cast an `fgl.FglRecord` object to a regular `RECORD`, you need to specify a user-defined type (`TYPE` definition):

```
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
TYPE mytype RECORD f1, f2 INTEGER END RECORD
MAIN
  DEFINE r mytype
  DEFINE jr fgl.FglRecord
  LET jr = r
  LET r = CAST(jr AS mytype)
  -- This is denied:
  --   CAST(jr AS RECORD f1, f2 INTEGER END RECORD)
END MAIN
```

INSTANCEOF

The `INSTANCEOF` checks the class of an object.

Syntax

```
expr INSTANCEOF type
```

1. *expr* can be any expression supported by the language.
2. *type* is a structured user defined type or a Java™ class.

Usage

The `INSTANCEOF` operator evaluates to `TRUE` if the object reference is of the type or class specified.

The `INSTANCEOF` operator is used to check if an expression (usually, an object reference) is one of the type or class specified by *type*.

Example

```
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
IMPORT JAVA java.lang.Number
MAIN
  DEFINE o java.lang.Object
  DEFINE sb java.lang.StringBuffer
  LET sb = StringBuffer.create()
  LET o = sb
  DISPLAY sb INSTANCEOF java.lang.StringBuffer  -- shows 1
  DISPLAY o INSTANCEOF java.lang.StringBuffer   -- shows 1
  DISPLAY o INSTANCEOF java.lang.Number         -- shows 0
END MAIN
```

Assignment operators

An assignment operator allows you to assign a variable with an expression.

Table 118: Assignment operators

Operator	Description
Assignment (:=) on page 259	The := operator assigns a variable with an expression and returns the result.

Assignment (:=)

The := operator assigns a variable with an expression and returns the result.

Syntax

```
variable := expr
```

Usage

The := assignment operator puts a value in the left-hand variable and the resulting value can again be used in an expression.

Do not confuse with the LET instruction.

The := assignment operator has the lowest precedence, it can be used at many places and can simplify coding.

Example

In the next example, the := operator is used to increment the array index before usage:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF STRING,
         idx INTEGER
  LET idx = 0
  LET arr[idx:=idx+1] = "One"
  LET arr[idx:=idx+1] = "Two"
  LET arr[idx:=idx+1] = "Three"
END MAIN
```

Date and time operators

Date and time operators allow you to work with date and time values.

Table 119: Date and time operators

Operator	Description
CURRENT on page 260	The CURRENT operator returns the current system date and time.
EXTEND() on page 260	The EXTEND( ) operator adjusts a date time value according to the qualifier.
DATE() on page 261	The DATE( ) operator converts an expression to a DATE value.
TIME() on page 261	The TIME( ) operator returns a time part of the date time expression.

Operator	Description
TODAY on page 262	The TODAY operator returns the current calendar date.
YEAR() on page 262	The YEAR( ) operator extracts the year of a date time expression.
MONTH() on page 263	The MONTH( ) operator extracts the month of a date time expression.
DAY() on page 263	The DAY( ) operator extracts the day of the month of a date time expression.
WEEKDAY() on page 263	The WEEKDAY( ) operator extracts the day of the week of a date time expression.
MDY() on page 264	The MDY( ) operator creates a date from month, day and year units.
UNITS on page 264	The UNITS operator converts an integer to an interval.

CURRENT
The CURRENT operator returns the current system date and time.

Syntax

```
CURRENT [ qual1 TO qual2 [(scale)] ]
```

1. *qual1*, *qual2* and *scale* define the date time qualifier.

Usage

The CURRENT operator returns the system date/time in the current local timezone.

This operator can be used to assign the current system date and time to a DATETIME variable.

Use optional datetime qualifiers to specify the precision of the returned value. The possible qualifiers are the same as in a DATETIME data type definition.

If the datetime qualifiers are not specified after the CURRENT keyword, the precision defaults to YEAR TO FRACTION(3) precision.

Example

```
MAIN
  DISPLAY CURRENT YEAR TO FRACTION(4)
  DISPLAY CURRENT HOUR TO SECOND
  DISPLAY CURRENT
END MAIN
```

EXTEND()
The EXTEND( ) operator adjusts a date time value according to the qualifier.

Syntax

```
EXTEND ( dt-expr, qual1 TO qual2 [(scale)])
```

1. *dt-expr* is a date / time expression.
2. *qual1*, *qual2* and *scale* define the date time qualifier.

Usage

The `EXTEND()` operator is used to convert a date time expression to a `DATETIME` value with a different precision.

The default qualifier is `YEAR TO DAY`.

The possible qualifiers are the same as in a `DATETIME` data type definition.

The expressions passed as first parameter must be a valid datetime value. If it is a character string, it must consist of valid and unambiguous time-unit values and separators, but with these restrictions:

- It cannot be a character string in date format, such as "12/12/99".
- It cannot be an ambiguous numeric datetime value, such as "05:06" or "05".
- It cannot be a time expression that returns an `INTERVAL` value.

Example

```
MAIN
  DISPLAY EXTEND ( TODAY, YEAR TO FRACTION(4) )
END MAIN
```

DATE()

The `DATE()` operator converts an expression to a `DATE` value.

Syntax

```
DATE [(expr)]
```

1. *expr* is the expression to be converted to a date.

Usage

`DATE()` converts a character string, an integer or datetime expression to a `DATE` value.

When *expr* is a character string expression, it must properly formatted according to datetime format settings like DBDATE.

If *expr* is an integer expression, it is used as the number of days since December 31, 1899.

If you supply no operand, it returns a character representation of the current date in the format "weekday month day year".

Example

```
MAIN
  DISPLAY DATE ( 34000 )
  DISPLAY DATE ( "12/04/1978" )
  DISPLAY DATE ( CURRENT )
END MAIN
```

TIME()

The `TIME()` operator returns a time part of the date time expression.

Syntax

```
TIME [(datetime-expr)]
```

1. *datetime-expr* is a datetime expression.

Usage

`TIME()` converts the time-of-day portion of its datetime operand to a character string.

This operator converts a date time expression to a character string representing the time-of-day part of its operand.

The format of the returned string is always "hh:mm:ss".

If you supply no operand, it returns a character representation of the current time. You can use the `CURRENT` operator to get a datetime result of the current system time.

Example

```
MAIN
  DISPLAY TIME ( CURRENT )
END MAIN
```

TODAY

The `TODAY` operator returns the current calendar date.

Syntax

```
TODAY
```

Usage

`TODAY` returns the current system date as a `DATE` value, in the current local timezone.

This operator can be used to assign the current system date to a `DATE` variable.

The `TODAY` operator is the `DATE` equivalent for the `CURRENT` operator used for `DATETIME`.

Example

```
MAIN
  DISPLAY TODAY
END MAIN
```

YEAR()

The `YEAR()` operator extracts the year of a date time expression.

Syntax

```
YEAR ( expr )
```

1. *expr* is a date / time expression.

Usage

Returns an integer corresponding to the year portion of its operand.

Example

```
MAIN
  DISPLAY YEAR ( TODAY )
  DISPLAY YEAR ( CURRENT )
```

```
END MAIN
```

MONTH()
The `MONTH()` operator extracts the month of a date time expression.

Syntax

```
MONTH ( expr )
```

1. *expr* is a date / time expression.

Usage

Returns a positive whole number between 1 and 12 corresponding to the month of its operand.

Example

```
MAIN
  DISPLAY MONTH ( TODAY )
  DISPLAY MONTH ( CURRENT )
END MAIN
```

DAY()
The `DAY()` operator extracts the day of the month of a date time expression.

Syntax

```
DAY ( expr )
```

1. *expr* is a date / time expression.

Usage

Returns a positive whole number between 1 and 31 corresponding to the day of the month of its operand.

Example

```
MAIN
  DISPLAY DAY ( TODAY )
  DISPLAY DAY ( CURRENT )
END MAIN
```

WEEKDAY()
The `WEEKDAY()` operator extracts the day of the week of a date time expression.

Syntax

```
WEEKDAY ( expr )
```

1. *expr* is a date / time expression.

Usage

Returns a positive whole number between 0 and 6 corresponding to the day of the week implied by its operand.

The integer 0 (Zero) represents Sunday.

Example

```
MAIN
  DISPLAY WEEKDAY( TODAY )
  DISPLAY WEEKDAY( CURRENT )
END MAIN
```

MDY()

The `MDY()` operator creates a date from month, day and year units.

Syntax

```
MDY ( expr1, expr2, expr3 )
```

1. *expr1* is an integer representing the month (from 1 to 12).
2. *expr2* is an integer representing the day (from 1 to 28, 29, 30 or 31 depending on the month).
3. *expr3* is an integer representing the year (four digits).

Usage

The `MDY()` operator builds a date value with 3 integers representing the month, day and year.

The result is a `DATE` value.

This function is sensitive to the `C1` modifier of the DBDATE environment variable, defining a Ming Guo date format.

Example

```
MAIN
  DISPLAY MDY ( 12, 3+2, 1998 )
END MAIN
```

UNITS

The `UNITS` operator converts an integer to an interval.

Syntax

```
expr UNITS qual[(scale)]
```

where *qual* can be one of:

```
  YEAR
  MONTH
  DAY
  HOUR
  MINUTE
  SECOND
  FRACTION(1-6)
```

1. *expr* is an integer expression.

Usage

The `UNITS` operator converts an integer expression to an `INTERVAL` value expressed in a single unit of time that you specify after the `UNITS` keyword.

For the qualifiers YEAR, MONTH, DAY, HOUR and SECOND, if the left-hand expression evaluates to a decimal number, any fractional part is discarded before the UNITS operator is applied. However, when using UNITS FRACTION, the expression can be a decimal number where the integer part is interpreted as a number of seconds, and the decimal part as the fraction of a second.

UNITS has a higher precedence than any arithmetic or boolean operator. As a result, a left-hand arithmetic expression that uses a UNITS operator must be enclosed in parentheses. For example, `10 + 20 UNITS MINUTES` will be evaluated as `10 + (20 UNITS MINUTES)` and give a conversion error. It must be written `(10 + 20) UNITS MINUTES` to get the expected result.

Because the difference between two DATE values is an integer count of days rather than an INTERVAL data type, you might want to use the UNITS operator to convert such differences explicitly to INTERVAL values.

Example

```
MAIN
  DEFINE d DATE
  LET d = TODAY + 200
  DISPLAY (d - TODAY) UNITS DAY
END MAIN
```

Dialog handling operators

Dialog handling operators allow you to handle variables in a DIALOG statement.

Table 120: Dialog handling operators

Operator	Description
GET_FLDBUF() on page 265	The GET_FLDBUF( ) operator returns as character strings the current values of the specified fields.
INFIELD() on page 266	The INFIELD( ) operator checks for the current screen field.
FIELD_TOUCHED() on page 266	The FIELD_TOUCHED( ) operator checks if fields were modified during the dialog execution.

GET_FLDBUF()

The GET_FLDBUF( ) operator returns as character strings the current values of the specified fields.

Syntax

```
GET_FLDBUF ( [group.]field  [,...] )
```

1. *group* can be a table name, a screen record, a screen array or FORMONLY.
2. *field* is the name of the screen field.

Usage

The GET_FLDBUF( ) operator is used to get the value of a screen field before the input buffer is copied into the associated variable.

> **Note:** This operator should only be used in dialogs allowing field input (INPUT, INPUT ARRAY, CONSTRUCT). The behavior is undefined when used in DISPLAY ARRAY.

The GET_FLDBUF( ) operator takes the field names as identifiers, not as string expressions:

```
LET v = GET_FLDBUF( customer.custname )
```

If multiple fields are specified between parentheses, use the RETURNING clause:

```
CALL GET_FLDBUF( customer.* ) RETURNING rec_customer.*
```

When used in a INPUT ARRAY instruction, the runtime system assumes that you are referring to the current row.

The values returned by this operator are context dependent; it must be used carefully. If possible, use the variable associated to the input field instead.

When using the UNBUFFERED mode, program variables are automatically assigned, and the GET_FLDBUF operator is not required in most cases.

Example

```
INPUT BY NAME ...
   ...
   ON KEY(CONTROL-Z)
      LET v = GET_FLDBUF( customer.custname )
      IF check_synonyms(v) THEN
         ...
```

INFIELD()

The INFIELD( ) operator checks for the current screen field.

Syntax

```
INFIELD ( [group.]field )
```

1. *group* can be a table name, a screen record, a screen array or FORMONLY.
2. *field* is the name of the field in the form.

Usage

INFIELD checks for the current field in a CONSTRUCT, INPUT or INPUT ARRAY dialog.

When used in an INPUT ARRAY instruction, the runtime system assumes that you are referring to the current row.

For a generic coding equivalent, use the DIALOG.getCurrentItem( ) method.

Example

```
INPUT ...
  IF INFIELD( customer.custname ) THEN
     MESSAGE "The current field is customer's name."
  ...
```

FIELD_TOUCHED()

The FIELD_TOUCHED( ) operator checks if fields were modified during the dialog execution.

Syntax

```
FIELD_TOUCHED (
```

```
{ [group.]field.*
| group.*
| *
} [,...] )
```

1. *group* can be a table name, a screen record, a screen array or `FORMONLY`.
2. *field* is the name of the field in the form.

Usage

`FIELD_TOUCHED` returns `TRUE` if the value of a screen field (or multiple fields) has changed since the beginning of the interactive instruction.

The operator accepts a list of explicit field names, and supports the [*group*.]* notation in order to check multiple fields in a single evaluation. When passing a simple asterisk (*) to the operator, the runtime system will check all fields used by the current dialog.

When used in an `INPUT ARRAY` instruction, the runtime system assumes that you are referring to the current row.

The `FIELD_TOUCHED` operator can only be used inside an `INPUT`, `INPUT ARRAY` and `CONSTRUCT` interaction block.

For more details about the `FIELD_TOUCHED` operator usage and the understand the "touched flag" concept, refer to the definition of the `DIALOG` instruction.

Do not confuse the `FIELD_TOUCHED` operator with`FGL_BUFFERTOUCHED` built-in function; which checks a different field modification flag, that is reset when entering the field. The global touched flag controlled by `FIELD_TOUCHED` is reset when the dialog starts or when `DIALOG.setFieldTouched()` is used.

Example

```
INPUT ...
  ...
  AFTER FIELD custname
    IF FIELD_TOUCHED( customer.custname ) THEN
       MESSAGE "Customer name was changed."
    END IF
  ...
  AFTER INPUT
    IF FIELD_TOUCHED( customer.* ) THEN
       MESSAGE "Customer record was changed."
    END IF
  ...
```

Flow control

Definition of language elements and instructions that control the flow of a program.

- CALL on page 268
- RETURN on page 270
- CASE on page 270
- CONTINUE block-name on page 272
- EXIT block-name on page 273
- FOR on page 274
- GOTO on page 275
- IF on page 276
- LABEL on page 276

- SLEEP on page 277
- WHILE on page 277

CALL

The CALL instruction invokes a specified function or method.

Syntax

```
CALL [ prefix. ] function ( [ parameter  [,...] ] )
      [ RETURNING variable  [,...] ]
```

1. *prefix* can be an imported module, an imported C-Extension module, a built-in class, a variable referencing an object of a built-in class, a Java™ class, a variable referencing a Java™ object.
2. *function* can a function defined in one of the modules of the program, a function defined in one of the modules of the program, a C function defined in a C extension module, a built-in function of the language, a built-in class or object method of the language or a Java™ class or object method of an imported Java™ class.
3. *parameter* can be any valid expression, including object references of built-in classes or Java™ classes.
4. *variable* is a variable receiving a value returned by the function.

Usage

The CALL instruction invokes the function or class/object method specified and passes the program flow control to that function/method. After the called function was executed, the flow control goes back to the caller, the runtime system executing the next statement that appears after the CALL instruction.

Function arguments can be any expression supported by the language. Use a double-pipe operator || to pass the concatenation of character string expressions as a parameter.

```
CALL my_function( TODAY, 20*0.5435, 'abc'||'def'||var1 )
```

The RETURNING clause assigns values returned by the function to variables in the calling routine. The RETURNING clause is only needed when the function returns parameters.

```
MAIN
  DEFINE var1 CHAR(15)
  DEFINE var2 CHAR(15)
  CALL foo() RETURNING var1, var2
  DISPLAY var1, var2
END MAIN

FUNCTION foo()
  DEFINE r1 CHAR(15)
  DEFINE r2 CHAR(15)
  LET r1 = "return value 1"
  LET r2 = "return value 2"
  RETURN r1, r2
END FUNCTION
```

If the function returns a unique parameter, the function can be used in an expression and can be directly assigned to a variable with `LET var = function(...)` statement.

```
MAIN
  DEFINE var1 CHAR(10)
  DEFINE var2 CHAR(2)
  LET var1 = foo()
  DISPLAY "var1 = " || var1
  CALL foo() RETURNING var2
```

```
  DISPLAY "var2 = " || var2
END MAIN

FUNCTION foo()
  RETURN "Hello"
END FUNCTION
```

The value of a receiving variable may be different from the value returned by the function, following the data conversion rules.

```
MAIN
  DEFINE s STRING
  LET s = div(10,2)
END MAIN

FUNCTION div(x,y)
  DEFINE x,y INTEGER
  RETURN x / y
END FUNCTION
```

Records can be passed to and returned from functions, but the record structure must be flat and each member is passed or returned individually by value. Records are not passed by reference.

```
MAIN
  DEFINE r RECORD
             x INT,
             y INT,
             z INT
           END RECORD
  CALL foo(r.*) RETURNING r.*
  DISPLAY r.*
END MAIN

FUNCTION foo(x,y,z)
  DEFINE x,y,z INT
  RETURN z,y,x
END FUNCTION
```

If the `IMPORT FGL` instruction was used to import a module, *function* can be prefixed with the name of the module followed by a dot (i.e. *module.function)*. The module prefix is required to fully-qualify the function in case of conflicts (i.e. when functions with the same name are defined in several modules).

```
-- main.4gl
IMPORT FGL module1
IMPORT FGL module2
MAIN
  CALL module1.show("aaa")
  CALL module2.show("aaa")
END MAIN
```

```
-- module1.4gl
FUNCTION show(s)
  DEFINE s STRING
  DISPLAY s
END FUNCTION
```

```
-- module2.4gl
FUNCTION show(s)
  DEFINE s STRING
  DISPLAY s
```

```
END FUNCTION
```

RETURN

The RETURN instruction returns flow control to the function caller.

Syntax

```
RETURN [ value [,...]  ]
```

1. *value* can be any valid expression, an object reference or dynamic array reference.

Usage

The RETURN instruction transfers the control back from a function with optional return values.

Record members can be returned with the .* or THRU notation. Each member is returned as an independent variable.

A function may have several RETURN points (not recommended in structured programming) but they must all return the same number of values.

The number of returned values must correspond to the number of variables listed in the RETURNING clause of the CALL statement invoking this function.

A function cannot return a static array, but can return the reference of a dynamic array.

Example

```
MAIN
  DEFINE fname, lname VARCHAR(30)
  CALL foo(NULL) RETURNING fname, lname
  DISPLAY fname CLIPPED, " ", upshift(lname) CLIPPED
  CALL foo(1) RETURNING forname, surname
  DISPLAY fname CLIPPED, " ", upshift(lname) CLIPPED
END MAIN

FUNCTION foo(code)
  DEFINE code INTEGER
  DEFINE person RECORD
                  fname VARCHAR(30),
                  lname VARCHAR(30)
                END RECORD
  IF code IS NULL THEN
     RETURN NULL, NULL
  ELSE
     LET person.fname = "John"
     LET person.lname = "Smith"
     RETURN person.*
  END IF
END FUNCTION
```

CASE

The CASE instruction specifies statement blocks that must be executed conditionally.

Syntax 1

```
CASE expression-1
  WHEN expression-2
```

```
    { statement | EXIT CASE }
    [...]
  [ OTHERWISE
    { statement | EXIT CASE }
    [...]
  ]
END CASE
```

Syntax 2

```
CASE
  WHEN boolean-expression
    { statement | EXIT CASE }
    [...]
  [ OTHERWISE
    { statement | EXIT CASE }
    [...]
  ]
END CASE
```

1. *expression-1* is any expression supported by the language.
2. *expression-2* is an expression that is tested against *expression-1*.
3. *expression-1* and *expression-2* should have the same data type.
4. *boolean-expression* is any boolean expression supported by the language.
5. *statement* is any instruction supported by the language.

Usage

In a `CASE` flow control block, the first matching `WHEN` block is executed. If there is no matching `WHEN` block, then the `OTHERWISE` block is executed. If there is no matching `WHEN` block and no `OTHERWISE` block, the program execution continues with the next statement following the `END CASE` keyword.

The `EXIT CASE` statement transfers the program control to the statement following the `END CASE` keyword. There is an implicit `EXIT CASE` statement at the end of each `WHEN` block and at the end of the `OTHERWISE` block. The `OTHERWISE` block must be the last block of the `CASE` instruction.

A null expression is considered as false: When doing a `CASE expr ... WHEN [NOT] NULL` using the syntax 1, it always evaluates to `FALSE`. Use syntax 2 as `CASE ... WHEN expr IS NULL` to test if an expression is null.

Make sure that *expression-2* is not a boolean expression when using the first syntax. The compiler will not raise an error in this case, but you might get unexpected results at runtime.

If there is more than one *expression-2* matching *expression-1* (syntax 1), or if two boolean expressions (syntax 2) are true, only the first matching `WHEN` block will be executed.

Example

```
MAIN
   DEFINE v CHAR(10)
   LET v = "C1"
   -- CASE Syntax 1
   CASE v
     WHEN "C1"
       DISPLAY "Value is C1"
     WHEN "C2"
       DISPLAY "Value is C2"
     WHEN "C3"
       DISPLAY "Value is C3"
     OTHERWISE
```

```
        DISPLAY "Unexpected value"
    END CASE
    -- CASE Syntax 2
    CASE
      WHEN ( v="C1" OR v="C2" )
        DISPLAY "Value is either C1 or C2"
      WHEN ( v="C3" OR v="C4" )
        DISPLAY "Value is either C3 or C4"
      OTHERWISE
        DISPLAY "Unexpected value"
    END CASE
END MAIN
```

CONTINUE *block-name*

The `CONTINUE` *`block-name`* instruction resumes execution of a loop or dialog statement.

Syntax

```
CONTINUE
 { FOR
 | FOREACH
 | WHILE
 | MENU
 | CONSTRUCT
 | INPUT
 | DIALOG
 }
```

Usage

The `CONTINUE` *`block-name`* instruction transfers the program execution from a statement block to another location in the compound statement that is currently being executed.

`CONTINUE` *`block-name`* can only be used within the statement block specified by *block-name*. For example, `CONTINUE FOR` can only be used within a `FOR ... END FOR` statement block.

The `CONTINUE FOR`, `CONTINUE FOREACH`, or `CONTINUE WHILE` keywords cause the current `FOR`, `FOREACH`, or `WHILE` loop (respectively) to begin a new cycle immediately. If conditions do not permit a new cycle, however, the looping statement terminates.

The `CONTINUE CONSTRUCT`, `CONTINUE INPUT` and `CONTINUE DIALOG` statements cause the program to skip all subsequent statements in the current control block. The screen cursor returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field.

The `CONTINUE MENU` statement causes the program to ignore the remaining statements in the current `MENU` control block and re-display the menu. The user can then choose another menu option.

`CONTINUE INPUT` is valid in `INPUT` and `INPUT ARRAY` statements.

Example

```
MAIN
  DEFINE i INTEGER
  LET i = 0
  WHILE i < 5
    LET i = i + 1
    DISPLAY "i=" || i
    CONTINUE WHILE
    DISPLAY "This will never be displayed!"
  END WHILE
```

```
END MAIN
```

EXIT *block-name*

The EXIT *block* instruction transfers control out of the current program block.

Syntax

```
EXIT
 { CASE
 | FOR
 | FOREACH
 | WHILE
 | MENU
 | CONSTRUCT
 | REPORT
 | DISPLAY
 | INPUT
 | DIALOG }
```

Usage

The EXIT *block-name* instruction transfers control out of a control structure (a block, a loop, a CASE statement, or an interface instruction).

The EXIT *block-name* instruction must be used inside the control structure specified by *block-name*. For example, EXIT FOR can only appear inside a FOR ... END FOR iteration block.

EXIT DISPLAY exits the DISPLAY ARRAY instruction and EXIT INPUT exits an INPUT or an INPUT ARRAY block.

EXIT CONSTRUCT exits current CONSTRUCT block.

EXIT DIALOG exits current DIALOG block.

To exit a function, use the RETURN instruction. To terminate a program, use the EXIT PROGRAM instruction.

Example

```
MAIN
  DEFINE i INTEGER
  LET i = 0
  WHILE TRUE
    DISPLAY "This is an infinite loop. How would you get out of
 here?"
    LET i = i + 1
    IF i = 100 THEN
       EXIT WHILE
    END IF
  END WHILE
  DISPLAY "Done."
END MAIN
```

FOR

The FOR instruction executes a statement block a specified number of times.

Syntax

```
FOR counter = start TO finish [ STEP value ]
   { statement
   | EXIT FOR
   | CONTINUE FOR }
   [...]
END FOR
```

1. *counter* is the loop counter and must be an integer variable.
2. *start* is an integer expression used to set an initial counter value.
3. *finish* is any valid integer expression used to specify an upper limit for *counter*.
4. *value* is any valid integer expression whose value is added to *counter* after each iteration of the statement block.
5. When the STEP keyword is not given, *counter* increments by 1.
6. *statement* is any instruction supported by the language.
7. If *value* is less than 0, *counter* is decreased. In this case, *start* should be higher than *finish*.

Usage

The FOR instruction block executes the statements up to the END FOR keyword a specified number of times, or until EXIT FOR terminates the FOR statement. The CONTINUE FOR instruction skips the next statements and continues with the next iteration.

On the first iteration through the loop, the counter is set to the initial expression at the left of the TO keyword. For all further iterations, the value of the increment expression in the STEP clause specification (1 by default) is added to the counter in each pass through the block of statements. When the sign of the difference between the values of counter and the finish expression at the right of the TO keyword changes, the runtime system exits from the FOR loop.

The FOR loop terminates after the iteration for which the left- and right-hand expressions are equal. Execution resumes at the statement following the END FOR keywords. If either expression returns NULL, the loop cannot terminate, because the boolean expression "left = right" cannot become TRUE.

A *value* that equals 0 causes an unending loop unless there is an adequate EXIT FOR statement.

Using NULL for *start*, *finish* or *value* is treated as 0. There is no way to catch this as an error.

If *statement* modifies the value of *counter*, you might get unexpected results at runtime. In this case, it is recommended that you use a WHILE loop instead.

It is highly recommended that you ensure that *statement* does not modify the values of *start*, *finish* or *value*.

Example

```
MAIN
  DEFINE i, i_min, i_max INTEGER
  LET i_min = 1
  LET i_max = 10
  DISPLAY "Count from " || i_min || " to " || i_max
  DISPLAY "Counting forwards..."
  FOR i = i_min TO i_max
      DISPLAY i
  END FOR
  DISPLAY "... and backwards."
  FOR i = i_max TO i_min STEP -1
```

```
      DISPLAY i
  END FOR
END MAIN
```

GOTO

The `GOTO` instruction transfers program control to a labeled line within the same program block.

Syntax

```
GOTO [:] label-id
```

1. *label-id* is the name of the `LABEL` statement to jump to.

Usage

A `GOTO` statement continues program execution in the line following the `LABEL` instruction using the *label-id* identifier specified in the `GOTO` instruction.

The `LABEL` jump point can be defined before or after the `GOTO` statement.

The `LABEL` and `GOTO` statements must use the *label-id* within a single `MAIN`, `FUNCTION`, or `REPORT` program block.

The `:` colon after the `GOTO` keyword is optional.

`GOTO` statements can reduce the readability of your program source and result in infinite loops. It is recommended that you use `FOR`, `WHILE`and `CASE` statements instead.

The `GOTO` statement can be used in a `WHENEVER` statement to handle exceptions.

Example

```
MAIN
  DEFINE exit_code INTEGER
  DEFINE l_status INTEGER

  WHENEVER ANY ERROR GOTO _error
  DISPLAY 1/0
  GOTO _noerror

LABEL _error:
  LET l_status = STATUS
  DISPLAY "The error number ", l_status, " has occurred."
  DISPLAY "Description: ", err_get(l_status)
  LET exit_code = -1
  GOTO _exit

LABEL _noerror:
  LET exit_code = 0
  GOTO _exit

LABEL _exit:
  EXIT PROGRAM exit_code

END MAIN
```

IF

The IF instruction executes a group of statements conditionally.

Syntax

```
IF condition THEN
   statement
   [...]
[ ELSE
   statement
   [...]
]
END IF
```

1. *condition* is a boolean expression.
2. *statement* is any instruction supported by the language.

Usage

If *condition* is TRUE, the runtime system executes the block of statements following the THEN keyword, until it reaches either the ELSE keyword or the END IF keywords and resumes execution after the END IF keywords.

If *condition* is FALSE, the runtime system executes the block of statements between the ELSE keyword and the END IF keywords. If ELSE is absent, it resumes execution after the END IF keywords.

By default, the runtime system evaluates all part of the condition. The semantics of boolean expressions can be controlled by the OPTIONS SHORT CIRCUIT compiler directive, to reduce expression evaluation when using AND / OR operators.

A NULL expression is considered as FALSE. Use the IS NULL keyword to test if an expression is null.

Example

```
MAIN
  DEFINE name CHAR(20)
  LET name = "John Smith"
  IF name MATCHES "John*" THEN
    DISPLAY "The name starts with [John]!"
  ELSE
    DISPLAY "The name is " || name || "."
  END IF
END MAIN
```

LABEL

The LABEL instruction declares a jump point that can be reached by a GOTO.

Syntax

```
LABEL label-id:
```

1. *label-id* is a unique identifier in a MAIN, REPORT, or FUNCTION program block.
2. The *label-id* must be followed by a colon (:).

Usage

The LABEL instruction declares a statement label, making the next statement one to which a GOTO statement can transfer program control.

Example

```
MAIN
  DISPLAY "Line 2"
  GOTO line5
  DISPLAY "Line 4"
  LABEL line5:
  DISPLAY "Line 6"
END MAIN
```

SLEEP

The SLEEP instruction causes the program to pause for the specified number of seconds.

Syntax

```
SLEEP seconds
```

1. *seconds* must be an integer expression.

Usage

The SLEEP instruction is typically invoked to let the end user read a message displayed on a character terminal.

With graphical applications, the SLEEP command is seldom used.

When *seconds* is lower than zero or is null, the program continues immediately with the next statement.

Example

```
MAIN
  DISPLAY "Please wait 5 seconds..."
  SLEEP 5
  DISPLAY "Thank you."
END MAIN
```

WHILE

The WHILE statement executes a block of statements until the specified condition becomes false.

Syntax

```
WHILE condition
    { statement | EXIT WHILE | CONTINUE WHILE }
   [...]
END WHILE
```

1. *condition* must be a boolean expression.
2. *statement* is any instruction supported by the language.

Usage

As long as the *condition* specified after a `WHILE` keyword is `TRUE`, all statements inside the `WHILE ... END WHILE` block are executed. After executing the last statement of the block, the runtime system again evaluates the condition, and if it is still `TRUE`, continues with the first statement in the block.

The loop stops when the condition becomes `FALSE` or when an `EXIT WHILE` is reached.

Use the `CONTINUE WHILE` instruction to skip the next statements and continue with the loop.

To avoid unending loops, make sure that the condition will become `FALSE` at some point, or that an `EXIT WHILE` statement will be executed.

Example

```
MAIN
  DEFINE cnt INTEGER
  LET cnt = 1
  WHILE cnt <= 100
    DISPLAY "Iter: " || cnt
    LET cnt = cnt + 1
    IF int_flag THEN
      EXIT WHILE
    END IF
  END WHILE
END MAIN
```

Functions

Describes the basics of user defined functions in the language.

- Understanding functions on page 278
- FUNCTION blocks on page 278
- Using functions in programs on page 279
- Examples on page 280

Understanding functions

Functions are named program blocks containing a set of statements to be executed when the function is invoked with a `CALL` statement, or when the function is used in an expression, or when the function is registered in a callback mechanism like `WHENEVER ERROR CALL`.

A functions is defined in a program module, and is by default visible to all modules (i.e. a function is global by default), but it can also be declared as private to the module where it is defined.

FUNCTION blocks

A `FUNCTION` block defines a named procedure with a set of statements.

Syntax

```
[PUBLIC|PRIVATE] FUNCTION function-name ( [ argument [,...]] )
    [ declaration [...] ]
    [ statement [...] ]
    [ return-clause ]
END FUNCTION
```

where *return-clause* is:

```
RETURN expression [,...]
```

1. *function-name* is the function identifier.
2. *argument* is the name of a formal argument of the function.
3. *declaration* is a `DEFINE`, `CONSTANT` or `TYPE` instruction.
4. *statement* is any instruction supported by the language.

Using functions in programs

The `FUNCTION` block defines the body and the signature (i.e. declaration) of a function. The function declaration specifies the name of the function and the identifiers of its formal arguments (if any).

Function names, like other identifiers are case-insensitive. If the function name is also the name of a built-in function, an error occurs at link time, even if the program does not reference the built-in function.

A `FUNCTION` block cannot appear within the `MAIN` block, in a `REPORT` block, or within another `FUNCTION` block.

A function can be invoked with the `CALL` statement, it can be used in an expression when returning a unique value, or it can be invoked automatically when registered by a callback mechanism like `WHENEVER ERROR CALL`.

If no argument is needed in a function call, an empty argument list must still be supplied, enclosed between the parentheses.

By default, functions are public; They can be called by any other module of the program. If a function is only used by the current module, you may want to hide that function to other modules, to make sure that it will not be called by mistake. To keep a function local to the module, add the `PRIVATE` keyword before the function header. Private functions are only hidden to external modules, all function of the current module can still call local private functions.

```
PRIVATE FUNCTION check_number(n)
  ...
END FUNCTION
```

The data type of each formal argument of the function must be specified by a `DEFINE` statement that immediately follows the argument list. The actual argument in a call to the function need not be of the declared data type of the formal argument. If data type conversion is not possible, a runtime error occurs.

```
FUNCTION check_address(zipcode, street, city)
  DEFINE zipcode CHAR(5),
         street VARCHAR(100),
         city VARCHAR(50)
  ...
END FUNCTION
```

Function arguments are passed by value (i.e. value is copied on the stack) for basic data types and records, while dynamic arrays and objects are passed by reference (i.e. a handle to the original data is copied on the stack and thus allows modification of the original data inside the function).

```
-- The following code is useless:
-- Variable x will not be modified by the function
MAIN
  DEFINE x INTEGER
  LET x = 123
  CALL increment(x)
  DISPLAY x   -- displays 123
END MAIN
```

```
FUNCTION increment(x)
  DEFINE x INTEGER
  LET x = x + 1
END FUNCTION
```

Local variables are not visible in other program blocks. The identifiers of local variables must be unique among the variables that are declared in the same `FUNCTION` definition. Any global or module variable that has the same identifier as a local variable, however, is not visible within the scope of the local variable.

```
DEFINE x INTEGER   -- Declares a module variable

FUNCTION func_a()
  DEFINE x INTEGER -- Declares a local variable
  LET x = 123      -- Assigns local variable
END FUNCTION

FUNCTION func_b()
  LET x = 123     -- Changes the module variable
END FUNCTION
```

A function that returns one or more values to the calling routine must include the *return-statement* . Values specified in `RETURN` must correspond in number and position, and must be of the same or of compatible data types , to the variables in the `RETURNING` clause of the `CALL` statement. If the function returns a single value, it can be invoked as an operand within a expression. Otherwise, you must invoke it with the `CALL` statement with a `RETURNING` clause. An error results if the list of returned values in the `RETURN` statement conflicts in number or in data type with the `RETURNING` clause of the `CALL` statement that invokes the function.

```
MAIN
  DEFINE zipcode CHAR(5),
         street VARCHAR(100),
         city VARCHAR(50)
  CALL get_address() RETURNING zipcode, street, city
END MAIN

FUNCTION get_address()
   ...
   RETURN "23500", "461 Ocean blvd", "Kreistone"
END FUNCTION
```

A function can invoke itself recursively with a `CALL` statement. This will result in a recursive call.

Examples

Example 1: Function fetching customer number

```
FUNCTION findCustomerNumber(name)
  DEFINE name VARCHAR(50)
  DEFINE num INTEGER
  CONSTANT sqltxt = "SELECT cust_num FROM customer WHERE cust_name = ?"
  PREPARE stmt FROM sqltxt
  EXECUTE stmt INTO num USING name
  IF SQLCA.SQLCODE = 100 THEN
     LET num = -1
  END IF
  RETURN num
END FUNCTION
```

Example 2: Private function definition

This function will not be visible to other modules:

```
PRIVATE FUNCTION checkIdentifier(name)
  DEFINE name VARCHAR(50)
  IF length(name) == 0 THEN
    RETURN FALSE
  ELSE
    RETURN TRUE
  END IF
END FUNCTION
```

Variables

Explains how to define program variables.

- Understanding variables on page 281
- DEFINE on page 281

- FREE (for TEXT/BYTE) on page 287
- LET on page 288
- VALIDATE on page 288
- THRU operator on page 289
- Examples on page 290

Understanding variables

A variable is a program element that can hold volatile data. The following list summarizes variables usage:

- Variables are declared in programs with the `DEFINE` instruction.
- After definition, variables get default values according their type.
- The scope of a variable can be global, local to a module, or local to a function.
- When defined at the module level, a variable can be declare it as `PRIVATE` or `PUBLIC`.
- You can define structured variables with records, and with arrays.
- Default values (or NULL) can be assigned with the `INITIALIZE` instruction.
- Direct value assignment is done with the `LET` instruction.
- Database validation rules can be applied with the `VALIDATE` instruction.
- Variables can be used as SQL parameters or fetch buffers in SQL statements.
- Interactive instructions use program variables as model to hold the data.

DEFINE

A variable contains volatile information of a specific data type.

Syntax

```
[PUBLIC|PRIVATE] DEFINE variable-definition [,...]
```

where *variable-definition* is:

```
identifier [,...]
   {
     datatype
   |
     LIKE [dbname:]tabname.colname
   }
   [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
```

1. *identifier* is the name of the variable to be defined.
2. *datatype* can be a data type, a record definition, an array definition, a user defined type, a built-in class, an imported package class, or a Java™ class.
3. *dbname* identifies a specific database schema file.
4. *tabname.colname* can be any column reference defined in the database schema file.
5. *attribute* is an attribute to extend the variable definition with properties.
6. *value* is the value for the variable attribute, it is optional for boolean attributes.

Usage

A *variable* is a named location in memory that can store a single value, or an ordered set of values. Variables can be global to the program, module-specific, or local to a function.

You cannot reference any program variable before it has been declared by the `DEFINE` statement.

By default, module-specific variables are private; They cannot be used by an other module of the program. In order to improve code re-usability by data encapsulation, we recommend you to keep module variables private, except if you want to share large data (like arrays) between modules. To make a module variable public, add the `PUBLIC` keyword before `DEFINE`. When a module variable is declared as public, it can be referenced by another module by using the `IMPORT` instruction.

When defining variables with the `LIKE` clause, the data types are taken from the database schema file at compile time. Make sure that the schema file of the database schema during development corresponds to the database schema of the production database; otherwise the variables defined in the compiled version of your modules will not match the table structures of the production database.

To write well-structured programs, avoid global variables. If you need persistent data storage during a program's execution, use variables local to the module and give access to them with functions, or make the module variables `PUBLIC` to other modules.

Variables can be defined with the `ATTRIBUTES()` clause, to specify meta-data information for the variable. This feature is especially used when defining variables for XML-based Web Services. For more details about XML attributes, see Attributes to customize XML serialization on page 2517.

Declaration context

The `DEFINE` statement declares the identifier of one or more variables, that will be visible to other program blocks according to the declaration context of the variables. The scope of reference of a variable defines where it can be referenced in the program. According to the location of the variable definition, memory will be allocated when the program starts, or during the program execution.

The context of a variable declaration in the source module determines where a variable can be referenced by other language statements, and when storage is allocated for the variable in memory. The `DEFINE` statement can appear in three contexts:

1. Within a `FUNCTION`, `MAIN`, or `REPORT` program block, `DEFINE` declares local variables, and causes memory to be allocated on the runtime stack when the function is called. These `DEFINE` declarations of local variables must precede any procedural statements within the same program block. The scope of reference of a local variable is restricted to the same program block. The variable is not visible elsewhere. Functions can be called recursively, and each recursive entry creates its own set of local

variables. The variable is unique to that invocation of its program block. Each time the block is entered, a new copy of the variable is created.

2. Outside any `FUNCTION`, `REPORT`, or `MAIN` program block, the `DEFINE` statement declares module variables. Module variables have a persistent state during program execution. Memory for module variables is allocated when the module is loaded. Module variable declarations (`DEFINE`) must appear before any program blocks. By default, the scope of reference is the whole module (module variables are private to the module), but it can be extended to the whole program when the variable is declared with the `PUBLIC` qualifier.
3. Inside a `GLOBALS` block, the `DEFINE` statement declares global variables that are visible to the whole program. Global variables have a persistent state during program execution. Memory for global variables is allocated when the program starts. Multiple `GLOBALS` blocks can be defined for a given module. Use one module to declare all global variables and reference that module within other modules by using the `GLOBALS "`*`filename`*`.4gl"` statement as the first statement in the module, outside any program block.

A compile-time error occurs if you declare the same name for two variables that have the same scope. You can, however, declare the same name for variables that differ in their scope. For example, you can use the same identifier to reference different local variables in different program blocks.

You can also declare the same name for two or more variables whose scopes of reference are different but overlapping. Within their intersection, the compiler interprets the identifier as referencing the variable whose scope is smaller, and therefore the variable whose scope is a superset of the other is not visible.

If a local variable has the same identifier as a global variable, then the local variable takes precedence inside the program block in which it is declared. Elsewhere in the program, the identifier references the global variable.

A module variable can have the same name as a global variable that is declared in a different module. Within the module where the module variable is declared, the module variable takes precedence over the global variable. Statements in that module cannot reference the global variable.

A module variable cannot have the same name as a global variable that is declared in the same module.

If a local variable has the same identifier as a module variable, then the local identifier takes precedence inside the program block in which it is declared. Elsewhere in the same source-code module, the name references the module variable.

If a variable needs to be persistent during program execution, instead of using global variables, consider defining that variable in the module it belongs to, by specifying the `PUBLIC` or `PRIVATE` modifiers, depending on the scope you want to give to your variable, for other modules.

Structured types

Variables can be defined as `RECORD` or `ARRAY` keywords to declare a structured object.

For example:

```
MAIN
  DEFINE myarr ARRAY[100] OF RECORD
     id INTEGER,
     name VARCHAR(100)
  END RECORD
  LET myarr[2].id = 52
END MAIN
```

Database column types

Variable defined with the `LIKE` keyword get the same data type of the column specified column in a database schema.

For example:

```
SCHEMA stores
DEFINE cname LIKE customer.cust_name
MAIN
  DEFINE cr RECORD LIKE customer.*
  ...
END MAIN
```

A SCHEMA statement must define the database name identifying the database schema files to be used.

The column data types are read from the schema file during compilation. Make sure that your schema files correspond exactly to the production database.

The database schema files must exist and must be located in one of the diretories specified in the FGLDBPATH environment variable.

When using database views, the column cannot be based on an aggregate function like SUM().

If LIKE references a SERIAL column, the variable will be defined with the INTEGER data type. If LIKE references an INT8, SERIAL8 or BIGSERIAL column, the variable will be defined with the BIGINT data type.

The table qualifier must specify *owner* if *table.column* is not a unique column identifier within its database, or if the database is ANSI-compliant and any user of your application is not the owner of *table*.

Database schema files must be generated with the fgldbsch tool before compiling the source module using a DEFINE LIKE instruction.

User defined types

Variables can be defined with a user defined type:

```
TYPE custlist DYNAMIC ARRAY OF RECORD LIKE customer.*
MAIN
  DEFINE cl custlist
  ...
END MAIN
```

The scope of a type can be global, local to a module or local to a function. Variables can be defined with a type defined in the same scope, or in a higher level of scope.

Variable initialization values

When a variable is defined, it is automatically initialized by the runtime system to a default value. The default value the variable is assigned with depends on the data type.

Table 121: data type specific default values for variables

data type	Default Value
CHAR	NULL
VARCHAR	NULL
STRING	NULL
INTEGER	Zero
SMALLINT	Zero
FLOAT	Zero
SMALLFLOAT	Zero

data type	Default Value
DECIMAL	NULL
MONEY	NULL
DATE	1899-12-31 (= Zero in number of days)
DATETIME	NULL
INTERVAL	NULL
TEXT	NULL, must use LOCATE
BYTE	NULL, must use LOCATE

INITIALIZE

The INITIALIZE instruction intializes program variables with NULL or default values.

Syntax

```
INITIALIZE target [,...]
  {
     TO NULL
  |
     LIKE {table.*|table.column}
  }
```

1. *target* is the name of the variable to be initialized.
2. *table.column* can be any column reference defined in the database schema files.

Usage

The INITIALIZE instruction assigns NULL or default values to variables.

The argument of the INITIALIZE instruction can be a simple variable, a record (with .* notation), a record member, a range of record members specified with the THRU keyword, an array or an array element.

The TO NULL clause initializes the variable to null.

When initializing a static array TO NULL, all elements will be initialized to null. When initializing a dynamic array TO NULL, all elements will be removed (i.e. the dynamic array is cleared).

The LIKE clause initializes the variable to the default value defined in the database schema validation file. This clause works only by specifying the *table.column* schema entry corresponding to the variable.

To initialize a complete record, you can use the star to reference all members:

```
INITIALIZE record.* LIKE table.*
```

You cannot initialize variables defined with a complex data type (like TEXT or BYTE) to a non-NULL value.

Example

```
SCHEMA stores
MAIN
  DEFINE cr RECORD LIKE customer.*
  DEFINE a1 ARRAY[100] OF INTEGER
  INITIALIZE cr.cust_name TO NULL
  INITIALIZE cr.cust_name THRU cr.cust_address TO NULL
  INITIALIZE cr.* LIKE customer.*
```

```
  INITIALIZE a1 TO NULL
  INITIALIZE a1[10] TO NULL
END MAIN
```

LOCATE (for TEXT/BYTE)

The LOCATE statement specifies where to store data of TEXT and BYTE variables.

Syntax 1: Locate in memory

```
LOCATE target [,...] IN MEMORY
```

Syntax 2: Locate in a specific file

```
LOCATE target [,...] IN FILE filename
```

Syntax 3: Locate in a temporary file

```
LOCATE target [,...] IN FILE
```

1. *target* is the name of a TEXT or BYTE variable to be located.
2. *filename* is a string expression defining the name of a file.

Usage

Before using TEXT and BYTE large objects, the data storage location must be specified with the LOCATE instruction. After defining the data storage, the variable can be used as input parameter or as a fetch buffer in SQL statements, as well as in interaction statements and reports.

The first syntax using the IN MEMORY clause specifies that the large object data must be located in memory.

The second syntax using the IN FILE *filename* clause specifies that the large object data must be located in a specific file.

The third syntax using the IN FILE clause specifies that the large object data must be located in a temporary file. The location of the temporary file can be defined with the DBTEMP environment variable. If DBTEMP is not defined, the default temporary directory dependents from the platform used.

The FREE instruction can be used to free the resources allocated to the large object variable.

Example

The following code example defines two TEXT variables. The first located in memory and the second located in a named file. The variables are then used in SQL statements:

```
MAIN
  DEFINE ctext1, ctext2 TEXT
  DATABASE stock
  LOCATE ctext1 IN MEMORY
  LOCATE ctext2 IN FILE "/tmp/data1.txt"
  CREATE TABLE lobtab ( key INTEGER, col1 TEXT, col2 TEXT )
  INSERT INTO lobtab VALUES ( 123, ctext1, ctext2 )
END MAIN
```

The next code example illustrates the storage semantics of BYTE and TEXT, by fetching large objects from the database into an array. Each member of the array needs to get an individual storage location, before the data is actually fetched into the LOB handler of the

array element. By using `LOCATE IN FILE`, a temporary file will be created for each large object:

```
MAIN
    DEFINE arr DYNAMIC ARRAY OF RECORD
                  id INTEGER,
                  cmt TEXT
               END RECORD,
           t TEXT, i INTEGER

    DATABASE test1

    LOCATE t IN MEMORY
    CREATE TEMP TABLE tt1 ( id INTEGER, cmt TEXT )
    LET t = "aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
    INSERT INTO tt1 VALUES ( 1, t )
    LET t = "bbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb"
    INSERT INTO tt1 VALUES ( 2, t )

    DECLARE c1 CURSOR FOR SELECT * FROM tt1
    LET i=1
    LOCATE arr[i].cmt IN FILE
    FOREACH c1 INTO arr[i].*
        LOCATE arr[i:=i+1].cmt IN FILE
    END FOREACH
    CALL arr.deleteElement(i)

    FOR i=1 TO arr.getLength()
        DISPLAY arr[i].*
    END FOR

END MAIN
```

FREE (for TEXT/BYTE)

The `FREE` statement releases resources allocated to the specified variable.

Syntax

```
FREE target
```

1. *target* is the name of a `TEXT` or `BYTE` variable to be freed.

Usage

When followed by a variable name, the `FREE` statement releases resources allocated to store the data of `TEXT` and `BYTE` variables.

If the `TEXT`/`BYTE` variable was located in memory, the runtime system releases the memory. If the variable was located in a file, the runtime system deletes the file.

For variables declared in a local scope of reference, the resources are automatically freed by the runtime system when returning from the function or `MAIN` block.

After freeing a `TEXT` or `BYTE` variable, it must be re-configured with a new `LOCATE` call.

Temporary files of large object are automatically deleted when the program ends.

Example

```
MAIN
```

```
  DEFINE ctext TEXT
  DATABASE stock
  LOCATE ctext IN FILE "/tmp/data1.txt"
  SELECT col1 INTO ctext FROM lobtab WHERE key=123
  FREE ctext
END MAIN
```

LET

The LET statement assigns values to variables.

Syntax

```
LET target = expr [,...]
```

1. *target* is the name of the variable to be assigned.
2. *expr* is any valid expression supported by the language.

Usage

The LET statement assigns a value to a variable, or a set of values to all members of a RECORD by using the .* notation.

The runtime system applies data type conversion rules if the data type of *expression* does not correspond to the data type of *target*.

When assigning a numeric of date/time value to a character string variable, the values are formatted for display (for example, the numeric data is right-aligned).

When specifying a comma-separated list of expressions for the right operand, the LET statement concatenates all expressions together. Unlike the || operator, if an expression in the comma-separated list evaluates to NULL, the concatenation result will not be null, except if all expressions to the right of the equal sign are null.

The target variable can be record followed by dot + star (record.*), to reference all record members of the record. In this case, the right operand must also be a record using this notation, and all members will be assigned individually.

Variables defined with a complex data type (like TEXT or BYTE) can only be assigned to NULL.

Example

```
SCHEMA stores
MAIN
  DEFINE c1, c2 RECORD LIKE customer.*
  -- Single variable assignment
  LET c1.customer_num = 123
  -- Complete RECORD assignment
  LET c1.* = c2.*
END MAIN
```

VALIDATE

The VALIDATE instructions checks a variable value according to schema validation rules.

Syntax

```
VALIDATE target [,...] LIKE
```

```
{
   table.*
|
   table.column
}
```

1. *target* is the name of the variable to be validated.
2. If *target* is a record, you can use the star notation to validate all members in the record.
3. *table.column* can be any column reference defined in the database schema.

Usage

The VALIDATE statement tests whether the value of the specified variable is within the range of values for a corresponding column in .val database schema file referenced by a SCHEMA clause. If the value does not match any value defined in the INCLUDE attribute of the corresponding column, the runtime system raises error -1321.

The argument of the VALIDATE instruction can be a simple variable, a record, or an array element. If the target is a record, you can use the dot + star notation to reference all record members in the validation, or specify a range of record members with the THRU clause.

Example

```
SCHEMA stores
MAIN
  DEFINE cname LIKE customer.cust_name
  LET cname = "aaa"
  VALIDATE cname LIKE customer.cust_name
END MAIN
```

THRU operator

The THRU keyword can be used to specify a range of members of a record.

Syntax

```
record.first-member [ THRU | THROUGH ] record.last-member
```

1. *record* defines the record to be used.
2. *first-member* defines the member of the record starting the group of variables.
3. *last-member* defines the member of the record ending the group of variables.
4. THROUGH is a synonym for THRU.

Usage

The THRU keyword can be used in several instructions such as INITIALIZE, VALIDATE, LOCATE, to specify a list of record members.

Example

```
SCHEMA stores
MAIN
  DEFINE cust LIKE customer.*
  INITIALIZE cust.cust_name THRU customer.cust_address TO NULL
END MAIN
```

Examples

Example 1: Local function variables

```
FUNCTION myfunc()
  DEFINE i INTEGER
  FOR i=1 TO 10
      DISPLAY i
  END FOR
END FUNCTION
```

Example 2: PRIVATE module variables

```
PRIVATE DEFINE s VARCHAR(100)

FUNCTION myfunc()
  DEFINE i INTEGER
  FOR i=1 TO 10
      LET s = "item #" || i
  END FOR
END FUNCTION
```

Example 3: PUBLIC module variables

This example declares public and private module variables. Public variables can be shared with other modules.

File "mydebug.4gl":

```
PUBLIC DEFINE level INTEGER,
              logfile STRING
PRIVATE DEFINE count INTEGER

FUNCTION message(m)
  DEFINE m STRING
  IF level THEN
     -- Write message to debug_logfile
     DISPLAY m
  END IF
  LET count = count + 1
END FUNCTION
```

File "mymain.4gl":

```
IMPORT FGL mydebug

MAIN
  LET mydebug.level = 4
  LET mydebug.logfile = "myfile.log"
  CALL mydebug.message("Some debug info...")
END MAIN
```

Example 4: Global variables

File "myglobs.4gl":

```
GLOBALS
  DEFINE userid CHAR(20)
  DEFINE extime DATETIME YEAR TO SECOND
END GLOBALS
```

File "mylib.4gl":

```
GLOBALS "myglobs.4gl"

DEFINE s VARCHAR(100)

FUNCTION myfunc()
  DEFINE i INTEGER
  DISPLAY "User Id = " || userid
  FOR i=1 TO 10
      LET s = "item #" || i
  END FOR
END FUNCTION
```

File "mymain.4gl":

```
GLOBALS "myglobs.4gl"

MAIN
  LET userid = fgl_getenv("LOGNAME")
  LET extime = CURRENT YEAR TO SECOND
  CALL myfunc()
END MAIN
```

Constants

The definition of constants allows to centralize common static values.

- Understanding constants on page 291
- CONSTANT on page 291
- Examples on page 293

Understanding constants

A constant defines a read-only value identified by a name. A constant is similar to a variable, except that its value cannot be modified by program code.

Constants as typically used to define common invariable values that will be used at several place in a program:

```
CONSTANT PI DECIMAL(12,10) = 3.1415926,
       MAX_SIZE INT = 10000,
       ERRMSG = "PROGRAM ERROR: %1" -- type defaults to STRING
```

A good practice is to define constants that belong to the same domain in a single .4gl module, define the constant as `PUBLIC`, and import the module where the constants are needed.

CONSTANT

The `CONSTANT` instruction defines a program constant.

Syntax

```
[PRIVATE|PUBLIC] CONSTANT constant-definition [,...]
```

where *constant-definition* is:

```
identifier [ datatype] = literal
```

1. *identifier* is the name of the constant to be defined.
2. *datatype* can be any data type except complex types like `TEXT` or `BYTE`.
3. *literal* must be an integer, decimal, string, or date/time literal, or an `MDY( )` expression.
4. *literal* cannot be `NULL`.

Usage:

Constants define final static values that can be used in other instructions.

Constants can be defined with global, module, or function scope.

By default, module constants are private; They cannot be used by an other module of the program. To make a module constant public, add the `PUBLIC` keyword before `CONSTANT`. When a module constant is declared as public, it can be referenced by another module by using the `IMPORT` instruction.

When declaring a constant, the data type specification can be omitted. The literal value automatically defines the data type:

```
CONSTANT c1 = "Drink" -- Declares a STRING constant
CONSTANT c2 = 4711    -- Declares an INTEGER constant
```

However, in some cases, you may need to specify the data type:

```
CONSTANT c1 SMALLINT = 12000 -- Would be an INTEGER by default
```

Constants can be used in variable, records, and array definitions:

```
CONSTANT n = 10
DEFINE a ARRAY[n] OF INTEGER
```

Constants can be used at any place in the language where you normally use literals:

```
CONSTANT n = 10
FOR i=1 TO n
  ...
```

Constants can be passed as function parameters, and returned from functions.

Define public constants in a module to be imported by others:

```
PUBLIC CONSTANT pi = 3.14159265
```

For date time constants, the value must be specified as an MDY(), DATETIME or INTERVAL literal:

```
CONSTANT my_date DATE = MDY(12,24,2011)
CONSTANT my_datetime DATETIME YEAR TO SECOND
             = DATETIME(2011-12-24 11:22:33) YEAR TO SECOND
CONSTANT my_interval INTERVAL HOUR(5) TO FRACTION(3)
             = INTERVAL(-54351:50:24.234) HOUR(5) TO FRACTION(3)
```

A constant cannot be used in the `ORDER BY` clause of a static `SELECT` statement, because the compiler considers identifiers after `ORDER BY` as part of the SQL statement (i.e. column names), not as constants:

```
CONSTANT pos = 3
-- Next line will produce an error at runtime
SELECT * FROM customers ORDER BY pos
```

Automatic data type conversion can take place in some cases:

```
CONSTANT c1 CHAR(10) = "123"
```

```
CONSTANT c2 CHAR(10) = "abc"
DEFINE i INTEGER
FOR i = 1 TO c1 -- Constant "123" is converted to 123 integer
   ...
FOR i = 1 TO c2 -- Constant "abc" is converted to zero!
   ...
```

Character constants defined with a string literal that is longer than the length of the data type are truncated:

```
CONSTANT s CHAR(3) = "abcdef"
DISPLAY s  -- Displays "abc"
```

The compiler throws an error when an undefined symbol is used in a constant declaration:

```
CONSTANT s CHAR(c) = "abc"
-- Compiler error: c is not defined.
```

The compiler throws an error when a variable is used in a constant declaration:

```
DEFINE c INTEGER
CONSTANT s CHAR(c) = "abc"
-- Compiler error: c is a variable, not a constant.
```

The compiler throws an error when you try to assign a value to a constant:

```
CONSTANT c INTEGER = 123
LET c = 345
-- Runtime error: c is a constant.
```

The compiler throws an error when the symbol used is not defined as an integer constant:

```
CONSTANT c CHAR(10) = "123"
DEFINE s CHAR(c)
-- Compiler error: c is a not an integer constant.
```

You typically define common special characters with constants:

```
CONSTANT c_esc  = '\x1b'
CONSTANT c_tab  = '\t'
CONSTANT c_cr   = '\r'
CONSTANT c_lf   = '\n'
CONSTANT c_crlf = '\r\n'
```

Examples

Example 1: Defining and using constants

```
CONSTANT
    c1 ="Drink",       # Declares a STRING constant
    c2 = 4711,         # Declares an INTEGER constant
    n = 10,            # Declares an INTEGER constant
    x SMALLINT=1       # Declares a SMALLINT constant

DEFINE a ARRAY[n] OF INTEGER

MAIN
  CONSTANT c1 = "Hello"
  DEFINE i INTEGER
  FOR i=1 TO n
      ...
```

```
  END FOR
  DISPLAY c1 || c2  # Displays "Hello4711"
END MAIN
```

Records

Records allow structured program variables definitions.

- DEFINE ... RECORD on page 294
- Examples on page 296

Understanding records

A record defines a structured variable, where each member can be defined with a specific data type. Records can contain other records, or arrays.

```
DEFINE person RECORD
            id INTEGER,
            name VARCHAR(100),
            birth DATE
       END RECORD
```

Records are typically used to store the values of a database row. Records can be defined according to the columns of a database table as defined in a database schema. Records are used in interactive instructions such as `INPUT` or `DIALOG` for user input, and can be used in `INSERT` and `UPDATE` SQL instructions to update the database table.

```
SCHEMA stores
DEFINE cust RECORD customer.*
-- cust is defined with the column of the customer table
```

DEFINE ... RECORD

Records define structured variables.

Syntax 1 (explicit record definition)

```
DEFINE variable RECORD
  [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
  member {
              datatype
           |
              LIKE [dbname:]tabname.colname
           }
           [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
  [,...]
END RECORD
```

Syntax 2 (database column based record)

```
DEFINE variable RECORD
    [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
    LIKE [dbname:]tabname.*
```

1. *variable* defines the name of the record.
2. *member* is an identifier for a record member variable.

3. *datatype* can be any data type, a record definition, a user defined type, an array definition, a built-in class, an imported package class, or a Java™ class.
4. *dbname* identifies a specific database schema file.
5. *tabname* identifies a database table defined in the database schema file specified by `SCHEMA`.
6. *colname* identifies a database column defined in the database schema file specified by `SCHEMA`.
7. *attribute* is an attribute to extend the record or record member definition with properties.
8. *value* is the value for the record definition attribute, it is optional for boolean attributes.

Usage

A record is an ordered set of variables (called members), where each member is defined with a specific type or in turn, structured type.

Records whose members correspond in number, order, and data type compatibility to a database table can be useful for transferring data from the database to the screen, to reports, or to functions.

In the first form (Syntax 1), record members are defined explicitly:

```
DEFINE rec RECORD
           cust_id INT,
           cust_name VARCHAR(50),
           cust_address VARCHAR(100),
           ...
       END RECORD
```

In the second form (Syntax 2), record members are created implicitly from the table definition found in the database schema file specified by the `SCHEMA` instruction:

```
SCHEMA stock
...
DEFINE rec RECORD LIKE customer.*
```

> **Important:** When using the `LIKE` clause, the data types are taken from the database schema file during compilation. Make sure that the database schema file of the development database corresponds to the production database, otherwise the records defined in the compiled version of your programs will not match the table structures of the production database. Statements like `SELECT * INTO record.* FROM table` would fail.

In the rest of the program, record members are accessed by a dot notation (`record.member`). The notation `record.member` refers to an individual member of a record. The notation `record.*` refers to the entire list of record members. The notation `record.first THRU record.last` refers to a consecutive set of members. (`THROUGH` is a synonym for `THRU`):

```
DISPLAY rec.*
```

Records can be passed as function parameters, and can be returned from functions. However, when passing records to functions, you must keep in mind that the record is expanded as if each individual member would have been passed as parameter:

```
CALL myfunction(rec.*)
```

It is possible to assign and compare records having the same structure, by using the dot star notation:

```
LET rec2.* = rec3.*
...
IF rec1.* == rec2.* THEN
   ...
END IF
```

When comparing records, all members will be compared. If two members are `NULL`, the result of this member comparison results in `TRUE`.

Records can be defined with the `ATTRIBUTES( )` clause, to specify meta-data information for the record. This feature is especially used when defining records for XML-based Web Services. For more details about XML attributes, see Attributes to customize XML serialization on page 2517.

Examples

Example 1: Defining a record with explicit member types

```
MAIN
  DEFINE rec RECORD
              id INTEGER,
              name VARCHAR(100),
              birth DATE
            END RECORD
  LET rec.id = 50
  LET rec.name = 'Scott'
  LET rec.birth = TODAY
  DISPLAY rec.*
END MAIN
```

Example 2: Defining a record with a database table structure

```
SCHEMA stores
DEFINE cust RECORD LIKE customer.*
MAIN
  DATABASE stores
  SELECT * INTO cust.* FROM customer WHERE customer_num=2
  DISPLAY cust.*
END MAIN
```

Example 3: Assigning an comparing records

```
SCHEMA stores
TYPE t_cust RECORD LIKE customer.*
MAIN
  DEFINE cust1, cust2 t_cust
  ...
  INITIALIZE cust1.* TO NULL
  ...
  LET cust2.* = cust1.*
  ...
  IF cust1.* != cust2.* THEN
     DISPLAY "Records are different!"
  END IF
  ...
END MAIN
```

Arrays

Arrays (static or dynamic) allow to handle an ordered collection of elements.

- Understanding arrays on page 297
- DEFINE ... ARRAY on page 297
- Static arrays on page 298
- Dynamic arrays on page 300

- Array methods on page 302
- Copying complete arrays on page 302
- Examples on page 302

Understanding arrays

Arrays can store a one-, two- or three-dimensional set of elements.

The language supports three kind of array types:

- Static arrays - introduced in early versions of the language.
- Dynamic arrays - to be used in new developments.
- Java™ arrays - to define an array referencing Java™ objects.

DEFINE ... ARRAY

An array defines a vector variable with a list of elements.

Syntax 1: Static array definition

```
DEFINE variable ARRAY [ size [,size  [,size] ] ]
    [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
    OF datatype
```

Syntax 2: Dynamic array definition

```
DEFINE variable DYNAMIC ARRAY
    [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
    [ WITH DIMENSION rank ]
    OF datatype
```

Syntax 3: Java™ array definition

```
DEFINE variable ARRAY [ ] OF javatype
```

1. *variable* defines the name of the array.
2. *size* can be an integer literal or an integer constant. The upper limit is **65535**.
3. *rank* an be an integer literal of 1, 2, or 3. Default is 1.
4. *datatype* can be a data type, a record definition, a user defined type, a built-in class, an imported package class, or a Java™ class.
5. *javatype* must be a Java™ class or a simple data type that has a corresponding primitive type in Java™, such as `INTEGER` (int), `FLOAT` (double).
6. *attribute* is an attribute to extend the array definition with properties.
7. *value* is the value for the array definition attribute, it is optional for boolean attributes.

Usage

The `DEFINE ... ARRAY` instruction creates a program variable as an array. The elements of the array can be of a simple type or structured records.

Consider using dynamic arrays instead of static arrays.

Java™-style arrays will only be useful to interface with Java calls.

Static and dynamic arrays can be defined with the `ATTRIBUTES( )` clause, to specify meta-data information for the variable. This feature is especially used when defining variables for XML-based Web

Services. For more details about XML attributes, see Attributes to customize XML serialization on page 2517.

Example

```
DEFINE arr DYNAMIC ARRAY OF RECORD
           p_num INTEGER,
           p_name VARCHAR(50),
           p_phone VARCHAR(20)
       END RECORD
LET arr[1].p_num = 84335
LET arr[1].p_name = "Scott McCallum"
LET arr[1].p_phone = NULL
DISPLAU arr[1].*
```

Static arrays

Defining static arrays

Static arrays can store a one-, two- or three-dimensional array of variables, all of the same type. An array member can be any type except another array (`ARRAY ... OF ARRAY`).

```
MAIN
  DEFINE custlist ARRAY[100] OF RECORD
             id INTEGER,
             name VARCHAR(50)
         END RECORD
  LET custlist[50].id = 12456
  LET custlist[50].name = "Beerlington"
END MAIN
```

Multi-dimentional static arrays

The multi-dimensional array syntax (`ARRAY[`*i*`[,`*j*`[,`*k*`]]]`) specifies static arrays defined with an explicit size for all dimensions. Static arrays have a size limit. The biggest static array size you can define is **65535**.

A single array element can be referenced by specifying its coordinates in each dimension of the array.

Avoid using large static arrays; All elements of static arrays are allocated and initialized when the program starts, even if the array is not used.

```
MAIN
  DEFINE a1 ARRAY[100] OF INTEGER
  LET a1[50] = 12456
  LET a1[5000] = 12456  -- Runtime error!
END MAIN
```

Element types

The elements of a static array variable can be of any data type except an array definition, but elements can be defined as a record containing an array member.

```
MAIN
  DEFINE arr ARRAY[50] OF RECORD
               key INTEGER,
               name CHAR(10),
               address VARCHAR(200),
```

```
               contacts ARRAY[50] OF VARCHAR(20)
       END RECORD
  LET arr[1].key = 12456
  LET arr[1].name = "Scott"
  LET arr[1].contacts[1] = "Bryan COX"
  LET arr[1].contacts[2] = "Mike FLOWER"
END MAIN
```

Passing static arrays to functions

Static arrays are passed by value to functions. This is not recommended, as all array members will be copied on the stack.

A static array cannot be returned from a function.

Consider using dynamic arrays if you need to pass/return a list of elements to/from functions.

Using array methods

Array methods can be used on static arrays; However these methods are designed for dynamic arrays and are not appropriate for static arrays.

Controlling out of bound in static arrays

Controlling of out of bounds index error

By default, when an array index is out of range, fglrun raises error -1326. This is only the case for static arrays: When using a dynamic array, new elements are allocated if the index is greater than the actual array size.

Raising an index out of bounds error is natural for static arrays. However, in some situations, code must execute without error and evaluate expressions using indexes that are greater than the size of the array, especially with boolean expressions in `IF` statements:

```
IF index <= max_index OR arr[index] == some_value THEN
   ...
END IF
```

In this example, as all parts of a boolean expression needs to be evaluated, the runtime system must get the value of the *arr[index]* element.

You can use an FGLPROFILE entry to control the behavior of the runtime system when an array index is out of bounds for a static array:

```
fglrun.arrayIgnoreRangeError = true
```

When this FGLPROFILE entry is set to true, the runtime system will return the first element of the array if the index is <=0 or greater than the size of the array and continue with the normal program flow.

Unless existing code is relying on this behavior, it is better to let the default get array out of bounds errors when the index is invalid.

You may also want to use the compiler directive to control boolean expression evaluation, with the `OPTIONS SHORT CIRCUIT` instruction.

Dynamic arrays

Defining dynamic arrays

Dynamic arrays are defined with the `DYNAMIC ARRAY` syntax and specify an array with a variable size. Dynamic arrays have no theoretical size limit. The elements of dynamic arrays are allocated automatically by the runtime system, according to the indexes used.

```
MAIN
  DEFINE a1 DYNAMIC ARRAY OF INTEGER
  LET a2[5000] = 12456  -- Automatic allocation for element 5000
END MAIN
```

Element types

The elements of a dynamic array variable can be of any data type except an array definition, but elements can be defined as a record containing an array member.

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
               key INTEGER,
               name VARCHAR(30),
               address VARCHAR(200),
               contacts ARRAY[50] OF VARCHAR(20)
       END RECORD
  LET arr[1].key = 12456
  LET arr[1].name = "Scott"
  LET arr[1].contacts[1] = "Bryan COX"
  LET arr[1].contacts[2] = "Mike FLOWER"
END MAIN
```

Automatic element allocation

When a dynamic array element does not exist, it is automatically allocated before it is used. For example, when you assign an array element with the `LET` instruction by specifying an array index greater as the current length of the array, the new element is created automatically before assigning the value. This is also true when using a dynamic array in a`FOREACH` loop or when dynamic array elements are used as r-values, for example in a DISPLAY.

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  LET a[50] = 33 -- Extends array size to 50 and assigns 33 to element #50
  DISPLAY a[100] -- Extends array size to 100 and displays NULL
END MAIN
```

Important:

Pay attention to automatic element allocation in dynamic arrays. The following code example creates an additional element because at each iteration, the runtime system must allocate a new element to fetch the row from the database. As result, you need to remove the last element of the array after the `FOREACH` loop:

```
DEFINE arr DYNAMIC ARRAY OF RECORD
               key INTEGER,
               name VARCHAR(30)
       END RECORD,
       x INTEGER
DECLARE c1 CURSOR FOR SELECT ckey, cname FROM mytable
LET x=1
```

```
FOREACH c1 INTO arr[x].*
   LET x=x+1
END FOREACH
CALL arr.deleteElement(x)

-- A more elegant way to fetch rows into an array:
TYPE my_type RECORD LIKE mytable.*
DEFINE arr DYNAMIC ARRAY OF my_type,
       rec my_type,
       x INTEGER
DECLARE c1 CURSOR FOR SELECT * FROM mytable
LET x=1
FOREACH c1 INTO rec.*
   LET arr[x:=x+1].* = rec.*
END FOREACH
```

Passing and returning dynamic arrays to functions

Dynamic arrays are passed (or returned) by reference to/from functions.

The dynamic array can be modified inside the called function, and the caller will see the modifications.

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  CALL fill(a)
  DISPLAY a.getLength() -- shows 2
END MAIN

FUNCTION fill(x)
  DEFINE x DYNAMIC ARRAY OF INTEGER
  CALL x.appendElement()
  CALL x.appendElement()
END FUNCTION
```

Dynamic array size

The `getLength()` array method method returns the number of allocated elements:

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  LET a[5000] = 12456
  DISPLAY a.getLength()
END MAIN
```

Dynamic array methods

A set of methods is available to manipulate dynamic arrays. For a complete list, see DYNAMIC ARRAY methods on page 1697.

Using multi-dimentional dynamic arrays

Multi-dimentional dynamic arrays can be defined by using the `WITH DIMENSION` syntax.

Array methods can be used on multi-dimensional arrays with the brackets notation:

```
MAIN
  DEFINE a2 DYNAMIC ARRAY WITH DIMENSION 2 OF INTEGER
  DEFINE a3 DYNAMIC ARRAY WITH DIMENSION 3 OF INTEGER
  LET a2[50,100]  = 12456
  LET a2[51,1000] = 12456
  DISPLAY a2.getLength()         -- shows 51
```

```
  DISPLAY a2[50].getLength()     -- shows 100
  DISPLAY a2[51].getLength()     -- shows 1000
  LET a3[50,100,100]  = 12456
  LET a3[51,101,1000] = 12456
  DISPLAY a3.getLength()         -- shows 51
  DISPLAY a3[50].getLength()     -- shows 100
  DISPLAY a3[51].getLength()     -- shows 101
  DISPLAY a3[50,100].getLength() -- shows 100
  DISPLAY a3[51,101].getLength() -- shows 1000
  CALL a3[50].insertElement(10)  -- inserts at 50,10
  CALL a3[50,10].insertElement(1)-- inserts at 50,10,1
END MAIN
```

Array methods

Native BDL arrays and Java arrays can be used to invoke built-in methods.

For the list of native array methods, see DYNAMIC ARRAY methods on page 1697.

For the list of Java array methods, see Java Array type methods on page 1701.

Copying complete arrays

The compiler allows the `.*` notation to assign an array to another array with the same structure. Static array elements are copied by value (except objects and LOB members), while elements of dynamic arrays are copied by reference, even for simple data types. This means that after assigning a dynamic array with the `.*` notation, if you modify an element in one of the arrays, the change will be visible in the other array. You must pay attention to this behavior if you are used to the `.*` notation for simple records.

Note: When assigning a dynamic array with the .* notation, all elements are copied by reference:

```
MAIN
  DEFINE a1, a2 DYNAMIC ARRAY OF RECORD
                key INTEGER
              END RECORD
  LET a1[1].key = 123
  LET a2.* = a1.*
  DISPLAY a2[1].key    -- shows 123
  LET a2[1].key = 456
  DISPLAY a1[1].key    -- shows 456
END MAIN
```

Examples

Example 1: Using static and dynamic arrays

```
MAIN
  DEFINE a1 DYNAMIC ARRAY OF INTEGER
  DEFINE a2 DYNAMIC ARRAY WITH DIMENSION 2 OF INTEGER
  DEFINE a3 ARRAY[10,20] OF RECORD
              id INTEGER,
              name VARCHAR(100),
              birth DATE
            END RECORD
  LET a1[5000] = 12456
  LET a2[5000,300] = 12456
  LET a3[5,1].id = a1[50]
  LET a3[5,1].name = 'Scott'
  LET a3[5,1].birth = TODAY
END MAIN
```

Example 2: Fetching database rows into a dynamic array

Automatic allocation of dynamic array element in the FOREACH statement creates an additional element that needs to be deleted after the loop:

```
SCHEMA stores

MAIN
  DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
  DEFINE index INTEGER

  DATABASE stores

  DECLARE curs CURSOR FOR SELECT * FROM customer
  LET index = 1
  FOREACH curs INTO custarr[index].*
    LET index = index+1
  END FOREACH
  CALL custarr.deleteElement(custarr.getLength())

  DISPLAY "Number of rows found: ", custarr.getLength()
  FOR index=1 TO custarr.getLength()
    DISPLAY custarr[index].*
  END FOR

END MAIN
```

Types

Types can be defined by the programmer to centralize the definition of complex/structured variables.

- Understanding type definition on page 303
- TYPE on page 303
- Using types in programs on page 304
- Examples on page 305

Understanding type definition

The TYPE instruction declares a user defined type, which is based on native data types, records or arrays. Once declared, a type can be referenced in the declaration of program variables, or in other types. Types are typically defined to avoid the repetition of complex structured types. Consider user PUBLIC TYPE definitions to share types accross modules, with IMPORT FGL.

TYPE

Types define a synonym for a base or structured data type.

Syntax:

```
[PUBLIC|PRIVATE] TYPE type-definition [,...]
```

where *type-definition* is:

```
identifier {
   {
     datatype
   |
     LIKE [dbname:]tabname.colname
   }
```

```
   [ ATTRIBUTES( attribute [ = "value" ] [,...] ) ]
```

1. *identifier* is the name of the type to be defined.
2. *datatype* is any data type, record structure, or array definition supported by the language.
3. *attribute* is an attribute to extend the type definition with properties.
4. *value* is the value for the type attribute, it is optional for boolean attributes.

Usage

User-defined types enforce reusability and simplify programming, by centralizing data structure definitions at a single place.

When defining types with the `LIKE` clause, the data types are taken from the database schema file at compile time. Make sure that the schema file of the database schema during development corresponds to the database schema of the production database; otherwise the types defined in the compiled version of your modules will not match the table structures of the production database.

Types can be defined with the `ATTRIBUTES( )` clause, to specify meta-data information for the type. This feature is especially used when defining types for XML-based Web Services. For more details about XML attributes, see Attributes to customize XML serialization on page 2517.

Using types in programs

Define a type as a synonym for an existing data type, or as a shortcut for records and array structures.

After declaring a type, it can be used as a normal data type to define variables.

```
TYPE t_customer RECORD
         cust_num INTEGER,
         cust_name VARCHAR(50),
         cust_addr VARCHAR(200)
    END RECORD
...
     DEFINE c1 t_customer
...
     DEFINE o1 RECORD
                order_num INTEGER,
                customer t_customer,
                ...
            END RECORD
...
     DEFINE custlist DYNAMIC ARRAY OF t_customer
```

The scope of a type is the same as for variables and constants. Types can be global, module-specific, or local to a function.

A good practice is to define types that belong to the same domain in a single .4gl module, and import that module in the modules where the types are needed.

By default, module-specific types are private; They cannot be used by an other module of the program. To make a module type public, add the `PUBLIC` keyword before `TYPE`. When a module type is declared as public, it can be referenced by another module by using the `IMPORT FGL` instruction:

```
-- customers.4gl
PUBLIC TYPE t_ord RECORD
           ord_id INTEGER,
           ord_date DATE,
           ord_total DECIMAL(10,2)
       END RECORD
PUBLIC TYPE t_cust RECORD
           cust_id INTEGER,
           cust_name VARCHAR(50),
```

```
           orders DYNAMIC ARRAY OF t_ord,
           ...
       END RECORD
...

-- main.4gl
IMPORT FGL customers
MAIN
    DEFINE custlist DYNAMIC ARRAY OF t_cust
    ...
END MAIN
```

Examples

Example 1: Defining a type with a record structure

```
TYPE t_customer RECORD
            cust_num INTEGER,
            cust_name VARCHAR(50),
            cust_addr VARCHAR(200)
    END RECORD

MAIN
    DEFINE custrec t_customer
    DEFINE custarr DYNAMIC ARRAY OF t_customer
    DEFINE index INTEGER

    LET custrec.cust_num = 123
    ...

    LET custarr[index].* = custrec.*
    ...

END MAIN
```

Example 2: Defining a type an using it in another module

The following example defines a type in first module, and then uses the type in a report program:

type_order.4gl:

```
PUBLIC TYPE rpt_order RECORD
                order_num INTEGER,
                store_num INTEGER,
                order_date DATE,
                cust_num INTEGER,
                fac_code CHAR(3)
             END RECORD
```

report.4gl:

```
IMPORT FGL type_order

MAIN
  DEFINE o type_order.rpt_order

  CONNECT TO "custdemo"

  DECLARE order_c CURSOR FOR
     SELECT orders.*
        FROM orders ORDER BY cust_num
  START REPORT order_list
```

```
  FOREACH order_c INTO o.*
    OUTPUT TO REPORT order_list(o.*)
  END FOREACH
  FINISH REPORT order_list

END MAIN

REPORT order_list(ro)
  DEFINE ro rpt_order
  FORMAT
    ON EVERY ROW
     PRINT ro.order_num, ...
  ...
```

Advanced features

These topics cover advanced features of the Genero Business Development Language

- Localization on page 307
- Runtime stack on page 336
- Exceptions on page 340
- OOP support on page 349
- XML support on page 351
- Globals on page 353
- Database schema on page 355
- Programs on page 368
- Program execution on page 390
- Deploying mobile apps on page 2572
- Front calls on page 395

Localization

Localization support allows you to implement programs that follow specific language and cultural rules.

Programs execute in a specific *application locale*. Beside the support of a locale specification which defines the character set used by programs, the internationalization of an application requires all strings in the sources that are subject to translation to be extracted and centralized. Localized strings are used to keep application messages and form labels in external resource files, which can be provided in different languages.

- Application locale on page 307
- Localized strings on page 327

Application locale

The *application locale* defines the language (for messages), country or territory (for currency symbols and date formats) and code set (for character set encoding). A program needs to be able to determine its locale and act accordingly, to be portable across different languages and character sets.

This section describes how to define the locale for your programs.

> **Important:** The same code point can represent different characters in different character sets. An invalid locale configuration in one of the components can result in invalid characters in the database. For example, a client application is configured to display glyphs (font) for CP437. If the application gets a 0xA2 (decimal 162) code point, it displays an o-acute character. Now imagine that the DB client is configured with character set CP1252. In this character set, the code point 0xA2 is actually the cent currency sign. As a result, if you insert the o-acute char (0xA2 in CP437) in the database, it will actually be seen as cent sign (0xA2 in CP1252) by the database server. When fetching that character back to the client, the database server returns the 0xA2 code point, which displays correctly as o-acute on the CP437 configured client, and the end user sees what was entered before. But with a different application configured properly with CP1252 and DB client codeset, the end user will see the cent currency sign instead of the o-acute character.

Quickstart guide for locale settings

This is a quick step-by-step guide to properly configure locale settings for your Genero application.

Setting the locale involves different components, which all must be properly configured.

> **Tip:** This is a quickstart guide for locale settings. It is highly recommended that you read the complete set of articles regarding localization.

1. The *application locale* is defined by the character set used in your source files (`.4gl`, `.per`, `.str`). The same character set will be used in the compiled files (`.42m`, `.42f`, `.42s`).
2. Set the operating system locale corresponding to the application locale.
   - On UNIX™ based systems (including Mac OS-X™), define the LANG (or LC_ALL) environment variable. Use `locale -a` command to check if the locale exists on the machine. If not, it must be installed. If not set, LANG defaults to POSIX (ASCII).
   - On Windows™ platforms, check if the regional settings for non-UNICODE applications match the application locale. If the regional settings do no match, you can define the LANG environment variable with a locale name supported by Microsoft™ C Runtime Library, such as `French_France.1252`, or set `LANG=.fglutf8` for the UTF-8 character set.
   - On iOS mobile devices, the application locale is always UTF-8, it cannot be changed.
   - On Android™ mobile devices, the application locale is always UTF-8, it cannot be changed.
3. When using UTF-8 as character encoding, define the **length semantics** with the FGL_LENGTH_SEMANTICS={BYTE|CHAR} environment variable. On server platforms, Genero is using Byte Length Semantics by default for compatibility reasons. It's highly recommended to set FGL_LENGTH_SEMANTICS=CHAR to use Character Length Semantics. On mobile platforms, character length semantics is the default (i.e. FGL_LENGTH_SEMANTICS does not need to be defined when running on a mobile device, it defaults to CHAR, and cannot be set to BYTE).
4. Set the **database client locale** with a character set corresponding to the application locale. For example, with Informix®, this is defined with the CLIENT_LOCALE environment variable. The name of the database client locale is certainly different from the application locale. But remember the application and database client character sets must match. The database server locale might be different from the db client locale.
5. Check the length semantics used by the database. For example, with Oracle, you might want to set the database option `NLS_LENGTH_SEMANTICS='CHAR'`, if the application uses CLS (typically with UTF-8).
6. With UTF-8, use the proper SQL character data type to store UTF-8 data: This data type might be different according to the type of database server. For more details, see SQL character type for Unicode/UTF-8 on page 418.
7. Set the **front-end locale and font**. By front-end, we mean the program the end user interacts with. This can be a Genero front-end or a terminal emulator like Gnome-term, Putty, or a Windows™ Console. When using a Genero front-end, the front-end character set is fixed by the type of the front end and conversion from/to application character set is automatic, but you may need to select a font different from the system default. If you want to execute a TUI application in a terminal emulator, you must be sure that the terminal is configured to display the correct character set. This is for example defined with the *chcp* command on Windows™, or in the "*Set Character Encoding*" menu option of a Gnome-term.
8. Define the date, numeric and monetary formats with the DBDATE, DBMONEY, DBFORMAT environment variables. On server platforms such as Unix and Windows, these default to US formats (month/day/year for dates, the dot as decimal separator and $ as currency symbol). On mobile platforms, these default to the regional settings defines on the device.

Locale and character set basics

Before starting with application/database design, configuration and settings, you must know some basics concerning language and character sets on computers. In this section, we attempt to describe these basics, but we strongly recommend you to carefully read the operating system and database server manuals covering localization or character set handling. You can also find a lot of information about character sets and character encoding on the internet.

Why do I need to care about the locale and character set?

If you don't know what you are doing with character sets, the end user might get strange characters displayed on the screen, and will probably not be able to input non-ASCII characters. In the worst case, as character set conversion can be symmetric for single-byte character sets, the end user might see correct characters on the workstation, but on the back-end you can get invalid characters in the database files. By upgrading to a newer OS, Genero Business Development Language runtime or database system, or

if a character set mapping utility was used somewhere in the chain, you can even get mixed character encoding in the database files.

Characters, code points, character sets, glyphs and fonts

In computers, a character is the unit of information corresponding to a symbol of a natural language. This can be a letter, a digit, a punctuation mark, a mathematic or even musical symbol. To represent a character in memory or in a file, computers must encode the character in a specific numeric value called code point. This code point uniquely identifies a character in a given character set. Mapping a character to a code point is called character encoding. The same code point might represent a different character in several character sets. The glyph is the graphical representation of the character. In other words, it's the way the character is drawn on the screen or on a printer. Computers implement the glyph of characters with fonts, by mapping a code point to a bitmap image or drawing instructions based on math formulas or vector graphics.

The ASCII character set

ASCII stands for the American Standard Code for Information Interchange. ASCII is a well-known character encoding based on the English alphabet. Characters are encoded in a single byte, using the 7 lower bits only. Up to 127 characters, printable and not printable (like control characters), are defined in ASCII. Nearly all other character sets (using 8 bits or multiple bytes) define the first 127 characters as the ASCII character set. Aliases for ASCII include ISO646-US, ANSI_X3.4-1968, IBM367, cp367, and more.

Single-byte character sets (SBCS)

A single-byte character set defines the encoding for characters on a unique byte. The size of a character is always one byte.

Example of single-byte character sets include ISO-8859-1, MS code page CP1252.

Genero Business Development Language supports single-byte character sets.

Double-byte character sets (DBCS)

A double-byte character set defines the encoding for characters on two bytes. The size of a character is always two bytes.

Example of double-byte character sets include UCS-2, used by SQL Server in NCHAR and NVARCHAR columns. Note that UTF-16 is not a (fixed) double-byte character set: You can have characters encoded on 2 or 4 bytes. UCS-2 is actually a subset of UTF-16.

Note that Genero Business Development Language does not support double-byte character sets.

Multibyte character sets (MBCS)

A multibyte character set defines the encoding for characters on a variable number of bytes. The size of a character can be one (usually ASCII chars), two, three or more bytes, depending on the character set.

Example of multibyte character sets are BIG5, EUC-JP, and UTF-8. BIG5 and EUC-JP characters can be one or two bytes long, while UTF-8 characters can be 1, 2, 3 or 4 bytes long (usually a maximum of 3 is sufficient).

Genero Business Development Language supports multibyte character sets.

Character size unit and length semantics

When programming an application for a Latin-based language sush as English, a single-byte character set can be used, and the logical size, storage size and print width of characters is the same. For example, in ISO-8859-1, the ê character takes one logical position, has a storage size of one byte and a print width of one.

When programming an international application using multiple languages and a multibyte character set encoding, you must distinguish three size units:

1. The size in **character unit**, to count or position logical characters used in a string. For example, the strings `abc` and `åôë` have both a length of 3, in character units.

2. The size in **byte unit**, used to encode the character in a given character set. For example, a Latin ê acute character will use a unique byte in the ISO-8859-1 character set, but needs two bytes in UTF-8.
3. The size in **width unit**, used in formatting and alignments. The width is the length of the glyph/font of characters, especially in a fixed font. For example, a latin character will take one width unit, while an asian ideogram will take 2 width units.

Working with byte units in a multibyte character set can be difficult: You need to calculate sizes, lengths and substring offsets in a number of bytes, when the natural way is to count in characters.

Length semantics define the unit to be used for character data type definition, charcater string lengths and positions.

With Byte Length Semantics, a length is expressed in bytes, while Character Length Semantics counts in characters.

The UNICODE Standard

UNICODE is a standard specification to map all possible characters to a numeric value, in order to cover all possible languages in a unique character set. UNICODE defines the mapping of characters to integer codes, but it does not define the exact implementation (i.e. encoding) for a character. Several character sets are based on the UNICODE standard, such as UTF-7, UTF-8, UTF-16, UTF-32, UCS-2, and UCS-4. Each of these character sets use a different encoding method. For example, with UTF-8, the letter **Æ** is encoded with two bytes as 0xC3 and 0xB6, while the same character will be encoded 0x00C6 with UTF-16.

When Microsoft™ Windows™ users talk about UNICODE, they typically mean UCS-2 or UTF-16, while UNIX™ users typically mean UTF-8.

When do I need a UNICODE character set?

With internationalization, people want to use different languages within the same application; for example, to have Chinese, Japanese, English, French and German addresses of customers in their database. UNICODE is a character encoding specification that defines characters for all languages. More and more databases will use a UNICODE character set on the database server, because it "standardizes" all data from different client applications. If needed, the client application can then use a different character set like ISO-8859-1 or BIG5: The database software takes care of character set conversions. However, if the end user needs to deal with different languages, all components of the system (from database backend to GUI front-end) must work in UNICODE.

The UNICODE character set supported by Genero Business Development Language is UTF-8. Double-byte based UNICODE character sets such as UCS-2 or UTF-16 are not supported. The database server can however store character data in another UNICODE character set, as long as the database client is able to handle to convertion to/from UTF-8 for the Genero runtime system.

What is the standard?

At this time, UNICODE tends to be the standard, but unfortunately not all platforms/systems use the same UNICODE character set. Recent UNIX™ distributions define UTF-8 as the default character set locale, XML files are UTF-8 by default, while Microsoft™ Windows™ standard is UTF-16 (NTFS) / UCS-2 (SQL Server).

What is my current character set?

On a UNIX™ box, you have the LANG / LC_ALL environment variables to define the locale. Each process / terminal can set its own locale. By default this is en_US.utf8 on recent UNIX™ systems. You can query for available locales with the *locale -a* command. Some systems come with only a few locales installed, you must then install an additional package to get more languages. You must also define the correct character set in the terminal (xterm or gnome-term), otherwise non-ASCII characters will not display properly.

On Windows™ platforms, for non-UNICODE (i.e. non-UTF-16/UCS-2) applications, you have ACP and OEMCP code pages. ACP stands for ANSI Code Page and were designed by Microsoft™ for first GUI applications, while OEMCP defines old code pages for MS/DOS console applications. You can select the default ACP/OEMCP code pages for non-UNICODE application in the language and regional settings

panel of Windows™ (make sure you define the settings for non-UNICODE applications, this is done in the "Advanced" panel on Windows™ XP). Code page can be changed in each console window with the *chcp* command. With Genero Business Development Language, you can use the LANG environment variable on Windows™ to define the character set for BDL. However, it is strongly recommended to use the default Windows™ system locale and avoid to set LANG on Windows™.

Understanding locale settings

It is critical to understand how the different components of a program handle locale settings. Each component (i.e. runtime system, database client software, front-end, terminal) has to be configured properly to get the correct character set conversions through the whole chain. The chain starts on the end-user workstation with front-end windows and ends in the database storage files.

Figure 20: The Locale Settings schema on page 312 shows the different components of a Genero Business Development Language process.

- The red rectangles show where character set conversion occurs. Conversion can happen in the front-end side, for C-based Web Services extension and in the database client. No conversion is done by the fglrun runtime system.
- In the runtime system (fglrun), the locale and code set support is based on the POSIX C runtime libraries driven by the **setlocale()** standard function. This locale setting is defined by the LC_ALL (or LANG) environment variable. The locale of the runtime system must match the code set of the deployed program modules (42m and 42f files).
- The terminal (for TUI applications) and the C runtime library are represented in magenta rectangles. These elements will use the locale of the runtime system.
- The locale of the database client must match the locale of the runtime system. Each database vendor uses it's own locale configuration system.
- The database server uses it's own locale settings, which can be different from the runtime system / db client locale. You can for example store the data in UTF-8 but have programs using ISO-8859-1.

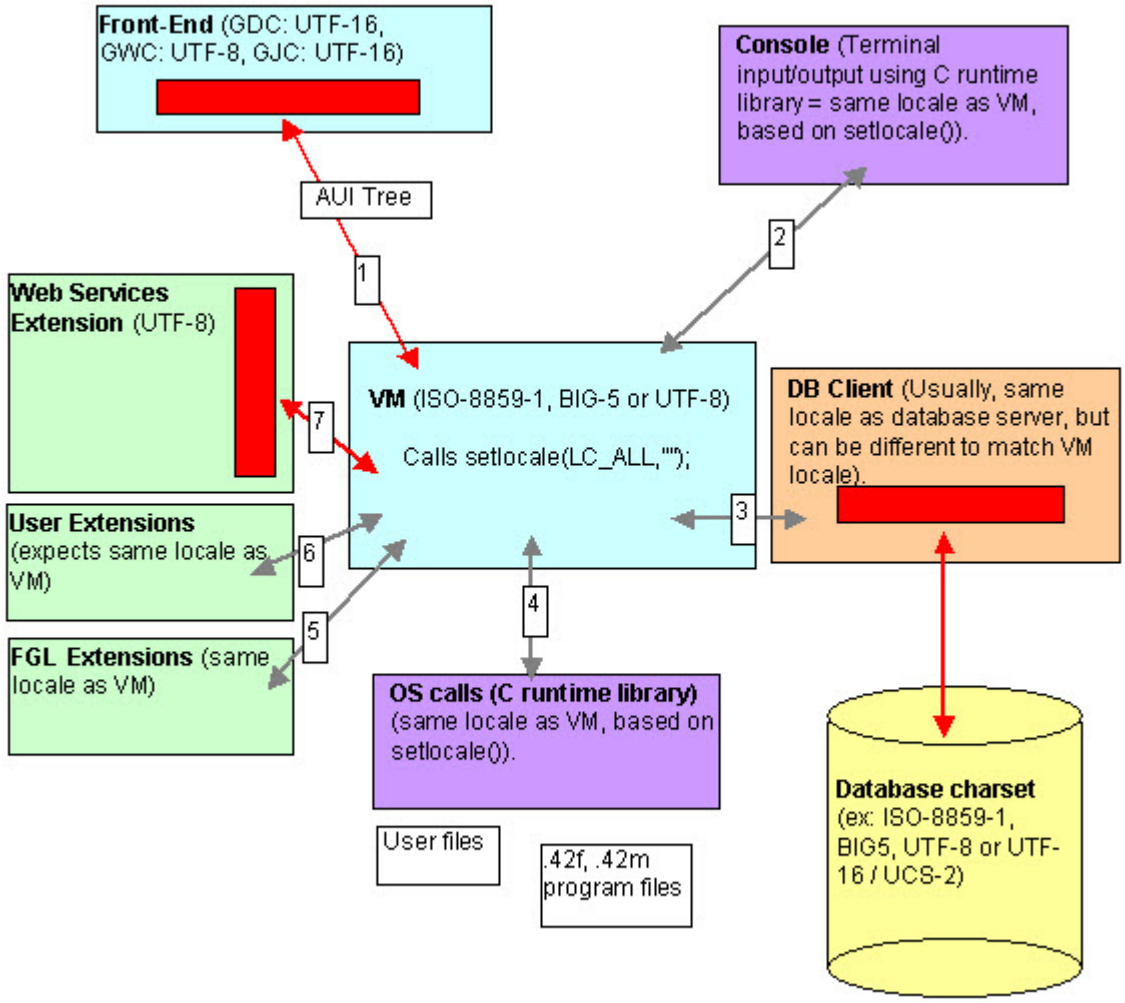

Figure 20: The Locale Settings schema

The typical mistake is to forget to set the runtime system locale (LANG/LC_ALL), or the database client software locale. Systems cannot detect that the current locale is appropriate and don't raise any error, except when a set of bytes does not represent a valid code point in the current codeset. A character string is just a set of bytes; The same code might represent different characters in different code sets. For example, the Latin letter é with acute (UNICODE: U+00E9) will be encoded as 0xE9/233 in CP1252 but will get the code 0x82/130 in CP437. The codes 233 or 130 are valid characters in both code sets, so if the database uses CP1252, 233 will represent an é and 130 will represent a curved quote. If the client application used CP437, the é will be encoded as 130, stored as curved quotes but are retrieved from the database as is and displayed back as é in the CP437 code page. From the front-end side, you can't see that the character in the database in wrong.

Pay attention that on recent UNIX™ systems, the default locale is set to UTF-8. If your application has been developed on an older system, it is probably using a single-byte character set like ISO-8859-1 or CP1252, and program need to be executed in this locale, not in the UTF-8 locale.

It is also important to identify database server character set (i.e. in what code set the characters are stored in the database). Usually the database character set is defined when creating a database entity.

The best way to test if the characters inserted in the database are correct is to use the database vendor SQL interpreter and select rows inserted from a BDL program. The rows most hold non-ASCII data to check if the code of the characters is correct. Some databases support the ASCII() or better, the UNICODE() SQL function to check the code of a character. Use such function to determine the value of a character in the database field. If the character code does not correspond to the expected value in the character set of the database server, there is a configuration mistake somewhere.

If you run a BDL application in TUI mode (or a batch program doing DISPLAYs), you must properly configure the code set in the terminal window (X11 xterm, Windows™ CMD, putty, etc). If the terminal code set does not match the runtime system locale, you will get invalid characters displayed on the screen. On Windows™ platforms, the OEM code page of the CMD window can be queried/changed with the chcp command. On a Gnome terminal, go to the menu "Terminal" - "Set Character Encoding".

Defining the application locale

This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

Language and character set settings

Purpose of application locale definition

The locale settings matters at compile time and at runtime. At runtime, the locale changes the behavior of the character handling functions, such as `UPSHIFT` and `DOWNSHIFT`. It also changes the handling of the character strings, which can be single byte or multibyte encoded. Compilation errors will occur if the source files contain characters that do not exist in the encoding defined by the current locale.

Always check that the local environment variable matches the locale of your Genero application, during development and at runtime:

```
$ fglrun -i mbcs
Charmap      : UTF-8
Multibyte    : yes
Stateless    : yes
Length Semantics : CHAR
```

Mobile plaforms

On iOS and Android™ mobile platforms, the locale is automatically defined to be UTF-8. This cannot be changed.

The language conventions and system messages are defined by the device settings.

Windows™ plaforms

On Windows™ platforms, if you don't specify the LANG environment variable, the language and character set defaults to the system locale which is defined by the regional settings for non-Unicode applications. For example, on a US-English Windows™, this defaults to the 1252 code page. You typically leave the default on Windows™ platforms (i.e. you should not set the LANG variable, except if your application uses a different character set as the Windows™ system locale).

On Windows™ platforms, the syntax of the LANG variable is:

```
  language[_territory[.codeset]]
| .codeset
```

For example:

```
C:\ set LANG=English_USA.1252
```

UNIX™ plaforms

On UNIX™-based platforms, The **LC_ALL** (or **LANG**) environment variable defines the global settings for the language used by the application.

With the **LANG** environment variable (or **LC_ALL**, on UNIX™), you define the *language*, the *territory* (aka country) and the *codeset* (aka character set or code page) to be used. The format of the value is normalized as follows, but may be specific on some operating systems:

```
language_territory.codeset
```

For example:

```
$ LC_ALL=en_US.iso88591; export LC_ALL
```

What are possible locales on my platform?

Usually OS vendors define a specific set of values for the *language*, *territory* and *codeset*. For example, on a UNIX™ platform, you typically have the value "en_US.ISO8859-1" for a US English locale, while Microsoft™ Windows™ requires the "English_USA.1252" value. For more details about supported locales, refer to the operating system documentation.

A list of available locales can be found on UNIX™ platform by running the *locale -a* command. You may also want to read the man pages of the *locale* command and the *setlocale* function. On Windows™ platforms, search the Microsoft™ MSDN documentation for "Language and Country/Region Strings".

UNICODE support (UTF-8)

To support multiple languages in your application, you must use UNICODE. The encoding supported by Genero for UNICODE applications is UTF-8.

On UNIX™ platforms, UTF-8 locales are natively supported with LANG/LC_ALL.

On Windows™ platforms, UTF-8 is not well supported by the operating system: Defining the LANG environment variable to code page 65001 will not work. To workaround this limitation, Genero implements UTF-8 support on Windows™ by setting the LANG environment variable to the value `.fglutf8` :

```
C:\ set LANG=.fglutf8
```

Length semantics settings

Understanding length semantics

The length semantics of character string data matters when using a multibyte character set. Length semantics involves data type length specification for database column and program variable definitions, as well as string manipulations (for string lengths, character positions, offsets and substring ranges).

In a single-byte characters set like ISO-8859-1, a character is encoded on one byte. The length of a string can be counted in bytes or characters, the unit does not matter. In other words, the length semantics is identical in bytes or characters, with a single byte encoding. However, with a multibyte character set like UTF-8 or BIG5, a character can be encoded on several bytes. In such case, the unit regarding length semantics matters, because the number of bytes of a character string can be different from the number of characters.

For multibyte characters sets, the language supports Byte Length Semantics (**BLS**) and Character Length Semantics (**CLS**) specification. BLS or CLS usage depends on the current character set of the application. BLS is typically used with a character set such as BIG5, because for historical reasons programmers are used to count 2 bytes for each Asian ideogram. For UTF-8, which is a variable size encoding, CLS should be used instead. CLS simplifies data type definition and string handling when using UTF-8.

Programming areas concerned by length semantics are illustrated in the following code example:

```
SCHEMA shop

# CREATE TABLE mytable (
#     k INT,
#     vc VARCHAR(10)
#         -- what is the unit for the column size and how many
#         -- characters can be stored in this column?
#  )

MAIN
  DEFINE buf, tmp VARCHAR(50)  -- what is the unit for the size?
  DEFINE rec RECORD LIKE mytable  -- what is the size of vc member?
  DEFINE str STRING, len INT

  DATABASE shop

  SELECT LENGTH(vc) INTO len -- What unit use string functions in SQL?
     FROM mytable WHERE k = 45

  LET buf = "abcdef..."  -- How many chars can this variable hold?

  DISPLAY length(buf)  -- In what unit is the length expressed?

  LET tmp = buf[1,5]  -- What is the unit for char positions?

  LET str = buf
  DISPLAY str.getLength() -- What is the unit for the length?
  DISPLAY str.getIndexOf("def") -- What is the unit for the offset?

END MAIN
```

Using Byte Length Semantics

Byte Length Semantics must be used if the current locale defines a multibyte character set different from UTF-8.

Important:

- Byte Length Semantics is the default on UNIX™ and Windows™ platforms.
- Byte Length Semantics cannot be set on mobile platforms.

With BLS, the size of CHAR/VARCHAR program variables is expressed in byte units. In a single-byte character set like ISO-8859-1, every character is encoded on a unique byte, so the number of bytes equals the number of characters. When using BLS with a multibyte character set, you must be aware of the storage size in byte units: Character encoding requires more than one byte, so the number of bytes to store a multibyte string is bigger than the number of characters. For example, in a BIG5 encoding, one Chinese character needs 2 bytes, so if you want to hold a BIG5 string with a maximum of 10 Chinese characters, you must define a CHAR(20). When using UTF-8, characters can take one or several bytes which can use two or three times more storage space as character count. You need to choose the right expansion factor to define CHAR or VARCHAR variables in byte units.

```
-- Using Byte Length Semantics
DEFINE var VARCHAR(10)  -- Can store 10 bytes / 10 single-byte chars.
```

In order to use BLS, you can define the FGL_LENGTH_SEMANTICS environment variable to "BYTE", or just leave it unset, if BLS is the default on your platform. For example, on UNIX™:

```
$ FGL_LENGTH_SEMANTICS="BYTE"
$ export FGL_LENGTH_SEMANTICS
```

Using Char Length Semantics

Character Length Semantics should be used with multibyte character sets such as UTF-8: Migrating to UTF-8 by using CLS will allow you to leave the source code untouched, even when doing complex string/substring manipulations.

The database should typically also use UTF-8 and CLS. If the database uses UTF-8 and only supports BLS, the programs can still use CLS with UTF-8.

> **Important:** Char Length Semantics is the default on iOS and Android™ mobile platforms, and cannot be changed (Byte Length Semantics cannot be used on mobile: only UTF-8 character set is allowed).

With CLS, the size of a CHAR/VARCHAR program variable is expressed in character units, and the number of bytes needed to store these characters is allocated automatically. A VARCHAR(10) variable will hold 10 characters, of any byte length. Further, language functions and class methods dealing with character string length and positions will use character units.

```
-- Using Character Length Semantics
DEFINE var VARCHAR(10)  -- Can store 10 chars in UTF-8, or any encoding.
LET var = "Forêt"  -- 5 chars, that take 6 bytes in UTF-8
DISPLAY length(var)  -- Displays a length of 5 (characters)
DISPLAY "[",var[4,5],"]"    -- Displays [êt]
```

To enable Char Length Semantics, define the FGL_LENGTH_SEMANTICS environment variable to "CHAR". For example, on UNIX™:

```
$ FGL_LENGTH_SEMANTICS="CHAR"
$ export FGL_LENGTH_SEMANTICS
```

Length Semantics in SQL

On the database server side, the length semantics used for character data types varies from a vendor to another. Some databases use BLS, other use CLS, and other support both semantics. For example, Informix® uses BLS only (with a special server configuration parameter `SQL_LOGICAL_CHAR` to define a size conversion ratio). Oracle supports both CLS and BLS at the database, session and even column level, with the `CHAR(10 BYTE|CHAR)` syntax. SQL Server supports non-UCS-2 character sets (Latin1, BIG5) in CHAR/VARCHAR/TEXT columns using BLS the size, while NCHAR/NVARCHAR/NTEXT columns store double-byte UCS-2 characters and use CLS.

This table shows the character data type length semantics of support database servers:

Table 122: Character data type length semantics of supported database servers

Database Engine	Length semantics in character data types	Summary
Oracle	Supports both Byte or Character Length Semantics in character type definition, can be defined globally for the database or at column level. Character string data is stored in database character set for CHAR /VARCHAR columns and in national character set for NCHAR /NVARCHAR columns.	BLS/CLS

Database Engine	Length semantics in character data types	Summary
Informix®	Uses Byte Length Semantics for the size of character columns. Can apply a ratio when creating columns, according to the SQL_LOGICAL_CHARS server configuration parameter. Character string data is stored in the database character set defined by DB_LOCALE.	BLS
IBM® DB2®	Uses Byte Length Semantics for the size of character columns. Character data is stored in the database character set defined by the CODESET of CREATE DATABASE.	BLS
Microsoft™ SQL Server	CHAR / VARCHAR sizes are specified in bytes; Data is stored in the character set defined by the database collation. NCHAR / NVARCHAR sizes are specified in characters; Data is stored in UCS-2. See SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592 for more details.	BLS/CLS
PostgreSQL	Uses Character Length Semantics for the size of character columns. Character string data is stored in the database character set defined by WITH ENCODING of CREATE DATABASE.	CLS
MySQL	Uses Character Length Semantics for the size of character columns. Character string data is stored in the server character set defined by a configuration parameter.	CLS
SQLite	Uses Character Length Semantics for the size of character columns. Character string data is stored in UTF-8.	CLS

Database Engine	Length semantics in character data types	Summary
Sybase Adaptive Server Enterprise (ASE)	CHAR / VARCHAR sizes are specified in bytes; Data is stored in the db character set. NCHAR / NVARCHAR sizes are specified in characters; Data is stored the db character set. UNICHAR / UNIVARCHAR sizes are specified in characters; Data is stored in UTF-16. See SQL adaptation guide for SAP Sybase ASE 16.x on page 723 for more details.	BLS/CLS

Other SQL elements like functions and operators are affected by the length semantic. For example, Informix® LENGTH() function always returns a number of bytes, while Oracle's LENGTH() function returns a number of characters (use LENGTHB() to get the number of bytes with Oracle).

It is important to understand properly how the database servers handle multibyte character sets. Check your database server reference manual: In most documentations you will find a "Localization" chapter which describes those concepts in detail.

Extracting database schemas

Database schema files (.sch) are used to resolve column data types when compiling .4gl modules and .per form files. This file contains size information for CHAR and VARCHAR types. It is important to identify the unit used by the database columns, to properly define CHAR/VARCHAR variables in programs and fields in forms.

Most database engines (like Oracle, SQL Server, PostgreSQL, Sybase, SQLite) provide catalog tables with column size information in character units. In this case, the fgldbsch tool extracts the column sizes in character units, without further conversion. If the column sizes is provided in bytes by catalog tables, fgldbsch will try to detect character length semantics usage in the database and apply a reduction factor to convert the number of bytes to chars.

As result - independently from the length semantics used in your programs - the CHAR/VARCHAR type sizes in the schema file are always expressed in character units. When using Byte Length Semantics, this makes no difference in a single-byte locale, because one character occupies a single byte. In a multibyte encoding (UTF-8) with BLS, this method garanties that the program variable will not hold more ASCII characters than the database column can hold. When using Character Length Semantics with a multibyte character set, the size in characters will define character type variables in the same unit.

For example, with BLS, a VARCHAR(10 *(bytes or chars)*) column will define a VARCHAR(10 *(bytes)*) in programs. With CLS, a VARCHAR(10 *(chars)*) column will define a VARCHAR(10 *(chars)*) in programs.

Moving from single-byte to UTF-8

Migration to Unicode (UTF-8) is facilitated with Char Length Semantics:

1. Verify that your database uses Char Length Semantics.
2. Convert your sources and string files from your single-byte locale to UTF-8 (iconv).
3. Turn on Char Length Semantics with FGL_LENGTH_SEMANTICS=CHAR.
4. Compile and run your programs untouched.

Collation ordering settings

The runtime system supports a sorting functionality in tables. To sort the data rows, the runtime systems uses the standard C library functions to order character strings.

The environment variable **LC_COLLATE** can be used to control sort order in Genero. You can for example define this variable as "C" or "POSIX" to get a binary sort order.

When using **LC_COLLATE**, set the **LANG** environment variable to define the global locale, if you use **LC_ALL**, it will overwrite all other LC_* variables defined.

Numeric and currency locale settings

The environment variables **LC_MONETARY** and **LC_NUMERIC** are ignored. To perform decimal to/from string conversions, the runtime system uses the DBMONEY or DBFORMAT environment variables. These variables define hundreds / decimal separators and currency symbols for `MONEY` data types.

Date and time locale settings

The environment variable **LC_TIME** is ignored. To perform date to/from string conversions, the runtime system uses by default the DBDATE environment variable.

Database client settings

This section describes the settings defining the locale for the database client. Each database software has its own client character set configuration.

You must properly configure the database client locale in order to send/receive data to the database server, according to the locale used by your application. Both database client locale and application locale settings must match (you cannot have a database client locale in Japanese and a runtime locale in Chinese).

Here is the list of environment variables defining the locale used by the application, for each supported database client:

Table 123: Environment variables defining the locale used by the application for each database client

Database Client	Settings
Oracle database server	The client locale settings can be set with environment variables like **NLS_LANG**, or after connection, with the ALTER SESSION instruction. By default, the client locale is set from the database server locale.
IBM® Informix®	The client locale is defined by the **CLIENT_LOCALE** environment variable. For backward compatibility, if CLIENT_LOCALE is not defined, other settings are used if defined (DBDATE / DBTIME / GL_DATE / GL_DATETIME, as well as standard LC_* variables).
IBM® DB2®	The client locale is defined by the **DB2CODEPAGE** profile variable. You cat set this variable with the db2set command. However, you usually do not need to set this variable: If DB2CODEPAGE is not set, DB2® uses the operating system code page on Windows™ and the LANG/LC_ALL locate setting on UNIX™. When using a UTF-8 locale on Windows™, DB2CODEPAGE must be set to **1208**.

Database Client	Settings
Microsoft™ SQL Server	For **MSV** and **SNC** drivers on Windows™ platforms, the database client locale is defined by the language settings for non-Unicode applications. The current ANSI code page (ACP) is used by the SQL Server client and the Genero runtime system. When using the **FTM** (FreeTDS) driver, the client character set is defined by the **client charset** parameter in freetds.conf or with the **ClientCharset** parameter in the DSN of the odbc.ini file. When using the **ESM** (EasySoft) driver, the client character set is defined by the **Client_CSet** parameter in the DSN of the odbc.ini file. When using CHAR/VARCHAR types in the database and when the database collation is different from the client locale, you must also set the Server_CSet parameter to an iconv name corresponding to the database collation. For example, if Client_CSet=BIG5 and the db collation is Chinese_Taiwan_Stroke_BIN, you must set Server_CSet=BIG5HKSCS, otherwise invalid data will be returned from the server.
PostgreSQL	The client locale can be set with the **PGCLIENTENCODING** environment variable, with the *client_encoding* configuration parameter in postgresql.conf, or after connection, with the SET CLIENT_ENCODING instruction. Check the *pg_conversion* system table for available character set conversions.
Oracle MySQL	The client locale is defined by the ***default-character-set*** option in the MySQL configuration file. The character set could also be changed by program after the connection, with the SET NAMES or SET CHARACTER SET statements, but this not supported: The driver needs to know the character set at connection initialization, and you would have to add this statement in all your programs.
Sybase Adaptive Server Enterprise (ASE)	By default, the Sybase database client character set is defined by the **operating system locale** where the database client runs. On Windows™, it is the ANSI code page of the login session (can be overwritten by setting the LANG environment variable), on UNIX™ it is defined by the LC_CTYPE, LC_ALL or LANG environment variable. You may need to edit the $SYBASE/locales/locales.dat file to map the OS locale name to a known Sybase character set. See Sybase ODBC documentation for more details regarding character set configuration.

See database vendor documentation for more details.

Front-end settings

The host operating system on the front-end workstation must be able to handle the character set and fonts. For instance, a Western-European Windows™ is not configured to handle Arabic applications. If you start an Arabic application, some graphical problems may occur (for instance the title bar won't display Arabic characters, but unwanted characters instead).

The GUI front-end software must support the conversion of the runtime system character set to/from the character set used internally by the client, and must be configured with the correct font to display the characters used by the application. For example, the default font for a front-end installed on an English Windows™ system might not be able to display Japanese characters. You must then change the font in the front-end configuration panel. Refer to the front-end documentation to see how character set conversion and fonts can be configured.

When using a TUI program in a terminal emulator such as Putty, XTerm or even the Windows™ Console, make sure the terminal is configured properly to display the characters of the application locale. For example, on a Windows™ Console you can use the *chcp* command to change the current code page.

Writing programs

Development and runtime character set must match

When writing a form or program source file, you use a specific character set. This character set depends upon the text editor or operating system settings you are using on the development platform. For example, when writing a string constant in a .4gl module, containing Arabic characters, you probably use the ISO-8859-6 character set. The character set used at runtime (during program execution) must match the character set used to write programs.

At runtime, a Genero program can only work in a specific character set. However, by using localized strings, you can start multiple instances of the same compiled program using different locales. For a given program instance the character set used by the strings resource files must correspond to the locale. Make sure the string identifiers use ASCII only.

Byte length semantics and substring expressions

When using Byte Length Semantics (BLS), all character positions in strings are actually byte positions. In a multibyte environment, if you don't pay attention to this, you can end up with invalid characters in strings. For example, an expression using a subscript operator `[x,y]` might refer to a byte position which is in fact in the middle of a multibyte character. If possible, use Character Length Semantics (CLS) with a multibyte locale to avoid such problems, or use only `STRING` methods to parse character strings.

Runtime system messages

While it is recommended to use localized strings to internationalize application messages, runtime system error messages are provided in **.iem** message files. The system message files use the same technique as user defined message files. The default message files (`msg`) are located in the `FGLDIR/msg/en_US` directory.

For backward compatibility with IBM® Informix® 4GL, some of these system error messages are used by the runtime system to display messages during a dialog instruction. For example, end users may get the error message -1309 "*There are no more rows in the direction you are going*" when scrolling an a `DISPLAY ARRAY` list in TUI mode.

If your application language is not English, you will need to translate some of the system messages to a specific locale and language. If your application language is English, you might just want to customize the default messages.

Here are some examples of system messages that can appear at runtime:

Table 124: Examples (subset) of system messages for localized strings

Number	Description
-1204	Invalid year in date.
-1304	Error in field.
-1305	This field requires an entered value.
-1306	Please type again for verification.
-1307	Cannot insert another row - the input array is full.
-1309	There are no more rows in the direction you are going.

To use your own customized system messages, do this:

1. Create a new directory under $FGLDIR/msg, using the same name as your current locale. For example, if `LANG=fr_FR.ISO8859-1`, you must create `$FGLDIR/msg/fr_FR.ISO8859-1`.
2. Copy the original system message source files (.msg) from `$FGLDIR/msg/en_US` to the locale-specific directory.
3. Edit the source files with the **.msg** suffix and translate the messages.
4. Recompile the message files with the fglmkmsg tool to produce **.iem** files. Make sure you have set the correct locale!
5. Run a program to check if the new messages are used.

With this technique, you can deploy multiple message files in different languages and locales in the same FGLDIR/msg directory.

You can use the fglmkmsg tool with the **-r** option to revert a **.iem** file to a source **.msg** file.

There is no need to translate all messages of the **.msg** files: Most of the error messages are unexpected during a program execution and therefore can stay in English. The messages subject of translation can be found in the **4glusr.msg** and **rds.msg** files.

The locale can be set with different environment variables (see setlocale manual pages for more details). To identify the locale name, the runtime system first looks for the LC_ALL value, then LC_CTYPE and finally LANG.

Pay attention to locale settings when editing message files and compiling with fglmkmsg: The current locale must match the locale used in the .msg files.

The **.iem** files used at runtime must match the current locale used by programs. This should be automatic, as long as you put the correct files in the corresponding `$FGLDIR/msg/$LANG` directory.

Using the charmap.alias file

The name of the character set defined within the LANG/LC_ALL environment variables can wary from system to system. For example, on a given platform, the ISO-8859-1 character set may be named "iso88591", while others platform will use "8859-1".

An example of locale configuration on HP/UX:

```
$ export LANG=en_US.iso88591
$ locale
LANG=en_US.iso88591
LC_CTYPE="en_US.iso88591"
LC_COLLATE="en_US.iso88591"
LC_MONETARY="en_US.iso88591"
LC_NUMERIC="en_US.iso88591"
LC_TIME="en_US.iso88591"
LC_MESSAGES="en_US.iso88591"
```

```
LC_ALL=
$ locale charmap
"iso88591.cm"
```

To communicate with other components like front-ends, or identify the encoding of XML files, Genero programs must use a normalized name for character sets. This normalized name must follow the IANA specifications [RFC2978].

In order to convert the operating system specific locale codeset name to an IANA name, the runtime system uses the `charmap.alias` mapping file, located in `$FGLDIR/etc`.

You can add your operating system specific locale, if not listed in the `s` file.

Date, numeric and monetary formats

Dates, numbers and monetary values must be displayed and entered in a format used in the country/region. These formats can be defined with the DBDATE and DBFORMAT environment variables.

Date and numeric format settings matter for data display and data input. For example, when displaying a `DATE` value to a form field, it will implicitely be formatted according to DBDATE. When the user enters a date in a form field bound to a `DATE` variable, the entered digits will be interpreted according the DBDATE.

The default value of these environment variables depends on the type of platform where the program executes:

When using the `FORMAT` field attribute or the `USING` operator to format dates with abbreviated day and month names- by using **ddd** / **mmm** markers - the system uses English-language based texts for the conversion. This means, day (ddd) and month (mmm) abbreviations are not localized according to the locale settings, they will always be in English.

- On destkop/server platforms, the default formats are set for the United States of America:
  - Dates are formatted as `mm/dd/yyyy`.
  - The decimal separator is a dot.
  - The currency symbol is the `$` dollar sign.
- On mobile platforms, the default formats are set according to the regional settings defined on the device.
  - Dates are formatted according to the regional settings.
  - The decimal separator is defined according to the regional settings.
  - The currency symbol is not defined. No currency symbol will display.

    Note: While it is possible to define environment settings for date and numeric formats with FGLPROFILE entries, it is strongly recommended to leave the defaults, to get the expected formats, if the user changes the regional settings on the mobile device.

Using the Ming Guo date format

The Ming Guo (or Minguo) calendar is still used in some Asian regions like Taiwan. This calendar is equivalent to the Gregorian calendar, except that the years are numbered with a different base: In the Ming Guo calendar, the first year (1) corresponds to the Gregorian year 1912, the year the Republic Of China was founded.

Digit-based year Ming Guo date format can be enabled by adding the C1 modifier at the end of the value set for the DBDATE environment variable:

```
$ DBDATE="Y3MD/C1"
$ export DBDATE
```

With this DBDATE setting, dates will be displayed with a year following the Ming Guo calendar, and date input will also be interpreted based on that calendar. For example, if the user enters 90/3/24, it is

equivalent to an input of 2002/3/24 when using the Gregorian calendar. Basically, the runtime system will subtract 1912 or add 1912 respectively when displaying or reading date values).

When using the C1 modifier, the possible values for the Yn symbol are Y4, Y3, Y2.

The `MDY( )` operator is sensitive to the C1 modifier usage in DBDATE. For example, if DBDATE=Y3MD/C1, MDY(3,24,1) will build a date the corresponds in the Gregorian to MDY(3,24,1912).

The `USING` operator supports the c1 modifier as well. The c1 modifier must be specified at the end of the format. You can for example use the following format string: "yyyy-mm-ddc1".

The C2 modifier to use Era names is not supported.

Unlike Informix® 4gl, when using negative years, the minus sign is placed over the left-most zero of the year, to avoid miss-aligned dates.

For example, if DBDATE=Y3MD/C1:

```
MDY(3,2, 1) USING "yyy/mm/ddc1"
MDY(3,2,-1) USING "yyy/mm/ddc1"
```

Will align properly as follows:

```
0001/03/02
-001/03/02
```

Note: Front-ends may not support the Ming Guo calendar for widgets like `DATEEDIT`.

Troubleshooting locale issues

Locale settings (LANG) corrupted on Microsoft™ platforms

On Microsoft™ Windows™ XP / 2000 platforms, some system updates (Services Pack 2) or Office versions do set the LANG environment variable with a value for Microsoft™ applications (for example 1033). Such value is not recognized by Genero as a valid locale specification. Make sure that the LANG environment variable is properly set in the context of Genero applications.

A form is displayed with invalid characters

You may have different codesets on the client workstation and the application server. The typical mistake that can happen is the following: You have edited a form-file with the encoding CP1253; you compile this form-file on a UNIX-server (encoding ISO-8859-7). When displaying the form, invalid characters will appear. This is usually the case when you write your source file under a Windows™ system (that uses Microsoft™ Code Page encodings), and use a Linux™ server (that uses ISO codepages).

Keep in mind that all source files must be created/edited in the encoding of the server (where fglcomp and fglrun will be executed).

Checking the locale configuration on UNIX™ platforms

On UNIX™ systems, the **locale** command without parameters outputs information about the current locale environment.

Once the **LANG** environment variable is set, check that the locale environment is correct:

```
$ export LANG=en_US.ISO8859-1
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="en_US.ISO8859-1"
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
LC_MESSAGES="en_US.ISO8859-1"
```

```
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
```

If the locale environment is not correct, then you should check the value of the following environment variables: LC_ALL, LC_CTYPE, LC_NUMERIC, LC_TIME, LC_COLLATE, ... value.

The following examples show the effect of LC_ALL and LC_CTYPE on locale configuration. The LC_ALL variable overrides all other LC_.... variables values.

```
$ export LANG=en_US.ISO8859-1
$ export LC_ALL=POSIX
$ export LC_CTYPE=fr_FR.ISO8859-15
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="POSIX"
LC_NUMERIC="POSIX"
LC_TIME="POSIX"
LC_COLLATE="POSIX"
LC_MONETARY="POSIX"
LC_MESSAGES="POSIX"
LC_PAPER="POSIX"
LC_NAME="POSIX"
LC_ADDRESS="POSIX"
LC_TELEPHONE="POSIX"
LC_MEASUREMENT="POSIX"
LC_IDENTIFICATION="POSIX"
LC_ALL=POSIX
$ fglrun -i mbcs
LANG honored: yes
Charmap     : ANSI_X3.4-1968
Multibyte   : no
Stateless   : yes
```

The charset used is the ASCII charset. Clearing the LC_ALL environment variable produces the following output:

```
$ unset LC_ALL
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE=fr_FR.ISO8859-15
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
LC_MESSAGES="en_US.ISO8859-1"
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
$ fglrun -i mbcs
Error: locale not supported by C library, check LANG.
$ locale charmap
ANSI_X3.4-1968
```

After clearing the LC_ALL value, the value of the variable LC_CTYPE is used. It appears that it is not correct. After clearing this value we get the following output:

```
$ unset LC_CTYPE
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="en_US.ISO8859-1"
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
LC_MESSAGES="en_US.ISO8859-1"
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
$ locale charmap
ISO-8859-1
$ fglrun -i mbcs
LANG honored: yes
Charmap     : ISO-8859-1
Multibyte   : no
Stateless   : yes
```

Verifying if the locale is properly supported by the runtime system

You can check if the LANG/LC_ALL locale is supported properly by using the `-i mbcs` option of the compilers and runner programs:

```
$ fglcomp -i mbcs
Charmap          : UTF-8
Multibyte        : yes
Stateless        : yes
Length Semantics : CHAR
```

The lines printed with this option indicate if the locale can be supported by the operating system libraries. Here is a short description of each line:

Table 125: -i info line descriptions

Verification Parameter	Description
Charmap	This is the normalized IANA name of the character set used by the runtime system to communicate with external components (front-end, I/O of XML files). The mapping from the system locale name to a normalized name is defined in `FGLDIR/etc/charmap.alias`.
Multibyte	This line indicates if the character set is multibyte.
Stateless	A few character sets are using an internal state that can change during the character flow. Only stateless character sets can be supported (the value must be 'yes').

How to retrieve the list of available locales on the system

On UNIX™ systems, the locale command with the parameter '-a' writes the names of available locales.

```
$ locale -a
...
en_US
en_US.iso885915
en_US.utf8
en_ZA
en_ZA.utf8
en_ZW
...
```

How to retrieve the list of available codesets on the system

On UNIX™ systems, the locale command with the parameter '-m' writes the names of available codesets.

```
$ locale -m
...
ISO-8859-1
ISO-8859-10
ISO-8859-13
ISO-8859-14
ISO-8859-15
...
```

Localized strings

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

This string localization feature is a simple way to define external resource files which the runtime system can search, in order to assign text to elements displayed by programs. It can be used to implement internationalization in your application, or to use site-specific text, for example, when business terms are specific to the territory where the application is used.

The localized string resource files (`.42s`) are loaded at runtime and shared by all fglrun processes. Localized strings are used to replace the original strings found in the p-code modules (`.42m`), in the compiled form (`.42f`), and in any XML resource files loaded in the abstract user interface tree (`.4ad` , `.4st` , `.4tb` , etc).

- Steps for application internationalization on page 327
- Creating source string files on page 328
- Localized strings in program sources on page 329
- Localized strings in XML resource files on page 330
- Extracting strings from sources on page 331
- Compiling string files on page 331
- Using localized strings at runtime on page 331
- Predefined application strings on page 334
- Example on page 334

Steps for application internationalization

Follow these steps to internationalize your application.

1. Identify the current character set used in your sources and make sure the application locale (LANG/LC_ALL) is set correctly.
2. In `.4gl` sources, add a % prefix to the strings that must be localized (i.e. translated).
3. In `.per` sources `LAYOUT` section, replace hard-coded form elements like text labels by static `LABEL` form items and define the `TEXT` attributes with a % prefix in the `ATTRIBUTES` section.

4. Extract the strings from the .4gl sources with `fglcomp -m` and use `fglform -m` for .per sources.
5. Organize the generated `.str` source string files (identify duplicated strings and put them in a common file).
6. At this point, the string identifiers (on the left) are the same as the string texts (on the right). These localized strings could be used as is, but it's better to define a normalized identifier for each string, by using ASCII characters only. For example, replace:

   ```
   "Customer List" = "Customer List"
   ```

   with:

   ```
   "customer.list.title" = "Customer List"
   ```
7. In sources, replace the original string text with the new string identifiers. Strings to be replaced can be located by their % prefix. You can, for example, use a script with an utility like the *sed* UNIX™ command to read the `.str` files and apply the changes automatically.
8. Recompile the `.4gl` and `.per` sources (these should be ASCII now, so the locale should not matter).
9. Compile the `.str` files in the locale used by these files, and check whether the application displays the text properly.
10. Copy the existing `.str` files, and translate the string text into another language (making sure the locale is correct).
11. Compile the new `.str` files, and copy the `.42s` files into another distribution directory, defined with the FGLRESOURCEPATH environment variable.

    A set of `.42s` files using the same language and codeset is typically copied in a distribution directory with a name identifying the locale.

    For example:

    ```
    /opt/app/resource/strings/en_US.iso8859-1
      -- English strings in iso8859-1 code-set
    /opt/app/resource/strings/fr_FR.iso8859-1
      -- French strings in iso8859-1 code-set
    /opt/app/resource/strings/jp_JP.utf8
      -- Japanese strings in utf-8 code-set
    ```

Future edits to the `.per` and `.4gl` source files should be done in the ASCII locale, and `.str` string files must be edited with their specific locale.

Creating source string files

A *source string file* contains localized string definitions for a given language (or localization context).

What is a source string file?

A source string file is basically a mapping table that defines an identifier for each string.

After compiling source string files, the programs can load and use a string found according to its identifier (or key).

By convention, the source files of localized strings have the `.str` extension.

Syntax

Define a list of string identifiers, and the corresponding text, by using the following syntax:

```
"string-identifier" = "string-text"
```

For example:

```
"common.button.cancel" = "Cancel"
```

> **Note:** Localized string keys are case sensitive. Consider using lower case characters only to avoid mistakes.

As an alternative, you can define string identifiers as a dot-separated list of identifiers:

```
identifier. [...] = "string-text"
```

For example:

```
common.button.cancel = "Cancel"
```

If needed, you can add comment lines with the # or -- markers, like in other Genero source files:

```
# a comment
-- another comment
```

Special characters

The fglmkstr compiler accepts the backslash "\" as the escape character, to define non-printable characters:

```
\l   \n   \r   \t   \\
```

Example

```
# A comment line
"Original text" = "Original text"
"forms.customer.list" = "Customer List"
"special.characters.backslash" = "\\"
"special.characters.newline" = "\n"
```

Localized strings in program sources

A *localized string* is specified in the source code of program modules or form specification files with the `%"string"` notation, to identify a string that must be replaced at runtime by the corresponding text found in compiled string files. In programs, localized strings can be loaded dynamically with the `LSTR()` operator.

Syntax 1: Static localized string

```
%"sid"
```

1. *sid* is a character string literal that defines both the string identifier and the default text.

Syntax 2: Dynamic localized string

```
LSTR(eid)
```

1. *eid* is a character string expression used at runtime as the string identifier to load the text.

Static localized strings

A static localized string specification begins with a percent sign (%), followed by the identifier of the string which will be used to find the text to be loaded. Since the identifier is a string, you can use any type of

characters, but it is recommended that you use a naming convention. For example, you can specify a path by using several names separated by a dot:

```
MAIN
  DISPLAY %"common.message.welcome"
END MAIN
```

The string after the percent sign defines both the localized string identifier and the default text to be used for extraction, or the default text when no string resource files are provided at runtime.

You can use this notation in form specification files any place where a string literal can be used.

```
LAYOUT
  VBOX
    GROUP g1 (TEXT=%"group01")
...
```

It is not possible to specify a static localized string directly in the area of containers like `GRID`, `TABLE`, `TREE` or `SCROLLGRID`. You can use static label form items to define localized strings in layout labels:

```
LAYOUT
  GRID
  {
    [lab01  |f001             ]
  {
  END
END
ATTRIBUTES
LABEL lab01: TEXT=%"myform.label01";
EDIT f001 = FORMONLY.field01;
END
```

Dynamic localized strings

The language provides a special operator to load a localized string dynamically, using an expression as string identifier. The name of this operator is `LSTR()`.

The following code example builds a localized string identifier with an integer and loads the corresponding string with the `LSTR()` operator:

```
MAIN
  DEFINE n INTEGER
  LET n = 234
  DISPLAY LSTR("str"||n)  -- loads string 'str234'
END MAIN
```

Localized strings in XML resource files

In XML resource files, localized string specification must follow the XML syntax and therefore must be defined as an XML node.

Syntax: Localized string in XML files

```
  <ParentNode attribute = "default" [...] >
     <LStr attribute = "sid" [...] />
  </ParentNode>
```

1. *ParentNode* is the node type of the parent where the localized strings must be applied.
2. *attribute* is the attribute in the parent node that will get the localized string identified by *sid*.
3. *default* is the default text of an attribute, if not localized string is found for *sid*.

4. *sid* is a character string literal that defines both the string identifier and the default text.

Description

In `.42m` p-code modules, the localized strings are coded in a proprietary binary format. But, for XML files such as action defaults files (`.4ad`), the localized strings must be written with a specific node, following the XML standards. To support localized strings in XML files, any file loaded into the Abstract User Interface tree is parsed to search for `<LStr>` nodes. The `<LStr>` nodes define the same attributes as in the parent node with localized string identifiers, for example:

```
<Label text="Hello!" >
  <LStr text="label01" />
</Label>
```

The runtime system automatically replaces corresponding attributes in the parent node (text="Hello!"), with the localized text found in the compiled string files, according to the string identifier (label01). After interpretation, the `<LStr>` nodes are removed from the XML data.

To take effect, a localized attribute in the `<LStr>` node must have a corresponding attribute in the parent node.

Extracting strings from sources

Localized strings can be easily extracted from `.4gl` and `.per` source files.

Use the `fglcomp` and `fglform` compilers with the `-m` option to extract localized strings.

```
$ fglcomp -m mymodule.4gl
```

The compilers dumps all localized string to stdout. This output can be redirected to a file to generate the default source string file with all the localized strings used in the source file. Source string files should then be re-organized, to centralize common messages in a unique `.str` file, and can then be compiled by fglmkstr into `.4st` files to be used by the runtime system.

Compiling string files

The source string files (with `.str` extension) must be compiled to binary files (with `.42s` extension) in order to be loaded by the runtime system.

To compile a source string file, use the `fglmkstr` compiler.

```
$ fglmkstr filename.str
```

The `fglmkstr` tool generates a `.42s` file with the *filename* prefix.

> **Important:** When compiling a `.str` source string file, you must set the locale (character set) corresponding to the encoding used in the `.str` file.

Using localized strings at runtime

Understand the rules for using localized strings at runtime.

Distributing compiled string files

The compiled string files (`.42s`) must be distributed with the program files in a directory specified in the `DBPATH`/`FGLRESOURCEPATH` environment variable.

Setting the correct locale

The locale (`LANG`/`LC_ALL`) corresponding to the encoding used in the `.42s` files must be set before starting the application. If the locale is wrong, the strings will not be loaded properly.

How does the runtime system load the strings?

The `.42s` compiled string resource files are loaded in following order of precedence:

1. The files defined in `FGLPROFILE`,
2. A file having the same name as the current program (`myprog.42m` loads `myprog.42s`),
3. A file with the name "`default.42s`".

For each string file, the runtime system looks in the following directories:

1. The current directory,
2. The path list defined in the `DBPATH`/`FGLRESOURCEPATH` environment variable,
3. The `FGLDIR/lib` directory.

String resource file sharing

Like `.42m` program pcode files, the `.42s` string resource files are shared by all fglrun processes running on the computer: The string file is loaded into memory with the mmap operating system function.

Defining a list of string files in FGLPROFILE

Specify a list of compiled string files with entries in the FGLPROFILE configuration file with the `fglrun.localization` entries.

First, define the total number of files with:

```
fglrun.localization.file.count = integer
```

For each file, define the filename (with the `.42s` extension), including an index number (start index must be 1):

```
fglrun.localization.file.index.name = "filename.42s"
```

Warning switches can be specified in FGLPROFILE.

If the text of a string is not found at runtime, the runtime system can show a warning, for development purposes.

```
fglrun.localization.warnKeyNotFound = boolean
```

By default, this warning switch is disabled.

What happens if a 42s string file is not found?

If the 42s string file was defined with `fglrun.localization.*` FGLPROFILE entries, it is considered as mandatory, and the runtime system will raise error -8006 if the file is not found. If the *`progname`*`.42s` and `default.42s` string files are not found, no error is raised, because these are fallback string resource files.

What happens if a string is not defined in a resource file?

If a localized string is not defined in one of the compiled string files, the runtime system uses the string identifier as default text.

What happens if a string is defined more that once?

When a localized string is defined in several compiled string files, the runtime system uses the first string found.

For example, if the string "hello" is defined in `program.42s` as "hello from program", and in `default.42s` as "hello from default", the runtime system will use the text "hello from program".

Organizing .42s resource files in distribution directories

A set of `.42s` files using the same language and codeset is typically copied in a distribution directory with a name identifying the locale.

For example:

```
/opt/app/resource/strings/en_US.iso8859-1  -- English strings in iso8859-1
 code-set
/opt/app/resource/strings/fr_FR.iso8859-1  -- French strings in iso8859-1
 code-set
/opt/app/resource/strings/jp_JP.utf8       -- Japanese strings in utf-8
 code-set
```

At runtime, specify the string file search path in the `DBPATH`/`FGLRESOURCEPATH` environment variable by adding the name of current locale as sub-directory. For example, to find the correct string files in one of the locale-specific directories shown above, set the `FGLRESOURCEPATH` variable as follows (UNIX™ shell):

```
$ echo $LC_ALL
jp_JP.utf8
$ FGLRESOURCEPATH="$FGLRESOURCEPATH:/opt/app/resource/strings/$LC_ALL"
$ export FGLRESOURCEPATH
$ echo $FGLRESOURCEPATH
/opt/app/forms:/opt/app/resource/strings/jp_JP.utf8
```

Localized string files on mobile devices

On mobile devices, the language is determined by the operating system regional settings.

- On iOS devices (version 8.1), the language is determined by Settings >> General >> International >> Language
- On Android™ devices (version 4.4), the language is determined by Settings >> Language & Input >> Language

The selected language is identified by a locale code following the ISO 639 standard. Below are some language code examples; see the mobile OS documentation for information about available languages and their corresponding ISO 639-x codes.

- `en` - English (for all regions)
- `en_US` - English in the United States
- `en_GB` - English in the United Kingdom

On startup, the mobile app will by default search for localized string files (.42s) in *`appdir/locale-code`*, the application sub-directory having the same name as the locale identifier (with language and category/region codes) (for an English-US locale: *`appdir/`*`en_US`). If the 42s files are not found in this sub-directory, the runtime system tries to load the files from a sub-directory with the language identified only (for an English-US locale: *`appdir/`*`en`). Finally, if the string files are not found in locale-specific directories, the files are loaded directly from *appdir*.

In order to localize your application, you simply need to place your `.42s` localized string files in the appropriate language sub-directory.

> **Note:** If the `.42s` file names do not match the main program name, define the list of localized strings files in app's `fglprofile` file.

If you want to distinguish language categories (Simplified/Tradition Chinese), or if you want to use different texts according to the territory for the same language (English in USA or Great Britain), create language sub-directories with the exact OS locale identifier:

- For English in the USA, use "`en_US`"
- For English in the United Kingdom, use "`en_GB`"

- For English in Canada, use "en_CA"
- etc...

```
appdir/en_US/mystrings.42s
appdir/en_GB/mystrings.42s
appdir/en_CA/mystrings.42s
```

If the language category or region can be ignored, create language sub-directories with names matching the language identifier only:

- For English, use "en"
- For French, use "fr"
- For German, use "de"
- etc...

```
appdir/en/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

Consider providing a default set of string files (in English) directly under *appdir*, in case if the regional settings of the device do not match one of the locale directories you provide, otherwise the application will stop with error -8006:

```
appdir/mystrings.42s
```

For more details about the mobile app directory structures (*appdir*), see Directory structure for GMA apps on page 2572 and Directory structure for GMI apps on page 2584.

Predefined application strings
The runtime system may need to display text to the user.

For example, the runtime system library includes a report viewer, which displays a form. By default the text is in English, and you may need to localize the text in another language. So the strings of this component must be 'localizable', as in other application strings.

To customize the built-in strings, the runtime system uses the mechanism of localized strings.

All strings used by the runtime system are centralized in a unique file:

```
$FGLDIR/src/default.str
```

which is compiled into:

```
$FGLDIR/lib/default.42s
```

This file is always loaded by the runtime system.

To overwrite the defaults, you can redefine these strings in your own localized string files.

Example
Here is an example using localized strings.

The source string file "common.str" (to be compiled with fglmkstr):

```
"common.accept" = "OK"
"common.cancel" = "Cancel"
"common.yes" = "Yes!"
"common.no" = "No!"
```

The source string file "customer.str" (to be compiled with fglmkstr):

```
"customer.mainwindow.title" = "Customers"
"customer.listwindow.title" = "Customer List"
"customer.l_custnum" = "Number:"
"customer.l_custname" = "Name:"
"customer.c_custname" = "The customer name"
"customer.q_delete" = "Do you want to delete this customer?"
```

The FGLPROFILE configuration file parameters:

```
fglrun.localization.file.count = 1
fglrun.localization.file.1.name = "common.42s"
```

Remark: The 'customer' string file does not have to listed in FGLPROFILE since it is loaded as it has the same name as the program.

The form specification file "customer.per":

```
ACTION DEFAULTS
  ACTION accept (TEXT=%"common.accept")
  ACTION cancel (TEXT=%"common.cancel")
END
LAYOUT (TEXT=%"customer.mainwindow.title")
GRID
{
[lab1       ] [f01           ]
[lab2       ] [f02                   ]
}
END
END
ATTRIBUTES
  LABEL lab1: TEXT=%"customer.l_custnum";
  EDIT f01 = FORMONLY.custnum;
  LABEL lab2: TEXT=%"customer.l_custname";
  EDIT f02 = FORMONLY.custname, COMMENT=%"customer.c_custname";
END
```

The program "customer.4gl" using the strings file:

```
MAIN
  DEFINE rec RECORD
           custnum INTEGER,
           custname CHAR(20)
         END RECORD
  OPEN FORM f1 FROM "customer"
  DISPLAY FORM f1
  INPUT BY NAME rec.*
    ON ACTION delete
       MENU %"customer.mainwindow.title"
                ATTRIBUTES(STYLE="dialog", COMMENT=%"customer.q_delete")
           COMMAND %"common.yes"
           COMMAND %"common.no"
       END MENU
  END INPUT
END MAIN
```

Runtime stack

The runtime stack is used to pass/return values to/from functions.

When passing arguments to a function or when returning values from a function, you are using the *runtime stack*. When you call a function, parameters are pushed on the stack; before the function code executes, parameters are popped from the stack in the local variables defined in the function. On the other hand, each parameter returned by a function is pushed on the stack and popped into variables specified in the `RETURNING` clause of the caller.

Elements are pushed on the stack in a given order, then popped from the stack in the reverse order. This is transparent to the programmer. However, if you want to implement a C extension, you must keep this in mind.

According to the data type, parameters are passed and returned by value or by reference. When an element is passed/returned by value, a complete copy of the value is passed. When an element is passed by reference, only the handle of the object is passed/returned. If the types allows it, elements passed by reference can be manipulated in the called function to modify the value.

Table 126: Function parameter and returning rules by language element type

Mode	Data type or data structure
By value	`BOOLEAN`, `BIGINT`, `INTEGER` , `SMALLINT`, `TINYINT`, `FLOAT` , `SMALLFLOAT`, `DECIMAL`, `MONEY`, `CHAR`, `VARCHAR`, `DATE`, `DATETIME`, `INTERVAL`, records and static arrays (cannot be returned).
By reference	Dynamic arrays, objects (from Java™, built-in or extension classes), `BYTE`/`TEXT`, `STRING` (but cannot be modified)

- Passing simple typed values as parameter on page 336
- Passing a record as parameter on page 337
- Passing a static array as parameter on page 337
- Passing a dynamic array as parameter on page 338
- Passing objects as parameter on page 338
- Passing a TEXT/BYTE as parameter on page 339
- Returning simple typed values from functions on page 339
- Returning dynamic arrays from functions on page 339
- Returning TEXT/BYTE values from functions on page 340
- Implicit data type conversion on the stack on page 340

Passing simple typed values as parameter

Simple data types such as `INTEGER`, `DECIMAL`, `VARCHAR` are passed by value in function parameters. When passing a function parameter by value, the runtime system pushes a copy of the data on the stack.

The `STRING` data type is an exception to this rule for simple types: elements of this type are passed by reference. In fact the runtime system passes a reference to the string value, so the actual string data is not copied on the stack as for other simple types. However, the value of the caller cannot be modified: If a `STRING` parameter gets a new value in a function, a new string reference is created. Passed `STRING` parameters improve performances compared to `CHAR`/`VARCHAR`, with the same semantics as `VARCHAR( )`.

When passing a simple typed value to a function, the local variable receiving the value can be changed without affecting the variable used by the caller:

```
MAIN
  DEFINE c CHAR(10), s STRING
  LET c = "abc"
```

```
  LET s = "def"
  CALL func(c,s)
  DISPLAY c -- Shows "abc"
  DISPLAY s -- Shows "def"
END MAIN

FUNCTION func(pc,ps)
  DEFINE pc CHAR(10), ps STRING
  DISPLAY c -- Shows "abc" (this is a copy of the string)
  DISPLAY s -- Shows "def" (this is the original string)
  LET pc = "zz" -- Assigns new value to local variable
  LET ps = "zz" -- Assigns new value to local variable
END FUNCTION
```

Passing a record as parameter

You can pass a `RECORD` structure as a function parameter with the dot star (`.*`) notation. In this case, the record is expanded and each member of the structure is pushed on the stack. The receiving local variables in the function can then be defined individually or with the same record structure as the caller. The next example illustrates this:

```
MAIN
  DEFINE rec RECORD
             a INT,
             b VARCHAR(50)
         END RECORD
  CALL func_r(rec.*)
  CALL func_ab(rec.*)
END MAIN

-- Function defining a record like that in the caller
FUNCTION func_r(r)
  DEFINE r RECORD
             a INT,
             b VARCHAR(50)
         END RECORD
  ...
END FUNCTION

-- Function defining two individual variables
FUNCTION func_ab(a, b)
  DEFINE a INT, b VARCHAR(50)
  ...
END FUNCTION
```

Passing a static array as parameter

It is possible to pass a complete static array as a function parameter, but this is not recommended. When passing a static array to a function, the complete array is copied on the stack and every element is passed by value. The receiving local variables in the function must be defined with the same static array definition as the caller:

```
MAIN
  DEFINE arr ARRAY[5] OF INT
  CALL func(arr)
END MAIN

-- function defining same static array as the caller
FUNCTION func(x)
  DEFINE x ARRAY[5] OF INT
  ...
```

```
END FUNCTION
```

Note that dynamic arrays are passed by reference.

Passing a dynamic array as parameter

Passing a dynamic array as a function parameter is legal and efficient. When passed as parameter, the runtime system pushes a reference of the dynamic array on the stack, and the receiving local variables in the function can then manipulate the original data.

Returning a dynamic array from a function is also possible: The runtime system pushes the reference of the dynamic array on the stack.

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF INT
  DISPLAY arr.getLength()
  LET arr = init(10)
  DISPLAY arr.getLength()
  CALL modify(arr)
  DISPLAY arr[50]
  DISPLAY arr[51]
  DISPLAY arr.getLength()
END MAIN

FUNCTION init(c)
  DEFINE c INT
  DEFINE x DYNAMIC ARRAY OF INT
  FOR i=1 TO c
     LET x[i] = i
  END FOR
  RETURN x
END FUNCTION

FUNCTION modify(x)
  DEFINE x DYNAMIC ARRAY OF INT
  LET x[50] = 222
  LET x[51] = 333
END FUNCTION
```

Output of the program:

```
0
10
222
333
51
```

Passing objects as parameter

Like other object oriented programming languages, objects of built-in classes or Java™ classes are passed by reference. It would not make much sense to pass an object by value, actually. The runtime pushes the reference of the object on the stack (i.e. the object handler is passed by value), and the reference is then popped to the receiving object variable in the function. The function can then be used to manipulate the original object.

```
MAIN
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL open(ch)
  CALL ch.close()
END MAIN
```

```
FUNCTION open(x)
  DEFINE x base.Channel -- Channel object reference
  CALL x.openFile("filename","r")
END FUNCTION
```

Passing a TEXT/BYTE as parameter

BYTE or TEXT data types define large data object (LOB) handlers internally implemented as "locators". When you pass a BYTE or TEXT to a function, the locator is pushed on the stack and popped to the receiving BYTE or TEXT variable in the function. The actual LOB data is not copied, only the locator is passed by value.

> **Important:** Since the information of the locator structure is copied (like the file name specified with a LOCATE IN FILE instruction). If you modify the locator storage information inside the function with a LOCATE instruction, the locator in the caller will become invalid. Therefore, only read and write the actual data of BYTE and TEXT parameters in functions, do not modify the storage.

Returning simple typed values from functions

Simple data types such as INTEGER, DECIMAL, VARCHAR are returned by value. When returning a simple typed value, the runtime system pushes a copy of the data on the stack. The STRING data type is an exception to this rule: elements of this type are return by mutable reference: the whole string value is not copied on the stack, only the reference to the string value is copied.

```
MAIN
  DEFINE x INTEGER
  LET x = int_add(10,20)
END MAIN

FUNCTION int_add(n1,n2)
  DEFINE n1, n2 INTEGER
  RETURN (n1+n2)
END FUNCTION
```

Returning dynamic arrays from functions

When returned by a function, dynamic arrays are pushed on the stack by reference. Therefore you can create a dynamic array in a function and return it to the caller for usage:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  LET arr = create_array(10)
  DISPLAY arr.getLength()
END MAIN

FUNCTION create_array(n)
  DEFINE n, i INTEGER
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  FOR i=1 TO n
     LET arr[i] = i
  END FOR
  RETURN arr
END FUNCTION
```

Returning TEXT/BYTE values from functions

When returning a TEXT or BYTE value from a function, the locator is pushed in on the stack. Storage information of the TEXT/BYTE is defined in the locator structure, therefore you can define the storage of the large object variable in a function, initialize the object with a value, and return it.

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  LET arr = create_array(10)
  DISPLAY arr.getLength()
END MAIN

FUNCTION create_array(n)
  DEFINE n, i INTEGER
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  FOR i=1 TO n
     LET arr[i] = i
  END FOR
  RETURN arr
END FUNCTION
```

Implicit data type conversion on the stack

When a value or a reference is popped from the stack, implicit data conversion takes place. This means, for example, that you can pass a string value to a function that defines the receiving variable as a numeric data type; no compilation error will occur, but you can get a runtime error if the string cannot be converted to a numeric. The same principle applies to values returned from functions, since the stack is also used in this case.

```
MAIN
  DEFINE s STRING
  LET s = "123"
  CALL display_integer(s) -- Will be accepted
  LET s = "abc"
  CALL display_integer(s) -- Will fail with conversion error
END MAIN

FUNCTION display_integer(x)
  DEFINE x INTEGER
  DISPLAY x
END FUNCTION
```

Exceptions

Describes exception (error) handling in the programs.

- Understanding exceptions on page 341
- Exception classes on page 341
- Exception actions on page 341
- WHENEVER instruction on page 342
- TRY - CATCH block on page 344
- Tracing exceptions on page 345
- Default exception handling on page 346
- Non-trappable errors on page 346
- Examples on page 346

Understanding exceptions

Exceptions are abnormal runtime events that can be trapped for control.

If an instruction executes abnormally, the runtime system throws exceptions that can be handled by the program.

Specific exception actions can be taken based on the class of the exception.

Runtime errors (i.e. exceptions) can be trapped by a `WHENEVER` exception handler or by a `TRY/CATCH` block. Note that some specific errors cannot be trapped.

A Genero exception is identified by its number and has a description. For a complete list of BDL errors, see Genero BDL errors on page 2297.

Exception handlers are typically used to detect database errors when executing SQL statement. For more details, see SQL execution diagnostics on page 398

Exception classes

Exception classes indirectly define the exception type.

The default action can be changed by specifying the exception class in the `WHENEVER` instruction.

Table 127: Exception classes

Class	Error reason	Default Action
`ERROR (or SQLERROR)`	Language or SQL statement error.	`STOP`
`ANY ERROR (or ANY SQLERROR)`	Language, SQL statement and expression error.	`CONTINUE` (1)
`NOT FOUND`	SQL statements returning status `NOTFOUND`.	`CONTINUE`
`WARNING`	SQL statements setting `SQLCA.SQLAWARN` flags.	`CONTINUE`

For example, the following `WHENEVER` instruction defines the behavior for the `ANY ERROR` exception class:

```
WHENEVER ANY ERROR CONTINUE
```

Exception actions

Exception actions define the type of action to be taken when an exception occurs.

There are five exception actions that can be executed if an exception is raised:

`STOP`
The program is immediately terminated. A message is displayed to the standard error with the location of the related statement, the error number, and the details of the exception.

`CONTINUE`
The program continues normally. The exception is ignored, but can be checked by testing the `STATUS`register, or the SQLCA.SQLCODE register for SQL errors.

`CALL` *exception-function*
The function *exception-function* is called by the runtime system. The function can be defined in any module, and must have zero parameters and zero

	return values. The STATUS variable will be set to the corresponding error number.
GOTO *exception-label*	The program execution continues at the label identified by *exception-label*, as if a GOTO instruction was issued after trapping the exception.
RAISE	This statement instructs the runtime system that the exception must propagated to the calling function. **Important:** Note that WHENEVER[ANY] ERROR RAISE is not supported in a REPORT routine.

WHENEVER instruction

Use the WHENEVER instruction to define how exceptions must be handled for the rest of the module.

Syntax

```
WHENEVER exception-class
 exception-action
```

where *exception-class* is one of:

```
{ [ANY] ERROR
| [ANY]  SQLERROR
|  NOT FOUND
|  WARNING
}
```

and *exception-action* is one of:

```
{ CONTINUE
| STOP
| CALL function
| RAISE
| GOTO label
}
```

1. *function* can be any function name defined in the program.
2. *label* must be a label defined in the current program block (main, function or report routine).

Usage

The WHENEVER instruction defines the exception handling by associating an *exception class* with an *exception action*.

> **Important:** The scope of a WHENEVER instruction is similar to a C preprocessor macro: It is local to the module defines the error handling for the rest of the module, unless a new WHENEVER instruction is encountered by the compiler, or a TRY/CATCH block is used.

This code example shows a typical WHENEVER instruction usage:

```
WHENEVER ERROR CONTINUE
DROP TABLE mytable -- SQL error will be ignored
CREATE TABLE mytable ( k INT, c VARCHAR(20) )
WHENEVER ERROR STOP
IF SQLCA.SQLCODE != 0 THEN
   ERROR "Could not create the table..."
```

```
END IF
```

Exception classes `ERROR` and `SQLERROR` are synonyms (compatibility issue). The previous example could have used `WHENEVER SQLERROR` instead of `WHENEVER ERROR`.

Actions for classes `ERROR`, `WARNING` and `NOT FOUND` can be set independently:

```
WHENEVER ERROR STOP
WHENEVER WARNING CONTINUE
WHENEVER NOT FOUND GOTO not_found_handler
...
```

When using the `WHENEVER ... CALL function` instruction, the program flow will go to the specified function and the return to the code block where the exception occured:

```
MAIN
    DEFINE x INTEGER
    WHENEVER ANY ERROR CALL error_handler
    -- WHENEVER handler takes effect
    LET x = 1/0
    DISPLAY "Back in MAIN..."
END MAIN

FUNCTION error_handler()
    DISPLAY "error_handler: ", STATUS
END FUNCTION

-- output:

error_handler:       -1202
Back in MAIN...
```

> **Note:** In a `WHENEVER ... CALL` instruction, you do not handle to specify braces after the function name.

A TRY/CATCH blocks takes precedence over the last `WHENEVER` instruction, see the following example:

```
MAIN
    DEFINE x INTEGER
    WHENEVER ANY ERROR CONTINUE
    -- WHENEVER handler takes effect
    LET x = 1/0
    DISPLAY "WHENEVER: ", STATUS
    -- WHENEVER handler is hidden by TRY/CATCH block
    TRY
        LET x = 1/0
    CATCH
        DISPLAY "CATCH   : ", STATUS
    END TRY
    -- WHENEVER handler takes again effect
    CALL func()
END MAIN

FUNCTION func()
    DEFINE x INTEGER
    LET x = 1/0
    DISPLAY "WHENEVER: ", STATUS
END FUNCTION

-- Output:

WHENEVER:       -1202
CATCH   :       -1202
```

```
WHENEVER:       -1202
```

The RAISE option can be used to propagate exceptions to the caller, which typically traps the error in a TRY/CATCH block:

```
-- main.4gl
IMPORT FGL myutils
MAIN
    TRY
       -- Pass a NULL form name to get error -1110
       CALL mutils.open_form(NULL)
    CATCH
       DISPLAY "Error: ", status
    END TRY
END MAIN

-- myutils.4gl
FUNCTION open_form(fn)
    DEFINE fn STRING
    WHENEVER ERROR RAISE -- Propagate exceptions to caller
    OPEN FORM f1 FROM fn
END FUNCTION
```

Important: WHENEVER [ANY] ERROR RAISE is not supported in a REPORT routine.

TRY - CATCH block

Use TRY / CATCH blocks to trap runtime exceptions in a delimited code block.

Syntax:

```
TRY
   instruction
   [...]
CATCH
   instruction
   [...]
END TRY
```

Usage:

Any language instruction in the TRY block will be executed until an exception is thrown. After an exception the program execution continues in the CATCH block. If no CATCH block is provided, the execution continues after END TRY.

If no exception is raised by the statements between the TRY and CATCH keywords, the instructions in the CATCH section are ignored and the program flow continues after END TRY.

This code example shows a TRY block executing an SQL statement:

```
TRY
    SELECT COUNT(*) INTO num_cust FROM customers WHERE ord_date <= max_date
CATCH
    ERROR "Error caught during SQL statement execution:", SQLCA.SQLCODE
END TRY
```

A TRY block be compared with WHENEVER ANY ERROR GOTO. Here is the equivalent of the previous code example:

```
WHENEVER ANY ERROR GOTO catch_error
```

```
    SELECT COUNT(*) INTO num_cust FROM customers WHERE ord_date <= max_date
    GOTO no_error
LABEL catch_error:
WHENEVER ERROR STOP
    ERROR "Error caught during SQL statement execution:", SQLCA.SQLCODE
LABEL no_error
```

The TRY statement can be nested in other TRY statements. In this example, the instruction in line #5 will be executed in case of SQL error:

```
TRY
    TRY
        SELECT COUNT(*) INTO num_cust FROM customers
    CATCH
        ERROR "Try block 2: ", SQLCA.SQLCODE
    END TRY
CATCH
    ERROR "Try block 1: ", SQLCA.SQLCODE
END TRY
```

The WHENEVER ERROR RAISE instruction can be used module-wide to define the behavior when an exception occurs in a function that is called from a TRY / CATCH block. If an exception occurs in a statement after the WHENEVER ERROR RAISE instruction, the program flow returns from the function and raises the exception as if it had occurred in the code of the caller. If the exception in thrown in the MAIN block, the program stops because the exception cannot be processed by a caller. In this example, the instruction in line #5 will be executed if an exception occurs in the *cust_report()* function:

```
MAIN
    TRY
        CALL cust_report()
    CATCH
        ERROR "An error occurred during report execution: ", STATUS
    END TRY
END MAIN

FUNCTION cust_report()
    WHENEVER ERROR RAISE
    START REPORT cust_rep ...
    ...
END FUNCTION
```

> **Important:** It is not possible to set a debugger break point at TRY, CATCH or END TRY: The TRY statement is a pseudo statement, the compiler does not generate p-code for this statement.

Tracing exceptions

Exception can be logged in a file when using the STARTLOG( ) function.

Exceptions will be automatically logged in a file, if all the following conditions are true:

- The STARTLOG function has been previously called to specify the name of the exception logging file.
- The exception action is set to CALL, GOTO or STOP. Exceptions are not logged when the action is CONTINUE or RAISE.
- The exception class is an ERROR, ANY ERROR or WARNING. NOT FOUND exceptions cannot be logged.

In other words, errors will not be logged in the case of WHENEVER { [ANY] ERROR | WARNING } CONTINUE, or when controlled by a TRY/CATCH block.

Each log entry contains:

- The system-time
- The location of the related instruction (source-file, line)

- The error-number
- The text of the error message, giving human-readable details for the exception

Default exception handling

By default, `WHENEVER ANY ERROR` action is to `CONTINUE` the program flow.

You can force the runtime system to execute the action defined with `WHENEVER ERROR` exception class with the following FGLPROFILE entry:

```
fglrun.mapAnyErrorToError = true
```

When this entry is set to true, `ET_EXPRESSION` expression errors such as a division by zero will be trapped and execute the action defined by the last `WHENEVER ERROR` instruction, the default being `STOP` the program with error display.

```
-- FGLPROFILE env var is defined to file with:
--    fglrun.mapAnyErrorToError = true

MAIN
  DEFINE x INT
  WHENEVER ERROR CALL my_error_handler
  LET x = 1 / 0   -- error handler will be called here
  DISPLAY "It continues...."
END MAIN

FUNCTION my_error_handler()
  DISPLAY "Handler: ", STATUS
END FUNCTION
```

Non-trappable errors

Some specific Genero runtime errors are not trappable.

If a non-trappable error occurs, neither WHENEVER instructions, nor TRY/CATCH blocks can trap the error: The runtime system will display the error message to the standard error stream, file an error log record if STARTLOG was previously called, and the program is stopped.

Non-trappable errors are typically fatal errors that generally deny further program execution. For example, the errors -1320, -1328 cannot be trapped.

Examples

Example 1: Defining a error handler function

This code example defines a WHENEVER ERROR handler function called `my_error_handler`. After connecting to the database, a `SELECT` statements tries to fetch a row from a table that does not exist, and raises SQL error -217 when connected to Informix®:

```
MAIN
  WHENEVER ERROR CALL my_error_handler
  DATABASE stores
  SELECT dummy FROM systables WHERE tabid=1
END MAIN

FUNCTION my_error_handler()
  DISPLAY "Error:", STATUS
  EXIT PROGRAM 1
END FUNCTION
```

Program output:

```
Error:      -217
```

Example 2: SQL error handling with WHENEVER

This code shows a typical SQL error handling block. It uses `WHENEVER ERROR CONTINUE` before executing SQL statements, tests the `SQLCA.SQLCODE` register for errors after each SQL instruction, and resets the default exception handler with `WHENEVER ERROR STOP` after the set of SQL commands to be controlled:

```
MAIN
  DEFINE
      tabname VARCHAR(50),
      sqlstmt STRING,
      rowcount INTEGER

  # In the DATABASE statement, no error should occur...
  DATABASE stores

  # But next SELECT may fail, if the user enters an invalid table name.
  WHENEVER ERROR CONTINUE
  PROMPT "Enter a table name:" FOR tabname
  LET sqlstmt = "SELECT COUNT(*) FROM " || tabname
  PREPARE s FROM sqlstmt
  IF sqlca.sqlcode THEN
     DISPLAY "SQL Error occurred:", sqlca.sqlcode
     EXIT PROGRAM 1
  END IF
  EXECUTE s INTO rowcount
  IF sqlca.sqlcode THEN
     DISPLAY "SQL Error occurred:", sqlca.sqlcode
     EXIT PROGRAM 1
  END IF
  WHENEVER ERROR STOP

  ... (more instructions, stopping the program in case of error)

END MAIN
```

Program output in case of invalid table name:

```
SQL Error occurred:      -217
```

Example 3: Typical TRY / CATCH block

This example uses a `TRY/CATCH` block to trap errors. In this case, we try to connect to an invalid database, which will raise an SQL error and make the program flow go to the line after the `CATCH` statement:

```
MAIN
    TRY
        DATABASE invalid_database_name
        DISPLAY "Will not be displayed"
    CATCH
        DISPLAY "Exception caught, SQL error: ", SQLCA.SQLCODE
    END TRY
END MAIN
```

Program output (with Informix®):

```
Exception caught, SQL error:        -329
```

Example 4: TRY / CATCH in conjuction with WHENEVER

This code illustrates the fact that a `TRY/CATCH` block can be used in conjunction with a `WHENEVER` instruction: The program first executes a `WHENEVER ANY ERROR` to define an error handler named *foo* and later it uses a `TRY/CATCH` block to trap expression errors. In this example, we intentionally force a division by zero. After the `TRY/CATCH` block, we force another division by zero error, which will call the *foo* error handler:

```
MAIN
  DEFINE i INTEGER
  WHENEVER ANY ERROR CALL foo
  TRY
    DISPLAY "Next exception should be handled by the catch statement"
    LET i = i / 0
  CATCH
    DISPLAY "Exception caught, status: ", STATUS
  END TRY
  -- Previous error handler is restored after the TRY - CATCH block
  LET status = 0
  DISPLAY "Next exception should be handled by the foo function"
  LET i = i / 0
END MAIN

FUNCTION foo()
  DISPLAY "Function foo called, status: ", STATUS
END FUNCTION
```

Program output:

```
Next exception should be handled by the catch statement
Exception caught, status:      -1202
Next exception should be handled by the foo function
Function foo called, status:      -1202
```

Example 5: WHENEVER RAISE expection propagation

This example shows the usage of `WHENEVER ... RAISE` to propagate a potential exception to the caller. First the program defines the *foo* function as exception handler with `WHENEVER ANY ERROR CALL foo`, then it calls the *do_exception* function, which instructs the runtime system to propagate a potential error to the caller. As result, the division by zero in line #13 will be caught by the error handler defined in the `MAIN` block and call the *foo* function:

```
MAIN
    DEFINE i INTEGER
    WHENEVER ANY ERROR CALL foo
    DISPLAY "Next function call will generate an exception"
    DISPLAY do_exception(100, 0)
    WHENEVER ANY ERROR STOP -- reset default handler for rest of program
    ...
END MAIN

FUNCTION do_exception(a, b)
    DEFINE a, b INTEGER
    WHENEVER ANY ERROR RAISE
    RETURN a / b
END FUNCTION
```

```
FUNCTION foo()
    DISPLAY "Exception caught, status: ", STATUS
END FUNCTION
```

Program output:

```
Next function call will generate an exception
Exception caught, status:    -1202
```

OOP support

Describes Object Oriented Programming basics in the language.

- Understanding classes and objects on page 349
- DEFINE ... package.class on page 349
- Distinguish class and object methods on page 349
- Working with objects on page 350
- What class packages exist? on page 351

Understanding classes and objects

The Genero language supports basic Object Oriented Programming (OOP) concepts.

Classes are grouped into packages which are: a) build in and directly usable, b) available as libraries which need to be imported with the `IMPORT` instruction.

It is not possible to define classes with the language.

DEFINE ... *package.class*

Object reference variables allow to manipulate class instances.

Syntax:

```
DEFINE object package.class
```

1. *object* is the variable that references the object.
2. *package* is the name of the package the class comes from.
3. *class* is the name of the class.

Distinguish class and object methods

Class methods can be invoked from the class, while object methods can only be invoked from the variable referencing the object.

Methods can be invoked like regular functions, by passing parameters and/or returning values, and can be used in expressions when they return a scalar value.

Class methods

Class methods are called by using the class identifier as prefix, with the period as separator. The class identifier includes the package name and class name.

```
package.classname.method( parameter [,...] )
```

For example, to call the `refresh()` method of the `Interface` class, which is part of the `ui` package:

```
CALL ui.Interface.refresh()
```

Object methods

Object methods are called through the variable referencing the object. To use object methods, the object must exist. Call the object methods by using the object variable as a prefix, with a period as the separator.

```
object.method( parameter [,...] )
```

For example, to call the `setFieldActive()` method of an object of the `Dialog` class, which is part of the `ui` package:

```
DEFINE d ui.Dialog
LET d = ui.Dialog.getCurrent()
CALL d.setFieldActive("cust_addr", FALSE)
```

Working with objects

This topic introduces to basic object usage in Genero BDL.

In order to use an object in your program:

1. define an object variable using the class identifier.
2. instantiate the object; this is usually done by invoking a class method.
3. call object methods to manipulate the created object.

```
DEFINE n  om.DomDocument, b DomNode
LET n = om.DomDocument.create("Stock")
LET b = n.getDocumentElement()
```

The object *n* is instantiated using the `create()` class method of the DomDocument class. The object *b* is instantiated using the `getDocumentElement()` object method of the DomDocument class. This method returns the DomNode object that is the root node of the DomDocument object *n*.

The object variable only contains the reference to the object. For example, when passed to a function, only the reference to the object is copied onto the stack.

You do not have to destroy objects. This is done automatically by the runtime system for you, based on a reference counter.

```
MAIN
  DEFINE d  om.DomDocument
  LET d = om.DomDocument.create("Stock")  -- Reference counter = 1
END MAIN  -- d is removed, reference counter = 0 => object is destroyed.
```

You can pass object variables to functions or return them from functions. Objects are passed by reference to functions. In this example, the function creates the object and returns its reference on the stack:

```
FUNCTION createStockDomDocument()
  DEFINE d  om.DomDocument
  LET d = om.DomDocument.create("Stock")  -- Reference counter = 1
  RETURN d
END FUNCTION  -- Reference counter is still 1 because d is on the stack
```

Another part of the program can get the result of that function and pass it as a parameter to another function.

Example

```
MAIN
  DEFINE x  om.DomDocument
  LET x = createStockDomDocument()
  CALL writeStockDomDocument( x )
```

```
END MAIN

FUNCTION createStockDomDocument()
  DEFINE d  om.DomDocument
  LET d = om.DomDocument.create("Stock")
  RETURN d
END FUNCTION

FUNCTION writeStockDomDocument( d )
  DEFINE d  om.DomDocument
  DEFINE r om.DomNode
  LET r = d.getDocumentElement()
  CALL r.writeXml("Stock.xml")
END FUNCTION
```

What class packages exist?

A set of utility packages including useful classes are part of the distribution.

Built-in packages such as `ui`, `om` and `base`, are part of the runtime system and can be referenced directly. Extension packages such as `util`, `os`, `com` and `xml` need to be loaded explicitly with the `IMPORT` instruction, at the beginning of program modules.

Recent versions of the language support Java™ classes. Note however that using Java™ will create a Java™ Virtual Machine (JVM) that will be part of the runtime system process.

XML support

Introduces to DOM and SAX standards and describes the XML utility classes built-in the language.

These classes are useful to perform basic XML processing and manipulate the abstract user interface tree.

Use the full-featured XML classes provided in the web services extension for other needs.

- DOM and SAX standards on page 351
- DOM and SAX built-in classes on page 351
- Limitations of XML built-in classes on page 352
- Exception handling with XML classes on page 352
- Controlling the user interface with XML classes on page 352

DOM and SAX standards

DOM and SAX are both programming interfaces that can work with XML.

The *DOM* (Document Object Model) is a programming interface specification being developed by the World Wide Web Consortium (W3C) that lets a programmer create and modify HTML pages and XML documents as full-fledged program objects. DOM is a full-fledged object-oriented, complex but complete API, providing methods to manipulate the full XML document as a whole. DOM is designed for small XML trees manipulation.

The *SAX* (Simple API for XML) is a programming interface for XML, simpler than DOM. SAX is event-driven, streamed-data based, and designed for large trees.

DOM and SAX built-in classes

The DOM and SAX APIs both contain a set of built-in classes.

The DOM API is composed of:

- The `om.DomDocument` class, that defines the interface to a DOM document. Instances of this class can be used to identify and manipulate an XML tree. *DomNode* object manipulation methods are provided by this class.
- The `om.DomNode` class, that defines the interface to an DOM node. Instances of this class can be used to identify and manipulate a branch of an XML tree. Child nodes and node attributes management methods are provided by this class.
- The `om.NodeList` class, to handle a list of DomNode objects.

The SAX API is composed of:

- The `om.SaxAttributes` class represents a set of element attributes. It is used with an `om.XmlReader` or an `om.XmlWriter` object.
- The `om.XmlReader` class, that is defined to read XML. The XML document processing is based on SAX events.
- The `om.XmlWriter` class, that is defined to write XML. The XML document processing is based on SAX events.
- The `om.SaxDocumentHandler` class, which provides an interface to implement a SAX driver using functions defined in a .4gl module loaded dynamically.

Limitations of XML built-in classes

The built-in XML classes are provided for convenience, to help you manipulate XML content easily without loading a complete external XML library such as Java™ XML classes or a C-based XML libraries.

The features of these built-in classes are limited to basic XML usage. For example, there is no DTD / XML Schema validation done; you can create the same attribute twice or set an invalid attribute value. You must take care to follow the definition of the XML document when using these classes.

For a complete XML support, use the full-featured XML classes provided in the web services extension.

Exception handling with XML classes

Errors can occur while using XML built-in classes.

For example, calling methods of a SAX handler in an invalid order raises the runtime error -8004.

By default, the program stops in case of exception. XML errors can be trapped with the `WHENEVER ERROR` or `TRY/CATCH` exception handlers of Genero. If an error occurs during a method call of an XML class, the runtime system sets the STATUS variable.

This code example shows the trapping of XML classes errors.

```
MAIN
  DEFINE w om.SaxDocumentHandler
  LET w = om.SaxDocumentHandler.createFileWriter("sample.xml")
  TRY
    CALL w.endDocument()
  CATCH
    DISPLAY "ERROR: ", STATUS
  END TRY
END
```

Controlling the user interface with XML classes

The runtime system represents the user interface of a program with a DOM tree. User interface elements can be manipulated with the DOM and SAX built-in classes.

However, you must pay attention when modifying the AUI tree directly through the use of these classes. Invalid node or attribute creation can lead to unpredictable results.

Globals

Global variables can be shared among all modules of a program.

- Understanding global blocks on page 353
- GLOBALS on page 353
- Rules for globals usage on page 353
- Database schema in globals on page 354
- Content of a globals file on page 354
- Examples on page 354

Understanding global blocks

Global symbols can be defined with the GLOBALS instruction

The `GLOBALS` instruction can be used to declare variables, constants and types for the whole program.

> **Important:** Defining global elements shared by all modules of a program is an old programming concept. To increase code re-usability and readability, avoid global elements in your programs. Use modular concepts instead, by defining `PUBLIC` variables, constants and types in modules that will be imported into other modules with the `IMPORT FGL` instruction.

GLOBALS

The GLOBALS / END GLOBALS block and the GLOBALS instruction.

Syntax 1: Global block declaration

```
GLOBALS
  declaration-statement
  [,...]
END GLOBALS
```

1. *declaration-statement* is a variable, constant or type declaration.

Syntax 2: Importing definitions from a globals file

```
GLOBALS "filename"
```

1. *filename* is the name of a file containing the definition of globals.
2. Use this syntax to include global declarations in the current module.

Rules for globals usage

Follow the rules described in this topic in order to use globals properly.

In order to extend the scope of variables, constants or user types to the whole program, define a module containing a `GLOBALS ... END GLOBALS` block and including this global module with the `GLOBALS "filename"` statement in other modules.

The *filename* must contain the `.4gl` suffix. It can be a relative or an absolute path. To specify a path, the slash (/) directory separator can be used for UNIX™ and Windows™ platforms.

If you modify the globals file, you must recompile all the modules that include the file.

If a local element has the same name as another variable that you declare in the `GLOBALS` statement, only the local variable is visible within its scope of reference.

You can declare several `GLOBALS .. END GLOBALS` blocks in the same module.

A `GLOBALS` file must not contain any executable statement.

Do not write a declaration statement outside a GLOBALS ... END GLOBALS block in a GLOBALS file.

You do not need to compile the source file containing the GLOBALS block. However, it is recommended to compile the globals file to detect errors.

You can declare several GLOBALS "*filename*" instructions in the same module.

Although you can include multiple GLOBALS ... END GLOBALS statements in the same application, do not declare the same identifier within more than oneGLOBALS declaration. Even if several declarations of a global elements defined in multiple places are identical, declaring any global element more than once can result in compilation errors or unpredictable runtime behavior.

A GLOBALS block can hold GLOBALS "*filename*" instructions. In such case, the specified files will be included recursively.

Using global elements is not recommended, prefer to export module elements with the PUBLIC keyword, and include the module into other modules with the IMPORT FGL instruction.

Database schema in globals

Globals files can define the database schema to be used by the compiler to resolve DEFINE ... LIKE statements.

The schema specification must appear before the GLOBALS keyword starting the globals block.

The schema specification is propagated to the modules including the globals file defining the database schema. These modules can use DEFINE ... LIKE without an explicit SCHEMA instruction.

Further, when using the DATABASE instruction instead of SCHEMA, if the module including the globals contains the MAIN block, the DATABASE specification of the globals file will be propagated and result in an implicit database connection at runtime.

Example

```
SCHEMA stores
GLOBALS
  DEFINE cust_rec LIKE customer.*
  ...
END GLOBALS
```

Content of a globals file

A globals file should only contain a GLOBALS ... END GLOBALS block.

Because the GLOBALS block can also be defined in regular modules, it is possible to include a source containing more than a GLOBALS block. When including such module, the sections before and after the GLOBALS block are ignored by the compiler. The source defining the global elements can be compiled individually.

For example, it is legal to define a module A with a GLOBALS ... END GLOBALS block, followed by function definitions. This module can be compiled and functions will be taken into account. Module A can then be included in module B with a GLOBALS "*filename*" instruction, and when compiling module B the function definitions of the included module A will be ignored. IMPORT instructions before the a GLOBALS ... END GLOBALS block will also be ignored in such case.

Examples

Example 1: Multiple GLOBALS file

Module "labels.4gl": This module defines the text that should be displayed on the screen

```
GLOBALS
```

```
  CONSTANT g_lbl_val = "Index:"
  CONSTANT g_lbl_idx = "Value:"
END GLOBALS
```

Module "globals.4gl": Declares a global array and a constant containing its size

```
GLOBALS "labels.4gl" -- this statement could be line 2 of main.4gl

GLOBALS
  DEFINE g_idx ARRAY[100] OF CHAR(10)
  CONSTANT g_idxsize = 100
END GLOBALS
```

Module "database.4gl": This module could be dedicated to database access

```
GLOBALS "globals.4gl"

FUNCTION get_id()
  DEFINE li INTEGER
  FOR li = 1 TO g_idxsize -- this could be a FOREACH statement
      LET g_idx[li] = g_idxsize - li
  END FOR
END FUNCTION
```

Module "main.4gl": Fill in the global array and display the result

```
GLOBALS "globals.4gl"

MAIN
  DISPLAY "Initializing constant values for this application..."
  DISPLAY "Filling the data from function get_idx in module database.4gl..."
  CALL get_id()
  DISPLAY "Retrieving a few values from g_idx"
  CALL display_data()
END MAIN

FUNCTION display_data()
  DEFINE li INTEGER
  LET li = 1
  WHILE li <= 10 AND li <= g_idxsize
      DISPLAY g_lbl_idx CLIPPED || li || " " || g_lbl_val CLIPPED ||
 g_idx[li]
      LET li = li + 1
  END WHILE
END FUNCTION
```

Database schema

Defines database table structures with column type information to be reused in program variable definitions.

- Understanding database schemas on page 356
- SCHEMA on page 356
- Structure of database schema files on page 357
- Database schema extractor options on page 364

Understanding database schemas

Database schemas hold the definition of the database tables and columns.

In program sources or form specification files, you must specify the database schema file with the SCHEMA instruction. When the database schema is specified, you can define program variables by referencing the database table or column name. The program variables will get the type of the database column as defined in the schema file.

> **Note:** To improve compilation time, the `fglcomp` compiler will automatically generate a `.42d` index file from the `.sch` schema file, in the same directory as the `.sch` file. When the `.sch` file changes, the `.42d` index file is re-generated, and can be safely removed, if you want to cleanup your projet.

The FGLDBPATH environment variable can be used to define a list of directories where the compiler can find database schema files.

The schema files contain the column data types (.sch file), validation rules (.val file), and tty display attributes (.att) for columns.

> **Note:** The .val and .att files are supported for backward compatibility and should not be used in new developments.

The data types, display attributes, and validation rules are taken from the database schema files during compilation. Make sure that the schema files of the development database correspond to the production database, otherwise the elements defined in the compiled version of your modules and forms will not match the table structures of the production database.

Program variables can be defined with the LIKE keyword to get the data type defined in the schema files:

```
SCHEMA stores
MAIN
   DEFINE custrec RECORD LIKE customer.*
   DEFINE name LIKE customer.cust_name
   ...
END MAIN
```

The database schema files are generated with the fgldbsch tool from the system tables of an existing database.

> **Note:** It is strongly recommended that you regenerate the schema files when upgrading to a new compiler version. Bug fixes and new data type support can required schema file changes. If the schema file holds data type codes that are unknown to the current version, the compilers will raise the error -6634.

The fgldbsch must connect to the database server, with a db user allowed to query the database system tables (for example, INFORMATION_SCHEMA in a MySQL database).

> **Note:** For some type of databases, the table owner is mandatory to extract schema information. If you do not specify the -ow option in the comment line, fgldbsch will take the -un user name as default. If you do not use the -un/-up options because you are using indirect database connection with FGLPROFILE settings to identify the database user, or if the database user is authenticated by the operating system, the fgldbsch tool will try to identify the current database user after connection and use this name as table owner to extract the schema.

SCHEMA

Identifies the database schema files to be used for compilation.

Syntax 1

```
SCHEMA dbname
```

Syntax 2

```
[DESCRIBE] DATABASE dbname
```

1. *dbname* identifies the name of the database schema file to be used.

Usage

The SCHEMA *dbname* instruction defines the database schema files to be used for compilation, where *dbname* identifies the name of the database schema file to be used.

[DESCRIBE] DATABASE is supported for backward compatibility, use the SCHEMA instruction instead. The [DESCRIBE] DATABASE defines the compilation database schema and the default connection when the program starts, while SCHEMA defines only the compilation database schema.

The *dbname* database name must be expressed explicitly; it cannot be a variable as in a regular DATABASE instruction inside a program block.

Use the SCHEMA instruction outside any program block, before a variable declaration with DEFINE LIKE instructions. SCHEMA must precede any program block in each module that includes a DEFINE...LIKE declaration or INITIALIZE...LIKE and VALIDATE...LIKE statements. It must also precede any DEFINE...LIKE declaration of module variables.

Database schema information such as data types for DEFINE...LIKE are taken from the schema files **during compilation**. Make sure that the database schema file of the development database corresponds to the production database; otherwise the program variables defined in the p-code modules will not match the table structures of the production database.

The *dbname* can be written with different syntaxes:

```
  database
| database @ server
| "string"   -- for ex: "//server/database"
```

Such database specification is IBM® Informix® specific and should be avoided. Use simple database identifiers only, in lowercase.

When using a simple identifier for the database name, the compiler converts the name to lowercase before searching the schema file. However, if a double quoted string is used as database name, the name will be used as is to find the schema file.

With the SCHEMA instruction, the name of the database schema during development can be different from the name of the database source used at runtime.

> **Note:** To handle uppercase characters in the database name you must quote the name: SCHEMA "myDatabase"

Example

```
SCHEMA dev_db -- Compilation database schema
DEFINE rec RECORD LIKE customer.*
MAIN
   DATABASE prod_db -- Runtime database specification
   SELECT * INTO rec.* FROM customer WHERE custno=1
END MAIN
```

Structure of database schema files

A database schema is composed by three files (.sch, .val, .att)

- Column Definition File (.sch) on page 358

- Column Validation File (.val) on page 361
- Column Video Attributes File (.att) on page 363

Column Definition File (.sch)
The .sch database schema file contains the data types of database table columns.

Description

The data type of program variables or form fields used to hold data of a given database column must match the data type used in the database. The definition of these elements is simplified by centralizing the information in external .sch files, which contain column data types.

In form files, you can directly specify the table and column name in the field definition in the `ATTRIBUTES` section of forms.

In programs, you can define variables with the data type of a database column by using the `LIKE` keyword.

As column data types are extracted from the database system tables, you may get different results with different database servers. For example, Informix® provides the DATE data type to store simple dates in year, month, and day format (= `DATE` FGL type), while Oracle stores dates as year to second (= `DATETIME YEAR TO SECOND` FGL type).

The table describes the fields you will find in a row of the .sch file:

Table 128: Structure of the .sch file

Pos	Type	Description
1	STRING	Database table name.
2	STRING	Column name.
3	SMALLINT	Coded column data type. If the column is NOT NULL, you must add 256 to the value.
4	SMALLINT	Coded data type length.
5	SMALLINT	Ordinal position of the column in the table.

Next table shows the data types and their corresponding type code that can be present in a .sch schema file:

Table 129: Database Schema file (.sch) data type codes

Data type name	Data type code (field #3)	Data type length (field #4)
CHAR	0	Maximum number of characters or bytes (see note)
SMALLINT	1	Fixed length of 2
INTEGER	2	Fixed length of 4
FLOAT / DOUBLE PRECISION	3	Fixed length of 8
SMALLFLOAT / REAL	4	Fixed length of 4
DECIMAL	5	If the decimal is defined with a precision and scale, the length is computed using this formula:

Data type name	Data type code (field #3)	Data type length (field #4)

		`length = (precision * 256) + scale`
		If the decimal is defined as a floating point decimal (i.e. with no scale), the length is computed as follows:
		`length = (precision * 256) + 255`

SERIAL	6	Fixed length of 4
DATE	7	Fixed length of 4
MONEY	8	The length is computed using this formula: `length = (precision * 256) + scale` A MONEY cannot be defined with a floating point, is has always a scale.
Unused	9	*N/A*

DATETIME	10	For DATETIME types, the length is determined using the next formula:
		`length = ( digits * 256 ) + ( qual1 * 16 ) + qual2`
		where *digits* is the total number of digits used when displaying the datetime value. For example, a DATETIME YEAR TO MINUTE (YYYY-MM-DD hh:mm) uses 12 digits.
		The *qual1* and *qual2* elements identify datetime qualifiers according to this list:
		• 0 = YEAR
		• 2 = MONTH
		• 4 = DAY
		• 6 = HOUR
		• 8 = MINUTE
		• 10 = SECOND
		• 11 = FRACTION(1)
		• 12 = FRACTION(2)
		• 13 = FRACTION(3)
		• 14 = FRACTION(4)
		• 15 = FRACTION(5)
		For example, a DATETIME YEAR TO MINUTE size length is computed as follows:
		`(12 * 256) + (0 * 16) + 8 = 3080`

BYTE	11	Length of descriptor
TEXT	12	Length of descriptor
VARCHAR	13	Maximum number of characters or bytes (see note) If the length is positive: `length = ( min_space * 256 ) + max_size`

Data type name	Data type code (field #3)	Data type length (field #4)
		If length is negative: `length + 65536 = ( min_space * 256 ) + max_size`

INTERVAL	14	For INTERVAL types, the length is determined using the next formula:
		`length = ( digits * 256 ) + ( qual1 * 16 ) + qual2`
		where *digits* is the total number of digits used when displaying the interval value. For example, a INTERVAL HOUR(5) TO FRACTION(3) (hhhhh:mm:ss.fff) uses 12 digits.
		The *qual1* and *qual2* elements identify datetime qualifiers according to this list:
		• 0 = YEAR
		• 2 = MONTH
		• 4 = DAY
		• 6 = HOUR
		• 8 = MINUTE
		• 10 = SECOND
		• 11 = FRACTION(1)
		• 12 = FRACTION(2)
		• 13 = FRACTION(3)
		• 14 = FRACTION(4)
		• 15 = FRACTION(5)
		For example, a INTERVAL HOUR(5) TO FRACTION(3) size length is computed as follows:
		`(12 * 256) + (6 * 16) + 13 = 3181`

NCHAR	15	Maximum number of characters or bytes (see note)
NVARCHAR	16	Maximum number of characters or bytes (see note)
INT8	17	Fixed length of 10 (size of int8 structure) In programs, will be converted to a `BIGINT` type.
SERIAL8	18	Fixed length of 10 (size of int8 structure) In programs, will be converted to `BIGINT` type.
BOOLEAN (SQLBOOL)	45	Boolean type, in the meaning of Informix® front-end SQLBOOL (sqltype.h)
BIGINT	52	Fixed length of 8 (bytes)
BIGSERIAL	53	Fixed length of 8 (bytes)
VARCHAR2	201	Maximum number of characters In programs, will be converted to a `VARCHAR` type.

Data type name	Data type code (field #3)	Data type length (field #4)
NVARCHAR2	202	Maximum number of characters In programs, will be converted to a VARCHAR type.

Note: Data type length (field #4) is a SMALLINT value encoding the length or composite length of the type. For character string types, the unit of the length used to define character program variables and form fields depends on the length semantics.

Informix® SERIAL types

When the database schema defines SERIAL, BIGSERIAL or SERIAL8 types, form fields referencing the serial column with get the `NOENTRY` attribute automatically, except if defined with the `TYPE LIKE` syntax.

Informix® DISTINCT types

Informix® IDS version 9.x and higher allow you to define DISTINCT types from a base types with the CREATE DISTINCT TYPE instruction. In the syscolumns table, Informix® identifies distinct types in the coltype column by adding the 0x0800 bit (2048) to the base type code. For example, a distinct type defined with the VARCHAR built-in type (i.e. code 13) will be identified with the code 2061 (13 + 2048). Informix® sets additional bits when the distinct type is based on the LVARCHAR or BOOLEAN opaque types: If the base type is an LVARCHAR, the type code used in coltype gets the 0x2000 bit set (8192) and when the base type is BOOLEAN, the type code gets the 0x4000 bit (16384).

When extracting a schema from an Informix® database defining columns with DISTINCT types, the schema extractor will keep the original type code of the distinct type in the .sch file for columns using distinct types based on built-in types (with the 0x0800 bit set). Regarding the exception of opaque types, BOOLEAN-based distinct types get the code 45 (+ 256 if NOT NULL), and LVARCHAR-based distinct types are mapped to the code 201 (+ 256 if NOT NULL) if the -cv option enables conversion from LVARCHAR to VARCHAR2.

The fglcomp and fglform compilers understand the distinct type code bit 0x0800, so you can define program variables with a DEFINE LIKE instruction based on a column that was created with a distinct Informix® type.

Example

```
customer^customer_num^258^4^1^
customer^customer_name^256^50^2^
customer^customer_address^0^100^3^
order^order_num^258^4^1^
order^order_custnum^258^4^2^
order^order_date^263^4^3^
order^order_total^261^1538^4^
```

Column Validation File (.val)

The .val database schema file holds functional and display attributes of database table columns.

Description

The .val file holds default attributes and validation rules for database columns.

Important: The form field attribute definition in the .val file is supported for backward compatibility. Do not use this feature in new developments.

In form files, the attributes are taken from the .val file as defaults if the corresponding attribute is not explicitly specified in the field definition of the `ATTRIBUTES` section. The attributes in the .val file can be considered as a default configuration for a form field.

In programs, you can validate variable values in accordance with the `INCLUDE` attribute by using the `VALIDATE` instruction.

The .val file can be generated by fgldbsch from the IBM® Informix® specific `syscolval` table, or can be edited by an external column attributes editor.

This table describes the structure of the .val file:

Table 130: Structure of the .val file

Pos	Type	Description
1	STRING	Database table name.
2	STRING	Column name.
3	STRING	Column property name.
4	STRING	Column property value.

The supported attribute definitions are:

Table 131: Supported attribute definitions of the .val file

Attribute Name	Description
`AUTONEXT`	Defines the `AUTONEXT` attribute. When this attribute is defined, value is `YES`.
`CENTURY`	Defines the `CENTURY` attribute. The value must be one of: `R`, `C`, `F`, or `P`.
`COLOR`	Defines the `COLOR` attribute. The value is a color identifier (RED, GREEN, BLUE, ...)
`COMMENTS`	Defines the `COMMENTS` attribute. The value is a quoted string or Localized String (`%"xxx"`).
`DEFAULT`	Defines the `DEFAULT` attribute. Number, quoted string or identifier (`TODAY`).
`FORMAT`	Defines the `FORMAT` attribute.

Attribute Name	Description
	The value is a quoted string.
INCLUDE	Defines an include list as the INCLUDE attribute. Value must be a list: (*value* [,...]), where *value* can be a number, quoted string or identifier (TODAY).
INVISIBLE	Defines the INVISIBLE attribute. When this attribute is defined, value is YES.
JUSTIFY	Defines the JUSTIFY attribute. The value must be one of: LEFT, CENTER or RIGHT.
PICTURE	Defines the PICTURE attribute. The value is a quoted string.
SHIFT	Corresponds to the UPSHIFT and DOWNSHIFT attributes. Values can be UP or DOWN.
VERIFY	Defines the VERIFY attribute. When this attribute is defined, value is YES.

Example

```
customer^customer_name^SHIFT^UP^
customer^customer_name^COMMENTS^"Name of the customer"^
order^order_date^DEFAULT^TODAY^
order^order_date^COMMENTS^"Creation date of the order"^
```

Column Video Attributes File (.att)

The .att database schema file contains the default video attributes of database table columns.

Description:

The **.att** file is generated by fgldbsch from the IBM® Informix® specific syscolatt table.

> **Important:** The form field video attributes definition in the .att file is supported for backward compatibility. Do not use this feature in new developments.

This table describes the structure of the .att file:

Table 132: Structure of the .att file

Pos	Type	Description
1	STRING	Database table name.
2	STRING	Column name.
3	SMALLINT	Ordinal number of the attribute record.
4	STRING	COLOR attribute (coded).
5	CHAR(1)	INVERSE attribute (y/n).
6	CHAR(1)	UNDERLINE attribute (y/n).
7	CHAR(1)	BLINK attribute (y/n).
8	CHAR(1)	LEFT attribute (y/n).
9	STRING	FORMAT attribute.
10	STRING	Condition.

Database schema extractor options

The fgldbsch tool extracts the schema description for an existing database.

Schema information is extracted from the database catalog tables. fgldbsch detects the type of the database server after connection and queries the appropriated system catalog tables.

The database system must be available and the database client environment must be set properly in order to connect to the database engine and generate the schema files.

Generate the database schema files in the directory when the source code resided or in one of the directories listed in the FGLDBPATH environment variable.

- Using the verbose mode on page 367

- IBM Informix synonym tables on page 367
- IBM Informix shadow columns on page 367
- Running schema extractor in old mode on page 367

Specifying the database source

Run fgldbsch with the `-db dbname` option to identify the database source to which to connect. The `dbname` and related options can be present in the FGLPROFILE file. Otherwise, related options have to be provided with the fgldbsch command.

```
fgldbsch -db test1
```

Specifying the database driver

The database driver can be specified with the `-dv dbdriver` option, if the default driver is not appropriate.

```
fgldbsch -db test1 -dv dbmora
```

Passing database user login and password

If the operating system user is not the database user, you can provide a database user name and password respectively with the `-un` and `-up` options.

```
fgldbsch -db test1 -un scott -up fourjs
```

Data type conversion control

The fglcomp and fglform compilers expect known language data types (FGL types) in the schema file. While most data types correspond to IBM® Informix® SQL data types, some databases (including Informix®) can use specific types that do not map to an FGL type. Therefore, data types in the schema file are generated from the system catalog tables according to some conversion rules.

Type conversion can be controlled with the `-cv` option. Each character position of the string passed by this option represents a line in the conversion table of the corresponding source database. Give a conversion code for each data type (for example: `-cv` AABAAAB).

When using X as conversion code, the columns using the corresponding data types will be ignored and not written to the **.sch** file. This is particularly useful in the case of auto-generated columns like SQL Server's *uniqueidentifier* data type, when using a `DEFAULT NEWID()` clause.

Run the tool with the `-ct` option to see all the data type conversion tables, or use the `-cx` *dbtype* option to display the conversion table for a given database type (*dbtype* must be ifx, ora, db2, msv, pgs, mys, ...).

```
fgldbsch -cx ifx
...
-------------------------------------------------------------------
Informix        Informix A          Informix B
-------------------------------------------------------------------
1 BOOLEAN       BOOLEAN (t=45)      CHAR(1)
2 INT8          INT8                DECIMAL(19,0)
3 SERIAL8       SERIAL8             DECIMAL(19,0)
4 LVARCHAR(m)   VARCHAR2(m)         VARCHAR2(m)
5 BIGINT        BIGINT              DECIMAL(19,0)
6 BIGSERIAL     BIGSERIAL           DECIMAL(19,0)
-------------------------------------------------------------------
(ns) = Not supported in 4gl.
...

fgldbsch -db test1 -cv BAAABB
```

```
                        123456
```

In the above example, the -cv option instructs fgldbsch to use the types of the "Informix® A" column for all original column types except for BOOLEAN, BIGINT and BIGSERIAL, which must be converted to a VARCHAR2(m) FGL type.

The IBM® Informix® LVARCHAR(m) type can be converted by default to a VARCHAR2(m) pseudo type (code 201), which will be identified as a VARCHAR(m) by compilers.

In schema files, VARCHAR2(m) (type code 201) is equivalent to VARCHAR(m) (type code 13), without the 255 bytes limitation of the original Informix® VARCHAR type.

Not all native data types can be converted to FGL types. For example, user-defined types or spatial types are not supported by the language. When a table column with such unsupported data type is found, fgldbsch stops and displays an error to bring the problem to your eyes. Use the -ie option of fgldbsch to ignore the database tables having columns with unsupported types. When this option is used, none of the table columns definition will be written to the schema file.

Specifying the table owner

With some databases, the owner of tables is mandatory to extract a schema, otherwise you could get multiple definitions of the same table in the **.sch** schema file if tables with the same name exist in different database user schemas. To prevent such mistakes, you can specify the schema owner with the -ow owner option. If this option is not used, fgldbsch will use the database login name passed with the -un user option. This is usually the case with SQL Server and Sybase, where the owner of tables is "dbo".

```
fgldbsch -db test1 -un scott -up fourjs -ow dbo
```

Force extraction of system tables

By default fgldbsch does not generate system table definitions. You may want to use the -st option to extract schema information of system tables.

```
fgldbsch -db test1 -st
```

Specifying the output file name

By default, the generated schema files get the name of the database source specified with the -db option. If needed, you can force the name of the schema file with the -of name option. Specify the output file name without the **.sch** extension. This name will also be used to generate the files containing column validation rules and column attributes (extracted from IBM® Informix® syscolval and syscolatt tables).

```
fgldbsch -db test1 -of myschema
```

Extracting definition of a single table

In some cases, you may just want to extract schema file of new created tables. You can achieve this by using the -tn tabname option, to extract schema information of a specific table.

```
fgldbsch -db test1 -tn customers
```

Controlling the character case

By default, table and column names are converted to lower case letters to enforce compatibility with IBM® Informix®. You can force lower case, upper case or case-sensitive generation by using the -cl, -cu or -cc options.

```
fgldbsch -db test1 -cc
```

As a general rule, it is strongly recommended to keep table and column names in lowercase, in all areas (including the objects created in the database entity).

Using the verbose mode

Use the `-v` option to get verbose output from fgldbsch:

```
fgldbsch -db test1 -v
```

Do not base other tools or development procedures on the output format, the output can change in later versions.

IBM® Informix® synonym tables

When using an IBM® Informix® database, fgldbsch extracts synonyms. By default, only PUBLIC synonyms are extracted to avoid duplicates in the .sch file when the same name is used by several synonyms by different owners.

If you want to extract PRIVATE synonyms, you must use the -ow option to specify the owner of the tables and synonyms.

IBM® Informix® shadow columns

Starting with IBM® Informix® IDS version 11.50.xC1, you can create shadow columns on tables by using DDL options such as ADD VERCOLS. These columns are visible in the system catalog tables and would be listed in the column descriptions of the .sch schema file. However, as shadow columns are not part of the SELECT * list, it is not expected to get these columns in the schema file.

By default, the fgldbsch tool will not extract shadow columns from an IBM® Informix® database. You can use the `-sc` option to force the extraction of shadow columns:

```
fgldbsch -db test1 -sc
```

Running schema extractor in old mode

The fgldbsch program can be executed in old mode by specifying the `-om` option as first parameter, followed by the database source. You can pass the `-c` and `-r` options after the database source:

```
fgldbsch -om test1 -c -r
```

Use this mode for IBM® Informix® databases only.

The `-c` option is equivalent to `-cv BBBBBBBBB` in the default mode: Columns defined with an SQL type that is not a native Genero type will be converted to an equivalent type (see -cv and -ct options for more details).

If the `-r` option is specified, the schema extractor will ignore columns defined with unsupported SQL types. Unsupported types have no equivalent FGL type to store and handle the value, such as BLOB or CLOB for example. Understand that unlike the `-ie` option, which skips the whole table definition, `-r` will exclude table columns with unsupported types, but the other columns defined with supported types will be written to the .sch file. Thus, a record declared with `DEFINE RECORD` *`rec`* `LIKE` *`table`*`.*` (from a partial schema definition of a table) cannot be used in a `SELECT * INTO` *`rec`*`.*` statement, because the number of columns in the database table is different from the record definition.

Note also that when using the old mode, fgldbsch will extract system catalog tables (informix.sys*) for IBM® Informix® databases.

Programs

Explains program structure basics and global instructions/registers.

- Structure of a program on page 368
- Structure of a module on page 368
- The MAIN block on page 370
- Importing modules on page 371
- Predefined constants on page 376
- Configuration options on page 378
- Program registers on page 387
- Program execution on page 390

Structure of a program

The structure of a program consists of `MAIN` and `FUNCTION` blocks defined in several modules.

The program starts from the `MAIN` block. The instruction blocks contain statements that are be executed by the runtime system in the order that they appear in the code. Program blocks cannot be nested, nor any program block divided among more than one source code module.

Some instructions can include other instructions. Such instructions are called *compound statements*. Every compound statement of the language supports the `END` *`statement`* keyword (where *statement* is the name of the compound statement), to mark the end of the compound statement construct within the source code module. Most compound statements also support the `EXIT` *`statement`* keywords, to transfer control of execution to the statement that follows the `END` *`statement`* keywords. By definition, every compound statement can contain at least one statement block, a group of one or more consecutive statements. In the syntax diagram of a compound statement, a statement block always includes this element.

Structure of a module

A module defines a set of program elements such as functions, report routines, types, constants and variables.

Syntax

The declaration order of elements defined in a program module is constrained. Define module elements in the following way:

```
[ compiler-options
| import-statement [...]
| schema-statement
| globals-inclusion
| constant-definition [...]
| type-definition [...]
| variable-definition [...]
]

[ MAIN-block ]

[ dialog-block
| function-block
| report-routine
    [...] ]
]
```

1. *compiler-options* are described in OPTIONS (Compilation) on page 378.
2. *import-statement* imports an external module, see Importing modules on page 371.

3. *schema-statement* defines a database schema for the compilation.
4. *globals-inclusion* includes a globals file.
5. *constant-definition* defines constants.
6. *type-definition* defines user types.
7. *variable-definition* defines variables.
8. *MAIN-block* declares the main block of the program.
9. *dialog-block* declares a declarative dialog.
10. *function-block* declares a function.
11. *report-routine* declares a report routine.

Usage

A module defines a set of program elements that can be used by other modules when defined as `PUBLIC`, or to be local to the current module when defined as `PRIVATE`. Program elements are user-defined types, variables, constants, functions, report routines, and declarative dialogs.

A module can import other modules with the `IMPORT FGL` instruction. A module can define functions, reports, module variables, constants and types, as well as declarative dialogs.

Program modules are written as .4gl source files and a compiled to .42m files. Compiled modules (.42m files) can be linked together to create a program. However, linking is supported for backward compatibility only. The preferred way is to define module dependencies with the `IMPORT FGL` instruction. For better code re-usability, module elements can be shared by each other with by qualifying module variables, constants, types and function with `PRIVATE` or `PUBLIC` keywords. `PUBLIC` module elements can be referenced in other modules.

Example

```
OPTIONS SHORT CIRCUIT
IMPORT FGL cust_data
SCHEMA stores

PRIVATE CONSTANT c_title = "Customer data form"
PUBLIC TYPE t_cust RECORD LIKE customer.*
PRIVATE DEFINE cust_arr DYNAMIC ARRAY OF t_cust

MAIN
    ...
END MAIN

DIALOG cust_dlg()
    INPUT BY NAME cust_rec.*
       ...
    END INPUT
END DIALOG

FUNCTION cust_display()
   ...
END FUNCTION

FUNCTION cust_input()
   ...
END FUNCTION

REPORT cust_rep(row)
   ...
END REPORT
```

The MAIN block

The `MAIN` block is the starting point of the program.

Syntax

```
MAIN
    [ define-statement
    | constant-statement
    | type-statement
    ]
    { [defer-statement]
    | fgl-statement
    | sql-statement
    }
    [...]
END MAIN
```

1. *define-statement* defines function arguments and local variables.
2. *constant-statement* can be used to declare local constants.
3. *type-statement* can be used to declare local user defined type.
4. *defer-statement* defines how to handle signals in the program.
5. *fgl-statement* is any instruction supported by the language.
6. *sql-statement* is any static SQL instruction supported by the language.

Usage

When the runtime system executes a program, after some initialization, it gives control to the `MAIN` program block.

The `MAIN` block typically consists of a set of interruption handling instructions, runtime configuration options, database connection and a call to the main function of the program.

Example

```
IMPORT cust_module

MAIN
    DEFINE uname, upswd STRING

    DEFER INTERRUPT
    DEFER QUIT

    OPTIONS FIELD ORDER FORM,
            INPUT WRAP,
            HELP FILE "myhelp"

    CALL get_login() RETURNING uname, upswd
    WHENEVER ERROR CONTINUE
    CONNECT TO "stores" USER uname USING upswd
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE < 0 THEN
       DISPLAY "Error: Could not connect to database."
       EXIT PROGRAM 1
    END IF

    CALL cust_module.customer_input()

END MAIN
```

Importing modules

Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

The `IMPORT {JAVA|FGL}` instruction can be used to declare the usage of an external module. All (public) symbols of the external module can be referenced in the current module.

The `IMPORT {JAVA|FGL}` instruction must be the first instruction in the current module. If you specify this instruction after `DEFINE`, `CONSTANT` or `GLOBALS`, fglcomp will report a syntax error.

The `IMPORT {JAVA|FGL}` instruction can import a compiled Genero module, a Java™ class or a C extension library:

- `IMPORT FGL` *`modulename`*: Imports a Genero module implementing functions, reports, types and variables.
- `IMPORT JAVA` *`classname`*: Imports a Java™ class or class element.
- `IMPORT` *`libname`*: Imports a C extension implementing functions and variables.

  Note: The name specified after the `IMPORT FGL` or `IMPORT JAVA` instruction is case-sensitive: Program module (.4gl) or Java™ class must exactly match the file name. However, for backward compatibility, C extension library names are converted to lowercase by the compiler (therefore, we recommend you to use lowercase file names for C extensions). A character case mismatch will be detected on UNIX™ platforms, but not on Windows™ where the file system is not case-sensitive. Regarding the usage of imported symbols in the rest of the code (i.e. not the `IMPORT` instruction): C extensions and Genero symbols are case-insensitive, while Java™ symbols are case-sensitive.

IMPORT *C-Extension*

The `IMPORT` instruction imports c extension module elements to be used by the current module.

Syntax

```
IMPORT filename
```

1. *filename* is the identifier (without the file extension) of the C extension module to be imported.

Usage

Using `IMPORT` *`libname`* instructs the compiler and runtime system to use the *libname* C extension for the current module.

Important: At runtime, all imported C extension modules are loaded when the program starts.

The name of the module specified after the `IMPORT` keyword is converted to lowercase by the compiler. Therefore it is recommended to use lowercase file names only.

The C extension must exist as a shared library (.DLL or .so) and be loadable (environment variables must be set properly). C extension modules used with the `IMPORT` instruction do not have to be linked to fglrun: The runtime system loads dependent C extension modules dynamically.

The FGLLDPATH environment variable specifies the directories to search for the C extension modules. You may also have to setup the system environment properly (i.e. PATH on Windows™ and LD_LIBRARY_PATH on UNIX™) if the C extension library depends from other libraries.

By default, the runtime system tries to load a C extension module with the name `userextension`, if it exists. This simplifies the migration of existing C extensions; you just need to create a shared library named userextension.so (or userextension.dll on Windows™), and copy the file to one of the directories defined in FGLLDPATH.

IMPORT FGL *module*

The `IMPORT FGL` instruction imports module symbols.

Syntax

```
IMPORT FGL modulename
```

1. *modulename* is the identifier (without the file extension) of the module to be imported.

Usage

With `IMPORT FGL modulename`, the symbols of the named .42m module can be referenced in the current module.

> **Important:** At runtime, the imported modules are only loaded on demand, when the program flow reaches an instruction that uses an element of the imported module. For example, when calling a function or when assigning a (public) module variable of the imported module.

The name specified after the `IMPORT FGL` instruction is case-sensitive.

The imported module symbols that can be referenced are:

- Public functions
- Public constants
- Public types
- Public module variables

The `PRIVATE`/`PUBLIC` modifiers can be used to hide / publish symbols to other modules. Functions are by default public, for backward compatibility. The next example declares a module variable that can be used by other modules, and a private function to be used only locally:

```
PUBLIC DEFINE custlist DYNAMIC ARRAY OF RECORD
  id INT,
  name VARCHAR(50),
  address VARCHAR(200)
END RECORD
...
PRIVATE FUNCTION myfunction()
...
```

When importing modules with the `IMPORT FGL` instruction, you instruct the fglcomp compiler and fglrun runtime system to load/check the specified modules, and there is no longer a need to link programs or use libraries.

With `IMPORT FGL`, the compiler can check the number of parameters and returning values in functions calls, and the completion in source code editors is improved as it can suggest all imported symbols.

Imported modules should be compiled before compiling the importing module. The FGLLDPATH environment variable specifies the directories to search for the `.42m` modules used by `IMPORT FGL`.

However, if the 42m file of the imported module is not existing, or is older as the corresponding source file, fglcomp will automatically compile the imported module. To avoid implicit compilation of imported modules, use the `--implicit=none` option of fglcomp. If the .42m file exists but the .4gl source file cannot be found, fglcomp imports the .42m file as is.

> **Important:** Auto-compilation of imported modules is only supported if the imported module is in the current directory. Modules located in other directories and found width FGLLDPATH must alredy be compiled.

No circular references are allowed. For example when module A imports module B, which in turn imports module A, you cannot compile one of the modules because the 42m file of the imported module is needed. Thus fglcomp will give error -8403, indicating that the imported module cannot be found:

Module "mod_a.4gl":

```
IMPORT FGL module_b
FUNCTION func_a()
  CALL func_b()
END FUNCTION
```

Module "mod_b.4gl":

```
IMPORT FGL module_a
FUNCTION func_b()
  CALL func_a()
END FUNCTION
```

Traditional linking is still supported for backward compatibility. To ease migration from traditional linking to imported modules, you can mix `IMPORT FGL` usage with fgllink. By default, even when `IMPORT FGL` is used, fglcomp does not raise an error if a referenced function is not found in the imported modules. This is mandatory to compile the 42m file to be linked later with the module defining the missing function. Use the `-W implicit` or the `--resolve-calls` option to check for imported functions.

When the `-W implicit` option is used and at least one `IMPORT FGL` is defined in the module, fglcomp will print warning -8406 for any referenced function that cannot be found in the imported modules. This option is silently ignored if no `IMPORT FGL` is used in the module.

To enable full symbol resolution by the compiler, use the `--resolve-calls` option. This option will force the compiler to check all function symbols referenced in a module, and raise error -8406, if a symbol could not be found in the imported modules. This option is typically used in programs that are only using `IMPORT FGL` and do not longer use the link phase.

When migrating existing projects using traditional linking, after compiling all the .4gl sources, consider using the `--print-imports` option of fglrun to print the `IMPORT FGL` suggestions for all the modules specified in the command line. This option will try to resolve all symbols as during linking, but instead of producing a .42r program, it will list the import instructions to be added in each module, and thus avoid linking:

```
$ cat main.4gl
MAIN
    CALL func1()
END MAIN
$ cat mod1.4gl
FUNCTION func1()
   CALL func2()
END FUNCTION
$ cat mod2.4gl
FUNCTION func2()
   CALL func1()
END FUNCTION

$ fglrun --print-imports main.42m mod1.42m mod2.42m
-- in main.4gl
IMPORT FGL mod1

-- in mod1.4gl
IMPORT FGL mod2

-- in mod2.4gl
# Cyclic import: IMPORT FGL mod1
#   caused by CALL func1
```

If a symbol is defined twice with the same name in two different modules, the symbol must be qualified by the name of the module. This feature overcomes the traditional 4gl limitation requiring unique function

names within a program. In the next example, both imported modules define the same "init()" function, but this can be resolved by adding the module name followed by a dot before the function names:

```
IMPORT FGL orders
IMPORT FGL customers
MAIN
  CALL orders.init()
  CALL customers.init()
  ...
END MAIN
```

If a symbol is defined twice with the same name in the current and the imported module, an unqualified symbol will reference the current module symbol. The next example calls the "init()" function with and without a module qualifier, the second call will reference the local function:

```
IMPORT FGL orders
MAIN
  CALL orders.init()  -- orders module function
  CALL init()  -- local function
  ...
END MAIN
FUNCTION init()
  ...
END FUNCTION
```

Example

Module "account.4gl":

```
PRIVATE DEFINE current_account VARCHAR(20)

PUBLIC FUNCTION set_account(id)
  DEFINE id VARCHAR(20)
  LET current_account = id
END FUNCTION
...  -- File: myutils.4gl
PRIVATE DEFINE initialized BOOLEAN

PUBLIC TYPE t_prog_info RECORD
        name STRING,
        version STRING,
        author STRING
     END RECORD

PUBLIC FUNCTION init()
  LET initialized = TRUE
  ...
END FUNCTION

PUBLIC FUNCTION fini()
  LET initialized = FALSE
  ...
END FUNCTION
```

Module "myutils.4gl":

```
PRIVATE DEFINE initialized BOOLEAN

PUBLIC TYPE t_prog_info RECORD
        name STRING,
        version STRING,
```

```
        author STRING
    END RECORD

PUBLIC FUNCTION init()
  LET initialized = TRUE
  ...
END FUNCTION

PUBLIC FUNCTION fini()
  LET initialized = FALSE
  ...
END FUNCTION
```

Module "program.4gl":

```
IMPORT FGL myutils
IMPORT FGL account
DEFINE filename STRING
DEFINE proginfo t_prog_info  -- Type is defined in myutils
MAIN
  LET proginfo.name = "program"
  LET proginfo.version = "0.99"
  LET proginfo.author = "scott"
  CALL myutils.init()  -- with module prefix
  CALL set_account("CFX4559")  -- without module prefix
END MAIN
```

IMPORT JAVA *classname*

The `IMPORT JAVA` instruction imports Java™ module elements.

Syntax

```
IMPORT JAVA classname
```

1. *classname* is the identifier of the Java™ class to be imported.

Usage

Using `IMPORT JAVA classname`, you can import and use a Java™ class.

> **Important:** At runtime, the imported Java™ classes are only loaded on demand, when the program flow reaches an instruction that uses the class. For example, when the reaching the declaration of a variable defined to reference an object of a Java™ class.

The name specified after the `IMPORT JAVA` instruction is case-sensitive.

The CLASSPATH environment variable defines the directories for Java™ packages. See the Java™ documentation for more details.

Actually *classname* must be a path with package names separated by a dot, so the actual syntax for `IMPORT JAVA` is:

```
IMPORT JAVA [ packagename . [...] ] filename
```

It is allowed to write several `IMPORT JAVA` instruction with the same class; Compilation will succeed to mimic the Java™ import rules. However, you should avoid this:

```
IMPORT JAVA java.util.regex.Matcher
 IMPORT JAVA java.util.regex.Matcher
```

Predefined constants

The language defines a set of global constants that can be used in the programs.

- NULL on page 376
- TRUE on page 376
- FALSE on page 377
- NOTFOUND on page 377

NULL

The `NULL` constant is provided as the "nil" value.

Syntax

```
NULL
```

Usage

When comparing variables to `NULL`, use the `IS NULL` operator, not the equal operator.

If an element of an expression is null, the expression is evaluated to `NULL`.

Variables are initialized to `NULL` or to zero, according to their data type.

Empty character string literals (`""`) are equivalent to `NULL`.

`NULL` cannot be used with the = equal comparison operation, you must use `IS NULL`.

Example

```
MAIN
  DEFINE s CHAR(5)
  LET s = NULL
  DISPLAY "s IS NULL evaluates to:"
  IF s IS NULL THEN
    DISPLAY "TRUE"
  ELSE
    DISPLAY "FALSE"
  END IF
END MAIN
```

TRUE

`TRUE` is a predefined constant to be used in boolean expressions.

Syntax

```
TRUE
```

Usage

`TRUE` is a predefined constant that can be used as a boolean value in boolean expressions.

The `TRUE` constant is equal to 1 (one).

`TRUE` and `FALSE` are typically used as return values of functions that give a binary result.

Example

```
MAIN
```

```
  DEFINE short BOOLEAN
  LET short = is_short("abcdef")
  IF short THEN
     DISPLAY "String is short."
  END IF
END MAIN

FUNCTION is_short(s)
  DEFINE s STRING
  IF s.getLength() < 10 THEN
     RETURN TRUE
  ELSE
     RETURN FALSE
  END IF
END FUNCTION
```

FALSE
FALSE is a predefined constant to be used in boolean expressions.

Syntax

```
FALSE
```

Usage

FALSE is a predefined constant that can be used as a boolean value in boolean expressions.

The FALSE constant is equal to 0 (zero).

TRUE and FALSE are typically used as return values of functions that give a binary result.

Example

```
MAIN
  DEFINE odd BOOLEAN
  LET odd = is_odd(125763)
  IF odd THEN
     DISPLAY "Number is odd."
  END IF
END MAIN

FUNCTION is_odd(value)
  DEFINE value INTEGER
  IF value MOD 2 = 1 THEN
     RETURN TRUE
  ELSE
     RETURN FALSE
  END IF
END FUNCTION
```

NOTFOUND
NOTFOUND is a predefined constant used to check if an SQL statement returns rows.

Syntax

```
NOTFOUND
```

Usage

The NOTFOUND constant is used to test the execution status of an SQL statement returning a result, to check whether rows have been found.

The NOTFOUND constant is equal to 100.

You typically compare SQLCA.SQLCODE to NOTFOUND, after a SELECT statement execution.

Example

```
MAIN
  DATABASE stores
  SELECT tabid FROM systables WHERE tabid = 1
  IF SQLCA.SQLCODE = NOTFOUND THEN
    DISPLAY "No row was found"
  END IF
END MAIN
```

Configuration options

Compiler and runtime system can be controlled with several configuration settings.

- OPTIONS (Compilation) on page 378
- OPTIONS (Runtime) on page 379
- Runtime configuration in FGLPROFILE on page 386
- DEFER INTERRUPT / QUIT on page 387

OPTIONS (Compilation)

OPTIONS outside program blocks defines semantics of the language for the compiler.

Syntax

```
OPTIONS
{ SHORT CIRCUIT
} [,...]
```

Usage

The OPTIONS statement used before any MAIN, FUNCTION or REPORT program block defines language semantics options, that will take effect for the current module only. Unlike runtime options, compiler options cannot be changed during program execution.

The statement to define compiler options must be placed before the MAIN block in the main module, or before the first FUNCTION / REPORT block in other modules:

The OPTIONS compiler directive allows to control following features:

- Controlling semantics of AND / OR operators on page 379

Example

```
OPTIONS SHORT CIRCUIT
MAIN
    DISPLAY "Global Options example"
END MAIN
```

Controlling semantics of AND / OR operators

The `OPTIONS SHORT CIRCUIT` defines the semantics of `AND`/`OR` operators.

When using `OPTIONS SHORT CIRCUIT` at the beginning of a module, the runtime system will optimize the evaluation of boolean expressions involving `AND` and `OR` operators, by using the *short-circuit evaluation* method (also called *minimal evaluation* method). This behavior is enabled for the whole module.

By default, the behavior of `AND` and `OR` operators is to evaluate all operands on the left and right side of the operator. In fact this is not required: If the left operand of the `AND` evaluates to `FALSE`, there is no need to evaluate the right operand, because the result of the `AND` operator will be false, anyway. Similarly, when the left operand of an `OR` expression evaluates to `TRUE`, there is not need to evaluate the right operand, since the result of the boolean expression will be true, anyway.

This method can improve performances and simplify programming. However, existing code may rely on the fact that all parts of a boolean expression are evaluated, especially when calling functions that do some processing. By using the short-circuit evaluation method, it is unsure that the function used in the right operand of AND/OR will be called, because it depends on the result of the left operand.

By using short-circuit evaluation, it is possible to reference a dynamic array in the same boolean expression, after checking that the index is in the current array element range:

```
IF x<=arr.getLength() AND arr[x].order_date > TODAY THEN
    ...
END IF
```

With the default `AND` semantics, in this code, the right operand is also evaluated. If the `x` index is greater as the array length, new array elements will be automatically created in the expression on the right of the `AND` operator. To avoid this situation, you are forced to write following code, when `OPTIONS SHORT CIRCUIT` is not used:

```
IF x<=arr.getLength() THEN
  IF arr[x].order_date > TODAY THEN
     ...
  END IF
END IF
```

OPTIONS (Runtime)

The `OPTIONS` instruction inside program blocks controls program behavior at runtime.

Syntax

```
OPTIONS options-clause [,...]
```

Usage

Use the `OPTIONS` instruction inside a function block to control the behavior of the runtime system for rest of the program execution.

A program can execute successive `OPTIONS` statements at different places in the code.

The runtime `OPTIONS` statement allows to control following runtime features:

- Defining the position of reserved lines on page 380
- Defining default TTY attributes on page 381
- Defining field tabbing order on page 382
- Defining the field input loop on page 381
- Application termination on page 383
- Front-end termination on page 383
- Defining the message file on page 384

- Defining control keys on page 384
- Setting default screen modes for sub-programs on page 385
- Enabling/disabling SQL interruption on page 386

Defining the position of reserved lines

The `OPTIONS` *`element`* `LINE` defines position of dedicated screen lines.

Syntax

```
OPTIONS
{ MENU LINE line-value
| MESSAGE LINE line-value
| COMMENT LINE {OFF|line-value}
| PROMPT LINE line-value
| ERROR LINE line-value
| FORM LINE line-value
}
```

Usage

The `OPTIONS` statement can define the positions of reserved lines for menus, forms and messages. Reserved window lines are used in TUI mode. These options are not required in GUI mode, as most have no effect on the display, except when using the traditional mode, where program windows are rendered as in a dumb terminal.

- `COMMENT LINE` specifies the position of the comment line. The comment line displays messages defined with the `COMMENT` attribute in the form specification file. The default is (`LAST-1`) for the `SCREEN`, and `LAST` for all other windows. You can hide the comment line with `COMMENT LINE OFF`.
- `ERROR LINE` specifies the position on the screen of the error line that displays the text of the `ERROR` statement. The default is the `LAST` line of the `SCREEN` window.
- `FORM LINE` specifies the window line where forms are displayed. The default is (`FIRST+2`), or line 3 of the current window.
- `MENU LINE` specifies the position of the menu line. This line displays the menu name and options, as defined by the `MENU` statement. The default is the `FIRST` line in the window.
- `MESSAGE LINE` specifies the position of the message line. This reserved line displays the text of the `MESSAGE` statement. The default is (`FIRST+1`), or line 2 of the current window.
- `PROMPT LINE` specifies the position of the prompt line where the text of `PROMPT` statements is displayed. The default value is the `FIRST` line in the window.

You can specify any of the following positions for each reserved line:

Table 133: Reserved line expressions

Expression	Description
`FIRST`	The first line of the screen or window.
`FIRST + integer`	A relative line position from the first line.
`integer`	An absolute line position in the screen or window.
`LAST - integer`	A relative line position from the last line.
`LAST`	The last line of the screen or window.

Defining default TTY attributes

The `OPTIONS {INPUT|DISPLAY} ATTRIBUTES` defines default TTY attributes for dialogs and display statements.

Syntax

```
OPTIONS { INPUT | DISPLAY } ATTRIBUTES ({FORM|WINDOW|attributes)
```

Usage

`OPTIONS INPUT ATTRIBUTES` defines the default color and terminal effect attributes that will be used in subsequent dialog statement.

`OPTIONS DISPLAY ATTRIBUTES` defines the default attributes for display statements.

The display attributes are based on dumb terminal (i.e. TTY) possibilities, but will be rendered accordingly on GUI mode. Graphical front-ends can be configured to render TTY attributes is a specific way. Instead of TTY based attributes, consider using presentation styles in new developments.

Any display attribute defined by the `OPTIONS` statement remains in effect until the runtime system encounters a statement that redefines the same attribute. This can be another `OPTIONS` statement, or an `ATTRIBUTE` clause in one of the following statements:

- `CONSTRUCT`
- `INPUT`
- `DISPLAY`
- `DIALOG`
- `INPUT ARRAY`
- `DISPLAY ARRAY`
- `OPEN WINDOW`

The `ATTRIBUTE` clause in these statements only redefines the attributes temporarily. After the window closes or after the dialog statement terminates, the runtime system restores the attributes from the most recent `OPTIONS` statement.

The `FORM` keyword in `INPUT ATTRIBUTE` or `DISPLAY ATTRIBUTE` clauses instructs the runtime system to use the input or display attributes of the current form. Similarly, you can use the `WINDOW` keyword of the same clauses to instruct the program to use the input or display attributes of the current window. You cannot combine the `FORM` or `WINDOW` attributes with any other attributes.

This table shows the valid input and display attributes:

Table 134: Input and display attributes

Attribute	Description
`BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, YELLOW`	The TTY color of the displayed text.
`BOLD, DIM, INVISIBLE, NORMAL`	The TTY font attribute of the displayed text.
`REVERSE, BLINK, UNDERLINE`	The TTY video attribute of the displayed text.

Defining the field input loop

The `OPTIONS INPUT [NO] WRAP` instructions defines field wrapping in dialogs.

Syntax

```
OPTIONS INPUT [NO] WRAP
```

Usage

By default, an interactive statement such as `CONSTRUCT` or `INPUT` terminates when the focus leaves the last field controlled by the dialog instruction.

The `OPTIONS INPUT WRAP` instruction can change this behavior, causing the cursor to move from the last field to the first, repeating the sequence of fields until the dialog is validated or canceled.

The `INPUT NO WRAP` option restores the default input loop behavior.

Example

```
MAIN
    OPTIONS INPUT WRAP
    ...
END MAIN
```

Defining field tabbing order

Syntax

```
OPTIONS FIELD ORDER { CONSTRAINED | UNCONSTRAINED | FORM }
```

Usage

Tabbing order is used in interactive instructions such as `INPUT`, `INPUT ARRAY` or `CONSTRUCT`, where individual fields can get the focus.

The `FIELD ORDER` runtime option defines the default behavior when moving from field to field with the TAB and SHIFT-TAB keys in GUI mode, and with the Up / Down arrow keys in TUI mode.

By default, the tabbing order is defined by the list of fields used by the program instruction. This corresponds to `FIELD ORDER CONSTRAINED` option, which is the default.

When using `FIELD ORDER UNCONSTRAINED` in TUI mode, the Up and Down arrow keys will move the cursor to the field above or below the current field, respectively. When using the default `FIELD ORDER CONSTRAINED` option, the Up and Down arrow keys move the cursor to the previous or next field, respectively. If `FIELD ORDER UNCONSTRAINED` is used, the `Dialog.fieldOrder` FGLPROFILE entry is ignored.

The `UNCONSTRAINED` option can only be supported in TUI mode, with a simple form layout. It is not recommended to use this option in sGUI mode.

The `FIELD ORDER FORM` option instructs interactive instructions to use the tabbing order defined by the `TABINDEX` attributes of the current form fields. With this option, tabbing order can be defined in the layout of the form, independently from the program instruction. This is the preferred way in GUI mode. When `FIELD ORDER FORM` is used, the `Dialog.fieldOrder` FGLPROFILE entry is ignored.

Example

Form "form1.per":

```
LAYOUT
GRID
{
  First name:  [f001            ] Last name:   [f002
  ]
  Address:     [f003
  ]
}
END
```

```
END

ATTRIBUTES
EDIT f001 = FORMONLY.fname, TABINDEX = 2;
EDIT f002 = FORMONLY.lname, TABINDEX = 1;
EDIT f003 = FORMONLY.address, TABINDEX = 0;
END
```

Module "main.4gl":

```
MAIN
  DEFINE fname, lname CHAR(20), address CHAR(50)

  OPTIONS INPUT WRAP

  OPEN FORM f1 FROM "f1"
  DISPLAY FORM f1

  OPTIONS FIELD ORDER CONSTRAINED
  INPUT BY NAME fname, address, lname

  OPTIONS FIELD ORDER UNCONSTRAINED
  INPUT BY NAME fname, address, lname

  OPTIONS FIELD ORDER FORM
  INPUT BY NAME fname, address, lname

END MAIN
```

Application termination

The `OPTIONS TERMINATE SIGNAL` defines a callback function in case of SIGTERM signal.

Syntax

```
OPTIONS ON TERMINATE SIGNAL CALL function
```

Usage

The `OPTIONS ON TERMINATE SIGNAL CALL` *`function`* defines the function that must be called when the application receives the SIGTERM signal. With this option, you can control program termination. If this statement is not called, the program is stopped with an exit value of SIGTERM (15).

On Microsoft™ Windows™ platforms, the function will be called in the following cases:

- The console window that the program was started from is closed.
- The current user session is terminated (i.e. the user logs off).
- The system is shut down.

Use the `OPTIONS ON TERMINATE SIGNAL CALL` *`function`* instruction with care, and do not execute complex code in the callback function. The code should only contain simple and short cleanup operations; Any interactive instruction must be avoided.

Front-end termination

The `OPTIONS CLOSE APPLICATION` instruction defines the callback function in case of front-end termination.

Syntax

```
OPTIONS ON CLOSE APPLICATION CALL function
```

Usage

The `OPTIONS ON CLOSE APPLICATION CALL` *`function`* can be used to execute specific code when the front-end stops. For example, when the front-end program is stopped, when the user workstation session is ended, or when the workstation is shut down.

Before stopping, the front-end sends a internal event that is trapped by the runtime system. When a callback function is specified with this program option command, the application code that was executing is canceled, and the callback function is executed before the program stops.

Use the `OPTIONS ON CLOSE APPLICATION CALL` *`function`* instruction with care, and do not execute complex code in the callback function. The code should only contain simple and short cleanup operations; Any interactive instruction must be avoided.

A front-end program crash or network failure is not detected and cannot be handled by this instruction.

Defining the message file
The `OPTIONS HELP FILE` instruction defines the name of the message file.

Syntax

```
OPTIONS HELP FILE filename
```

Usage

The `OPTIONS HELP FILE` instruction specifies an expression that returns the filename of a help file. This filename can also include a pathname. Messages in this file can be referenced by number in form-related statements, and are displayed at runtime when the user presses the Help key.

By default, message files are searched in the current directory, then DBPATH / FGLRESOURCEPATH environment variable is scanned to find the file.

Defining control keys
The `OPTIONS` *`action`* `KEY` instruction defines physical keys for common dialog actions.

Syntax

```
OPTIONS
{ INSERT
| DELETE
| NEXT
| PREVIOUS
| ACCEPT
| HELP
} KEY key-name
```

Usage

This `OPTIONS` clause can specify physical keys to support logical key functions in the interactive instructions.

The physical key definition options are only provided for backward compatibility with the TUI mode. Use the action defaults configuration to define accelerator keys for actions.

Description of the keys:

- The `ACCEPT KEY` specifies the key that validates a `CONSTRUCT`, `INPUT`, `DIALOG`, `INPUT ARRAY`, or `DISPLAY ARRAY` statement.

  The default `ACCEPT KEY` is `ESCAPE`.
- The `DELETE KEY` specifies the key in `INPUT ARRAY` statements that deletes a screen record.

The default DELETE KEY is F2.

- The INSERT KEY specifies the key that opens a screen record for data entry in INPUT ARRAY.

  The default INSERT KEY is F1.
- The NEXT KEY specifies the key that scrolls to the next page of a program array of records in an INPUT ARRAY or DISPLAY ARRAY statement.

  The default NEXT KEY is F3.
- The PREVIOUS KEY specifies the key that scrolls to the previous page of program records in an INPUT ARRAY or DISPLAY ARRAY statement.

  The default PREVIOUS KEY is F4.
- The HELP KEY specifies the key to display help messages.

  The default HELP KEY is CONTROL-W.

You can specify the following keywords for the physical key names:

Table 135: Keywords for physical key names

Key Name	Description
ESC or ESCAPE	The ESC key (not recommended, use ACCEPT instead).
INTERRUPT	The interruption key (on UNIX™, interruption signal).
TAB	The TAB key (not recommended).
CONTROL-*char*	A control key where *char* can be any character except A, D, H, I, J, K, L, M, R, or X
F1 through F255	A function key.
LEFT	The left arrow key.
RETURN or ENTER	The return key.
RIGHT	The right arrow key.
DOWN	The down arrow key.
UP	The up arrow key.
PREVIOUS or PREVPAGE	The previous page key.
NEXT or NEXTPAGE	The next page key.

You might not be able to use other keys that have special meaning to your version of the operating system. For example, CONTROL-C, CONTROL-Q, and CONTROL-S specify the Interrupt, XON, and XOFF signals on many UNIX™ systems.

Setting default screen modes for sub-programs

The OPTIONS RUN IN instruction defines the TTY mode to run sub-programs.

Syntax

```
OPTIONS RUN IN {FORM|LINE} MODE
```

Usage

When using character terminals, the runtime system recognizes two screen display modes: line mode (`IN LINE MODE`) and formatted mode (`IN FORM MODE`). The `OPTIONS` and `RUN` statements can explicitly specify a screen mode. The `OPTIONS` statement can set separate defaults for these statements.

After `IN LINE MODE` is specified, the terminal is in the same state (in terms of stty options) as when the program began. This usually means that the terminal input is in cooked mode, with interruption enabled, and input not available until after a newline character has been typed.

The `IN FORM MODE` keywords specify raw mode, in which each character of input becomes available to the program as it is typed or read.

By default, a program operates in line mode, but so many statements take it into formatted mode (including `OPTIONS` statements that set keys, `DISPLAY`, `OPEN WINDOW`, `DISPLAY FORM`, and other screen interaction statements), that typical programs are actually in formatted mode most of the time.

When the `OPTIONS` statement specifies `RUN IN FORM MODE`, the program remains in formatted mode if it currently is in formatted mode, but it does not enter formatted mode if it is currently in line mode.

When the `OPTIONS` statement specifies `RUN IN LINE MODE`, the program remains in line mode if it is currently in line mode, and it switches to line mode if it is currently in formatted mode.

Enabling/disabling SQL interruption
The `OPTIONS SQL INTERRUPT` instruction enables or disables SQL statement interruption.

Syntax

```
OPTIONS SQL INTERRUPT { ON | OFF }
```

Usage

The `OPTIONS SQL INTERRUPT` instruction controls interruption event detection during the execution of long running SQL statements.

Pay attention to the fact that not all database servers support SQL interruption.

By default, SQL interruption is off.

Runtime configuration in FGLPROFILE

The behavior of the runtime system can be controlled with FGLPROFILE configuration parameters.

- Responding to CTRL_LOGOFF_EVENT on page 386

Responding to CTRL_LOGOFF_EVENT
FGLPROFILE `fglrun.ignoreLogoffEvent` controls program behavior in case of logoff events on Windows™ platforms.

Syntax

```
fglrun.ignoreLogoffEvent = true
```

Usage

On Windows™ platforms, when the user disconnects, the system sends a CTRL_LOGOFF_EVENT event to all console applications. When the runtime system receives this event, it stops immediately.

On a Windows™ Terminal Server, if an Administrator user closes his session, a CTRL_LOGOFF_EVENT is sent to all console applications started by ANY user connected to the machine (even if these applications were not started by the administrator).

To prevent the runtime system from stopping on a logoff event, you can use the `fglrun.ignoreLogoffEvent` entry in the FGLPROFILE configuration file. If this entry is set to `true`, the CTRL_LOGOFF_EVENT event is ignored by the runtime system.

As a result, when the administrator user disconnects on a Windows™ Terminal Server, programs started by remote users would not stop.

DEFER INTERRUPT / QUIT
The `DEFER` instruction defines the program behavior when *interruption* or *quit* signals are received.

Syntax

```
DEFER { INTERRUPT | QUIT }
```

Usage

The `DEFER` instruction controls the behavior of the program when an *interruption* or *quit* signal has been received.

`DEFER INTERRUPT` and `DEFER QUIT` instructions can only appear in the MAIN block.

`DEFER INTERRUPT` indicates that the program must continue when it receives an *interrupt* signal. By default, the program stops when it receives an *interrupt* signal.

Once deferred, you cannot reset to the default behavior.

When an *interrupt* signal is caught by the runtime system and `DEFER INTERRUPT` is used, the `INT_FLAG` global variable is set to true by the runtime system.

Interrupt signals are raised on terminal consoles when the user presses a key like CTRL-C, depending on the stty configuration. When a program is displayed through a front end, no terminal console is used; therefore, users cannot send interrupt signals with the CTRL-C key. To send an interruption request from the front end, you must define an 'interrupt' action view.

`DEFER QUIT` indicates that the program must continue when it receives a *quit* signal. By default, the program stops when it receives a *quit* signal.

When a *quit* signal is caught by the runtime system and `DEFER QUIT` is used, the `QUIT_FLAG` global variable is set to true by the runtime system.

Program registers

Predefined global registers can be used in programs to detect errors, signals and events.

- STATUS on page 387
- INT_FLAG on page 388
- QUIT_FLAG on page 389

STATUS
`STATUS` is a predefined variable that contains the execution status of the last instruction.

Syntax

```
STATUS
```

Usage

`STATUS` is a predefined variable that contains the execution status of the last program instruction.

`STATUS` allows to get diagnostic of procedural, interactive, and SQL instructions.

The data type of STATUS is INTEGER.

> **Note:** While STATUS can be modified by hand, it is not recommended except in specific situations as shown in the STATUS example.

STATUS is typically used with WHENEVER ERROR CONTINUE or WHENEVER ERROR CALL, or TRY/CATCH blocks, to identify the type of error that occurred.

STATUS will be set for expression evaluation errors only when WHENEVER ANY ERROR is used.

After an SQL statement execution, STATUS contains the value of SQLCA.SQLCODE.

STATUS is set to an error code when an instruction produces an error, or it is reset to zero when non-assignment instructions succeed. A typical mistake is to test STATUS after a DISPLAY STATUS instruction, written after an SQL statement:

```
WHENEVER ERROR CONTINUE
DELETE FROM _invalid_table_name_ where col = 1
WHENEVER ERROR STOP
DISPLAY "STATUS:", STATUS   -- this DISPLAY instruction reset STATUS to zero
IF STATUS<0 THEN            -- Will never be the case, since STATUS==0
   DISPLAY "SQL Error!"
   EXIT PROGRAM 1
END IF
```

> **Tip:** Use SQLCA.SQLCODE for SQL error detection, and use STATUS for other language instructions.

Example

```
MAIN
  DISPLAY is_number(NULL)
  DISPLAY is_number("abc")
  DISPLAY is_number("-12.45")
END MAIN

FUNCTION is_number(s)
  DEFINE s STRING
  DEFINE f FLOAT, l_status INTEGER
  IF length(s)==0 THEN
     RETURN FALSE
  END IF
  WHENEVER ANY ERROR CONTINUE
  LET STATUS=0 # Needed, as STATUS won't be set if succeeds
  LET f = s
  LET l_status = STATUS
  WHENEVER ANY ERROR CONTINUE
  IF l_status == 0 THEN
     RETURN TRUE
  ELSE
     RETURN FALSE
  END IF
END FUNCTION
```

INT_FLAG

INT_FLAG is a predefined variable set to TRUE when an interruption event is detected.

Syntax

```
INT_FLAG
```

Usage

INT_FLAG is set to TRUE by the runtime system when an interruption event is detected by the runtime system. The interruption event is raised when the user presses the interruption key, or when the graphical front-end sends an interruption event while the program is running in a procedure or SQL query.

INT_FLAG must be used with the DEFER INTERRUPT configuration instruction. If the DEFER INTERRUPT instruction is not specified, and interruption signal will stop the program execution.

When the interruption event arrives during a procedural instruction (FOR loop), the runtime system sets INT_FLAG to TRUE. It is up to the program to check the INT_FLAG variable.

When the interruption event arrives during an interactive instruction (INPUT, CONSTRUCT), the runtime system sets INT_FLAG to TRUE and exits from the interactive instruction. It is recommended that you test INT_FLAG after an interactive instruction to check whether the input has been cancelled.

Once INT_FLAG is set to TRUE, it must be reset to FALSE in order to detect a new interruption event.

INT_FLAG will also be used by the runtime system as diagnostic flag for predefined action block execution such as ON INSERT in DISPLAY ARRAY.

Example

```
MAIN
  DEFER INTERRUPT
  LET INT_FLAG = FALSE
  INPUT BY NAME ...
     AFTER INPUT
        IF INT_FLAG THEN
           MESSAGE "The input is canceled."
        END IF
     ...
  END INPUT
  ...
END MAIN
```

QUIT_FLAG

QUIT_FLAG is a predefined variable set to TRUE when a quit event is detected.

Syntax

```
QUIT_FLAG
```

Usage

QUIT_FLAG is set to TRUE when a quit event is detected by the runtime system. The quit event is raised when the user presses the quit signal key ([Ctrl]+[Backslash]), or when another process sends the quit signal to the runtime system process.

QUIT_FLAG must be used with the DEFER QUIT configuration instruction. If the DEFER QUIT instruction is not specified, and quit signal will stop the program execution.

When the quit event arrives during a procedural instruction (FOR loop), the runtime system sets QUIT_FLAG to TRUEand continues the program execution. It is up to the program to check the QUIT_FLAG variable.

When the quit event arrives during an interactive instruction (INPUT, CONSTRUCT), the runtime system sets QUIT_FLAG to TRUE and continues with the execution of the interactive instruction.

Once QUIT_FLAG is set to TRUE, it must be reset to FALSE to detect a new quit event.

Example

```
MAIN
  DEFINE n INTEGER
  DEFER QUIT
  LET QUIT_FLAG = FALSE
  FOR n = 1 TO 1000
     IF QUIT_FLAG THEN EXIT FOR END IF
     ...
  END FOR
END MAIN
```

Program execution

This section describes program execution and language instructions related to program execution.

- Executing programs on page 390
- RUN on page 391
- EXIT PROGRAM on page 394
- BREAKPOINT on page 394

Executing programs

There are different ways to execute compiled programs, according to the configuration and the development or production context.

Prerequisites before executing a program

Make sure that all required environment variables are properly defined, such as FGLPROFILE, FGLGUI, FGLSERVER, FGLLDPATH, LANG/LC_ALL.

To display program forms in graphical mode, the GUI front-end must run on the computer defined by FGLSERVER, and all network security components (i.e. firewalls) must allow TCP connections on the port defined by this environment variable.

Verify the database client environment settings, and check that the database server is running and can be accessed, for example by using a database vendor specific tool to execute SQL commands.

Starting a program from the command line on the server

A program can be executed with the `fglrun` tool from the server command line:

```
fglrun myprogram
```

This method is typically used in development context. After compiling the programs and forms, for example with the `make` utility, execute the programs with `fglrun`.

> **Note:** The file extension (`.42m` or `.42r`) can be omitted. If no file extension is specified, `fglrun` will try to load *`progname`*`.42r`, then *`progname`*`.42m`.

Executing sub-programs from a parent program with RUN

Sub-programs can be executed from the main program with the `RUN` instruction. There can be limitations, according to the platform where the parent program executes.

Starting a program from the front-end

It is also possible to start programs on the application server from the platform where the front-end resides.

This is actually the typical way to start applications in a production environment.

- For a desktop front-end (GDC) application, define application shortcuts and use rlogin/ssh network protocols to start programs on the server or by using HTTP through a web server (GAS).
- For a web-browser application (GWC), configure the application server (GAS) to run applications from an URL.
- For a mobile device application (GMI/GMA), in a configuration where the programs run on a GAS application server, use the "`runOnServer`" front call, to start a program from the GAS.

Starting programs on a mobile device

After deploying program files on a mobile device, it can be executed as a local application, typically with a tap on the application icon.

- For a GMA (Android™) application, program files and GMA must be bundled together in an `.apk` Android package to be deployed. For more details, see Deploying mobile apps on Android devices on page 2572.
- For a GMI (iOS) application, program files and GMI must be bundled together in an `.ipa` package to be deployed. For more details, see Deploying mobile apps on iOS devices on page 2584.
- To start programs on an application server from a small embedded mobile application (starter), use the `runOnServer` front call. For more details, see Running mobile apps on an application server on page 2595.

Common app directories on mobile platforms

On mobile devices, you can use the following APIs to get common directories:

1. `base.Application.getProgramDir` `on page 1705` returns the directory path where the main `.42m` is located. Consider this location read-only and safe (no other app can access it).
2. `os.Path.pwd` `on page 2004` returns the path to the current working directory. When a mobile application is started, the GMA and the GMI set the working directory to the default application directory. Consider this location read-write and safe (no other app can access it).
3. The front call `standard.feInfo/dataDirectory` returns the front-end side temporary directory. Storage on this directory may be erased by the OS. On an embedded mobile application, as the runtime and the front-end run on the same system, the program can use this front call to retrieve a temporary directory and use the path to store temporary files. Consider this location read-write and unsafe. Applications executed remotely through a `runOnServer` front call, can use the `sandboxRunOnServer` directory under the directory returned by the `feInfo/dataDirectory` front call, to exchange files with the embedded application.

RUN

The `RUN` instruction executes the command passed as argument.

Syntax

```
RUN command
  [ IN {FORM|LINE} MODE ]
  [ RETURNING variable | WITHOUT WAITING ]
```

1. *command* is a string expression with the command to be executed.
2. *variable* is an integer variable receiving the execution status of the command.

Understanding the RUN command

The RUN instruction hands the argument command to the command interpreter. When not specifying the WITHOUT WAITING clause, the calling process waits for the called process to finish execution. Otherwise, the calling process waits the command termination.

Important: The RUN instruction has limited support on mobile platforms.

- The RUN instruction is not supported on mobile devices, because of operating system limitations.
- RUN *command* WITHOUT WAITING is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

Defining the command execution shell

In order to execute the command line, the RUN instruction uses the OS-specific shell defined in the environment of the current user. On UNIX™, this is defined by the **SHELL** environment variable. On Windows™, this is defined by **COMSPEC**. On Windows™, the program defined by the **COMSPEC** variable must support the ***/c*** option as CMD.EXE.

Waiting for the subprocess

By default, the runtime system waits for the end of the execution of the command, suspending the execution of the current program. After executing the command, the display of the parent program is restored.

If you specify WITHOUT WAITING, the specified command line is executed as a background process, and generally does not affect the visual display. This clause can be used when the command takes some time to execute, and the parent program does not need the result to continue. It is also typically used in GUI mode to start another program. Do not use this clause in TUI mode when the sub-program displays forms, otherwise both programs would run simultaneously on the same terminal.

Catching the execution status

The RETURNING clause saves the termination status code of the command that RUN executes in a program variable of type SMALLINT. Examine the variable after execution to determine the next action to take. A status code of zero usually indicates that the command has terminated normally. A non-zero exit status indicates an error.

Important:

The execution status provided by the RETURNING clause is platform-dependent. On UNIX™ systems, the value is composed of two bytes having different meanings. On Windows™ platforms, the execution status is usually zero for success, not zero if an error occurred.

On UNIX™ systems, the lower byte (x mod 256) of the return status defines the termination status of the RUN command. The higher byte (x / 256) of the return status defines the execution status of the program. On Windows™ systems, the value of the return status defines the execution status of the program.

IN LINE MODE and IN FORM MODE

When using the TUI mode, programs operate by default in *line mode*, but as many statements take it into *form mode* (including OPTIONS statements that set keys, DISPLAY, OPEN WINDOW, DISPLAY FORM>, and other screen interaction statements), typical interactive TUI programs are actually in *form mode* most of the time.

According to the type of command to be executed, you may need to use the IN {LINE|FORM} MODE clause with the RUN instruction. It defines how the terminal or the graphical front-end behaves when running the child process.

Besides RUN, the OPTIONS, START REPORT and REPORT statements can explicitly specify a screen mode. If no screen mode is specified in the RUN command, the current value from the OPTIONS statement is used. This is, by default, IN LINE MODE. The default screen mode for PIPE specifications in reports is IN FORM MODE.

When the RUN statement specifies IN FORM MODE, the program remains in *form mode* if it is currently in *form mode*, but it does not enter *form mode* if it is currently in *line mode*. When the prevailing RUN option specifies IN LINE MODE, the program remains in *line mode* if it is currently in *line mode*, and it switches to *line mode* if it is currently in *form mode*. This also applies to the PIPE option.

Typically, if you need to run another interactive program, you must use the IN LINE MODE clause:

- In TUI mode, the terminal is in the same state (in terms if *tty* options) as when the program began. Usually the terminal input is in cooked mode, with interrupts enabled and input not becoming available until after a newline character is typed.
- In GUI mode, if the WITHOUT WAITING clause in used, the front-end is warned before the child process is started (this causes a first network round-trip) After the child is started, the front-end is warned that the command was executed (second network round-trip). If the RUN command must wait for child termination (i.e. no WITHOUT WAITING clause is used), no particular action is taken.

However, if you want to execute a subprocess running silently (batch program without output), you must use the IN FORM MODE clause:

- In TUI mode, the screen stays in *form mode* if it was in *form mode*, which saves a clear / redraw of the screen. The FORM mode specifies the terminal raw mode, in which each character of input becomes available to the program as it is typed or read.
- In GUI mode, no particular action is taken to warn the front-end (there is no need to warn the front-end for batch program execution).

To summarize, no matter if you are in TUI or GUI mode, run silent (batch) programs in FORM MODE, and if the program to run is interactive, displays messages to the terminal, or if you don't known what it does, use the LINE MODE (witch is the default).

A good practice is to encapsulate child program and system command execution in functions.

Example

```
MAIN
  DEFINE result SMALLINT
  CALL runApplication("app2 -p xxx")
  CALL runBatch("ls -l", FALSE) RETURNING result
  CALL runBatch("ls -l > /tmp/files", TRUE) RETURNING result
END MAIN

FUNCTION runApplication(pname)
  DEFINE pname, cmd STRING
  LET cmd = "fglrun " || pname
  IF fgl_getenv("FGLGUI") == 0 THEN
    RUN cmd
  ELSE
    RUN cmd WITHOUT WAITING
  END IF
END FUNCTION

FUNCTION runBatch(cmd, silent)
  DEFINE cmd STRING
  DEFINE silent STRING
  DEFINE result SMALLINT
  IF silent THEN
    RUN cmd IN FORM MODE RETURNING result
  ELSE
    RUN cmd IN LINE MODE RETURNING result
```

```
  END IF
  IF fgl_getenv("OS") MATCHES "Win*" THEN
    RETURN result
  ELSE
    RETURN ( result / 256 )
  END IF
END FUNCTION
```

EXIT PROGRAM

The `EXIT PROGRAM` instruction terminates the execution of the program.

Syntax

```
EXIT PROGRAM [ exit-code ]
```

1. *exit-code* is a valid integer expression that can be read by the process which invoked the program.

Usage

Use the `EXIT PROGRAM` instruction to stop the execution of the current program instance.

exit-code must be zero by default for normal, successful program termination.

exit-code is converted into a positive integer between 0 and 255 (8 bits).

Example

```
MAIN
  DISPLAY "Emergency exit."
  EXIT PROGRAM -1
  DISPLAY "This will never be displayed."
END MAIN
```

BREAKPOINT

The `BREAKPOINT` instruction sets a program breakpoint when running in debug mode.

Syntax

```
BREAKPOINT
```

Usage

Normally, to set a breakpoint when you debug a program, you must use the *break* command of the debugger. But in some situations, you might need to set the breakpoint in program sources. Therefore, the `BREAKPOINT` instruction has been added to the language.

When you start fglrun in debug mode with the -d option, if the program flow encounters a `BREAKPOINT` instruction, the program execution stops and the debug prompt is displayed, to let you enter a debugger command. The `BREAKPOINT` instruction is ignored when not running in debug mode.

Example

```
MAIN
  DEFINE i INTEGER
  LET i=123
```

```
  BREAKPOINT
  DISPLAY i
END MAIN
```

Front calls

Front call functions execute on the platform where the front-end is installed.

- Understanding front calls on page 395
- ui.Interface.frontCall on page 395
- User-defined front calls on page 397

Understanding front calls

Front calls execute a native function on the front-end platform.

In your Genero program, use the `ui.Interface.frontCall()` class method to invoke front-end functions. When calling a user function from programs, specify a module name and a function name. Input and output parameters can be passed/returned in order to transmit/receive values to/from the front-end. A typical example is an "open file" dialog window that allows you to select a file from the front-end workstation file system.

> **Important:** Some front calls are specific to the platform or front-end technology and may not by supported. For example, it is not possible to execute a shell command (shellexec) with the Web Browser front-end.

A set of front-end functions is built-in by default in front-ends. However, it is possible to write your own functions in order to extend the front-end possibilities.

> **Tip:** While you can use DDE/OLE APIs to manipulate Microsoft™ Office documents, there are freeware alternatives such as the Apache POI Java™ library which can be used with the Java™ Interface. For an example, see Java™ Interface: Example 2 .

ui.Interface.frontCall

`ui.Interface.frontCall` performs a function call to the current front-end.

Syntax

```
ui.Interface.frontCall(
   module STRING,
   function STRING,
   [ parameter-list ],
   [ returning-list ] )
```

1. *module* defines the shared library or classpath where the function is implemented.
2. *function* defines the name of the function to be called.
3. *parameter-list* is a list of input parameters.
4. *returning-list* is a list of output parameters.

> **Important:** The *returning-list* variables are passed by reference to the `frontCall()` method.

Usage

The `ui.Interface.frontCall()` class method can be used to execute a procedure on the front-end workstation through the front-end software component. You can for example launch a front-end specific application like a browser or a text editor, or manage the clipboard content.

The method takes four parameters:

1. The module, identifying the shared library (.so or .DLL) or the Java class (GMA) implementing the front call function.
2. The function of the module the be executed.
3. The list of input parameters, using the square brace notation.
4. The list of output parameters, using the square brace notation.

Input and output parameters are provided as a variable list of parameters, by using the square braces notation (`[param1,param2,...]`). Input parameters can be an expression supported by the language; output parameters must be variables only, to receive the returning values. An empty list is specified with `[]`. Output parameters are optional: If the front call returns values, they will be ignored by the runtime system.

Simple front call example:

```
FUNCTION call()
  DEFINE info STRING
  CALL ui.Interface.frontCall( "standard", "feInfo", ["feName"], [info] )
END FUNCTION
```

Some front calls need a file path as parameter. File paths must follow the syntax of the front end workstation file system. You may need to escape backslash characters in such parameters. The next example shows how to pass a file path with a space in a directory name to a front-end running on a Microsoft™ Windows™ workstation:

```
FUNCTION call()
   DEFINE path STRING, res INTEGER
   LET path = "\"c:\\work dir\\my report.doc\""
   -- This is: "c:\work dir\my report.doc"
   CALL ui.Interface.frontCall( "standard", "shellExec", [path], [res] )
END FUNCTION
```

Front call error handling

Exception handling instructions can be used to check the execution status of a front call. Both `WHENEVER ERROR` directives or `TRY/CATCH` block can surround the front call to avoid program stop in case of error, and check the error number returned in the `STATUS` variable.

> **Note:** There is not need to surround front calls with exception handlers such as `TRY/CATCH`, if the front call is always supposed to execute without error. For example, the feInfo front call will never produce an exception.

Example of front call error handling with a `TRY/CATCH` block:

```
FUNCTION takePhoto()
   DEFINE path STRING
   TRY -- This front call may fail if the front-end is not a mobile device:
       CALL ui.Interface.frontCall( "mobile", "takePhoto", [], [path] )
   CATCH
       MESSAGE "Cannot take photo: ", STATUS, " ", err_get(STATUS)
       LET path = NULL
   END TRY
   RETURN path
END FUNCTION
```

If the front call module name or the function name is invalid, the errors -6331 or -6332 will be raised, respectively.

If the front call execution failed for some reason, the error -6333 will be raised. The description of the problem can be found in the second part of the error message, returned by a call to the ERR_GET() function.

The error -6334 can be raised in case of input or output parameter mismatch. The control of the number of input and output parameters is in the hands of the front-end. Most of the standard front calls have optional returning parameters and will not raise error -6334, if the output parameter list is left empty. However, front-end specific extensions or user-defined front-end functions may return an invalid execution status in case of input or output parameter mismatch, raising error -6334. If the front-end sends an call execution status of zero (OK), and the number of returned values does not match the number of program variables, the runtime system will set unmatched program variables to `NULL`. As a general rule, the program should provide the expected input and output parameters as specified in the documentation.

User-defined front calls

Extend the Genero language possibilities by implementing your own front-end functions.

For more details, see User-defined front calls on page 1615.

SQL support

These topics cover SQL support in the Genero Business Development Language.

- SQL programming on page 398
- Database connections on page 457
- Database transactions on page 480
- Static SQL statements on page 486
- Dynamic SQL management on page 500

- The base.SQLHandle built-in class on page 410

SQL execution diagnostics

If an SQL statement execution failed, error description can be found in the `SQLCA.SQLCODE`, `SQLSTATE`, `STATUS` and `SQLERRMESSAGE` predefined registers.

Trapping SQL errors

By default, SQL errors stop program execution and display the error message to the standard output. Most SQL statements executed by a program should not return an error and thus do not require error trapping. However, in some cases, a program must keep the control when an SQL error occurs. For example, when connecting to the database, the user might enter an invalid password that will raise a login denied error. The program must trap such SQL connection error to return to the login dialog and let the user enter a new login and password.

To trap potential SQL errors, surround the SQL statements to be checked either with a `WHENEVER ERROR` exception handler or with a `TRY / CATCH` block:

```
-- WHENEVER ERROR handler
WHENENEVER ERROR CONTINUE
  INSERT INTO orders VALUES ( rec_ord. * )
  IF SQLCA.SQLCODE = -75623 THEN
     ...
  END IF
WHENEVER ERROR STOP -- restore the default

-- TRY/CATCH block
TRY
  INSERT INTO orders VALUES ( rec_ord. * )
CATCH
  IF SQLCA.SQLCODE = -75623 THEN
     ...
  END IF
END TRY
```

Using SQLCA.SQLCODE

SQL error codes are provided in the `SQLCA.SQLCODE` register. This register always contains an IBM® Informix® error code, even when connected to a database different from IBM® Informix®.

`STATUS` is the global language error code register, set for any kind of error (even non-SQL). When an SQL error occurs, the error held in `SQLCA.SQLCODE` is copied into `STATUS`.

Use `SQLCA.SQLCODE` for SQL error management, and `STATUS` to detect errors with other language instructions.

When connecting to a database different from IBM® Informix®, the database driver tries to convert the native SQL error to an IBM® Informix® error which will be copied into the `SQLCA.SQLCODE` and `STATUS` registers. If the native SQL error cannot be converted, `SQLCA.SQLCODE` and `STATUS` will be set to **-6372** (a general SQL error), you can then check the native SQL error in `SQLCA.SQLERRD[2]`. The native SQL error code is always available in `SQLCA.SQLERRD[2]`, even if it could not be converted to an IBM® Informix® error.

Using SQLSTATE

`SQLSTATE` contains an error code that follows ISO/ANSI standard error specification, but not all database servers support this register. Using `SQLSTATE` for SQL error checking should be the preferred way for portable SQL programming, as long as the target databases support this feature.

The `SQLSTATE` codes are defined by the ANSI/ISO standard specification, however not all database types support this standard.

Table 136: SQLSTATE error codes support per database server type

Database Server Type	Supports SQLSTATE errors
IBM® DB2® UDB (UNIX™)	Yes, since version 7.1
IBM® Informix®	Yes, since IDS 10
Microsoft™ SQL Server	Yes, since version 8 (2000)
MySQL	Yes
Oracle Database Server	Not in version 10.2
PostgreSQL	Yes, since version 7.4

Database Server Type	Supports SQLSTATE errors
Sybase ASE	Yes

Centralize SQL error checking

SQL error identification sometimes requires complex code, checking different error numbers that can be RDBMS-specific. Therefore, it is strongly recommended that you centralize SQL error identification in a function. This will allow you to write RDBMS-specific code, when needed, only once.

For maximum SQL portability, centralize SQL error checking in functions, to test either `SQLCA.SQLCODE` or `SQLSTATE`, according to the target database, and define your own error identifiers with constants:

```
CONSTANT SQLERR_INVALID_DATABASE = -1001,
         SQLERR_INVALID_USER = -1002,
         ...

FUNCTION do_connect()
  DEFINE uname, upswd VARCHAR(100)
  WHILE TRUE
    CALL login() RETURNING uname, upswd
    TRY
       CONNECT TO "stores" USER uname USING upswd
    CATCH
       CASE check_sql_error()
       WHEN SQLERR_INVALID_DATABASE
          DISPLAY SQLERRMESSAGE
          EXIT PROGRAM 1 -- Fatal error: Stop!
       WHEN SQLERR_INVALID_USER
          ERROR "Invalid login, try again"
          CONTINUE WHILE
       END CASE
    END TRY
    EXIT WHILE
  END WHILE
END FUNCTION
```

SQL error messages

`SQLERRMESSAGE` contains the database-specific error message. These messages are different for every database type and should only be used to print or log SQL execution diagnostic information.

SQL warnings

Some SQL instructions can produce SQL Warnings. Compared to SQL Errors which do normally stop the program execution, SQL Warnings indicate a minor issue that can often be ignored. For example, when connecting to an IBM® Informix® database, a warning is returned to indicate that a database was opened, and an other warning might be returned if that database supports transactions. None of these facts are critical problems, but knowing that information can help for further program execution.

If an SQL Warning is raised, `SQLCA.SQLCODE` / `STATUS` remain zero, and the program flow continues. To detect if an SQL Warning occurs, the SQLCA.SQLAWARN register must be used. `SQLCA.SQLAWARN` is defined as a `CHAR(7)` variable. If `SQLCA.SQLAWARN[1]` contains the `W` letter, it means that the last SQL instruction has returned a warning. The other character positions (`SQLCA.SQLAWARN[2-8]`) may contain W letters. Each position from 2 to 8 has a special meaning according to the database server type, and the SQL instructions type.

If `SQLCA.SQLAWARN` is set, you can also check the `SQLSTATE` and `SQLCA.SQLERRD[2]` registers to get more details about the warning. The `SQLERRMESSAGE` register might also contain the warning description.

In the next example, the program connects to a database and displays the content of the SQLCA.SQLAWARN register. When connecting to an IBM® Informix® database with transactions, the program will display [WW W]:

```
MAIN
  DATABASE stores
  DISPLAY "[", sqlca.sqlawarn, "]"
END MAIN
```

By default SQL Warnings do not stop the program execution. To trap SQL Warnings with an exception handle, use the WHENEVER WARNING instruction, as shown in this example.

```
MAIN
  DEFINE cust_name VARCHAR(50)
  DATABASE stores
  WHENEVER WARNING STOP
  SELECT cust_lname, cust_address INTO cust_name
       FROM customer WHERE cust_id = 101
  WHENEVER WARNING CONTINUE
END MAIN
```

The SELECT statement in this example uses two columns in the select list, but only one INTO variable is provided. This is legal and does not raise an SQL Error, however, it will set the SQLCA.SQLAWARN register to indicate that the number of target variables does not match the select-list items.

See also WHENEVER WARNING exception.

Display detailed debug information in case of internal driver error

If an unexpected problem happens within the database driver, the driver will return the error **-6319** (internal error in the database library). When this SQL error occurs, set the FGLSQLDEBUG environment variable to get more details about the internal error.

The SQLCA diagnostic record

The SQLCA variable is a predefined record containing SQL statement execution information.

The SQLCA record definition

The SQLCA record is defined as follows:

```
DEFINE SQLCA RECORD
  SQLCODE INTEGER,
  SQLERRM VARCHAR(71),
  SQLERRP CHAR(7),
  SQLERRD ARRAY[6] OF INTEGER,
  SQLAWARN CHAR(7)
END RECORD
```

1. SQLCODE contains the SQL execution code (0 = OK, 100 = not row found, <0 = error).
2. SQLERRM contains the error message parameter.
3. SQLERRP is not used at this time.
4. SQLERRD[1] is not used at this time.
5. SQLERRD[2] contains the last SERIAL or the native SQL error code.
6. SQLERRD[3] contains the number of rows processed in the last statement (server dependent).
7. SQLERRD[4] contains the estimated CPU cost for the query (server dependent).
8. SQLERRD[5] contains the offset of the error in the SQL statement text (server dependent).
9. SQLERRD[6] contains the ROWID of the last row that was processed (server dependent).
10. SQLAWARN contains the ANSI warning represented by a W character at a given position in the string.

11.SQLAWARN[1] is set to W when any of the other warning characters have been set to W.
12.SQLAWARN[2-7] have specific meanings, see database server documentation for more details.

Usage

SQLCA stands for the *SQL Communication Area* variable.

The SQLCA can be used to get an SQL execution diagnostic. Error and warning information can be found in this structure.

The SQLCA record is filled after each SQL statement execution.

SQLCA is not designed to be modified by user code, it must be used as a read-only record.

Portability

SQLCA.SQLCODE will be set to a specific IBM® Informix® SQL error code, if the database driver can convert the native SQL error to an IBM® Informix® SQL error. In case of error, SQLCA.SQLERRD[2] will hold the native SQL error produced by the database server.

Other SQLCA record members are specific to IBM® Informix® databases. For example, after inserting a row in a table with a SERIAL column, SQLCA.SQLERRD[2] contains the new generated serial number. After an SQL error, SQLCA.SQLERRD[2] contains the native SQL error. The SQLCA.SQLERRD[3] member may be set with the number of processed rows, if the database client provides the API. Other SQLCA.SQLERRD[n] members must be considered as not portable.

Example

```
MAIN
  WHENEVER ERROR CONTINUE
  DATABASE stores
  SELECT COUNT(*) FROM foo   -- Table should not exist!
  DISPLAY SQLCA.SQLCODE, SQLCA.SQLERRD[2]
END MAIN
```

SQL error identification

Identify SQL exceptions in your programs with SQLCA.SQLCODE.

Every database type has its own error numbers. Portable SQL code must take care of this when checking for SQL errors in programs.

The IBM® Informix® compatible error code is stored in the SQLCA.SQLCODE register. This is done to simplify migration to another database type. Existing code based on Informix® error numbers does not need to be modified.

Database drivers map native SQL errors to Informix SQL errors, as listed in the following table:

Table 137: Native SQL error to Informix SQL error mappings

Informix SQL	Oracle DB	SQL Server	IBM DB2	PostgreSQ	MySQL	Sybase ASE	SQLite	Netezza

Sometimes the native error code of the database cannot be converted to an Informix® error code. In such case, the `SQLCA.SQLCODE` register will be set to **-6372**. To properly identify an SQL error, the native SQL error code is also provided in the `SQLCA.SQLERRD[2]` register.

Centralize SQL error identification in a function:

```
-- sqlerr.4gl module

PUBLIC CONSTANT SQLERRTYPE_FATAL = -1
PUBLIC CONSTANT SQLERRTYPE_LOCK  = -2
PUBLIC CONSTANT SQLERRTYPE_CONN  = -3

FUNCTION lastSqlErrorType()
   CASE
     WHEN SQLCA.SQLCODE == -201
            OR SQLCA.SQLERRD[2] == ...
       RETURN SQLERR_FATAL
     WHEN SQLCA.SQLCODE == -263
            OR SQLCA.SQLCODE == -244
            OR SQLCA.SQLERRD[2] == ...
```

```
        RETURN SQLERR_LOCK
      ...
   END CASE
END FUNCTION
```

You can then easily use this function after every SQL statement in your programs:

```
IMPORT FGL sqlerr
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   UPDATE customer SET cust_address = NULL
     WHEN cust_name IS NULL
   IF lastSqlErrorType() == SQLERRTYPE_LOCK THEN
       ...
   END IF
   ...
END MAIN
```

SQL interruption
Interrupt long running SQL queries, or interrupt waiting queries because data is locked.

If the database server supports SQL interruption, a program can interrupt a long running SQL statement.

SQL interruption is not enabled by default. use the `OPTIONS SQL INTERRUPT ON` program option to turn on SQL interruption.

With `OPTIONS SQL INTERRUPT ON`, when the program gets an interruption event (a SIGINT signal from the system, or an interrupt event from the front-end), the running SQL statement is stopped, the `INT_FLAG` global variable is set to `TRUE`, and `SQLCA.SQLCODE` is set with error -213.

SQL interrupt must be used in conjunction with signal handling instructions `DEFER INTERRUPT` and `DEFER QUIT`, otherwise the program would stop immediately in case of interruption event.

SQL interruption results in abnormal SQL statement execution and raises a runtime error. Therefore, the SQL statement that can be subject of interruption must be protected by a `WHENEVER ERROR` exception handler.

```
MAIN
  DEFINE n INTEGER
  DEFER INTERRUPT
  OPTIONS SQL INTERRUPT ON
  DATABASE test1
  WHENEVER ERROR CONTINUE
  -- Start long query (self join takes time)
  -- From now on, user can hit CTRL-C in TUI mode to stop the query
  SELECT COUNT(*) INTO n FROM customers a, customers b
       WHERE a.cust_id <> b.cust_id
  IF SQLCA.SQLCODE == -213 THEN
     DISPLAY "Statement was interrupted by user..."
     EXIT PROGRAM 1
  END IF
  WHENEVER ERROR STOP
  ...
END MAIN
```

When SQL interruption is supported by the database server type that is different from IBM® Informix®, the database drivers will return error -213 in case of interruption, to behave as in IBM® Informix®.

> **Important:** Not all database servers support SQL interruption.

Table 138: Database server support of SQL interruption

Database Server Type	SQL Interruption API	SQL error code for interrupted query
IBM® DB2® UDB (Since version 9.x)	SQLCancel()	Native error -952
IBM® Informix®	sqlbreak()	Native error -213
Microsoft™ SQL Server (Only 2005+ with SNC driver)	SQLCancel()	SQLSTATE HY008
MySQL	KILL QUERY command	Native error -1317
Oracle Database Server	OCIBreak()	Native error -1013
PostgreSQL	PQCancel()	SQLSTATE 57014
Sybase ASE	ct_cancel()	SQLSTATE HY008
SQLite	sqlite3_interrupt()	Native error SQLITE_ABORT

Debugging SQL
Set the FGLSQLDEBUG environment variable to print SQL debug info.

SQL debug information is printed by the runtime system when the FGLSQLDEBUG environment variable is defined. This variable can be set to an integer value from 0 to 10, according to the debugging details you want to see. The debug messages are sent to the standard error stream. If needed, you can redirect the standard error output into a file.

UNIX™ (shell) example:

```
FGLSQLDEBUG=3
export FGLSQLDEBUG
fglrun myprog 2>sqldbg.txt
```

An SQL debug header is printed before executing the underlying ODI driver code. If the driver code crashes or raises an assertion, you can easily find the last SQL instruction that was executed by the program, and report to you support center.

Cursors and connections
Several database connections can be opened simultaneously with the `CONNECT TO` instruction. Once connected, you can `DECLARE` cursors or `PREPARE` statements to be used in parallel within different connection contexts. This section describes how to use SQL cursors and SQL statements in a multiple-connection program.

When you `DECLARE` a cursor or when you `PREPARE` a statement, you actually create an *SQL statement handle*; the runtime system allocates resources for that statement handle before sending the SQL text to the database server via the database driver.

The SQL statement handle is created in the context of the current connection, and must be used in that context, until it is freed or recreated with another `DECLARE` or `PREPARE` statement. Using an SQL statement handle in a different connection context than the one for which it was created will produce a runtime error.

The `SET CONNECTION` instruction changes the connection context. Connections are identified by a name. The `AS` clause of the `CONNECT TO` instruction allows to specify a connection name. If the `AS` clause is omitted, the connection gets a default name based on the data source name.

This small program example illustrates the use of two cursors with two different connections:

```
MAIN
```

```
   CONNECT TO "db1" AS "s1"
   CONNECT TO "db2" AS "s2"
   SET CONNECTION "s1"
   DECLARE c1 CURSOR FOR SELECT tab1.* FROM tab1
   SET CONNECTION "s2"
   DECLARE c2 CURSOR FOR SELECT tab1.* FROM tab1
   SET CONNECTION "s1"
   OPEN c1
   SET CONNECTION "s2"
   OPEN c2
   ...
END MAIN
```

The DECLARE and PREPARE instructions are a type of creator instructions; if an SQL statement handle is recreated in a connection other than the original connection for which it was created, old resources are freed and new resources are allocated in the current connection context.

This allows you to re-execute the same cursor code in different connection contexts, as in this example:

```
MAIN
   CONNECT TO "db1" AS "s1"
   CONNECT TO "db2" AS "s2"
   SET CONNECTION "s1"
   IF checkForOrders() > 0 ...
   SET CONNECTION "s2"
   IF checkForOrders() > 0 ...
   ...
END MAIN

FUNCTION checkForOrders(d)
   DEFINE d DATE, i INTEGER
   DECLARE c1 CURSOR FOR SELECT COUNT(*) FROM orders WHERE ord_date = d
   OPEN c1
   FETCH c1 INTO i
   CLOSE c1
   FREE c1
   RETURN i
END FUNCTION
```

If the SQL statement handle was created in a different connection, the resources used in the old connection context are freed automatically, and new statement handle resources are allocated in the current connection context.

Implicit database connection

An implicit database connection is made with the DATABASE instruction used before MAIN; use SCHEMA to avoid the implicit connection.

The DATABASE statement can be used in two distinct ways, depending on the context of the statement within its source module:

- To specify a default database.

  Typically used in a GLOBALS module, to define variables with the DEFINE ... LIKE, but it is also used for the INITIALIZE and VALIDATE statements. Using the DATABASE statement in this way results in that database being opened automatically at run time.
- To specify a current database.

  In MAIN or in a FUNCTION, used to connect to a database. A variable can be used in this context (DATABASE *varname*).

A default database is almost always used, because many programs contain `DEFINE ... LIKE` statements. A problem occurs when the production database name differs from the development database name, because the default database specification will result in an automatic connection (just after `MAIN`):

```
DATABASE stock_dev  -- Default database, used at compile time
DEFINE
   p_cust RECORD LIKE customer.*
MAIN -- Connection to default database occurs at MAIN
   DEFINE dbname CHAR(30)
   LET dbname = "stock1"
   DATABASE dbname -- Real database used in production
   ...
END MAIN
```

In order to avoid the implicit connection, you can use the `SCHEMA` instruction instead of `DATABASE`:

```
SCHEMA stock_dev -- Schema specification only
DEFINE
   p_cust RECORD LIKE customer.*
MAIN -- No default connection occurs...
   DEFINE dbname CHAR(30)
   LET dbname = "stock1"
   DATABASE dbname
END MAIN
```

This instruction will define the database schema for compilation only, and will not make an implicit connection at runtime.

The database utility library

The `fgldbutl.4gl` library provides several database-related utility functions.

You find this library in the `FGLDIR/src` directory.

The DB utility library implements helpers for the following areas:

- Database type identification
- Sequence number generation
- Nested transaction control

See the `fgldbutl.4gl` source file for more details.

Handling nested transactions

You can manage nested transactions in different parts of a program.

A program can become very complex if it contains a lot of nested functions calls, doing SQL processing within transactions. You may want to centralize transaction control commands in wrapper functions. The `fgldbutl.4gl` library contains special functions to manage the beginning and the end of a transaction with an internal counter, in order to implement nested function calls inside a unique transaction.

```
MAIN
  IF a() <> 0 THEN
       ERROR "..."
  END IF
  IF b() <> 0 THEN
       ERROR "..."
  END IF
END MAIN

FUNCTION a()
  DEFINE s INTEGER
  LET s = db_start_transaction()
  UPDATE ...
```

```
  LET s = SQLCA.SQLCODE
  IF s = 0 THEN
     LET s = b()
  END IF
  LET s = db_finish_transaction((s==0))
  RETURN s
END FUNCTION

FUNCTION b()
   DEFINE s INTEGER
   LET s = db_start_transaction()
   UPDATE ...
   LET s = SQLCA.SQLCODE
   LET s = db_finish_transaction((s==0))
   RETURN s
END FUNCTION
```

In this example, you see in the `MAIN` block that both functions `a()` and `b()` can be called separately. However, the transaction SQL commands will be used only if needed: When function `a()` is called, it starts the transaction, then calls `b()`, which does not start the transaction since it was already started by `a()`. When function `b()` is called directly, it starts the transaction.

The function `db_finish_transaction()` is called with the expression `(s==0)`, which is evaluated before the call. This allows you to write in one line the equivalent of the following `IF` statement:

```
IF s==0 THEN
   LET s = db_finish_transaction(1)
ELSE
   LET s = db_finish_transaction(0)
END IF
```

Transaction blocks across connections

Transaction blocks manage transactions when connected to several database servers.

In some cases, you need to copy data from a database to another. Database vendor export / import tools exist for this task and should be used when a large amount of data needs to be transferred. However, it is also possible to achieve this with a BDL program connected to both databases, reading data from the source database and inserting rows into the target database.

If the rows created in the target database need to be committed as a whole, you must open a transaction with the `BEGIN WORK` instruction, use `SET CONNECTION` to switch between the connections to read/write rows, and terminate the transaction with a `COMMIT WORK`.

In order to keep a transaction open when switching to another database connection, the connection must be initiated with the `WITH CONCURRENT TRANSACTION` clause. If this option is not used, databases servers might raise an error when changing the connection context. For example IBM® Informix® will return the SQL error -1801: Multiple-server transaction not supported.

The example below opens two database connections, reads rows from a table of the first database, and uses a transaction to insert rows in a table of the second database:

```
MAIN
   DEFINE rec RECORD
               pk INTEGER,
               name VARCHAR(50)
           END RECORD

   CONNECT TO "test1+driver='dbmifx'" AS "s1"
           USER "ifxuser" USING "fourjs"
           WITH CONCURRENT TRANSACTION
   CREATE TEMP TABLE tt1 ( pk INT, name VARCHAR(50) )
   INSERT INTO tt1 VALUES ( 1, "Item 1" )
```

```
    INSERT INTO tt1 VALUES ( 2, "Item 2" )

    CONNECT TO "test1+driver='dbmmys'" AS "s2"
            USER "mysuser" USING "fourjs"
            WITH CONCURRENT TRANSACTION
    CREATE TEMP TABLE tt2 ( pk INT, name VARCHAR(50) )

    SET CONNECTION "s1"
    DECLARE c1 CURSOR FOR SELECT * FROM tt1

    SET CONNECTION "s2"
    BEGIN WORK

    SET CONNECTION "s1"
    FOREACH c1 INTO rec.*
        SET CONNECTION "s2"
        INSERT INTO tt2 VALUES ( rec.* )
        SET CONNECTION "s1"
    END FOREACH

    SET CONNECTION "s2"
    COMMIT WORK

END MAIN
```

The base.SQLHandle built-in class
Handle SQL queries with a 3GL API.

Genero BDL provides a 3GL API to execute SQL queries and introspect result set column information with the `base.SqlHandle` built-in class.

The class implements typical SQL statement execution methods existing in well-known APIs, such as:

- `prepare("sql-text")`
- `setParameter()`
- `execute()`
- `open()`, `openScrollCursor()`
- `fetch()`, `fetchFirst()`, `fetchLast()`, ...

The class also implements introspection methods for the result set columns:

- `getResultCount()`
- `getResultType(`*`index`*`)`
- `getResultName(`*`index`*`)`
- `getResultValue(`*`index`*`)`

This class is provided to allow generic code implementation for specific needs. Consider using traditional static and dynamic SQL instruction for regular code implementing your business rules; the 3GL code based on the SqlHandle class is not as readable as static or dynamic SQL.

SQL security

- Database user authentication on page 410
- Avoiding SQL injection on page 411

Database user authentication
Understanding how users are authenticated to the database server.

When connecting to a database server, the user must be identified by the server. Once connected, the current user is authenticated and identified by the db server, and the database system can then apply specific privileges, audit user activity, and so on.

Database user authentication is typically achieved by specifying a login and password in the `CONNECT TO` instruction. However, most database servers support additional user authentication methods, such as OS user authentication, trusted connections, LDAP authentication, Single Sign-On authentication and even specific pluggable authentication methods.

Follow these simple security patterns to avoid basic user authentication problems:

- Make sure that application files installed on your production server have the appropriate file system permissions set. Regular users should have read-only access to program and resource files. If any OS user can replace a program file with another program, it could harm your database or retrieve sensitive private data.
- Each physical end user must have a specific database account. If several end users connect as the same db application account, they cannot be distinguished in the security and auditing system.
- For normal application users, always use database accounts with the minimum database privileges required to achieve the daily work (GRANT/REVOKE). For example, regular users should not be able to execute Data Definition Language statements (drop tables).
- Instead of asking a name and password in a login dialog when an application starts, some applications hard code the db user names and passwords in the program code, in scripts or configurations files such as FGLPROFILE. This is not a good practice and must be avoided. If a login dialog is not appropriate, you must set up another user authentication method supported by the database server, such as Single Sign-On.

Avoiding SQL injection
Prevent SQL injection attacks in your programs.

SQL injection is a well-known attack that started to appear with Web applications, where the end user enters SQL statement fragments in form fields that are normally designed to hold simple data. When the entered text is used to complete a SQL statement without further checking, there is a risk of SQL statements being injected by the user to intentionally harm the database.

To illustrate the problem, see the following code:

```
MAIN
   DEFINE sql CHAR(200), cn CHAR(50), n INTEGER
   OPEN FORM f FROM "custform"
   DISPLAY FORM f
   INPUT BY NAME cn
   LET sql = "SELECT COUNT(*) FROM customers WHERE custname = '", cn, "'"
   PREPARE stmt FROM sql
   EXECUTE stmt INTO n
   DISPLAY "Count = ", n
END MAIN
```

If the end user enters for example:

```
[xxx' ; delete from customers   ]
```

The resulting SQL statement will contain an additional `DELETE` command that will drop all rows of the *customers* table:

```
SELECT COUNT(*) FROM customers WHERE custname = 'xxx'; DELETE FROM customers
```

In some applications, you may also want to let the end user choose sort columns to be added in an `ORDER BY` clause. The code for such a feature should control the user input. For example, by providing a list of columns to choose from, instead of allowing free text input that will be added to the `ORDER BY` clause.

To avoid SQL injection attacks, do not build SQL instructions dynamically by concatenating user input that is not checked. Instead of basic concatenation, use static SQL statements with program variables (if dynamic SQL is not needed), use parameterized queries (with ? parameter placeholders), or use the `CONSTRUCT` instruction to implement a query by example form.

Simple static SQL example:

```
MAIN
   DEFINE cn CHAR(50), n INTEGER
   OPEN FORM f FROM "custform"
   DISPLAY FORM f
   INPUT BY NAME cn
   SELECT COUNT(*) INTO n FROM customers WHERE custname = cn
   DISPLAY "Count = ", n
END MAIN
```

Parameterized query example:

```
MAIN
   DEFINE sql CHAR(200), cn CHAR(50), n INTEGER
   OPEN FORM f FROM "custform"
   DISPLAY FORM f
   INPUT BY NAME cn
   LET sql = "SELECT COUNT(*) FROM customers WHERE custname = ?"
   PREPARE stmt FROM sql
   EXECUTE stmt USING cn INTO n
   DISPLAY "Count = ", n
END MAIN
```

`CONSTRUCT` example:

```
MAIN
   DEFINE sql CHAR(200), cond CHAR(50), n INTEGER
   OPEN FORM f FROM "custform"
   DISPLAY FORM f
   CONSTRUCT BY NAME cond ON custname
   LET sql = "SELECT COUNT(*) FROM customers WHERE ", cond
   PREPARE stmt FROM sql
   EXECUTE stmt INTO n
   DISPLAY "Count = ", n
END MAIN
```

SQL portability

Writing portable SQL is mandatory if you want to succeed with different kind of database servers. This section gives you some hints to solve SQL incompatibility problems in your programs. Read this section carefully and review your program source code if needed. You should also read carefully the ODI adaptation guides which contain database specific information about SQL compatibility issues.

To easily detect SQL statements with specific syntax, you can use the `-W stdsql` option of `fglcomp`:

```
$ fglcomp -W stdsql orders.4gl
module.4gl:15: SQL Statement or language instruction with specific SQL
 syntax.
```

This compiler option can only detect non-portable SQL syntax in static SQL statements.

Database entities
The database entity concept across different database engines.

Most database servers can handle multiple database entities (you can create multiple 'databases'), but this is not possible with all engines:

Table 139: Multiple database entities by Database server type

Database Server Type	Multiple Database Entities
IBM® DB2® UDB	Yes
IBM® Informix®	Yes
Microsoft™ SQL Server	Yes
MySQL	Yes
Oracle Database Server	No
PostgreSQL	Yes
Sybase ASE	Yes
SQLite	Yes

When using a database server that does not support multiple database entities, you can emulate different databases with schema entities, but this requires you to check for the database user definition. Each database user must have privileges to access any schema, and to see any table of any schema without needing to set a schema prefix before table names in SQL statements.

Some database drivers allow to select a specific schema at connection with the following FGLPROFILE entry:

```
dbi.database.dbname.dbtype.schema = "schema-name"
```

Some databases also allow you to define a default schema for each database user. When the user connects to the database, the default schema is automatically selected.

Database users and security

Properly identifying database users allows to use database security and audit features.

To get the benefit of the database server security features, you should identify each physical user as a database user.

Some applications use a single database user for different end users, to avoid user management and connection issues in the database. This is not good practice because all user-related features of the database are unusable. Further, the single db user often has all database privileges and thus can lead in security issues.

According to the type of server, you must do this steps to create a database user:

1. Define the user as an operating system user.
2. Declare the user in the database server.
3. Grant database access privileges.

Each database server has its specific users management and data access privilege mechanisms. Check the vendor documentation for security features and make sure you can define the users, groups, and privileges in all database servers you want to use.

Creating a database from programs

Creating a database from within a program requires special consideration.

Understanding database creation statements

The Genero language syntax supports database creation statements such as:

```
CREATE DATABASE mydb WITH BUFFERED LOG
```

Such instruction performs an implicit connection to the database server (i.e., no `CONNECT TO` or `DATABASE` is required before a `CREATE DATABASE`), and leads to a default connection.

Creating a database in a database server

When using a database server engine, the creation of a database entity is not a trivial operation. The process usually requires additional tasks such as data storage configuration, database user creation, data access policy, and so on. These tasks are typically left to the database administrator.

Database creation statements such as `CREATE DATABASE`, `CREATE DBSPACE`, and `DROP DATABASE` can be used in programs connected to an IBM® Informix® server, but these statements are not portable. Use database creation statements only for development or testing purpose.

Creating a database on mobile devices (SQLite)

Mobile applications usually create their database at first execution. Database creation on a mobile device is a much simpler operation than database creation on a database server. For example, with SQLite, creating a database only requires creating an empty file.

The SQLite database file must be created in the application sandbox, in a writable directory. This directory is specific to the type of mobile device, and can be found in programs with the `os.Path.pwd` on page `2004` method.

To build the full path to the database file, get the current working directory (`os.Path.pwd()`) and add this path to the database file name. This defines the `source` specification in the database connection parameters, to build the string used for the `CONNECT` instruction:

```
IMPORT os
...
DEFINE dbfile, source, connstr VARCHAR(256)
```

```
FUNCTION init_connection_strings()
   LET dbfile = "contacts.dbs"
   LET source = os.Path.join(os.Path.pwd(), dbfile)
   LET connstr = SFMT("contacts+source='%1'", source)
   IF NOT base.Application.isMobile() THEN
      -- Add db driver spec when in development mode
      LET connstr = connstr, ",driver='dbmsqt'"
   END IF
END FUNCTION
```

If not specified, the `source` connection parameter (i.e., the path to the database file) defaults to the database name specification in the `CONNECT` instruction. Thus, the `source='`*`dbpath`*`'` parameter is usually omitted, and *dbpath* is specified directly as the database name. In this case, however, the identifier of the database connection is the complete path to the SQLite database file. For more details about database connection parameters, see Database connections on page 457.

Before executing the `CONNECT` instruction, check if the database file already exists with `os.Path.exists(source)`. Create the database file and tables only if needed:

```
IMPORT os
...
   CALL init_connection_strings()
   IF os.Path.exists(source) THEN
      CONNECT TO connstr AS "c1"
   ELSE
      CALL create_empty_file(source)
      CONNECT TO connstr AS "c1"
      CALL create_database_tables()
   END IF
   ...

FUNCTION create_empty_file(fn)
   DEFINE fn STRING
   DEFINE ch base.Channel()
   LET ch = base.Channel.create()
   CALL ch.openFile(fn,"w")
   CALL ch.close()
END FUNCTION
```

Instead of creating an empty database file, it is also possible to prepare a template (pre-configured) SQLite database file on the development platform, deploy the template database with the other program files, and copy the template file from the program files directory (`base.Application.getProgramDir` on `page 1705`) into the working directory (`os.Path.pwd` on `page 2004`) on the first application execution (i.e. when the database file in the working directory does not yet exist):

```
IMPORT os
...
   CALL init_connection_strings()
   IF NOT prepare_database("template.dbs", source) THEN
      ERROR "Could not prepare database"
      EXIT PROGRAM 1
   END IF
   CONNECT TO connstr AS "c1"
   ...

FUNCTION prepare_database(template, target)
   DEFINE template, target STRING
   DEFINE tplpath STRING
   IF os.Path.exists(target) THEN
      RETURN TRUE
   END IF
   LET tplpath = os.Path.join(base.Application.getProgramDir(), template)
```

```
   IF NOT os.Path.exists(tplpath) THEN
      ERROR "Database template file not found"
      RETURN FALSE
   END IF
   RETURN os.Path.copy(tplpath, target)
END FUNCTION
```

> **Important:** When creating an initial database file into the working directory from a template file deployed in the program files directory, different file names should be used for the template and actual database file, as folders pointed by `base.Application.getProgramDir` on page 1705 and `os.Path.pwd` on page 2004 could be the same on some devices.

Data definition statements
DDL statements should be avoided in programs.

When using Data Definition Statements like `CREATE TABLE`, `ALTER TABLE`, `DROP TABLE`, only a limited SQL syntax works on all database servers. Most databases support `NOT NULL`, `CHECK`, `PRIMARY KEY`, `UNIQUE`, `FOREIGN KEY` constraints, but the syntax for naming constraints is different.

The following statement works with most database servers and creates a table with equivalent properties in all cases:

```
 CREATE TABLE customer  (
     cust_id INTEGER NOT NULL,
     cust_name CHAR(50) NOT NULL,
     cust_lastorder DATE NOT NULL,
     cust_group INTEGER,
       PRIMARY KEY (cust_id),
       UNIQUE (cust_name),
       FOREIGN KEY (cust_group) REFERENCES group (group_id)
 )
```

Some engines like SQL Server have a different default behavior for `NULL` columns when you create a table. You may need to set up database properties to make sure that a column allows nulls if the `NOT NULL` constraint is not specified.

When you want to create tables in programs using non-standard clauses (for example to define storage options), you must use dynamic SQL and adapt the statement to the target database server.

Using portable data types
Only a limited set of data types are really portable across several database engines.

The ANSI SQL specification defines standard data types, but for historical reasons most databases vendors have implemented native (non-standard) data types. You can usually use a synonym for ANSI types, but the database server will uses the native types behind the scenes. For example, when you create a table with an `INTEGER` column in Oracle, the native `NUMBER` data type is used.

In your programs, avoid data types that do not have a native equivalent in the target database. This includes simple types like floating point numbers, as well as complex data types like `INTERVAL`. Numbers may cause rounding or overflow problems, because the values stored in the database have different limits. For the `DECIMAL` types, always use the same precision and scale for the program variables and the database columns.

To write portable applications, we strongly recommend using the following data types only:

- `CHAR(n)`
- `VARCHAR(n)`
- `BIGINT`
- `INTEGER`
- `SMALLINT`
- `DECIMAL(p,s)`

- DATE
- DATETIME HOUR TO MINUTE
- DATETIME HOUR TO SECOND
- DATETIME YEAR TO MINUTE
- DATETIME YEAR TO FRACTION(n)

Data manipulation statements

Make sure that SQL statement syntaxes are supported by all target database engines.

Several SQL syntaxes for the INSERT, UPDATE and DELETE statements are supported by the compiler. Some of the syntaxes are IBM® Informix® specific, but will be converted to standard SQL at compile time.

The following statements are standard SQL and work with all database servers:

```
(1) INSERT INTO table (column-list) VALUES (value-list)
(2) UPDATE table SET column = value, ... [WHERE condition]
(3) DELETE FROM table [WHERE condition]
```

The next statements are not standard SQL, but are converted by the compiler to standard SQL, working with all database servers:

```
(4) INSERT INTO table VALUES record.*
    -- where record is defined LIKE a table from db schema
(5) UPDATE table SET (column-list) = (value-list) [WHERE condition]
(6) UPDATE table SET {[table.]*|(column-list)}
 = record.* ... [WHERE condition]
   -- where record is defined LIKE a table from db schema
```

The next statement is not standard SQL and will not be converted by the compiler, so it must be reviewed:

```
(7) UPDATE table SET [table.]* = (value-list) [WHERE condition]
```

You can easily search for non-portable SQL statements in your sources by compiling with the `-W stdall` fglcomp option.

For maximum SQL portability, INSERT statements should be reviewed to avoid the SERIAL column from the value list.

For example, the following statement:

```
INSERT INTO tab (col1, col2, ...) VALUES ( 0, p_value2, ... )
```

should be converted to:

```
INSERT INTO tab (col2, ...) VALUES ( p_value2, ... )
```

A static SQL INSERT statement using records defined from the schema file should also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.* )   -- will use the serial column
```

should be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

For more details about supported SQL DML statements, see static SQL.

CHAR and VARCHAR types

Using the CHAR and VARCHAR data types with different sort of databases.

The CHAR and VARCHAR types are designed to store character strings, but all database servers do not have the same semantics for these types.

The behavior of database servers may defer in the following areas related to CHAR/VARCHAR types.

- Byte or Character Length semantics? on page 418
- SQL character type for Unicode/UTF-8 on page 418
- Empty strings and NULLs on page 419
- Trailing blanks in CHAR/VARCHAR on page 419
- What should you do? on page 421

Byte or Character Length semantics?

When defining a CHAR/VARCHAR database column or program variable, you must specify a size. When using a multibyte character set, the unit of this size matters: it can be specified in bytes or characters. In programs, the size unit of CHAR/VARCHAR variables depends on the length semantics defined by the FGL_LENGTH_SEMANTICS environment variable. In databases, the size unit of the CHAR/VARCHAR columns can be expressed in bytes or characters, depending on the database server and its configuration.

SQL character type for Unicode/UTF-8

This section explains database server specifics regarding Unicode / UTF-8 support with character string SQL types.

All database servers can store UNICODE data in character strings types, but there are some specifics you must be aware of. Genero BDL programs typically use the CHAR and VARCHAR types to store UTF-8 strings. But the correspond SQL type may have a different name, according to the database server type. Use the correct SQL type when creating you database tables. When the database uses a different UNICODE codeset as UTF-8 to store the character string data, the database client or the Genero database driver take care of the codeset conversion, as long as the runtime system and database client locale are properly defined.

Table 140: Database server character types for Unicode / UTF-8 data

Database Server Type	Char types to be used for Unicode/UTF-8
IBM® DB2® UDB	CHAR / VARCHAR if the database was created with UTF-8 codeset. Otherwise, you must use GRAPHIC, VARGRAPHIC types. For more details, see CHARACTER data types on page 547.
IBM® Informix®	CHAR / VARCHAR, the database must be created with UTF-8 locale.
IBM® Netezza	NCHAR / NVARCHAR (data always stored in UTF-8). For more details, see CHARACTER data types on page 577.
Microsoft™ SQL Server	NCHAR / NVARCHAR, to store UTF-16 data (drivers make the conversion for application codeset UTF-8) The CHAR/VARCHAR types can only store non-unicode data. For more details, see CHARACTER data types on page 600.

Database Server Type	Char types to be used for Unicode/UTF-8
Oracle MySQL	`CHAR` / `VARCHAR` if the database locale is UTF-8. `NCHAR` / `NVARCHAR` if you need to use the national character set. For more details, see CHARACTER data types on page 630.
Oracle Database Server	`CHAR` / `VARCHAR2` if the database locale is UTF-8. `NCHAR` / `NVARCHAR2` if you need to use the national character set. For more details, see CHARACTER data types on page 653.
PostgreSQL	`CHAR` / `VARCHAR`, the database locale must be UTF-8. For more details, see CHARACTER data types on page 689.
Sybase ASE	`CHAR` / `VARCHAR` if the database locale is UTF-8. `NCHAR` / `NVARCHAR` or `UNICHAR` / `UNIVARCHAR` if you need to use the national character set. For more details, see CHARACTER data types on page 729.
SQLite	`CHAR` / `VARCHAR` (data always stored in UTF-8). For more details, see CHARACTER data types on page 712.

Empty strings and NULLs

At the SQL level, most databases distinguish `''` empty strings from `NULL` (with some exceptions like Oracle DB). However, in programs, an empty string is the equivalent to `NULL` in program variables. As result, it is not possible to distinguish an empty string from a `NULL` when such values are fetched from the database. This limitation is only visible when fetching `VARCHAR` columns and expressions fetched into `VARCHAR` variables, because `CHAR` columns get filled with blanks if the database returns a `CHAR` column value that was filled with an empty string; `CHAR` columns get blanks up to the max size.

Trailing blanks in CHAR/VARCHAR

Trailing blanks in CHAR/VARCHAR database columns

With all kinds of databases servers, `CHAR` columns are always filled with blanks up to the size of the column (this is called blank padding). However, trailing blanks are not significant in comparisons:

```
CHAR('abc ') = CHAR('abc')
```

With all database servers except IBM® Informix®, trailing blanks are significant when comparing `VARCHAR` values:

```
VARCHAR('abc ') != VARCHAR('abc')
```

This is a major issue if you mix CHAR and VARCHAR columns and variables in your SQL statements, because the result of an SQL query can be different depending on whether you are using IBM® Informix® or another database server.

Further, the semantics of the SQL LIKE operator regarding trailing blanks and CHAR/VARCHAR types can differ from database to database. For example, try the following expressions with you database, with a CHAR(5) column containing a row with the value 'abc':

```
CREATE TABLE t1 ( k INT, c CHAR(5), vc VARCHAR(5) )
INSERT INTO t1 VALUES ( 1, 'abc', 'abc' )
SELECT * FROM t1 WHERE c LIKE 'ab_'
SELECT * FROM t1 WHERE vc LIKE 'ab_'
SELECT * FROM t1 WHERE RTRIM(c) LIKE 'ab_'
SELECT * FROM t1 WHERE c LIKE '%c'
SELECT * FROM t1 WHERE vc LIKE '%c'
SELECT * FROM t1 WHERE RTRIM(c) LIKE '%c'
```

See discussion about MATCHES and LIKE operators in adaption guides for more details.

Trailing blanks in CHAR/VARCHAR program variables

In programs, CHAR variables are filled with blanks, even if the value used does not contain all spaces.

The following example:

```
DEFINE c CHAR(5)
LET c = "abc"
DISPLAY c || "."
```

shows the value "abc ." (5 chars + dot).

VARCHAR variables are assigned with the exact value specified, with significant trailing blanks.

For example, this code:

```
DEFINE v VARCHAR(5)
LET v = "abc "
DISPLAY v || "."
```

shows the value "abc ." (4 chars + dot).

Assigning an empty string to a CHAR or VARCHAR variable will set the variable to NULL:

```
DEFINE v VARCHAR(5)
LET v = ""
IF v IS NULL THEN
   DISPLAY "is null"   -- will be displayed
END IF
```

When comparing CHAR or VARCHAR variables in an expression, the trailing blanks are not significant:

```
DEFINE c CHAR(5)
DEFINE v1, v2 VARCHAR(5)
LET c = "abc"
LET v1 = "abc "
LET v2 = "abc  "
IF c == v1 THEN
   DISPLAY "c==v1"
END IF
IF c == v2 THEN
   DISPLAY "c==v2"
END IF
```

```
IF v1 == v2 THEN
   DISPLAY "v1==v2"
END IF
```

All three messages are shown.

Additionally, when you assign a VARCHAR variable from a CHAR, the target variable gets the trailing blanks of the CHAR variable:

```
DEFINE pc CHAR(50)
DEFINE pv VARCHAR(50)
LET pc = "abc"
LET pv = pc
DISPLAY pv || "."
```

"abc <47 spaces>. " (50 chars + dot) is shown.

To avoid this, use the CLIPPED operator:

```
LET pv = pc CLIPPED
```

Trailing blanks in SQL statement parameters

When you insert a row containing a CHAR variable into a CHAR or VARCHAR column, the database interface removes the trailing blanks to avoid overflow problems, (insert CHAR(100) into CHAR(20) when value is "abc" must work).

In this example:

```
DEFINE c CHAR(5)
LET c = "abc"
CREATE TABLE t ( v1 CHAR(10), v2 VARCHAR(10) )
INSERT INTO tab VALUES ( c, c )
```

The value in column v1 and v2 would be "abc" (3 chars in both columns).

When you insert a row containing a VARCHAR variable into a VARCHAR column, the VARCHAR value in the database gets the trailing blanks as set in the variable. When the column is a CHAR(N), the database server fills the value with blanks so that the size of the string is N characters.

In this example:

```
DEFINE vc VARCHAR(5)
LET vc = "abc  "  -- note 2 spaces at end of string
CREATE TABLE t ( v1 CHAR(10), v2 VARCHAR(10) )
INSERT INTO tab VALUES ( vc, vc )
```

The value in column v1 would be "abc " (10 chars) and v2 would be "abc " (5 chars).

What should you do?

Make sure that you have correctly defined the locale and length semantics for your character string data types.

When designing your database tables, consider using CHAR(N) for fixed-length string data (such as codes) and VARCHAR(N) for variable-length string data, such as names, address and comments.

Use VARCHAR variables for VARCHAR columns, and CHAR variables for CHAR columns to achieve portability across all kinds of database servers.

Avoid storing empty strings in VARCHAR columns, or make sure that your program is prepared to get nulls while the database stores empty strings.

Using byte or character length semantics depends mainly on the character set of your application. When using a single-byte character set, keep the default byte length semantics. When using a multibyte character set such as UTF-8, use character length semantics in both the database and the programs. The database column definition and the program variable definition must match, this can be simplified by using a database schema.

Concurrent data access

Understanding concurrent data access and data consistency.

Data concurrency is the simultaneous access of the same data by many users. On the other hand, *data consistency* means that each user sees a consistent view of the database. Without adequate concurrency and consistency controls, data could be changed improperly, compromising data integrity. To write inter-operable applications, you must adapt the program logic to the behavior of the database server regarding concurrency and consistency management. This issue requires good knowledge of multiuser application programming, transactions, locking mechanisms, isolation levels and wait mode. If you are not familiar with these concepts, carefully read the documentation of each database server which covers this subject.

Processes accessing the database can change transaction parameters such as the isolation level. Existing programs might have to be adapted in order to work with this new behavior.

The following is the best configuration to get common behavior with all types of database engines:

- The database must support transactions; this is usually the case.
- Transactions must be as short as possible (under a second is fine, 3 or more seconds is a long transaction).
- The isolation Level should be set to `COMMITTED READ` or `CURSOR STABILITY`. IBM® Informix® IDS 11 has introduced the `LAST COMMITTED` option for the `COMMITTED READ` isolation level, which makes IDS behave like other database server using row-versioning, returning the most recently committed version of the row, rather than wait for a lock to be released. This option can also be turned on implicitly with the `USELASTCOMMITTED` configuration parameter, saving code changes.
- The wait mode for locks must be `WAIT` or `WAIT n` (timeout). Wait mode can be adapted to wait for the longest transaction.

Remarks: With this configuration, the locking granularity does not have to be at the row level. To improve performance with IBM® Informix® databases, you can use the `LOCK MODE PAGE` locking level, which is the default.

Scrollable cursors

How scrollable cursors can be supported on different databases.

Scrollable cursors can be used to go forward and backward in an SQL query result set:

```
DEFINE cust_rec RECORD LIKE customer.*
DECLARE sc SCROLL CURSOR
   FOR SELECT * FROM customer
OPEN sc
FETCH NEXT sc INTO cust_rec.*
FETCH LAST sc INTO cust_rec.*
FETCH FIRST sc INTO cust_rec.*
CLOSE sc
```

This is a useful feature, to implement record set navigation in applications. Scrollable cursors are typically implemented in the database server. But not all database servers support scrollable cursors.

When scrollable cursors are not supported by the target database server, the database driver will emulate it with temporary files.

The temporary files are create in a temporary directory, that can be defined with the DBTEMP environment variable. If DBTEMP is not defined, the default temporary directory dependents from the platform used.

You should consider to avoid scroll cursor usage if the target database does not support this feature:

With emulated scrollable cursors, when scrolling to the last row, all rows will be fetched into the temporary file. This can generate a lot of network traffic and can produce a large temporary file if the result-set contains a lot of rows. Additionally, programs are dependent on the file system resource allocated to the OS user (ulimit).

The following table lists the native scroll cursor availability for each supported database:

Table 141: Database server support for scrollable cursors

Database Server Type	Native scroll cursors?
IBM® DB2® UDB	Yes
IBM® Informix®	Yes
IBM® Netezza	No, emulated by the drivers.
Microsoft™ SQL Server	Yes
Oracle MySQL	No, emulated by the drivers.
Oracle Database Server	Yes
PostgreSQL	Yes
Sybase ASE	Yes
SQLite	No, emulated by the drivers.

Optimistic locking
Implementing optimistic locking to handle access concurrently to the same database records.

This section describes how to implement *optimistic locking* in applications. Optimistic locking is a portable solution to control simultaneous modification of the same record by multiple users.

Traditional IBM® Informix® applications use a `SELECT FOR UPDATE` to set a lock on the row to be edited by the user. This is called *pessimistic locking*. The `SELECT FOR UPDATE` is executed before the interactive part of the code, as described in here:

1. When the end user chooses to modify a record, the program declares and opens a cursor with a `SELECT FOR UPDATE`. At this point, an SQL error might be raised if the record is already locked by another process. Otherwise, the lock is acquired and user can modify the record.
2. The user edits the current record in the input form.
3. The user validates the dialog.
4. The `UPDATE` SQL instruction is executed.
5. The transaction is committed or the `SELECT FOR UPDATE` cursor is closed. The lock is released.

If the IBM® Informix® database was created with transaction logging, you must either start a transaction or define the `SELECT FOR UPDATE` cursor `WITH HOLD` option.

Unfortunately, this is not a portable solution. The lock wait mode should preferably be `WAIT` for portability reasons. Pessimistic locking is based on a `NOT WAIT` mode to return control to the program if a record is already locked by another process. Therefore, following the portable concurrency model, the pessimistic locking mechanisms must be replaced by the optimistic locking technique.

Basically, instead of locking the row before the user starts to modify the record data, the optimistic locking technique makes a copy of the current values (i.e. before modification values (BVM)), lets the user edit the record, and when it's time to write data into the database, checks if the BMVs still correspond to the current values in the database:

1. A `SELECT` is executed to fill the record variable used by the interactive instruction for modifications.
2. The record variable is copied into a backup record to keep Before Modification Values.
3. The user enters modifications in the input form; this updates the values in the modification record.

4. The user validates the dialog.
5. A transaction is started with `BEGIN WORK`.
6. Declare a cursor with a `SELECT FOR UPDATE`, to select the row to be updated.
7. Open the `SELECT FOR UPDATE` cursor and fetch the row into the temporary record.
8. If the SQL status is `NOTFOUND`, the row has been deleted by another process, and the transaction can stop with `ROLLBACK WORK`.
9. If the row was found, the program compares the temporary record values with the backup record values with the `(rec1.*==rec2.*)` notation.
10. If these values have changed, the row has been modified by another process, and the transaction can stop with `ROLLBACK WORK`.
11. If the values in the database have not changed, the `UPDATE` statement is executed to apply the last changes of the user.
12. The transaction is committed with a `COMMIT WORK`.

To compare 2 records (with `NULL` checking), simply write:

```
IF new_record.* != bmv_record.* THEN
   LET values_have_changed = TRUE
END IF
```

The optimistic locking technique could be implemented with a unique SQL instruction: an `UPDATE` could compare the column values to the BMVs directly (`UPDATE ... WHERE kcol = kvar AND col1 = bmv.var1 AND ...`). But, this is not possible when BMVs can be `NULL`. The database engine always evaluates conditional expressions such as "`col=NULL`" to `FALSE`. Therefore, you must use "`col IS NULL`" when the BMV is `NULL`. This means dynamic SQL statement generation based on the DMV values. Additionally, to use the same number of SQL parameters (? markers), you would have to use "`col=?`" when the BMV is not null and "`col IS NULL and ? IS NULL`" when the BMV is null. Unfortunately, the expression " `? IS [NOT] NULL` " is not supported by all database servers (DB2® raises error SQL0418N).

If you are designing a new database application from scratch, you can also use the row versioning method. Each tables of the database must have a column that identifies the current version of the row. The column can be a simple `INTEGER` (to hold a row version number) or it can be a timestamp (`DATETIME YEAR TO FRACTION(5)` for example). To guaranty that the version or timestamp column is updated each time the row is updated, you should implement a trigger to increment the version or set the timestamp when an `UPDATE` statement is issued. If this is in place, you just need to check that the row version or timestamp has not changed since the user modifications started, instead of testing all field of the BMV record. If you are only using one specific database type, you may check if the server supports a versioning column natively. For example, IBM® Informix® IDS 11.50.xC1 introduced the `ALTER TABLE ... ADD VERCOLS` option to get a version + checksum column to a table, you can then query the table with the `ifx_insert_checksum` and `ifx_row_version` columns.

Auto-incremented columns (serials)
How to implement automatic record keys?

IBM® Informix® provides the SERIAL, BIGSERIAL or SERIAL8 data types which can be emulated with database drivers for most non-Informix database engines by using native sequence generators (when "`ifxemul.serial`" FGLPROFILE setting is `true`). But, this requires additional configuration and maintenance tasks. If you plan to review the programming pattern of sequences, you should use a portable implementation instead of the serial emulation provided by the database drivers. This section describes different solutions to implement *auto-incremented fields*. The preferred implementation is the solution using SEQUENCES.

Solution 1: Use database specific serial generators

Principle

In accordance with the target database, you must use the appropriate native serial generation method. Get the database type with the `fgl_db_driver_type()` built-in function and use the appropriate SQL statements to insert rows with serial generation.

This solution uses the native auto-increment feature of the target database and is fast at execution, but is not very convenient as it requires to write different code for each database type. However, it is covered here to make you understand that each database vendor has it's own specific solution for auto-incremented columns. It is of course not realistic to use this solution in a large application with hundreds of tables.

Implementation

1. Create the database objects required for serial generation in the target database (for example, create tables with SERIAL columns in IBM® Informix®, tables with IDENTITY columns in SQL Server and SEQUENCE database objects in Oracle).
2. Adapt your programs to use the native sequence generators in accordance with the database type.

Example

```
DEFINE t1rec RECORD
          id    INTEGER,
          name  CHAR(50),
          cdate DATE
    END RECORD

CASE fgl_db_driver_type()
 WHEN "ifx"
   INSERT INTO t1 ( id, name, cdate )
          VALUES ( 0, t1rec.name, t1rec.cdate )
   LET t1rec.id = SQLCA.SQLERRD[2]
 WHEN "ora"
   INSERT INTO t1 ( id, name, cdate )
          VALUES ( t1seq.nextval, t1rec.name, t1rec.cdate )
   SELECT t1seq.currval INTO t1rec.id FROM dual
 WHEN "msv"
   INSERT INTO t1 ( name, cdate )
           VALUES ( t1rec.name, t1rec.cdate )
   PREPARE s FROM "SELECT @@IDENTITY"
   EXECUTE s INTO t1rec.id
END CASE
```

As you can see in this example, this solution requires database engine specific coding. Querying the last generated serial can be centralized in a function, but the insert statements would still need to be specific to the type of database.

Solution 2: Generate serial numbers from your own sequence table

Purpose

The goal is to generate unique `INTEGER` or `BIGINT` numbers. These numbers will usually be used for primary keys.

Prerequisites

1. The database must use transactions. This is usually the case with non-INFORMIX databases, but IBM® Informix® databases default to auto commit mode. Make sure your IBM® Informix® database allows transactions.
2. The sequence generation must be called inside a transaction (`BEGIN WORK` / `COMMIT WORK`).
3. The transaction isolation level must guarantee that a row UPDATEd in a transaction cannot be read or written by other db sessions until the transaction has ended (typically, `COMMITTED READ` is ok, but some db servers require a higher isolation level)
4. The lock wait mode must be `WAIT`. This is usually the case in non-INFORMIX databases, but INFORMIX defaults to `NOT WAIT`. You must change the lock wait mode with "`SET LOCK MODE TO WAIT`" or "`WAIT` *`seconds`*" when using IBM® Informix®.
5. Other applications or stored procedures must implement the same technique when inserting records in the table having auto-incremented columns.

Principle

A dedicated table named "`SEQREG`" is used to register sequence numbers. The key is the name of the sequence. This name will usually be the table name the sequence is generated for. In short, this table contains a primary key that identifies the sequence and a column containing the last generated number.

The uniqueness is granted by the concurrency management of the database server. The first executed instruction is an `UPDATE` that sets an exclusive lock on the `SEQREG` record. When two processes try to get a sequence at the same time, one will wait for the other until its transaction is finished.

Implementation

The "`fgldbutl.4gl`" utility library implements a function called "`db_get_sequence()`" which generates a new sequence. You must create the `SEQREG` table as described in the `fgldbutl.4gl` source found in `FGLDIR/src`, and make sure that every user has the privileges to access and modify this table.

In order to guarantee the uniqueness of the generated number, the call to `db_get_sequence()` must be done inside a transaction block that includes the `INSERT` statement. Concurrent db sessions must wait for each other in case of conflict and the transaction isolation level must be high enough to make sure that the row of the sequence table will not be read or written by other db sessions until the transaction end.

Example

```
IMPORT FGL fgldbutl
DEFINE rec RECORD
           id    INTEGER,
           name  CHAR(100)
     END RECORD
...
BEGIN WORK
LET rec.id = db_get_sequence( "CUSTID" )
INSERT INTO CUSTOMER ( CUSTID, CUSTNAME ) VALUES ( rec.* )
COMMIT WORK
```

Solution 3: Use native SEQUENCE database objects

Principle

Most recent database engines support `SEQUENCE` database objects; If all database server types you want to use do support sequences, you should use this solution.

Implementation

1. Create a `SEQUENCE` object for each table using previously a `SERIAL` column in the IBM® Informix® database.
2. In database creation scripts (`CREATE TABLE`), replace all `SERIAL` types by `INTEGER` (or `BIGINT` if you need large integers).
3. Adapt your programs to retrieve a new sequence before inserting a new row. Consider writing a function to retrieve a new sequence number, using dynamic SQL to pass the name of the sequence as parameter, and adapt to the target database specifics to retrieve a single row (see example below).

Example

```
MAIN
  DEFINE item_rec RECORD
           item_num BIGINT,
           item_name VARCHAR(40)
         END RECORD
  DEFINE i INT
  DATABASE test1
  CREATE TABLE item (
           item_num BIGINT NOT NULL PRIMARY KEY,
           item_name VARCHAR(50)
          )
  CALL sequence_create("item")
  LET item_rec.item_num = sequence_next("item")
  DISPLAY "New sequence: ", item_rec.item_num
  LET item_rec.item_name = "Item#" || item_rec.item_num
  INSERT INTO item VALUES ( item_rec.* )
  DROP TABLE item
  DROP SEQUENCE item_seq
END MAIN

PRIVATE FUNCTION is_sql_server()
  RETURN (fgl_db_driver_type()=="esm" OR
 fgl_db_driver_type()=="snc")
END FUNCTION

FUNCTION sequence_create(tabname)
  DEFINE tabname STRING
  IF is_sql_server() THEN
     EXECUTE IMMEDIATE "CREATE SEQUENCE item_seq START WITH 1"
  ELSE
     CREATE SEQUENCE item_seq
  END IF
END FUNCTION

FUNCTION sequence_next(tabname)
  DEFINE tabname STRING
  DEFINE sql STRING, newseq BIGINT
  CASE
     WHEN fgl_db_driver_type()=="pgs"
          LET sql = "SELECT nextval('"||tabname||"_seq')"||
unique_row_condition()
     WHEN is_sql_server()
          LET sql = "SELECT NEXT VALUE FOR "||tabname||"_seq"
     OTHERWISE
          LET sql = "SELECT "||tabname||"_seq.nextval "||
unique_row_condition()
  END CASE
  PREPARE seq FROM sql
  IF SQLCA.SQLCODE!=0 THEN RETURN -1 END IF
  EXECUTE seq INTO newseq
```

```
  IF SQLCA.SQLCODE!=0 THEN RETURN -1 END IF
  RETURN newseq
END FUNCTION

FUNCTION unique_row_condition()
    CASE fgl_db_driver_type()
        WHEN "ifx" RETURN " FROM systables WHERE tabid=1"
        WHEN "db2" RETURN " FROM sysibm.systables WHERE
 name='SYSTABLES'"
        WHEN "pgs" RETURN " FROM pg_class WHERE
 relname='pg_class'"
        WHEN "ora" RETURN " FROM dual"
        OTHERWISE RETURN " "
    END CASE
END FUNCTION
```

IBM® Informix® SQL ANSI Mode
Understanding the impact of the SQL ANSI mode of IBM® Informix®.

IBM® Informix® allows you to create databases in ANSI mode, which is supposed to be closer to ANSI standard behavior. Other databases like ORACLE and DB2® are 'ANSI' by default.

If you are not using the ANSI mode with IBM® Informix®, we suggest you keep the database as is, because turning an IBM® Informix® database into ANSI mode can result in unexpected behavior of the programs.

Here are some ANSI mode issues extracted from the IBM® Informix® books:

- Some actions, like `CREATE INDEX` will generate a warning but will not be forbidden.
- Buffered logging is not allowed to enforce data recovery. (Buffered logging provides better performance)
- The table-naming scheme allows different users to create tables without having to worry about name conflicts.
- Owner specification is required in database object names (`SELECT ... FROM "owner".table`). You must quote the owner name to prevent automatic translation of the owner name into uppercase: `SELECT ... FROM owner.table` becomes `SELECT .. FROM OWNER.table` and thus, the table is not found in the database.
- Default privileges differ: When creating a table, the server grants privileges to the table owner and the DBA only. The same thing happens for the 'Execute' privilege when creating stored procedures.
- Default isolation level is `REPEATABLE READ`.
- An error is generated if any character field is filled with a value that is longer than the field width.
- `DECIMAL(p)` (floating point decimals) are automatically converted to `DECIMAL(p,0)` (fixed point decimals).
- Closing a closed cursor generates an SQL error.

It will take more time to adapt the programs to the IBM® Informix® ANSI mode than using the database interface to simulate the native mode of IBM® Informix®.

Positioned updates/deletes
Using positioned updates/deletes with named database cursors.

The "`WHERE CURRENT OF` *`cursor-name`*" clause in `UPDATE` and `DELETE` statements is not supported by all database engines.

Table 142: Database server support of WHERE CURRENT OF

Database Server Type	WHERE CURRENT OF supported?
IBM® DB2® UDB	Yes

Database Server Type	WHERE CURRENT OF supported?
IBM® Informix®	Yes
Microsoft™ SQL Server	Yes
MySQL	Yes
Oracle Database Server	No, emulated by driver with ROWIDs
PostgreSQL	No, emulated by driver with OIDs
Sybase ASE	Yes
SQLite	No

Some database drivers can emulate `WHERE CURRENT OF` mechanisms by using rowids, but this requires additional processing. You should review the code to disable this option.

The standard SQL solution is to use primary keys in all tables and write `UPDATE` / `DELETE` statements with a `WHERE` clause based on the primary key:

```
DEFINE rec RECORD
           id    INTEGER,
           name  CHAR(100)
     END RECORD
BEGIN WORK
  SELECT CUSTID FROM CUSTOMER
         WHERE CUSTID=rec.id FOR UPDATE
  UPDATE CUSTOMER SET CUSTNAME = rec.name
        WHERE CUSTID = rec.id
COMMIT WORK
```

WITH HOLD and FOR UPDATE
Hold cursors and not portable.

IBM® Informix® supports `WITH HOLD` cursors using the `FOR UPDATE` clause. Such cursors can remain open across transactions (when using `FOR UPDATE`, locks are released at the end of a transaction, but the `WITH HOLD` cursor is not closed). This kind of cursor is IBM® Informix-specific and not portable. The SQL standards recommend closing `FOR UPDATE` cursors and release locks at the end of a transaction. Most database servers close `FOR UPDATE` cursors when a `COMMIT WORK` or `ROLLBACK WORK` is done. All database servers release locks when a transaction ends.

Table 143: Database server support of WITH HOLD FOR UPDATE

Database Server Type	WITH HOLD FOR UPDATE supported?
IBM® DB2® UDB	No
IBM® Informix®	Yes
Microsoft™ SQL Server	No
MySQL	No
Oracle Database Server	No
PostgreSQL	No
Sybase ASE	No
SQLite	No

It is mandatory to review code using `WITH HOLD` cursors with a `SELECT` statement having the `FOR UPDATE` clause.

The standard SQL solution is to declare a simple `FOR UPDATE` cursor outside the transaction and open the cursor inside the transaction:

```
DECLARE c1 CURSOR FOR SELECT ... FOR UPDATE
BEGIN WORK
  OPEN c1
  FETCH c1 INTO ...
  UPDATE ...
COMMIT WORK
```

If you need to process a complete result set with many rows including updates of master and detail rows, first fetch the primary keys of all master rows into a program array, declare a cursor with the `SELECT FOR UPDATE`, then for all rows in the array, start a transaction and perform the `UPDATE WHERE CURRENT OF` for the current master record and the `UPDATE` for detail rows, then commit the transaction and continue with the next master record:

```
DEFINE x, mkeys DYNAMIC ARRAY OF INTEGER
DECLARE c1 CURSOR FOR SELECT key FROM master ...
FOREACH c1 INTO x
    LET mkeys[mkeys.getLength()+1] = x
END FOREACH
DECLARE c2 CURSOR FOR SELECT * FROM master WHERE key=? FOR UPDATE
FOR x = 1 TO mkeys.getLength()
  BEGIN WORK
  OPEN c2 USING mkeys[x]
  FETCH c2 INTO mrec.*
  IF STATUS==NOTFOUND THEN
     ROLLBACK WORK
     CONTINUE FOREACH
  END IF
  UPDATE master SET ... WHERE CURRENT OF c2
  UPDATE detail SET ... WHERE master_key=mkeys[x]
  COMMIT WORK
END FOR
```

Insert cursors
Using insert cursors with non-Informix databases.

Database cursors defined with "`DECLARE` *`cursor-name`* `CURSOR FOR INSERT ...`" are designed for IBM® Informix® databases, to optimize row insertion when a lot of data must be loaded in the table.

This is an IBM® Informix® specifc feature. With non-Informix databases, insert cursors are emulated by executing the INSERT

```
DEFINE rec RECORD
           id    INTEGER,
           name  CHAR(100)
     END RECORD,
     i INTEGER
DECLARE c1 CURSOR FOR INSERT INTO customer VALUES (?,?)
BEGIN WORK
  OPEN c1
  FOR i=1 TO 100
      LET rec.id = i
      LET rec.name = "name"||i
      PUT c1 FROM rec.*
  END FOR
  FLUSH c1
  CLOSE c1
```

```
COMMIT WORK
```

Insert cursors are an IBM® Informix® specifc feature. The IBM® Informix® insert cursors buffers the provided rows and flushes blocks of rows into the database after a given number of rows, or when the program explicitly executes a `FLUSH` or `CLOSE`. In can of errors, for example when inserting a character string value for a numeric column, the SQL error is returned at "flush time" with Informix®.

With non-Informix databases, the rows are not buffered: insert cursors are emulated in db drivers by executing the `INSERT` statement on every `PUT` instruction. As result, this can lead to poor performances, and SQL errors can be returned earlier at `PUT` time.

Note that the `LOAD` instruction is based on an insert cursor. The same performance issue applies to the `LOAD` instruction when using a non-Informix database.

If you need to feed your database with a lot of data, coming for example from external sources, we recommend to use database vendor specific tools to load the data. This option is much more efficient as using a Genero program to load data.

String literals in SQL statements
Single quotes is the standard for delimiting string literals in SQL.

Some database servers like IBM® Informix® allow single and double quoted string literals in SQL statements, both are equivalent:

```
SELECT COUNT(*) FROM table
 WHERE col1 = "abc'def""ghi"
   AND col1 = 'abc''def"ghi'
```

Most database servers do not support this specific feature.

Table 144: Database servers support of double-quoted string literals

Database Server Type	Double quoted string literals
IBM® DB2® UDB	No
IBM® Informix®	Yes
Microsoft™ SQL Server	Yes
MySQL	No
Oracle Database Server	No
PostgreSQL	No
Sybase ASE	No
SQLite	Yes

The ANSI SQL standards define doubles quotes as database object names delimiters, while single quotes are dedicated to string literals:

```
CREATE TABLE "my table" ( "column 1" CHAR(10) )
SELECT COUNT(*) FROM "my table" WHERE "column 1" = 'abc'
```

If you want to write a single quote character inside a string literal, you must write 2 single quotes:

```
... WHERE comment = 'John''s house'
```

When writing static SQL in your programs, the double quoted string literals as converted to ANSI single quoted string literals by the fglcomp compiler. However, dynamic SQL statements are not parsed by the compiler and therefore need to use single quoted string literals.

We recommend that you always use single quotes for string literals and, if needed, double quotes for database object names.

Date and time in SQL statements
Good practices for date and time handling in SQL.

Date and time strings in SQL Statements

IBM® Informix® allows you to specify date and time values as a quoted character string in a specific format, depending upon DBDATE and GLS environment variables. For example, if `DBDATE=DMY4`, the following statement specifies a valid `DATE` represented by a string literal:

```
SELECT COUNT(*) FROM table WHERE date_col = '24/12/2005'
```

Other database servers do support date/time literals as quoted character strings, but the date/time format specification is quite different. The parameter to specify the date/time format can be a database parameter, an environment variable, or a session option.

In order to write portable SQL, use SQL parameters instead of string literals for date-time values:

```
DEFINE cnt INTEGER
DEFINE adate DATE
LET adate = MDY(12,24,2005)
SELECT COUNT(*) INTO cnt FROM table
    WHERE date_col = adate
```

Or, when using dynamic SQL:

```
DEFINE cnt INTEGER
DEFINE adate DATE
LET adate = MDY(12,24,2005)
PREPARE s1 FROM "SELECT COUNT(*) FROM table WHERE date_col = ?"
EXECUTE s1 USING adate INTO cnt
```

Date-time literals

IBM® Informix® `DATETIME` and `INTERVAL` literals are not converted automatically by the SQL translator of the database driver:

```
SELECT COUNT(*) FROM order WHERE ord_when > DATETIME (1999-10-12) YEAR TO
 DAY
```

Check your code, to detect where you are using such expressions in the SQL statements, and use an SQL parameter instead.

Informix-specific keywords

SQL Statements using expressions such as TODAY, CURRENT and EXTEND must be reviewed and adapted to the native syntax of the target database engine.

Check your code, to detect where you are using such expressions in the SQL statements.

Date-time expressions with parameters

Date-time arithmetic expressions using SQL parameters (USING variables) are not portable.

For example:

```
PREPARE s1 FROM "SELECT ... WHERE datecol < ? + 1"
```

Might generate an error with non-Informix databases.

DATEs as a number of days

IBM® Informix® can automatically convert integers to a DATE values, as a number of days since 12/31/1899 (1 = 01/01/1900). This is however not supported by other database engines.

Check your code, to detect where you are using integers with DATE columns.

Naming database objects

Name syntax

Database object naming conventions are different for each database engine.

The table below describes the naming conventions for database objects (i.e. tables, sequences, stored procedures):

Table 145: Database server naming conventions for database objects

Database Server Type	Naming Syntax
IBM® DB2® UDB	`[[database.]owner.]identifier`
IBM® Informix®	`[database[@dbservername]:][owner.]identifier`
Microsoft™ SQL Server	`[[[server.][database].][owner_name].]object_name`
MySQL	`[database.]identifier`
Oracle Database Server	`[schema.]identifier[@database-link]`
PostgreSQL	`[owner.]identifier`
Sybase ASE	`[database.]identifier`
SQLite	`[database.]identifier`

Case-sensitivity

Handling case-sensitivity with different database engines.

Most database engines have case-sensitive object identifiers. In most cases, when you do not specify identifiers in double quotes, the SQL parser automatically converts names to uppercase or lowercase, so that the identifiers match if the objects are also created without double quoted identifiers.

```
CREATE TABLE Customer ( cust_ID INTEGER )
```

In ORACLE, this statement would create a table named "`CUSTOMER`" with a "`CUST_ID`" column.

This table shows the behavior of each database engine regarding case sensitivity and double quoted identifiers:

Table 146: Database server support of case sensitivity and double-quoted identifiers

Database Server Type	Un-quoted names	Double-quoted names
IBM® DB2® UDB	Converts to uppercase	Case sensitive
IBM® Informix® (1)	Converts to lowercase	Syntax disallowed (non-ANSI mode)
Microsoft™ SQL Server (2)	Not converted, kept as is	Case sensitive
MySQL	Not converted, kept as is	Syntax disallowed
Oracle Database Server	Converts to uppercase	Uppercase
PostgreSQL	Converts to lowercase	Lowercase
Sybase ASE	Converts to lowercase	Lowercase
SQLite	Not converted, kept as is	Case insensitive

(1) If not ANSI database mode.

(2) When case-sensitive charset/collation used.

Take care with database servers marked in red, because object identifiers are case sensitive and are not converted to uppercase or lowercase if not delimited by double-quotes. This means that, by error, you can create two tables with a similar name:

```
CREATE TABLE customer ( cust_id INTEGER )  -- first table
CREATE TABLE Customer ( cust_id INTEGER )  -- second table
```

It is recommended to design databases with lowercase table and column names.

Size of identifiers
Avoid using long database object names.

The maximum size of a table or column name depends on the database server type. Some database engines allow very large names (256c), while others support only short names (30c max). Therefore, using short names is required for writing portable SQL. Short names also simplify SQL programs.

We recommend that you use simple and short (<30c) database object names, without double quotes and without a schema/owner prefix:

```
CREATE TABLE customer ( cust_id INTEGER )
SELECT customer.cust_id FROM table
```

You may need to set the database schema after connection, so that the current database user can see the application tables without specifying the owner/schema prefix each time.

> **Tip:** Even if all database engines do not required unique column names for all tables, we recommend that you define column names with a small table prefix (for example, CUST_ID in CUSTOMER table).

Temporary tables
Syntax for temporary table creation is not unique across all database engines.

Not all database servers support temporary tables. The engines supporting this feature often provide it with a specific table creation statement:

Table 147: Database server support of temporary tables

Database Server Type	Temp table creation syntax	Local to SQL session?
IBM® DB2® UDB	`DECLARE GLOBAL TEMPORARY TABLE tablename ( column-defs )` `DECLARE GLOBAL TEMPORARY TABLE tablename AS ( SELECT ... )`	Yes
IBM® Informix®	`CREATE TEMP TABLE tablename ( column-defs )` `SELECT ... INTO TEMP tablename`	Yes
Microsoft™ SQL Server	`CREATE TABLE #tablename ( column-defs )` `SELECT select-list INTO #tablename FROM ...`	Yes
MySQL	`CREATE TEMPORARY TABLE tablename ( column-defs )` `CREATE TEMPORARY TABLE tablename LIKE other-table`	Yes
Oracle Database Server	`CREATE GLOBAL TEMPORARY TABLE tablename ( column-defs )` `CREATE GLOBAL TEMPORARY TABLE tablename AS SELECT ...`	No: only data is local to session
PostgreSQL	`CREATE TEMP TABLE tablename ( column-defs )` `SELECT select-list INTO TEMP tablename FROM ...`	Yes
Sybase ASE	`CREATE TABLE #tablename ( column-defs )` `SELECT select-list INTO #tablename FROM ...`	Yes
SQLite	`CREATE TEMP TABLE tablename ( column-defs )`	Yes

Some databases even have a different behavior when using temporary tables. For example, ORACLE 9i supports a kind of temporary table, but it must be created as a permanent table. The table is not specific to an SQL session: it is shared by all processes - only the data is local to a database session.

You must review the programs using temporary tables, and adapt the code to use database-specific temporary tables.

Outer joins

Use standard ISO outer join syntax instead of the old IBM® Informix® `OUTER()` syntax.

Old IBM® Informix® SQL outer joins specified with the `OUTER` keyword in the `FROM` part are not standard:

```
SELECT * FROM master, OUTER ( detail )
  WHERE master.mid = detail.mid
    AND master.cdate IS NOT NULL
```

Table 148: Database server support of OUTER JOIN syntax

Database Server Type	Supports IBM® Informix® OUTER join syntax
IBM® DB2® UDB	No (but translated by driver)
IBM® Informix® (1)	Yes
Microsoft™ SQL Server (2)	No (but translated by driver)
MySQL	No (but translated by driver)
Oracle Database Server	No (but translated by driver)
PostgreSQL	No (but translated by driver)
Sybase ASE	No (but translated by driver)
SQLite	No (but translated by driver)

Most recent database servers now support the standard ANSI outer join specification:

```
SELECT * FROM master LEFT OUTER JOIN detail ON (master.mid = detail.mid)
  WHERE master.cdate IS NOT NULL
```

You should use recent database servers and use ANSI outer joins only.

Substring expressions
Handle substrings expressions with different database engines.

Only IBM® Informix® supports substring specification with square brackets:

```
SELECT * FROM item WHERE item_code[1,4] = "XBFG"
```

However, most database servers support a function that extracts substrings from a character string:

Table 149: Database server support of extraction of substrings

Database Server Type	Supports col[x,y] substrings?	Provides substring function?
IBM® DB2® UDB	No	`SUBSTR(expr,start,length)`
IBM® Informix® (1)	Yes	`SUBSTR(expr,start,length)`
Microsoft™ SQL Server (2)	No	`SUBSTRING(expr,start,length)`
MySQL	No	`SUBSTR(expr,start,length)`
Oracle Database Server	No	`SUBSTRING(expr,start,length)`
PostgreSQL	No	`SUBSTRING(expr FROM start FOR length )`
Sybase ASE	No	`SUBSTRING(expr,start,length)`
SQLite	No	`SUBSTR(expr,start,length)`

Informix® allows you to update some parts of a CHAR and VARCHAR column by using the substring specification (`UPDATE tab SET col[1,2] ='ab'`). This is not possible with other databases.

Review the SQL statements using substring expressions and use the database specific substring function.

You could also create your own SUBSTRING() user function in all databases that do not support this function, to have a common way to extract substrings. In Microsoft™ SQL Server, when you create a user function, you must specify the owner as prefix when using the function. Therefore, you should create a SUBSTRING() user function instead of SUBSTR().

Using ROWIDs

Automatic ROWIDs is not a common database feature.

Rowids are implicit primary keys generated by the database engine. Not all database servers support rowids:

Table 150: Database server support of rowid

Database Server Type	Rowid keyword?	Rowid type?
IBM® DB2® UDB	none	none
IBM® Informix® (1)	ROWID	INTEGER
Microsoft™ SQL Server (2)	none	none
MySQL	none	none
Oracle Database Server	ROWID	CHAR(18)

Database Server Type	Rowid keyword?	Rowid type?
PostgreSQL	OID	internal type
Sybase ASE	none	none
SQLite	ROWID	BIGINT

Informix® fills the `SQLCA.SQLERRD[6]` register with the ROWID of the last updated row. This register is an INTEGER and cannot be filled with rowids having CHAR(*) type.

Search for ROWID and SQLCA.SQLERRD[6] in your code and review the code to remove the usage of rowids.

MATCHES and LIKE operators
Use the standard LIKE operator instead of the MATCHES operator.

The MATCHES operator allows you to scan a string expression:

```
SELECT * FROM customer WHERE customer_name MATCHES "A*[0-9]"
```

Here is a table listing the database servers which support the MATCHES operator:

Table 151: Database server support for MATCHES operator

Database Server Type	Support for SQL MATCHES operator?
IBM® DB2® UDB	No
IBM® Informix® (1)	Yes
Microsoft™ SQL Server (2)	No
MySQL	No
Oracle Database Server	No
PostgreSQL	No
Sybase ASE	No
SQLite	No

The `MATCHES` operator is specific to IBM® Informix® SQL. The equivalent standard operator is `LIKE`. For maximum portability, replace `MATCHES` expressions in your SQL statements with a standard `LIKE` expression. `MATCHES` uses `*` and `?` as wildcards. The equivalent wildcards in the `LIKE` operator are `%` and `_`. Character ranges `[a-z]` are not supported by the `LIKE` operator.

Note that the Genero language includes a `MATCHES` operator. For example, in expressions such as: `IF custname MATCHES "S*"`. Do not confuse the language `MATCHES` operator with the SQL `MATCHES` operator, used in SQL statements. There is no problem in using the `MATCHES` operator of the language.

A program variable can be used as parameter for the `MATCHES` or `LIKE` operator, but you must pay attention to blank padding semantics of the target database. If the program variable is defined as a `CHAR(N)`, it is filled by the runtime system with trailing blanks, in order to have a size of N. For example, when a `CHAR(10)` variable is assigned with `"ABC%"`, it contains actually `"ABC% "` (with 6 additional blanks). If this variable is used in a `LIKE` expression in an SQL statement, the database server will search for column values matching "ABC"+ some characters + 6 blanks. To avoid automatic blanks, use a `VARCHAR(N)` data type instead of `CHAR(N)` to hold LIKE patterns.

Pay also attention to database specific semantics of the `LIKE` operation, especially when using CHAR(N) data types. For example, with Oracle DB, the expression `custname LIKE '%h'`, if custname is defined as CHAR(30), Oracle will only find the rows when the custname values end with a `'h'` at the last character

position (30), values such as `'Smith'` will not be found. Similarly, when doing `custname LIKE 'ab_'`, rows where the column type is CHAR(N>3), with values such as `'abc'` will not match in Oracle, IBM® DB2® and PostgreSQL, because of the significant trailing blanks.

As a general advice, use the VARCHAR type for variable string data, and leave CHAR usage for fixed-length character string data such as codes.

GROUP BY clause

Some databases allow you to specify a column index in the GROUP BY clause:

```
SELECT a, b, sum(c) FROM table GROUP BY 1,2
```

This is not possible with all database servers:

Table 152: Database server support of GROUP BY column index

Database Server Type	GROUP BY colindex, ... ?
IBM® DB2® UDB	No
IBM® Informix® (1)	Yes
Microsoft™ SQL Server (2)	No
MySQL	Yes
Oracle Database Server	No
PostgreSQL	Yes
Sybase ASE	No
SQLite	Yes

Search for GROUP BY in your SQL statements and use explicit column names.

The LENGTH() function in SQL

The semantics of the LENGTH() SQL function differs according to the database engine.

The SQL LENGTH() function must be used with care: Each database server has different semantics for this function, regarding length and trailing blanks handling.

> **Note:** The language provides a LENGTH built-in function which is part of the runtime system. Do not confuse this with the SQL LENGTH() function, used in SQL statements. The LENGTH() function of the language returns zero when the string expression is NULL.

Table 153: Database server support of LENGTH()

Database Server Type	Function name	Counting unit	Significant trailing blanks for CHAR() columns	Return value when NULL
IBM® DB2® UDB	`LENGTH(expr)`	Octets	Yes	NULL
IBM® Informix® (1)	`LENGTH(expr)`	Octets	No	NULL
Microsoft™ SQL Server (2)	`LEN(expr)`	Characters	No	NULL
MySQL	`LENGTH(expr)`	Characters	No	NULL
Oracle Database Server	`LENGTH(expr)`	Characters	Yes	NULL
PostgreSQL	`LENGTH(expr)`	Characters	Yes	NULL
Sybase ASE (2)	`LEN(expr)`	Characters	No	NULL
SQLite	`LENGTH(expr)`	Characters	Yes	NULL

Search for LENGTH() usage in your SQL statements and review the code of the database-specific function.

Transaction savepoints
Using transaction savepoints with different database engines.

IBM® Informix® IDS 11.50 introduced transaction savepoints, following the ANSI SQL standards. While most recent database severs support savepoints, you must pay attention and avoid Informix® specific features. For example, Oracle (11), SQL Server (2008 R2), Sybase ASE (15.5) do not support the `RELEASE SAVEPOINT` instruction. The `UNIQUE` clause of `SAVEPOINT` is only supported by IBM® Informix® and IBM® DB2® UDB.

Database Server Type	SAVEPOINT & ROLLBACK WORK TO SAVEPOINT	RELEASE SAVEPOINT	SAVEPOINT UNIQUE
IBM® DB2® UDB	Yes	Yes	Yes
IBM® Informix®	Yes	Yes	Yes
Microsoft™ SQL Server (Only 2005+ with SNC driver)	Yes	No	No
MySQL	Yes	Yes	No
Oracle Database Server	Yes	No	No
PostgreSQL	Yes	Yes	No

Database Server Type	SAVEPOINT & ROLLBACK WORK TO SAVEPOINT	RELEASE SAVEPOINT	SAVEPOINT UNIQUE
Sybase ASE	Yes	No	No
SQLite	Yes	Yes	No

Stored procedures
Executing stored procedures with different database engine types.

Stored procedures execution needs to be addressed specifically according to the database type. There are different ways to execute a stored procedure. This section describes how to execute stored procedures on the supported database engines.

> **Tip:** In order to write reusable code, you should encapsulate each stored procedure execution in a `FUNCTION` performing database-specific SQL based on a global database type variable. The program function would just take the input parameters and return the output parameters of the stored procedure, hiding database-specific execution steps from the caller.

Specifying input and output parameters

Input and ouput parameters can be specified in SQL statement execution to pass and return values to/from stored procedures, according to the database type:

```
EXECUTE stmt USING param1 IN, param2 INOUT, param3 INOUT
```

Stored procedures returning a result set

With some database servers it is possible to execute stored procedures that produce a result set, and fetch the rows as normal `SELECT` statements, by using `DECLARE`, `OPEN`, `FETCH`. Some databases can return multiple result sets and cursor handles declared in a stored procedure as output parameters, but Genero supports only unique and anonymous result sets. See the examples.

Calling stored procedures with supported databases

- Stored procedure call with IBM Informix on page 441
- Stored procedure call with Oracle DB on page 443
- Stored procedure call with IBM DB2 on page 444
- Stored procedure call with Microsoft SQL Server on page 445
- Stored procedure call with PostgreSQL on page 447
- Stored procedure call with Oracle MySQL on page 449

Stored procedure call with IBM® Informix®

IBM® Informix® stored procedures are written in the SPL, C or Java™ programming languages, also known as User Defined Routines.

See Informix IDS documentation for more details.

Stored functions returning values

To return values from an IBM® Informix® SPL routine, execute the routine and fetch the output values, as you would for a regular `SELECT` statement producing a result set.

> **Note:** Informix distinguishes between *stored functions* from *stored procedures*. Only stored functions (with a `RETURNING` clause) can return values. Stored procedures do not return values.

To execute an Informix stored function from a BDL program, use the `EXECUTE FUNCTION` SQL instruction:

```
PREPARE stmt FROM "execute function proc1(?)"
```

In order to retrieve returning values into program variables, use an `INTO` clause in the `EXECUTE` instruction.

This example shows how to call a stored function:

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE "create function proc1( p1 integer )"
               || " returning decimal(6,2), varchar(200);"
               || "  define p2 decimal(6,2);"
               || "  define p3 varchar(200);"
               || "  let p2 = p1 + 0.23;"
               || "  let p3 = 'Value = ' || p1;"
               || "  return p2, p3;"
               || " end function;"
   PREPARE stmt FROM "execute function proc1(?)"
   LET n = 111
   EXECUTE stmt USING n INTO d, c
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored functions defined with output parameters

Starting with IDS 10.00, IBM® Informix® introduced the concept of output parameters for stored functions.

To retrieve the output parameters, you must execute the routine in a `SELECT` statement defining *Statement Local Variables*. These variables will be listed in the select clause to be fetched as regular column values. See Informix documentation for more details.

In order to retrieve returning values into program variables, use an `INTO` clause in the `EXECUTE` instruction.

This example shows how to call a stored function with output parameters:

```
MAIN
    DEFINE pi, pr INTEGER
    DATABASE test1
    EXECUTE IMMEDIATE "create function proc2(i INT, OUT r INT)"
                    ||" returning int;"
                    ||" let r=i+10;"
                    ||" return 1;"
                    ||" end function"
    PREPARE s FROM "select r from systables where tabid=1 and
 proc2(?,r#int)==1"
    LET pi = 33
    EXECUTE s USING pi INTO pr
    DISPLAY "Output value: ", pr
    EXECUTE IMMEDIATE "drop function proc2"
END MAIN
```

Stored functions returning a result set

To retrieve the rows of a result set produced by an IBM® Informix® stored function, you must create a cursor, as you would for a regular `SELECT` statement.

This example shows how to execute a stored function producing a result set:

```
MAIN
    DEFINE m, p_pk INT, p_name VARCHAR(10)
    DATABASE test1
```

```
    CREATE TABLE t1 ( pk INT, name VARCHAR(10) )
    INSERT INTO t1 VALUES (1, 'aaaa')
    INSERT INTO t1 VALUES (2, 'bbbbbb')
    INSERT INTO t1 VALUES (3, 'cccc')
    EXECUTE IMMEDIATE "create function proc3(v_max INT)"
                    ||" returning int, lvarchar;"
                    ||" define r_pk integer;"
                    ||" define r_name lvarchar;"
                    ||" foreach c1 for select pk,name into r_pk, r_name from
 t1 where pk <= v_max"
                    ||" return r_pk,r_name with resume;"
                    ||" end foreach;"
                    ||" end function"
    DECLARE c CURSOR FROM "EXECUTE FUNCTION proc3(?)"
    LET m = 100
    FOREACH c USING m INTO p_pk, p_name
        DISPLAY p_pk, p_name
    END FOREACH
    EXECUTE IMMEDIATE "drop function proc3"
    DROP TABLE t1
END MAIN
```

Stored procedure call with Oracle DB

Oracle supports stored procedures and stored functions as a group of PL/SQL statements that you can call by name. Oracle stored functions are very similar to stored procedures, except that a function returns a value to the environment in which it is called. Functions can be used in SQL expressions.

Stored procedures with output parameters

Oracle stored procedures or stored functions must be called with the input and output parameters specification in the `USING` clause of the `EXECUTE`, `OPEN` or `FOREACH` instruction. As in normal dynamic SQL, parameters must correspond by position, and the `IN/OUT/INOUT` options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must include the procedure in an anonymous PL/SQL block with `BEGIN` and `END` keywords:

```
PREPARE stmt FROM "begin proc1(?,?,?); end;"
```

Remark: Oracle stored procedures do not specify the size of number and character parameters. The size of output values (especially character strings) are defined by the calling context (i.e. the data type of the variable used when calling the procedure). When you pass a CHAR(10) to the procedure, the returning value will be filled with blanks to reach a size of 10 bytes.

Note that for technical reasons, the Oracle driver uses dynamic binding with `OCIBindDynamic()`. The Oracle Call Interface does not support stored procedures parameters with the `CHAR` data type when using dynamic binding. You must use `VARCHAR2` instead of `CHAR` to define character string parameters for stored procedures.

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                   "create procedure proc1("
                || "         p1 in int,"
                || "         p2 in out number,"
                || "         p3 in out varchar2"
                || "      )"
```

```
                || " is begin"
                || "  p2:= p1 + 0.23;"
                || "  p3:= 'Value = ' || to_char(p1);"
                || "end;"
   PREPARE stmt FROM "begin proc1(?,?,?); end;"
   LET n = 111
   EXECUTE stmt USING n IN, d INOUT, c INOUT
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored functions with a return value

To execute the stored function returning a value, you must include the function in an anonymous PL/SQL block with `BEGIN` and `END` keywords, and use an assignment expression to specify the place holder for the returning value:

```
PREPARE stmt FROM "begin ?:= func1(?,?,?); end;"
```

Stored procedures producing a result set

Oracle supports result set generation from stored procedures with the concept of cursor variables (`REF CURSOR`).

Note that Genero does not support cursor references produced by Oracle stored procedures or functions.

Stored procedure call with IBM® DB2®

IBM® DB2® implements stored procedures as a saved collection of SQL statements, which can accept and return user-supplied parameters. IBM® DB2® stored procedures can also produce one or more result sets. Beside stored procedures, IBM® DB2® supports user defined functions, typically used to define scalar functions returning a simple value which can be part of SQL expressions.

Stored procedures with output parameters

IBM® DB2® stored procedures must be called with the input and output parameters specification in the `USING` clause of the `EXECUTE`, `OPEN` or `FOREACH` instruction. As in normal dynamic SQL, parameters must correspond by position and the `IN/OUT/INOUT` options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use the `CALL` SQL instruction:

```
PREPARE stmt FROM "call proc1(?,?,?)"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                   "create procedure proc1("
                || "          in p1 int,"
                || "          out p2 decimal(6,2),"
                || "         inout p3 varchar(20)"
                || "        )"
                || " language sql begin"
                || "  set p2 = p1 + 0.23;"
                || "  set p3 = 'Value = ' || char(p1);"
                || "end"
   PREPARE stmt FROM "call proc1(?,?,?)"
   LET n = 111
```

```
   EXECUTE stmt USING n IN, d OUT, c INOUT
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored procedures producing a result set

With DB2® UDB, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows:

```
MAIN
   DEFINE i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc2( in key integer )"
                || " result sets 1"
                || " language sql"
                || "  begin"
                || "  declare c1 cursor with return for"
                || "    select * from tab1 where c1 > key;"
                || "  open c1;"
                || "  end"
   DECLARE curs CURSOR FROM "call proc2(?)"
   LET i = 1
   FOREACH curs USING i INTO n, d, c
       DISPLAY n, d, c
   END FOREACH
END MAIN
```

Stored procedures with output parameters and result set

It is possible to execute DB2® UDB stored procedures with output parameters and a result set.

The output parameter values are available after the `OPEN` cursor instruction:

```
   OPEN curs USING n IN, d OUT, c INOUT
   FETCH curs INTO rec.*
```

Stored procedure call with Microsoft™ SQL Server

SQL Server implements stored procedures, which are a saved collection of Transact-SQL statements that can take and return user-supplied parameters.

SQL Server stored procedures can also produce one or more result sets.

Stored procedures with output parameters

SQL Server stored procedures must be called with the input and output parameters specification in the `USING` clause of the `EXECUTE`, `OPEN` or `FOREACH` instruction. As in normal dynamic SQL, parameters must correspond by position and the `IN/OUT/INOUT` options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use an ODBC `call` escape sequence:

```
PREPARE stmt FROM "{ call proc1(?,?,?) }"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
```

```
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                  "create procedure proc1"
               || "             @v1 integer,"
               || "             @v2 decimal(6,2) output,"
               || "             @v3 varchar(20) output"
               || " as begin"
               || "  set @v2 = @v1 + 0.23"
               || "  set @v3 = 'Value = ' || cast(@v1 as varchar)"
               || "end"
   PREPARE stmt FROM "{ call proc1(?,?,?) }"
   LET n = 111
   EXECUTE stmt USING n IN, d OUT, c OUT
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored procedures producing a result set

With SQL Server, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows.

The next example uses a stored procedure with a simple `SELECT` statement. If the stored procedure contains additional Transact-SQL statements such as `SET` or `IF` (which is the case in complex stored procedures), SQL Server generates multiple result sets. By default the Genero SQL Server driver uses "server cursors" to support multiple active SQL statements. But SQL Server stored procedures generating multiple result sets cannot be used with server cursors: The server cursor is silently converted to a "default result set" cursor by the ODBC driver. Since Default result set cursors do not support multiple active statements, you cannot use another SQL statement while processing the results of such stored procedure. You must `CLOSE` the cursor created for the stored procedure before continuing with other SQL statements.

```
MAIN
   DEFINE i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc2 @key integer"
               || "  as select * from tab1 where c1 > @key"
   DECLARE curs CURSOR FROM "{ call proc2(?) }"
   LET i = 1
   FOREACH curs USING i INTO n, d, c
       DISPLAY n, d, c
   END FOREACH
END MAIN
```

It is possible to fetch large objects (text/image) from stored procedure generating a result set, however, if the stored procedure executes other statements as the `SELECT` (like `SET`/`IF` commands), the SQL Server ODBC driver will convert the server cursor to a regular default result set cursor, requiring the LOB columns to appear at the end of the select list. Thus, in most cases (stored procedures typically use `SET` / `IF` statements), you will have to move the LOB columns and the end of the column list.

Stored procedures returning a cursor as output parameter

SQL Server supports "cursor output parameters": A stored procedure can declare/open a cursor and return a reference of the cursor to the caller.

SQL Server stored procedures returning a cursor as output parameter are not supported. There are two reasons for this: The language does not have a data type to store a server cursor reference, and the underlying ODBC driver does not support this anyway.

Stored procedures with return code

SQL Server stored procedures can return integer values. To get the return value of a stored procedure, you must use an assignment expression in the ODBC `call` escape sequence:

```
PREPARE stmt FROM "{ ? = call proc3(?,?,?) }"
```

Stored procedures with output parameters, return code and result set

With SQL Server you can call stored procedures with a return code, output parameters and producing a result set.

Return codes and output parameters are the last items returned to the application by SQL Server; they are not returned until the last row of the result set has been fetched, after the `SQLMoreResults()` ODBC function is called. If output parameters are used, the SQL Server driver executes a `SQLMoreResults()` call when closing the cursor instead of `SQLCloseCursor()`, to get the return code and output parameter values from SQL Server.

```
MAIN
   DEFINE r, i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc3 @key integer output"
                || "  as begin"
                || "     set @key = @key - 1"
                || "     select * from tab1 where c1 > @key"
                || "     return (@key * 3)"
                || "  end"
   DECLARE curs CURSOR FROM "{ ? = call proc3(?) }"
   LET i = 1
   OPEN curs USING r INOUT, i INOUT
   DISPLAY r, i
   FETCH curs INTO n, d, c
   FETCH curs INTO n, d, c
   FETCH curs INTO n, d, c
   DISPLAY r, i
   CLOSE curs
   DISPLAY r, i -- Now the returned values are available
END MAIN
```

The return code and output parameter variables must be defined as `INOUT` in the `OPEN` instruction.

Stored procedure call with PostgreSQL

PostgreSQL implements stored functions that can return values. If the function returns more that one value, you must specify the returning values as function parameters with the `OUT` keyword. If the function returns a unique value, you can use the `RETURNS` clause.

Pay attention to the function signature; PostgreSQL allows function overloading. For example, `func(int)` and `func(char)` are two different functions. To drop a function, you must specify the parameter type to identify the function signature properly.

Stored functions with output parameters

To execute a stored function with PostgreSQL, you must use `SELECT * FROM function`, as shown in this line:

```
PREPARE stmt FROM "select * from proc1(?)"
```

In order to retrieve returning values into program variables, you must use an `INTO` clause in the `EXECUTE` instruction.

The following example shows how to call a stored function with PostgreSQL:

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                  "create function proc1("
               || "          p1 integer,"
               || "          out p2 numeric(6,2),"
               || "          out p3 varchar(200)"
               || "          )"
               || " as $$"
               || "  begin"
               || "    p2:= p1 + 0.23;"
               || "    p3:= 'Value = ' || cast(p1 as text);"
               || "  end;"
               || " $$ language plpgsql"
   PREPARE stmt FROM "select * from proc1(?)"
   LET n = 111
   EXECUTE stmt USING n INTO d, c
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored functions producing a result set

With PostgreSQL, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows:

```
MAIN
   DEFINE i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create function proc2(integer)"
               || " returns setof tab1"
               || " as $$"
               || "  select * from tab1 where c1 > $1;"
               || " $$ language sql"
   DECLARE curs CURSOR FROM "select * from proc2(?)"
   LET i = 1
   FOREACH curs USING i INTO n, d, c
       DISPLAY n, d, c
   END FOREACH
END MAIN
```

Stored functions with output parameters and result set

With PostgreSQL you cannot return output parameters and a result set from the same stored procedure; both use the same technique to return values to the client, in the context of result columns to be fetched.

Stored procedure call with Oracle MySQL

MySQL implements stored procedures and stored functions as a collection of SQL statements that can take and return user-supplied parameters. Functions are very similar to procedures, except that they return a scalar value and can be used in SQL expressions.

Stored procedures with output parameters

Since MySQL C API (version 5.0) does not support an output parameter specification, the `IN`/`OUT`/`INOUT` technique cannot be used.

In order to return values from a MySQL stored procedure or stored function, you must use SQL variables. There are three steps to execute the procedure or function:

1. With the `SET` SQL statement, create and assign an SQL variables for each parameter.
2. `CALL` the stored procedure or stored function with the created SQL variables.
3. Perform a `SELECT` statement to return the SQL variables to the application.

In order to retrieve returning values into program variables, you must use an `INTO` clause in the `EXECUTE` instruction.

The following example shows how to call a stored procedure with output parameters:

MySQL version 5.0 does not allow you to prepare the `CREATE PROCEDURE` statement; you may need to execute this statement from the mysql command line tool.

MySQL version 5.0 cannot execute "`SELECT @variable`" with server-side cursors. Since the MySQL driver uses server-side cursors to support multiple active result sets, it is not possible to execute the `SELECT` statement to return output parameter values.

MySQL version >=5.0 evaluates "`@variable`" user variables assigned with a string as large `text` (CLOB) expressions. That type of values must normally be fetched into `TEXT` variable. To workaround this behavior, you can use the `substring(@var,1,255)` function to return a `VARCHAR()` expression from MySQL and fetch into a `VARCHAR()` variable.

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                  "create procedure proc1("
               || "   p1 integer,"
               || "   out p2 numeric(6,2),"
               || "   out p3 varchar(200)
               || " )"
               || " no sql begin"
               || "    set p2 = p1 + 0.23;"
               || "    set p3 = concat( 'Value = ', p1 );"
               || "  end;"
   LET n = 111
   EXECUTE IMMEDIATE "set @p1 = ", n
   EXECUTE IMMEDIATE "set @p2 = NULL"
   EXECUTE IMMEDIATE "set @p3 = NULL"
   EXECUTE IMMEDIATE "call proc1(@p1, @p2, @p3)"
   PREPARE stmt FROM "select @p2, substring(@p3,1,200)"
   EXECUTE stmt INTO d, c
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored functions returning values

The following example shows how to retrieve the return value of a stored function with MySQL:

MySQL version 5.0 does not allow you to prepare the `CREATE FUNCTION` statement; you may need to execute this statement from the mysql command line tool.

```
MAIN
   DEFINE n INTEGER
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE "create function func1(p1 integer)"
                || " no sql begin"
                || "    return concat( 'Value = ', p1 );"
                || "  end;"
   PREPARE stmt FROM "select func1(?)"
   LET n = 111
   EXECUTE stmt USING n INTO c
   DISPLAY c
END MAIN
```

Stored procedures producing a result set

Note that MySQL version 5.0 stored procedures and stored functions cannot return a result set.

Stored procedure call with SAP Sybase ASE

Sybase ASE supports stored procedures, which can take and return user-supplied parameters.

Sybase ASE stored procedures can also produce one or more result sets.

Stored procedures with output parameters

Sybase ASE stored procedures must be called with the input and output parameters specification in the `USING` clause of the `EXECUTE`, `OPEN` or `FOREACH` instruction. As in normal dynamic SQL, parameters must correspond by position and the `IN/OUT/INOUT` options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use a specific syntax to have the database driver identify the statement as an RPC call. The syntax of an RPC call must be:

```
!rpc procedure-name ( [ @param-name [,...] ] )
```

The parameter names must be specified, with the same names as the arguments of the stored procedure, because the ODI driver must bind stored procedure parameters by name.

Example:

```
PREPARE stmt FROM "!rpc update_account ( @custid, @old, @new )"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
   DEFINE n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   EXECUTE IMMEDIATE
                   "create procedure proc1"
                || "   @v1 integer,"
                || "   @v2 decimal(6,2) output,"
                || "   @v3 varchar(20) output"
                || " as begin"
                || "  set @v2 = @v1 + 0.23"
```

```
                || "  set @v3 = 'Value = ' || cast(@v1 as varchar)"
                || "end"
   PREPARE stmt FROM "!rpc proc1( @v1, @v2, @v3 )"
   LET n = 111
   EXECUTE stmt USING n IN, d OUT, c OUT
   DISPLAY d
   DISPLAY c
END MAIN
```

Stored procedures producing a result set

With Sybase, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows.

When the stored procedure generates multiple active statements, you cannot use another SQL statement while processing the results of such stored procedure. You must `CLOSE` the cursor created for the stored procedure before continuing with other SQL statements.

```
MAIN
   DEFINE i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc2 @key integer"
                || "  as select * from tab1 where c1 > @key"
   DECLARE curs CURSOR FROM "!rpc proc2( @key )"
   LET i = 1
   FOREACH curs USING i INTO n, d, c
       DISPLAY n, d, c
   END FOREACH
END MAIN
```

Stored procedures with output parameters, return code and result set

With Sybase ASE stored procedures, you call stored procedures with a return code, output parameters and producing a result set.

Return codes and output parameters are the last items returned to the application by Sybase; they are not returned until the last row of the result set has been fetched.

```
MAIN
   DEFINE r, i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc3 @key integer output"
                || "  as begin"
                || "     set @key = @key - 1"
                || "     select * from tab1 where c1 > @key"
                || "     return (@key * 3)"
                || "  end"
   DECLARE curs CURSOR FROM "!rpc proc3( @key ) }"
   LET i = 1
   OPEN curs USING r OUT, i OUT
   DISPLAY r, i
```

```
   FETCH curs INTO n, d, c
   FETCH curs INTO n, d, c
   FETCH curs INTO n, d, c
   DISPLAY r, i
   CLOSE curs
   DISPLAY r, i -- Now the returned values are available
END MAIN
```

SQL performance

- Performance with transactions on page 453
- Avoiding long transactions on page 454
- Declaring prepared statements on page 454
- Saving SQL resources on page 454
- Optimizing scrollable cursors on page 455

Performance with dynamic SQL

Comparing static SQL statements and dynamc SQL statements used in a loop.

Although SQL statements can be directly specified in the program source as a part of the language as static SQL, it is sometimes more efficient to use dynamic SQL instead, when you are executing SQL statements repeatedly.

Dynamic SQL allows you to PREPARE the SQL statements once and EXECUTE N times, improving performance.

Note however that implementing prepared statements with dynamic SQL has a cost in terms of database resources and code readability: When a simple static SQL statement is executed, database client and server resources are allocated for the statement and are reused for the next Static SQL statement. With dynamic SQL, you define a statement handle and allocate database resources that last until you FREE the handle. Regarding code readability, static SQL statements can be written directly in the source code (as another language statement), while Dynamic SQL uses several instructions and takes the SQL text as a string expression. Additionally, static SQL statements are parsed at compile time so you can detect syntax errors in the SQL text before executing the programs.

Therefore, dynamic SQL should only be used if the SQL statement is created at runtime (with a where part generated by a CONSTRUCT for example) or if the execution time is too long with static SQL (assuming that it's only a statement preparation issue).

To perform static SQL statement execution, the database interface must use the basic API functions provided by the database client. These are usually equivalent to the PREPARE and EXECUTE instructions. So when you write a static SQL statement in your program, it is actually converted to a PREPARE + EXECUTE behing the scene.

For example, the following code:

```
FOR n=1 TO 100
   INSERT INTO tab VALUES ( n, c )
END FOR
```

is actually equivalent to:

```
FOR n=1 TO 100
   PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
   EXECUTE s USING n, c
END FOR
```

To improve the performance of the preceding code, use a PREPARE instruction before the loop and put an EXECUTE instruction inside the loop:

```
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
FOR n=1 TO 100
   EXECUTE s USING n, c
END FOR
```

Performance with transactions

Commit database changes by blocks of transaction speeds performance with some database servers.

To mimic the IBM® Informix® auto-commit behavior with an ANSI compliant RDBMS like Oracle or DB2® UDB, the database driver must perform an implicit commit after each statement execution, if the SQL statement is not inside a transaction block. This generates unnecessary database operations and can slow down big loops. To avoid this implicit commit, you can control the transaction with BEGIN WORK / COMMIT WORK around the code containing a lot of SQL statement execution.

This technique is especially recommended with SQLite, because the SQLite database library performs a lot of operations during a commit.

For example, the following loop will generate 2000 basic SQL operations (1000 inserts plus 1000 commits):

```
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
FOR n=1 TO 100
   EXECUTE s USING n, c   -- Generates implicit COMMIT
END FOR
```

You can improve performance if you put a transaction block around the loop:

```
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
BEGIN WORK
FOR n=1 TO 100
   EXECUTE s USING n, c   -- In transaction -> no implicit COMMIT
END FOR
COMMIT WORK
```

With this code, only 1001 basic SQL operations will be executed (1000 inserts plus 1 commit).

However, you must take care when generating large transactions because all modifications are registered in transaction logs. This can result in a lack of database server resources ("transaction too long" errors, for example) when the number of operations is very big. If the SQL operation does not require a unique transaction for database consistency reasons, you can split the operation into several transactions, as in this example:

```
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
BEGIN WORK
FOR n=1 TO 100
   IF n MOD 10 == 0 THEN
      COMMIT WORK
      BEGIN WORK
   END IF
   EXECUTE s USING n, c   -- In transaction -> no implicit COMMIT
END FOR
COMMIT WORK
```

Note that the LOAD instruction automatically starts a transaction, if not yet initiated. Therefore there is no need to enclose the LOAD statement within a BEGIN WORK / COMMIT WORK, except if other SQL statements are part of the transaction and need to be processed as a single atomic database change.

Avoiding long transactions

Long transactions consume resources and decrease concurrent data access.

Old applications based on IBM® Informix® database without transaction logging might perform long running SQL modifications.

With recent database engines, using huge transactions can lead to errors because of transaction log buffer overflow. For example, if a table holds many rows, a "`DELETE FROM table`" might produce a "snapshot too old" error in Oracle, if the rollback segments are too small.

Therefore, you must avoid long transactions when connected to a database using transactions:

- keep transactions as short as possible.
- access the least amount of data possible while in a transaction.
- split a long transaction into many short transactions. Use a loop to handle each block.
- to delete all rows from a table use the "`TRUNCATE TABLE`" instruction instead of "`DELETE FROM`" (Not for all vendors).
- In the end, increase the size of the transaction log to avoid filling it up.

Declaring prepared statements

Optimize prepared cursor statements by using the `FROM` clause of `DECLARE CURSOR`.

Line 2 of this example shows a cursor declared with a prepared statement:

```
PREPARE s FROM "SELECT * FROM table WHERE ", condition
DECLARE c CURSOR FOR s
```

While this has no performance impact with IBM® Informix® database drivers, it can become a bottleneck when using non-IBM Informix® databases:

Statement preparation consumes a lot of memory and processor resources. Declaring a cursor with a prepared statement is a native IBM® Informix® feature, which consumes only one real statement preparation. Non-IBM Informix® databases do not support this feature, so the statement is prepared twice (once for the `PREPARE`, and once for the `DECLARE`). When used in a big loop, this code can cause performance problems.

To optimize the code, use the `FROM` clause in the `DECLARE` statement:

```
DECLARE c CURSOR FROM "SELECT * FROM table WHERE " || condition
```

By using this solution only one statement preparation will be done by the database server.

> **Note:** This performance problem does not occur with `DECLARE` statements using static SQL.

Saving SQL resources

SQL cursors and prepared statement consume resources that should be freed when useless.

To write efficient SQL in your programs, you can use dynamic SQL. However, when using dynamic SQL, you allocate an SQL statement handle on the client and server side, consuming resources. According to the database type, this can be a few bytes or a significant amount of memory. When executing several static SQL statements, the same statement handle is reused and thus less memory is needed.

The language allows you to use either static SQL or dynamic SQL, so it's in your hands to choose memory or performance. However, in some cases the same code will be used by different kinds of programs, needing either low resource usage or good performance. In many OLTP applications you can actually distinguish two type of programs:

- Programs where memory usage is not a problem but good performance is needed (typically, batch programs executed as a unique instance during the night).
- Programs where performance is less important but memory usage must be limited (typically, interactive programs executed as multiple instances for each application user).

To reuse the same code for interactive programs and batch programs, you can do this:

1. Define a local module variable as an indicator for the prepared statement.
2. Write a function returning the type of program (for example, 'interactive' or 'batch' mode).
3. Then, in a reusable function using SQL statements, prepare and free the statement according to the indicators, as shown in the next example.

```
PRIVATE DEFINE up_prepared BOOLEAN

FUNCTION getUserPermissions( username )
  DEFINE username VARCHAR(20)
  DEFINE cre, upd, del CHAR(1)

  IF NOT up_prepared THEN
     PREPARE up_stmt FROM "SELECT can_create, can_update, cab_delete"
                          || " FROM user_perms WHERE name = ?"
     LET up_prepared = TRUE
  END IF

  EXECUTE up_stmt USING username INTO cre, upd, del

  IF isInteractive() THEN
     FREE up_stmt
     LET up_prepared = FALSE
  END IF

  RETURN cre, upd, del

END FUNCTION
```

The first time this function is called, the `up_prepared` value will be `FALSE`, so the statement will be prepared. The next time the function is called, the statement will be re-prepared only if `up_prepared` is `TRUE`. The statement is executed and values are fetched into the variables returned. If the program is interactive, the statement is freed and set the `up_prepared` module variable back to `FALSE`, forcing statement preparation in the next call of this function.

Optimizing scrollable cursors

A programming pattern to get fresh data from scrollable cursors.

Generally, when using scrollable cursors, the database server or the database client software (i.e. the application) will make a static copy of the result set produced by the `SELECT` statement. For example, when using an IBM® Informix® database engine, each scrollable cursor will create a temporary table to hold the result set. Thus, if the `SELECT` statement returns all columns of the table(s) in the `FROM` clause, the database software will make a copy of all these values. This practice has two disadvantages: A lot of resources are consumed, and the data is static.

A good programming pattern to save resources and always get fresh data from the database server is to declare two cursors based on the primary key usage, if the underlying database table has a primary key (or unique index constraint): The first cursor must be a scrollable cursor that executes the `SELECT` statement, but returns only the primary keys. The `SELECT` statement of this first cursor is typically assembled at runtime with the where-part produced by a `CONSTRUCT` interactive instruction, to give a subset of the rows stored in the database. The second cursor (actually, a `PREPARE`/`EXECUTE` statement handle) performs a single-row `SELECT` statement listing all columns to be fetched for a given record, based on the primary key value of the current row in the scrollable cursor list. The second statement must use a ? question mark place holder to execute the single-row `SELECT` with the current primary key as SQL parameter.

If the primary key `SELECT` statement needs to be ordered, check that the database engine allows that columns used in the `ORDER BY` clause do not need to appear in the `SELECT` list. For example, this was the case with IBM® Informix® servers prior to version 9.4. If needed, the `SELECT` list can be completed with

the columns used in `ORDER BY`, you can then just list the variable that holds the primary key in the `INTO` clause of `FETCH`.

Note also that the primary key result set is static. That is, if new rows are inserted in the database or if rows referenced by the scroll cursor are deleted after the scroll cursor was opened, the result set will be outdated. In this case, you can refresh the primary key result set by re-executing the scroll cursor with `CLOSE`/`OPEN` commands.

This code example illustrates this programming pattern:

```
MAIN
   DEFINE wp VARCHAR(500)
   DATABASE test1
   -- OPEN FORM / DISPLAY FORM with c_id and c_name fields
   ...
   -- CONSTRUCT generates wp string...
   ...
   LET wp = "c_name LIKE 'J%'"
   DECLARE clist SCROLL CURSOR FROM "SELECT c_id FROM customer WHERE " || wp
   PREPARE crec FROM "SELECT * FROM customer WHERE c_id = ?"
   OPEN clist
   MENU "Test"
        COMMAND "First"    CALL disp_cust("F")
        COMMAND "Next"     CALL disp_cust("N")
        COMMAND "Previous" CALL disp_cust("P")
        COMMAND "Last"     CALL disp_cust("L")
        COMMAND "Refresh"  CLOSE clist OPEN clist
        COMMAND "Quit" EXIT MENU
   END MENU
   FREE crec
   FREE clist

END MAIN

FUNCTION disp_cust(m)
   DEFINE m CHAR(1)
   DEFINE rec RECORD
          c_id INTEGER,
          c_name VARCHAR(50)
      END RECORD
   CASE m
       WHEN "F" FETCH FIRST clist INTO rec.c_id
       WHEN "N" FETCH NEXT clist INTO rec.c_id
       WHEN "P" FETCH PREVIOUS clist INTO rec.c_id
       WHEN "L" FETCH LAST clist INTO rec.c_id
   END CASE
   INITIALIZE rec.* TO NULL
   IF SQLCA.SQLCODE == NOTFOUND THEN
      ERROR "You reached to top or bottom of the result set."
   ELSE
      EXECUTE crec USING rec.c_id INTO rec.*
      IF SQLCA.SQLCODE == NOTFOUND THEN
         ERROR "Row was not found in the database, refresh the result set."
      END IF
   END IF
   DISPLAY BY NAME rec.*
END FUNCTION
```

Database connections

Explains how to manage database connections in a program.

- Miscellaneous SQL statements on page 480

Understanding database connections

A *database connection* is a session of work, opened by the program to communicate with a specific database server, in order to execute SQL statements as a specific user.

Before working with database connections, make sure you have properly installed and configured all software, using the correct database client software/environment, and BDL database driver. It is very important to understand database client settings, regarding user authentication as well as database client character set configuration.

Note that on some platforms like on mobile devices, Genero BDL includes the SQLite lightweight database library, which is the default. Therefore, when executing programs on these platforms, there is no need to install a database client sowftare and configure the database driver for the runtime system.

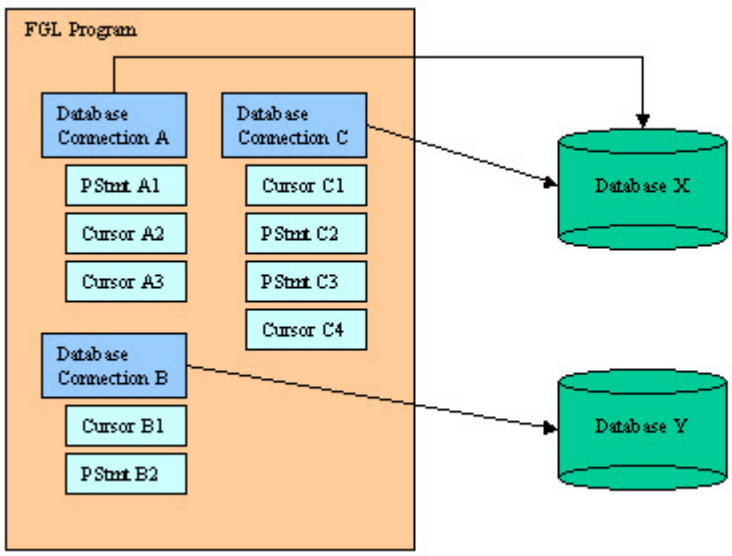

Figure 21: Schema example of a program using three database connections

The database user can be identified explicitly for each connection. Usually, the user is identified by a login and a password, or by using the authentication mechanism of the operating system (or even from a tier security system).

Database connection instructions DATABASE / CONNECT TO can not be prepared and executed as dynamic SQL statements.

There are two kind of connection modes: *unique-session* and *multi-session* mode. When using the DATABASE and CLOSE DATABASE instructions, the program is in unique-session mode. When using the CONNECT TO, SET CONNECTION and DISCONNECT instructions, the program is in *multi-session* mode. These connection modes are not compatible.

In unique-session mode, the DATABASE instruction initiates a connection the the database server and creates the current session. The database connection is terminated with the CLOSE DATABASE instruction, or when another DATABASE instruction is executed, or when the program ends.

In multi-session mode, open a database session with the CONNECT TO instruction. Other connections can be created with subsequent CONNECT TO instructions. To switch to a specific session, use the SET CONNECTION instruction; this suspends other opened connections. Disconnect from a specific or from all sessions with the DISCONNECT instruction. The end of the program disconnects all sessions automatically.

Once connected to a database server, the program uses the current session to execute SQL statements in that context.

Opening a database connection

A database connection identifies the SQL database server and the database entity the program connects to, in order to execute SQL statements.

To connect to a database server, the database driver needs to be loaded, and the SQL data source most be provided. Additionally, user authentication with user name / password may also be needed. All these parameters define connection information.

There are different ways to give connection information, and it is possible to mix the different methods to specify connection parameters. However, if provided, the database user name and password have to be specified together with the same method.

A database connection is performed in programs with the DATABASE or CONNECT TO instruction:

```
CONNECT TO dbspec [USER username USING password]
```

or

```
DATABASE dbspec
```

Prefer the CONNECT TO instruction, as it allows to specify a user name and password.

For portability reasons, it is not recommended that you use database vendor specific syntax (such as 'dbname@dbserver') in the DATABASE or CONNECT TO instructions: Connections must be identified in programs by a single name, while connection parameters are provided in external files.

Indirect database specification uses entries in the FGLPROFILE configuration file: When a DATABASE or CONNECT TO instruction is executed with the parameter *dbspec*, the runtime system first looks into FGLPROFILE for entries starting with dbi.database.*dbspec*, and uses these connection parameters if found. Otherwise, the runtime system will do direct database specification, by using the *dbspec* string to connect to the server.

> **Important:** When using FGLPROFILE entries for database connection parameters, keep in mind that entries must be written in lowercase.

Use a string variable with the DATABASE or CONNECT TO statement, in order to specify the database source at runtime. This solution gives you the best flexibility.

The string variable can be set from your own configuration file, from a program argument or from an environment variable.

Example

```
MAIN
  DEFINE db, us, pwd CHAR(50)
  LET db = fgl_getenv("MYDBSOURCE")
  LET us = arg_val(2)
  LET pwd = arg_val(3)
  CONNECT TO db USER us USING pwd
  ...
END MAIN
```

Database client environment

To connect to a database server, the programs must be executed in the correct database client environment. The database client software is usually included in the database server software, so you do not need to install it when your programs are executed on the same machine as the database server. However, you must install the database client software in three-tier configurations, when applications and database servers run on different systems.

This section describes basic configuration elements of the database client environment for some well-known database servers.

IBM® DB2 Universal Database™

1. The DB2DIR environment variable must define the DB2® software installation path.
2. The PATH environment variable must define the access path to database client programs.
3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to `$DB2DIR/lib`.
4. The DB2® client library `'DB2DIR/lib/libdb2*'` must be available.
5. The remote server node and the remote database must be declared locally with the CATALOG db2 command.
6. Make sure the database client locale is properly defined.
7. You can make a connection test with the IBM® db2 tool.

IBM® Informix® Dynamic Server

1. The INFORMIXDIR environment variable must define the IBM® Informix® software installation path.
2. The PATH environment variable must define the access path to database client programs.
3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to `$INFORMIXDIR/lib:$INFORMIXDIR/lib/esql`.
4. The IBM® Informix® client libraries `'INFORMIXDIR/lib/*'` must be available.
5. The INFORMIXSERVER environment variable can be used to define the name of the database server.
6. The sqlhost file must define the database server identified by INFORMIXSERVER.
7. Make sure the database client locale is properly defined.
8. You can make a connection test with the IBM® Informix® dbaccess tool.

Oracle MySQL

1. The MYSQL_HOME environment variable must define the MySQL software installation path.
2. The PATH environment variable must define the access path to database client programs.
3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to `$MYSQL_HOME/lib`.
4. Make sure the database client locale is properly defined.
5. You can make a connection test with the MySQL tool.

Oracle database

1. The ORACLE_HOME environment variable must define the Oracle software installation path.

2. The ORACLE_SID environment variable can be used to define the name of the local database instance.
3. The PATH environment variable must define the access path to database client programs.
4. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to `$ORACLE_HOME/lib`.
5. The Oracle client library `'ORACLE_HOME/lib/libclntsh*'` must be available.
6. The TNSNAMES.ORA file must define the database server identifiers for remote connections (the Oracle Listener must be started on the database server to allow remote connections).
7. The SQLNET.ORA file must define network settings for remote connections.
8. Make sure the database client locale is properly defined.
9. You can make a connection test with the Oracle sqlplus tool.

PostgreSQL

1. The PGDIR environment variable must define the PostgreSQL software installation path.
2. The PATH environment variable must define the access path to database client programs.
3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to `$PGDIR/lib`.
4. The PostgreSQL client library `'PGDIR/lib/libpq*'` must be available.
5. On the database server, the `pg_hba.conf` file must define security policies.
6. Make sure the database client locale is properly defined.
7. You can make a connection test with the PostgreSQL psql tool.

Microsoft™ SQL Server

1. Make sure that ODBC data source is defined on database client and database server systems, with the correct ODBC driver. Note that Genero FGL provides different sort of SQL Server drivers:
   - The SNC driver is based on the SQL Native Client ODBC driver (SQLNCLI*.DLL). The version of the SQL Native Client must match the ODI driver.
   - The FTM driver is based on the FreeTDS ODBC driver (libtdsodbc.so). This driver can be used if you want to connect to SQL Server from a UNIX™ machine.
   - The ESM driver is based on the EasySoft ODBC driver (libessqlsrv.so). This driver can be used if you want to connect to SQL Server from a UNIX™ machine.
2. On Windows™ platforms, the PATH environment variable must define the access path to database client programs (ODBC32.DLL). On UNIX/Linux platforms, check database client software documentation for environment settings (LD_LIBRARY_PATH, ldconfig).
3. On Windows™, Check the SQL Server Client configuration with the Client Network Utility tool: Verify that the ANSI to OEM conversion corresponds to the execution of applications in a CONSOLE environment.
4. Make sure the database client locale is properly defined. On UNIX/Linux platforms, check that the client character set parameter of the ODBC data source corresponds the the locale used by the application (LANG/LC_ALL).
5. On Windows™, you can make a connection test with the Microsoft™ Query Analyzer tool. On UNIX/Linux, see client software documentation for available SQL command tools (isql for example).

SQLite

1. The SQLite database driver includes the SQLite library, except on systems where that library is commonly available, like Linux distributions, Mac OS X and mobile devices.
2. Make sure the database client locale is properly defined. The SQLite library uses UTF-8. If the current character set (LANG/LC_ALL) is not UTF-8, like plain ASCII or UTF-8, the database driver will make appropriate character set conversions.
3. You can make a connection test with the `sqlite3` command line tool.

Sybase Adaptive Server Enterprise (ASE)

1. The SYBASE environment variable must define the Sybase ASE software installation path.

2. The PATH environment variable must define the access path to database client programs.
3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to the client libraries `libsybct.so` and `libsybcs.so`. On Windows™, the path to the DLLs must be defined in PATH.
4. Check the Sybase Client configuration, especially server name definition in connection's directory source, see DSQUERY environment variable.
5. Make sure the database client locale is properly defined.
6. You can make a connection test with the Sybase ISQL tool.

Connection parameters

This section describes the different parameters which need to be specified in order to connect to a database. The parameters can be provided with different methods (in the connection string or in FGLPROFILE settings). Some of these parameters are optional. For example, if the database user is authenticated by the operating system, username/password parameters are not needed.

Database source specification (source)

In database connection parameters, the `source` parameter identifies the data source name.

If the `source` parameter is defined with an empty value (""), the database interface connects to the default database server, which is usually the local server.

If the `source` entry is not present in FGLPROFILE, direct database specification method takes place.

Table 154: Meaning of the `source` connection parameter for supported databases

Database Type	Value of "source" entry	Description
Generic ODBC	*datasource*	ODBC Data Source
IBM® Informix®	*dbname*[@*dbserver*]	IBM® Informix® database specification
IBM® DB2®	*dsname*	DB2® Catalogued Database
Oracle MySQL / MariaDB	*dbname*[@*host*[:*port*]] or *dbname*[@*localhost~socket*]	Database Name @ Host Name: TCP Port or Database Name @ Local host ~ UNIX™ socket file
Oracle Database	*tnsname*	Oracle TNS Service name
PostgreSQL	*dbname*[@*host*[:*port*]][?*options*]	Database Name @ Host Name : TCP Port ? PostgreSQL URI-style query string options
SQL Server	*datasource*	ODBC Data Source
SQLite	*filename* or `:memory:`	Database file path, or simple file name to be found with DBPATH, or `:memory:` to create a database in memory.
Sybase Adaptive Server Enterprise (ASE)	*dbname*[@*engine*]	Database Name @ Engine Name

Database driver specification (driver)

In database connection parameters, the `driver` parameter identifies the type of database driver to be used.

The driver must correspond to the database client software.

> **Important:** Pay attention to the binary architecture of the database client software: Genero runtime system and database client binaries must match. For example, a 32 bit Oracle client can not be used with a Genero 64 bit runtime system.

We distinguish two sort of database driver names:

- Generic driver names ("`dbmora`", "`dbmsnc`"), and aliases ("`oracle`", "`sqlserver`")
- Version-stamped driver names ("`dbmora_12`", "`dbmsnc_10`", "`dbmsnc_11`")

A driver name "`dbm`*`xxx`*" identifies a generic driver name for the database server identified by the code `xxx`.

For example, in FGLPROFILE, to define the database driver for the Oracle OCI client (code "`ora`"), use the name "`dbmora`":

```
dbi.database.stores.driver = "dbmora"
```

For convenience, it is also possible to specify a long name (alias) such as "`oracle`" or "`sqlserver`", as defined in the database driver table below.

Use generic named drivers (with the latest database client software available on the platform), instead of version-stamped driver names. Use the version-stamped driver name only if the most recent database client software is not available on the platform.

Check for library dependency on your system, to identify the database client library required by the driver with the generic name. The driver definition table below lists the driver names for each supported database client types and versions. For example, on Linux platform, use the ldd command:

```
$ ldd $FGLDIR/dbdrivers/dbmmys.so
      ...
      libmysqlclient.so.18 => ...
      ...
```

Drivers with generic name are compatible with the latest database client version available on the platform. Thus, according to the platform, the same generic driver name can refer for different database client software. For example, on a platform where only MySQL 5.1 is available, `dbmmys` will match the MySQL 5.1 client, while on a more recent platform, `dbmmys` will match the MySQL 5.5 client.

To limit the number of drivers, if the database client software allows it, the drivers are build with the oldest database client version that is compatible with the latest available database client versions. For example, the `dbmmys_5_5` driver is build with the MySQL Client 5.5, but is compatible with MySQL 5.6 and 5.7 clients.

Note that given driver (combined with the corresponding database client software) can connect to a database server of an older version, if the database vendor client/server protocol supports the combination. For example, you can use an Oracle client version 12c to connect to an Oracle 11g server.

A default driver can be specified with the `dbi.default.driver` FGLPROFILE entry. This driver will be used for all database connections that do not specify the driver explicitely:

```
dbi.default.driver = "dbmora"
```

If this entry is not defined, and if no driver parameter is specified for the data source, the driver name defaults to `dbmdefault`. This default driver is a copy of the database driver that was chosen during installation.

Table 155: Database driver names according to database client type

Name with db client version	Generic name / alias	Code	Database client software version	UNIX™ shared objects	Microsoft™ Windows™ DLLs	Mac OS X™ dynamic libraries
dbmase_16	dbmase / sybase_ase	ase	Sybase ASE Open Client Library 16.x	libsybct[64].so, libsybcs[64].so	libsybct[64].dll, libsybcs[64].dll	N/A
dbmdb2_10	dbmdb2 / db2	db2	IBM® DB2® UDB Client 10.x	libdb2.so.1	db2cli.dll	N/A
dbmesm_1	dbmesm / easysoft_sqlserver	esm	EasySoft ODBC for SQL Server	libessqlsrv.so	N/A	N/A
dbmifx_9	dbmifx / informix	ifx	IBM® Informix® CSDK 2.80 and higher	libifsql.so, libifasf.so, libifgen.so, libifos.so, libifgls.so, libifglx.so	isqlt09a.dll	libifsql.dylib, libifasf.dylib, libifgen.dylib, libifos.dylib, libifgls.dylib, libifglx.dylib
dbmmys_5_1		mys	MySQL Client 5.1.x	libmysqlclient.so.16	libmysql.dll	libmysqlclient.16.dylib
dbmmys_5_5	dbmmys / mysql	mys	MySQL Client 5.5.x and higher / MariaDB 10.x and higher	libmysqlclient.so.18	libmysql.dll	libmysqlclient.18.dylib
dbmntz_6	dbmntz / netezza	ntz	IBM® Netezza® (6.x)	libnzodbc.so	odbc32.dll	N/A
dbmodc_3	dbmodc / odbc	odc	Generic ODBC (ODBC 3.x)	libodbc.so	odbc32.dll	libodbc.dylib
dbmora_11		ora	OCI Client V11	libclntsh.so.11.1	oci.dll	N/A
dbmora_12	dbmora / oracle	ora	OCI Client V12	libclntsh.so.12.1	oci.dll	N/A
dbmpgs_9	dbmpgs / postgresql	pgs	PostgreSQL Client 9.x	libpq.so.5	libpq.dll	libpq.5.dylib
dbmsnc_9		snc	SQL Native client 2005 (V9)	N/A	odbc32.dll / SQLNCLI.DLL	N/A
dbmsnc_10		snc	SQL Native client 2008 (V10)	N/A	odbc32.dll / SQLNCLI10.DLL	N/A

Name with db client version	Generic name / alias	Code	Database client software version	UNIX™ shared objects	Microsoft™ Windows™ DLLs	Mac OS X™ dynamic libraries
dbmsnc_11	dbmsnc / sqlserver	snc	SQL Native Client 2012 (V11)	N/A	odbc32.dll / SQLNCLI11.DLL	N/A
dbmftm_0	dbmftm / freetds_sqlserver	ftm	FreeTDS ODBC version 0.82 to 0.95	libtdsodbc.so.0	N/A	N/A
dbmsqt_3	dbmsqt / sqlite	sqt	SQLite 3.x	libsqlite3.so.0	N/A (statically linked)	libsqlite3.dylib

Default database driver

The dbi.default.driver FGLPROFILE entry defines a default database driver to be loaded, if the driver is not specified by the connection parameters.

```
dbi.default.driver = "driver-name"
```

The driver name must be specified without the .so or .DLL extension.

If this configuration entry is not defined, the driver name defaults to dbmdefault.

User name and password (username/password)

In database connection parameters, the username and password parameters define the default database user, when the program uses the DATABASE instruction or the CONNECT TO instruction without the USER/USING clause.

The username and password FGLPROFILE entries are not encrypted. These parameters are provided to simplify migration and should not be used in production. You better use CONNECT TO with a USER / USING clause to avoid any security hole, setup OS user authentication or use the connection callback method. Example of database servers supporting OS user authentication: IBM® Informix®, Oracle and SQL Server.

> **Important: Do not write clear user passwords in your sources! The username and password parameters should be set from a variables.**

For backward compatibility reasons, when using the IBM® Informix® driver, the username / password specification is ignored by the DATABASE instruction, only the CONNECT TO instruction takes external (or callback) login parameters into account.

Connection parameters in database specification

For development or testing purpose, connection parameters can be provided in the database specification string passed to the DATABASE and CONNECT TO instructions. Do not hard code connection specification parameters in programs to be installed on a production site, use the indirect database specification method instead, or build the connection string at runtime, to keep the database connection flexible.

The connection specification parameters override the dbi.database connection parameters defined in FGLPROFILE.

A + plus sign in the database specification starts the list of connection parameters. Each parameter is defined with a name followed by an equal sign an a value enclosed in single quotes. Connection specification parameters must be separated by a comma:

```
dbname+parameter='value'[,...]
```

In this syntax, *parameter* can be one of the following:

Table 156: Connection parameters in the database specification string

Parameter	Description
`resource`	Specifies which '`dbi.database`' entries have to be read from the FGLPROFILE configuration file. When this property is set, the database interface reads `dbi.database.`*`name`*`.*` entries, where *name* is the value specified for the *resource* parameter.
`driver`	Defines the database driver library to be loaded (filename without extension).
`source`	Specifies the data source of the database.
`username`	Defines the name of the database user.
`password`	Defines the password of the database user. **Important: Do not write clear user passwords in your sources! This parameter should be set from a variable value.**

In the next example, `driver`, `source` and `resource` are specified in the connection string:

```
MAIN
  DEFINE db CHAR(50)
  LET db = "stores+driver='dbmora',source='orcl',resource='myconfig'"
  DATABASE db
  ...
END MAIN
```

Direct database specification method

Direct database specification method takes place when the database name used in a `DATABASE` or `CONNECT TO` instruction is not defined in FGLPROFILE with a '`dbi.database.`*`dbname`*`.source`' entry. In this case, the database specification used in the connection instruction is used as the data source.

This method is well known for IBM® Informix® databases, for example to specify the IBM® Informix® server:

```
MAIN
  DATABASE stores@orion
  ...
END MAIN
```

In the next example, the database server is PostgreSQL. The string used in the connection instruction defines the PostgreSQL database (stock), the host (localhost), and the TCP service (5432) the postmaster is listening to. As PostgreSQL syntax is not allowed in the language, a CHAR variable must be used:

```
MAIN
  DEFINE db CHAR(50)
  LET db = "stock@localhost:5432"
  DATABASE db
  ...
```

```
END MAIN
```

This method tieds the compiler programs to a given database server configuration. Prefer indirect database specification method instead of direct database specification.

Indirect database specification method

Indirect database specification method takes place when the database name used in the `DATABASE` or `CONNECT TO` instruction corresponds to a '`dbi.database.`*`dbname`*`.source`' entry defined in the FGLPROFILE configuration file. In this case, the *dbname* database specification is used as a key to read the connection information from the configuration file.

In FGLPROFILE, the entries starting with '`dbi.database`' group information defining connection parameters for indirect database specification:

```
dbi.database.dbname.source   = "value"
dbi.database.dbname.driver   = "value"
dbi.database.dbname.username = "value"
dbi.database.dbname.password = "value"
-- Warning: Password is not encrypted, do not use in production!
```

Keep in mind that FGLPROFILE entry names are converted to lower case when loaded by the runtime system. In order to avoid any mistakes, it is recommended to write FGLPROFILE entry names and program database names in lower case.

In the next example, the program specifies a data source with the name `stores`, and FGLPROFILE defines the *source* and *driver* parameters for the `stores` data source:

Program:

```
MAIN
  DATABASE stores
  ...
END MAIN
```

FGLPROFILE:

```
dbi.database.stores.source   = "stock@localhost:5432"
dbi.database.stores.driver   = "dbmpgs"
```

The indirect database specification technique is a flexible technique to define the database source: The database name in programs is a kind of alias for the real data source, which is defined in an external configuration file (i.e. FGLPROFILE), where entries can be easily changed on production sites without needing program recompilation.

IBM® Informix® emulation parameters in FGLPROFILE

What are Informix SQL emulation settings used for?

To simplify the migration process to other database servers as IBM® Informix®, the database drivers can emulate some IBM® Informix-specific features like SERIAL columns and temporary tables; the drivers can also do some SQL syntax translation.

Avoid using IBM® Informix® emulations; write portable SQL code instead. IBM® Informix® emulations are only provided to help you in the migration process. Disabling IBM® Informix® emulations improves performance, because SQL statements do not have to be parsed to search for IBM® Informix-specific syntax.

Emulations can be controlled with FGLPROFILE parameters. You can disable all possible switches step-by-step, in order to test your programs for SQL compatibility.

`dbi.database.dsname.ifxemul`

This is a global switch to enable or disable IBM® Informix® emulations.

Values can be true or false. Default is true.

```
dbi.database.stores.ifxemul = false
```

`dbi.database.dsname.ifxemul.datatype.type`

The '`ifxemul.datatype`' switches define whether the specified data type must be converted to a native type (for example, when creating a table with the CREATE TABLE statement).

Where *type* can be one of `char, varchar, datetime, decimal, money, float, real, integer, smallint, serial, text, byte, bigint, bigserial, int8, serial8, boolean`.

Default is true for all types.

```
dbi.database.stores.ifxemul.datatype.serial = false
```

`dbi.database.dsname.ifxemul.datatype.serial.emulation`

This parameter can be used to control the SERIAL generation technique used by the driver to generate auto-incremented values.

The value can be one of following:

- `native` uses database's native sequence generator directly in the table definitions (depends on the db type).
- `native2` uses a secondary native sequence generator directly in the table definitions (depends on the db type).
- `regtable` uses the SERIALREG table with triggers. It is slower than the `native` emulation.
- `trigseq`", uses database sequence generator with triggers (not supported by all drivers).

Default is "`native`".

```
dbi.database.stores.ifxemul.datatype.serial.emulation = "native"
```

SERIAL emulations depend on the type of database server used. See SQL adaptation guides on page 529 for more details.

`dbi.database.dsname.ifxemul.temptables`

This switch can be used to control temporary table emulation.

Defaults is true.

```
dbi.database.stores.ifxemul.temptables = false
```

`dbi.database.dsname.ifxemul.temptables.emulation`

This parameter can be used to specify what technique must be used to emulate temporary tables in the database server.

Possible values are "`default`" and "`global`".

```
dbi.database.stores.ifxemul.temptables.emulation = "global"
```

See SQL adaptation guides on page 529 for more details.

dbi.database.*dsname*.ifxemul.dblquotes

This switch can be used to define whether double quoted strings must be converted to single quoted strings.

Default is true.

```
dbi.database.stores.ifxemul.dblquotes = false
```

If this emulation is enabled, all double quoted strings are converted, including database object names.

dbi.database.*dsname*.ifxemul.outers

This switch can be used to control IBM® Informix® `OUTER` translation to native SQL outer join syntax.

Default is true.

```
dbi.database.stores.ifxemul.outers = false
```

Note: Consider using standard ISO outer joins in your SQL statements (LEFT OUTER).

dbi.database.*dsname*.ifxemul.today

This switch can be used to convert the `TODAY` keyword to a native expression returning the current date.

Default is true.

```
dbi.database.stores.ifxemul.today = false
```

dbi.database.*dsname*.ifxemul.current

This switch can be used to convert the `CURRENT X TO Y` expressions to a native expression returning the current time.

Default is true.

```
dbi.database.stores.ifxemul.current = false
```

dbi.database.*dsname*.ifxemul.selectunique

This switch can be used to convert the `SELECT UNIQUE` to `SELECT DISTINCT`.

Default is true.

```
dbi.database.stores.ifxemul.selectunique = false
```

Note: Consider replacing all `UNIQUE` keywords by `DISTINCT`.

dbi.database.*dsname*.ifxemul.colsubs

This switch can be used to control column substrings expressions (col[x,y]) to native substring expressions.

Default is true.

```
dbi.database.stores.ifxemul.colsubs = false
```

Note: Consider using substring SQL functions instead of [x,y] expressions in SQL.

dbi.database.*dsname*.ifxemul.matches

This switch can be used to define whether MATCHES expressions must be converted to LIKE expressions.

Default is true.

```
dbi.database.stores.ifxemul.matches = false
```

Note: Consider using LIKE expressions instead of MATCHES in SQL.

dbi.database.*dsname*.ifxemul.length

This switch can be used to define whether LENGTH( ) function names have to be converted to the native equivalent.

Default is true.

```
dbi.database.stores.ifxemul.length = true
```

dbi.database.*dsname*.ifxemul.rowid

This switch can be used to define whether ROWID keywords have to be converted to native equivalent (for example, OID in PostgreSQL).

Default is true.

```
dbi.database.stores.ifxemul.rowid = false
```

Note: Consider using primary keys instead of ROWIDs.

dbi.database.*dsname*.ifxemul.listupdate

This switch can be used to convert the UPDATE statements using non-ANSI syntax.

Default is true.

```
dbi.database.stores.ifxemul.listupdate = false
```

dbi.database.*dsname*.ifxemul.extend

This switch can be used to convert simple EXTEND( ) expressions to native date/time expressions.

Default is true.

```
dbi.database.stores.ifxemul.extend = true
```

Database vendor specific parameters in FGLPROFILE

Database vendor specific connection parameters can be configured by using FGLPROFILE entries with the following syntax:

```
dbi.database.dsname.dbtype.param.[.subparam] = "value"
```

Where *dbtype* identifies the database vendor type, such as "ifx", "ora", "db2".

- IBM DB2 specific FGLPROFILE parameters on page 470
- Oracle DB specific FGLPROFILE parameters on page 470
- Oracle MySQL / MariaDB specific FGLPROFILE parameters on page 471

- SQL Server (Native Client driver) specific FGLPROFILE parameters on page 471
- SQL Server (Native Client driver) specific FGLPROFILE parameters on page 471
- SQL Server (EasySoft driver) specific FGLPROFILE parameters on page 473
- SQL Server (FreeTDS driver) specific FGLPROFILE parameters on page 472
- Sybase ASE specific FGLPROFILE parameters on page 473

IBM® DB2® specific FGLPROFILE parameters

`dbi.database.`*`dsname`*`.db2.schema`

Name of the database schema to be selected after connection is established.

```
dbi.database.stores.db2.schema = "store2"
```

Set this parameter to a specific schema in order to share the same table with all users.

`dbi.database.`*`dsname`*`.db2.prepare.deferred`

True/False boolean to enable/disable deferred prepare.

```
dbi.database.stores.db2.prepare.deferred = true
```

Set this parameter to true if you do not need to get SQL errors during PREPARE statements: SQL statements will be sent to the server when executing the statement (OPEN or EXECUTE). The default is false (SQL statements are sent to the server when doing the PREPARE).

Default is `false` .

Oracle DB specific FGLPROFILE parameters

`dbi.database.`*`dsname`*`.ora.schema`

Name of the database schema to be selected after connection is established.

```
dbi.database.stores.ora.schema = "store2"
```

Set this parameter to a specific schema in order to share the same table with all users.

`dbi.database.`*`dsname`*`.ora.prefetch.rows`

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.ora.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program. This parameter applies to all cursors in the program.

The default is 10 rows.

`dbi.database.`*`dsname`*`.ora.prefetch.memory`

Maximum buffer size for pre-fetching (in bytes).

```
dbi.database.stores.ora.prefetch.memory = 4096
```

This parameter is equivalent to prefetch.rows, but here you can specify the memory size instead of the number of rows. Like `prefetch.rows`, this parameter applies to all cursors in the program.

The default is 0, which means that memory size is not included in computing the number of rows to pre-fetch.

dbi.database.*dsname*.ora.sid.command

SQL command (SELECT) to generate a unique session id (used for temp table names).

```
dbi.database.stores.ora.sid.command =
 "SELECT TO_CHAR(SID)||'_'||TO_CHAR(SERIAL#)
      FROM V$SESSION WHERE AUDSID=USERENV('SESSIONID')"
```

By default the driver uses "`SELECT USERENV('SESSIONID') FROM DUAL`". This is the standard session identifier in Oracle, but it can become a very large number and can't be reset.

This parameter gives you the freedom to provide your own way to generate a session id.

The SELECT statement must return a single row with one single column.

Value can be an integer or an identifier.

dbi.database.*dsname*.ora.date.ifxfetch

Controls the way an Oracle DATE is fetched into program variables, especially CHAR/VARCHAR targets.

```
dbi.database.stores.ora.date.ifxfetch = true
```

By default, since ORACLE DATE type is equivalent to `DATETIME YEAR TO SECOND`, values are fetched into `CHAR/VARCHAR` with time information and are formatted with the style `YYYY-MM-DD hh:mm:ss` If you need to get the IBM® Informix® behavior, to fetch DATEs only with the YMD part following the DBDATE environment variable, set this parameter to true. Note however that this parameter is useless when fetching ORACLE DATEs into `DATE` or `DATETIME` variables, which is the recommended way to hold date and time values in programs.

Default is `false` (with time information, using normalized format).

Oracle MySQL / MariaDB specific FGLPROFILE parameters

dbi.database.*dsname*.mys.config

Defines an explicit configration to read MySQL options from

```
dbi.database.stores.mys.config = "/opt/myapp/etc/my.cnf"
```

Set this parameter will be passed to the MySQL API function `mysql_options((MYSQL*), MYSQL_READ_DEFAULT_FILE, *filename* )`.

It can be used to bypass the default MySQL configuration files reading, to define database client settings in the `[client]` group, such as the client character set with the `default-character-set` option.

> **Note:**
>
> On Microsoft™ Windows™ platforms, the configuration file must be in DOS format.

SQL Server (Native Client driver) specific FGLPROFILE parameters

dbi.database.*dsname*.snc.logintime

Connection timeout (in seconds).

```
dbi.database.stores.snc.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds.

The default is 5 seconds.

dbi.database.*dsname*.snc.prefetch.rows

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.snc.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.

The default is 10 rows.

dbi.database.*dsname*.snc.widechar

Control wide char usage for character string data.

Set this parameter to `false` if you use char/varchar columns in the SQL Server database.

```
dbi.database.stores.snc.widechar = false
```

By default the SNC driver uses wide char ODBC functions, by converting the character data from the current locale to UCS/2, by adding the N prefix before string literals and by binding SQL parameters with SQL_C_WCHAR and SQL_WCHAR/SQL_WVARCHAR types.

If you set this parameter to `false`, the driver will pass the character strings as is without character set conversion, leave the string literals without N prefix and bind character string parameters with SQL_C_CHAR and SQL_CHAR/SQL_VARCHAR.

The default is `true` (use wide chars).

SQL Server (FreeTDS driver) specific FGLPROFILE parameters

dbi.database.*dsname*.ftm.logintime

Connection timeout (in seconds).

```
dbi.database.stores.ftm.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds.

The default is 5 seconds.

dbi.database.*dsname*.ftm.prefetch.rows

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.ftm.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.

The default is 10 rows.

SQL Server (EasySoft driver) specific FGLPROFILE parameters

dbi.database.*dsname*.esm.logintime

Connection timeout (in seconds).

```
dbi.database.stores.esm.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds.

The default is 5 seconds.

dbi.database.*dsname*.esm.prefetch.rows

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.esm.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.

The default is 10 rows.

Sybase ASE specific FGLPROFILE parameters

dbi.database.*dsname*.ase.logintime

Connection timeout (in seconds).

```
dbi.database.stores.ase.logintime = 10
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds.

The default is 5 seconds.

dbi.database.*dsname*.ase.prefetch.rows

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.ase.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.

The default is 10 rows.

Database user authentication

Connecting to a database server is not just specifying a database name: The current user must be identified by the database server. Database users must be declared in the database server and must be authenticated.

The typical user authentication is done by passing a login name and password at connection time. Some database servers support external authentication methods, that do not require login/password information (for example when db users as based on operating system users), as well as delegated user authentication via credential tokens (for example, when using an LDAP dinstinguished name). See database vendor specific documentation for more details.

Additional user authentication solutions are provided to simplify migration from IBM® Informix®databases, but should not be used in production for security reasons.

See also SQL adaptation guides for database vendor specific notes regarding user authentication.

Specifying a user name and password with CONNECT

In order to specify a user name and password, use the `CONNECT` instruction with the `USER/USING` clause:

```
MAIN
  DEFINE uname, upswd STRING
  CALL login_dialog() RETURNING uname, upswd
  CONNECT TO "stock" USER uname USING upswd
  ...
END MAIN
```

This is the recommended way to connect to a database server.

With some database types, it is possible to use an external user authentication service, such as Kerberos / SSL / LDAP-based directory services. To connect as an external user, configure database client settings to authenticate the external user and perform the CONNECT TO instruction without specifying a login/ password:

```
CONNECT TO "stock"
```

For more details, see for example database user handling in the Oracle SQL Adaptation Guide.

Specifying a user name and password with DATABASE

The `DATABASE` instruction does not support the `USER/USING` clause as `CONNECT TO` does. If you don't use an automatic user authentication method of the database server, you must provide a user name and password in some way.

The best way to identify database users is to replace every `DATABASE` instruction by a `CONNECT TO` with `USER/USING` clause. However, it is also possible to provide the user name and password with the user authentication callback function, by defining a global FGLPROFILE entry.

In a development environment, a default login and password can be specified with the `dbi.database.`*`dbname`*`.username` and `dbi.database.`*`dbname`*`.password` FGLPROFILE entries. This solution must not be used in a production environment because the password is not encrypted. For backward compatibility reasons, when using the IBM® Informix® driver, these FGLPROFILE entries are ignored by the `DATABASE` instruction, only the `CONNECT TO` instruction takes external (or callback) login parameters into account.

Login parameters can also be provided in the connection string used in the database name specification in `DATABASE` instruction.

User authentication callback function

When using the `DATABASE` connection instruction, you can define an FGLPROFILE entry with the name of a function to be called when the `DATABASE` instruction is executed, in order to provide a user name and password dynamically.

```
dbi.default.userauth.callback = "[module-name.]function-name"
```

This callback method is not a password encryption solution, it is only provided as workaround to provide a user credentials for programs using the `DATABASE` instructions. If possible, use the `CONNECT TO` instruction with the `USER/USING` clause instead. This callback method is provided to connect to databases different from IBM® Informix®, when a lot of existing code uses the `DATABASE` instruction. With the IBM® Informix® driver, the callback method is also called, but the user name and password are ignored by the `DATABASE` instruction: Only `CONNECT TO` will take the login parameters into account for IBM® Informix®.

The callback function must have the following signature:

```
CALL function-name(dbspec STRING)
      RETURNING STRING (username), STRING (password)
```

If you do not specify the module name, the callback function must be linked to the 42r program. By using the "*module-name.function-name*" syntax in the FGLPROFILE entry, the runtime system will automatically load the module. In both cases, the module must be located in a directory where the runtime system can find it, defined by the FGLLDPATH environment variable.

In the callback function body, the value of *dbspec* can be used to identify the database source, read user name and encrypted password from FGLPROFILE entries with the `fgl_getResource()` function, then decrypt password with the algorithm of your choice and return user name and decrypted password.

User authentication callback function for DATABASE:

```
FUNCTION getUserAuth(dbspec)
  DEFINE dbspec STRING
  DEFINE un, ep STRING
  LET un = fgl_getResource("dbi.database."||
dbspec||".username")
  LET ep = fgl_getResource("dbi.database."||
dbspec||".password.encrypted")
  RETURN un, decrypt_user_password(dbspec, un, ep)
END FUNCTION
```

Order of precedence for database user specification

Database user login can be specified with different methods, as show in this table. Precedence order if defined from top to bottom:

Table 157: Database user login methods

Connection Instruction	FGLPROFILE	Effect

`CONNECT TO "dbname" USER "user" USING "pswd"`
or
`DEFINE db VARCHAR(200)`
`LET db = "dbname +username='username', password='pswd'" DATABASE db`
	N/A (ignored)	The user information in the `USER`/`USING` clause of the `CONNECT TO` instruction or in the connection string of the `DATABASE` instruction are used to identify the actual user. are used to identify the actual user.
		Connection string can also be used with `CONNECT TO`.

`DATABASE dbname`
or
`CONNECT TO "dbname"`
	No specific `dbi.*` entry	No user login and password is provided to the database server. Usually, the Operating System authentication takes place.

`DATABASE dbname` or	`dbi.default.userauth.callback = "fx"`	Callback function `fx` is called to get user name and password when connection instruction is executed.

Connection Instruction	FGLPROFILE	Effect
`CONNECT TO "dbname"`		

`DATABASE dbname`
or
`CONNECT TO "dbname"`
	`dbi.database.dbname.username = ...`
	`dbi.database.dbname.password = ...`
		The FGLPROFILE default user name and password are used to connect to the database server.
		Important: NOT RECOMMENDED IN PRODUCTION!

Unique session mode connection instructions

Opening and closing a database for a unique session.

- DATABASE on page 476
- CLOSE DATABASE on page 477

DATABASE

Opens a new database connection in unique-session mode.

Syntax

```
DATABASE { dbname[@dbserver] | variable | string } [EXCLUSIVE]
```

1. *dbname* identifies the database name.
2. *dbserver* identifies the IBM® Informix® database server (INFORMIXSERVER).
3. *variable* can be any character string defined variable containing the database specification.
4. *string* can be a string literal containing the database specification.

Usage

The DATABASE instruction opens a connection to the database server, like `CONNECT TO`, but without user and password specification.

```
MAIN
  DATABASE stores
  ...
END MAIN
```

It is possible to use a program variable containing the database specification.

```
MAIN
  DEFINE dbname VARCHAR(100)
  LET dbname = arg_val(1)
  DATABASE dbname
  ...
END MAIN
```

If a current connection exists, it is automatically closed before connecting to the new database.

The connection is closed with the `CLOSE DATABASE` instruction, or when the program ends.

The DATABASE instruction raises an exception if the connection could not be established, for example, if you specify a database that the runtime system cannot locate, or cannot open, or for which the user of your program does not have access privileges.

The EXCLUSIVE keyword can be used to open an IBM® Informix® database in exclusive mode to prevent access by anyone but the current user. This keyword is IBM® Informix® specific and should be avoided when writing a portable SQL application.

The CONNECT TO instructions allow better control over database connections; you should use these instructions instead of DATABASE and CLOSE DATABASE.

When used outside a program block, the DATABASE instruction defines the database schema for compilation. See SCHEMA on page 356 for more details.

CLOSE DATABASE

Closes the current database connection created by a DATABASE instruction.

Syntax

```
CLOSE DATABASE
```

Usage

The CLOSE DATABASE instruction closes the current database connection opened by a DATABASE instruction.

The current connection is automatically closed when the program ends.

Example

```
MAIN
  DATABASE stores1
  CLOSE DATABASE
  DATABASE stores2
  CLOSE DATABASE
END MAINs
```

Multi-session mode connection instructions

Opening and closing a database for a unique session.

- CONNECT TO on page 477
- SET CONNECTION on page 478
- DISCONNECT on page 479

CONNECT TO

Opens a new database session in multi-session mode.

Syntax

```
CONNECT TO { dbname | DEFAULT } [ AS session ]
    [ USER login USING auth ]
    [ WITH CONCURRENT TRANSACTION ]
```

1. *dbname* is the database specification.
2. *session* identifies the database session. By default, it is *dbname*.
3. *login* is the name of the database user.
4. *auth* is a string to authenticate the database user, like a password.

Usage

The CONNECT TO instruction opens a database connection. If the instruction successfully connects to the database environment, the connection becomes the current database session for the program.

The session name is case-sensitive.

A program can connect to several database environments at the same time (using different database drivers), and it can establish multiple connections to the same database environment, provided each connection has a unique connection name.

The connection is closed with the DISCONNECT instruction, or when the program ends.

When the USER *login* USING *auth* clause is specified, the database user is identified by *login* and *auth*, ignoring all other user settings defined in FGLPROFILE or as connection string parameters.

The *auth* parameter can be a simple password for internal dabase users, but for some type of database engines, it can be used to specify an external authentication token, such as a distinguished name (DN). For more details, see the SQL adaptation guide of you database type.

The WITH CONCURRENT TRANSACTION clause allows a program to open several transactions concurrently in different database sessions: The transaction can be started with the BEGIN WORK statement in a given connection context, then the program can switch to another connection with SET CONNECTION, and when done, switch back to the first connection to issue a COMMIT WORK or ROLLBACK WORK. This is supported for IBM® Informix® database servers. The option is ignored with other database server types, but it can be used in the CONNECT statement for consistency with Informix.

A CONNECT TO statement cannot be executed with dynamic SQL (i.e. PREPARE + EXECUTE).

With IBM® Informix® database servers, when using the CONNECT TO DEFAULT, you connect to the default IBM® Informix® database server, identified by the INFORMIXSERVER environment variable, without any database selection.

When using IBM® Informix® databases on UNIX™, the only restriction on establishing multiple connections to the same database environment is that an program can establish only one connection to each local server that uses the shared-memory connection mechanism. To find out whether a local server uses the shared-memory connection mechanism or the local-loopback connection mechanism, examine the $INFORMIXDIR/etc/sqlhosts file.

Example

```
MAIN
  DEFINE uname, upswd VARCHAR(50)
  CONNECT TO "stores1" -- Session name is "stores1"
  CONNECT TO "stores1" AS "SA" -- Session name is "SA"
  CALL login_dialog() RETURNING uname, upswd
  CONNECT TO "stores2" AS "SB" USER uname USING upswd
END MAIN
```

SET CONNECTION

Selects the current session when in multi-session mode.

Syntax

```
SET CONNECTION {
    { session | DEFAULT } [DORMANT]
    | CURRENT DORMANT }
```

1. *session* is a string expression identifying the name of the database session to be set as current.

Usage

The SET CONNECTION instruction makes a given connection current.

The session name is case-sensitive.

When using the DEFAULT keyword, it identifies the default database server connection established with a CONNECT TO DEFAULT or a DATABASE instruction. This clause is specific to IBM® Informix® databases.

To make the current connection dormant, use CURRENT DORMANT keyword. This clause is specific to IBM® Informix® databases.

A SET CONNECTION statement cannot be executed with dynamic SQL (i.e. PREPARE + EXECUTE).

Example

```
MAIN
  DEFINE c1, c2, c3 INT
  CONNECT TO "stores1"
  CONNECT TO "stores2" AS "SA"
  CONNECT TO "stores3" AS "SB"
  SET CONNECTION "stores1"    -- Select first session
  SELECT COUNT(*) INTO c1 FROM customers
  SET CONNECTION "SA"         -- Select second session
  SELECT COUNT(*) INTO c2 FROM customers
  SET CONNECTION "SB"         -- Select third session
  SELECT COUNT(*) INTO c3 FROM customers
  SET CONNECTION "stores1"    -- Select first session again
END MAIN
```

DISCONNECT

Terminates database sessions when in multi-session mode.

Syntax

```
DISCONNECT { ALL | CURRENT | session }
```

1. *session* is a string expression identifying the name of the database session to be terminated.

Usage

The DISCONNECT instruction closes a given database connection.

The session name is case-sensitive.

When using the DEFAULT keyword, it identifies the default database server connection established with a CONNECT TO DEFAULT or a DATABASE instruction. This clause is specific to IBM® Informix® databases.

Use the ALL keyword to terminate all opened connections. From that point, you must establish a new connection to execute SQL statements.

Use the CURRENT keyword to terminate the current connection only. From that point, in order to execute SQL statements, you must select another connection with SET CONNECTION, or establish a new connection with CONNECT TO.

A DISCONNECT statement cannot be executed with dynamic SQL (i.e. PREPARE + EXECUTE).

If a DISCONNECT statement is used while a database transaction is active, the transaction is automatically rolled back.

Example

```
MAIN
  CONNECT TO  "stores1"  -- Will be identified by "stores1"
  CONNECT TO  "stores1" AS "SA"
  CONNECT TO  "stores2" AS "SB" USER "scott" USING "tiger"
  DISCONNECT "stores1"
  DISCONNECT "SB"
  SET CONNECTION "SA"
END MAIN
```

Miscellaneous SQL statements

These are particular SQL statements supported in the static SQL syntax.

- SET EXPLAIN on page 480
- UPDATE STATISTICS on page 480

SET EXPLAIN

Turns on/off SQL report of the optimizer plan.

Syntax:

```
SET EXPLAIN { ON | OFF }
```

Usage:

Important: This SQL instruction is specific to IBM® Informix® databases.

UPDATE STATISTICS

Updates the statistics for all or for the specified table in the database.

Syntax:

```
UPDATE STATISTICS [ FOR TABLE table-specification ]
```

Usage:

Important: This SQL instruction is specific to IBM® Informix® databases.

Database transactions

Database transaction concepts and handling.

- Understanding database transactions on page 481
- BEGIN WORK on page 482
- SAVEPOINT on page 483
- COMMIT WORK on page 483
- ROLLBACK WORK on page 484
- RELEASE SAVEPOINT on page 484
- SET ISOLATION on page 485
- SET LOCK MODE on page 486

Understanding database transactions

A *database transaction* delimits a set of database operations (i.e. SQL statements), that are processed as a whole.

Database operations included inside a transaction are validated or canceled as a unique operation.

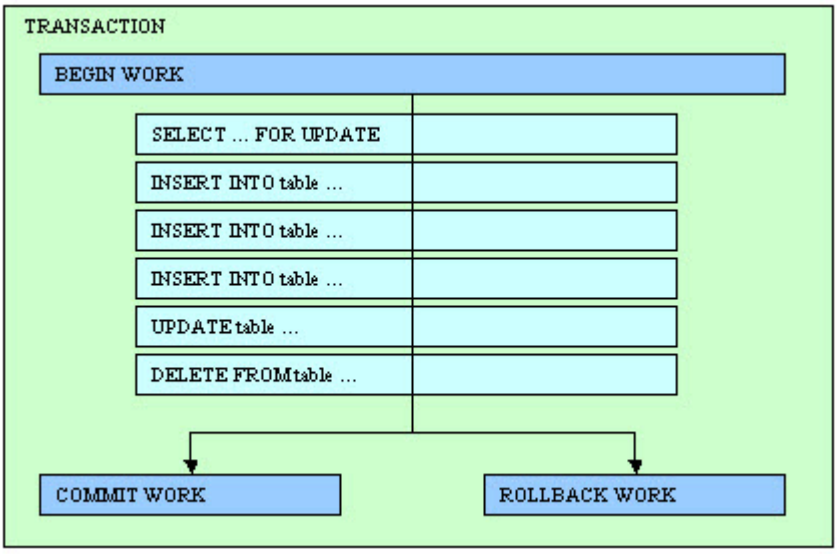

Figure 22: Database transaction

The database server is in charge of *data concurrency* and *data consistency*. Data concurrency allows the simultaneous access of the same data by many users, while data consistency gives each user a consistent view of the database.

Without adequate concurrency and consistency control, data can be changed improperly, compromising integrity of your database. If you want to write applications that can work with different kinds of database servers, you must adapt the program logic to the behavior of the database servers, regarding concurrency and consistency management. This requires good knowledge of multiuser database application programming, transactions, locking mechanisms, isolation levels and wait mode. If you are not familiar with these concepts, carefully read the documentation of each database server that covers this subject.

Usually, database servers set exclusive locks on rows that are modified or deleted inside a transaction. These locks are held until the end of the transaction to control concurrent access to that data. Some database servers implement row versioning (before modifying a row, the server makes a copy of the original row). This technique allows readers to see a consistent copy of the rows that are updated during a transaction not yet committed. When the isolation level is high (REPEATABLE READ) or when using a `SELECT FOR UPDATE` statement, the database server sets shared locks on fetched rows, to prevent other users from changing the rows fetched by the reader. These locks are held until the end of the transaction. Some database servers allow read locks to be held regardless of the transactions (`WITH HOLD` cursor option), but this is not a standard.

Programs accessing the database can change transaction parameters such as the isolation level or lock wait mode. To write portable applications, you must use a configuration that produces the same behavior on every database engine.

The recommended programming pattern regarding transactions is following:

- The database must support transactions; this is usually the case.
- Transactions must be as short as possible (a few seconds).
- The isolation level must be at least `COMMITTED READ`.
- The wait mode for locks must be `WAIT` or `WAIT` n (lock timeout).

To write portable SQL applications, programmers use the `BEGIN WORK`, `COMMIT WORK` and `ROLLBACK WORK` instructions described in this section to delimit transaction blocks and define concurrency parameters with `SET ISOLATION` and `SET LOCK MODE`. These instructions are part of the language syntax. At runtime, the database driver generates the appropriate SQL commands to be used with the target database server. This allows you to use the same source code for different kinds of database servers.

If you initiate a transaction with a `BEGIN WORK` statement, you must issue a `COMMIT WORK` at the end of the transaction. If one of the SQL statement fails in the transaction, you typically issue a `ROLLBACK WORK` to force the database server to cancel any modifications that the transaction made to the database. If you do not issue a `BEGIN WORK` statement to start a transaction, each statement executes within its own transaction. These single-statement transactions do not require either a `BEGIN WORK` statement or a `COMMIT WORK` statement.

Recent database engines support transaction savepoints, which allowing to set markers in the current transaction, in order to rollback to a specific point without canceling the complete transaction. The transaction savepoint instructions `SAVEPOINT`, `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT` are part of the language syntax and can be directly used in the code.

Some database servers do not support a Data Definition Language (DDL) statements (like `CREATE TABLE`) inside transactions, and some commit automatically the transaction when such a statement is executed. Therefore, it is strongly recommended that you avoid DDL statements inside transactions.

A transaction that processes many rows can exceed the limits that your operating system or the database server configuration imposes on the maximum number of simultaneous locks. Include a limited number of SQL operations in a transaction blocks.

When a program is using several database connections, and if transactions are not terminated before switching to another connection (`SET CONNECTION`), it is mandatory to use the `WITH CONCURRENT TRANSACTION` option in the `CONNECT` instruction.

BEGIN WORK

Starts a database transaction in the current connection.

Syntax

```
BEGIN WORK
```

Usage

Use the `BEGIN WORK` instruction to indicate where the database transaction starts in your program. Each row that an `UPDATE`, `DELETE`, or `INSERT` statement affects during a transaction is locked and remains locked throughout the transaction.

`BEGIN WORK` is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

In order the

Example

The next code example starts a transaction block, inserts a row and updates the row, then commits the transaction. To other users, the `INSERT` and `UPDATE` instruction will be seen as an single atomic database modification:

```
MAIN
  DATABASE stock
  BEGIN WORK
  INSERT INTO items VALUES ( ... )
  UPDATE items SET ...
  COMMIT WORK
```

```
END MAIN
```

SAVEPOINT

Defines or resets the position of a rollback point in the current transaction.

Syntax

```
SAVEPOINT spVname [UNIQUE]
```

1. *spname* is the savepoint identifier.

Usage

The SAVEPOINT instruction declares a new rollback label at the current position in the lexical order within the current transaction. After defining a savepoint, you can rollback to the specified point in the transaction by using the ROLLBACK WORK TO SAVEPOINT instruction.

If the same savepoint name was used in a prior SAVEPOINT instruction, the previous savepoint is destroyed and the name is reused to flag the new rollback position. The optional UNIQUE keyword specifies that you do not want to reuse the same savepoint name in a subsequent SAVEPOINT instruction. Reusing the same name after a SAVEPOINT *spname* UNIQUE will raise an SQL error.

Example

In this example, a first savepoint is defined before the INSERT statement, then reset before the UPDATE statement. The ROLLBACK TO SAVEPOINT instruction will cancel the UPDATE statement only:

```
MAIN
  DATABASE stock
  BEGIN WORK
  DELETE FROM items
  SAVEPOINT sp1
  INSERT INTO items VALUES ( ... )
  SAVEPOINT sp1  -- releases previous savepoint named sp1
  UPDATE items SET ...
  ROLLBACK WORK TO SAVEPOINT sp1
  COMMIT WORK
END MAIN
```

COMMIT WORK

Validates and terminates a database transaction in the current connection.

Syntax

```
COMMIT WORK
```

Usage

Use the COMMIT WORK instruction to commit all modifications made to the database from the beginning of a transaction. The database server takes the required steps to make sure that all modifications that the transaction makes are completed correctly and saved to disk.

COMMIT WORK is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

The COMMIT WORK statement releases all exclusive locks that have been set during the transaction. With some databases, shared locks are not released if the FOR UPDATE cursor is declared WITH HOLD option. However, the COMMIT WORK statement closes all cursors not declared with the WITH HOLD option.

ROLLBACK WORK

Cancels and terminates a database transaction in the current connection.

Syntax

```
ROLLBACK WORK [TO SAVEPOINT [spname]]
```

- *spname* is the savepoint identifier.

Usage

Use ROLLBACK WORK to cancel the current transaction and invalidate all changes since the beginning of the transaction. After the execution of this instruction, the database is restored to the state that it was in before the transaction began. All row and table locks that the canceled transaction holds are released. If you issue this statement when no transaction is pending, an error occurs.

ROLLBACK WORK is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

When specifying a savepoint with the TO SAVEPOINT clause, all SQL statements executed since the specified savepoint will be canceled. The transaction is not canceled, however, and you can continue to execute other SQL statements.

Example

This example checks for a potential SQL error after the DELETE statement and cancels the complete transaction with a ROLLBACK instruction:

```
MAIN
  DATABASE stock
  WHENEVER ERROR CONTINUE
  BEGIN WORK
  INSERT INTO orders_hist VALUES ( ... )
  DELETE FROM orders WHERE ...
  IF SQLCA.SQLCODE < 0 THEN
    ROLLBACK WORK
  ELSE
    COMMIT WORK
  END IF
END MAIN
```

RELEASE SAVEPOINT

Destroys the specified savepoint in the current transaction.

Syntax

```
RELEASE SAVEPOINT spname
```

- *spname* is the savepoint identifier.

Usage

Use the `RELEASE SAVEPOINT` instruction to delete a savepoint defined by the `SAVEPOINT` instruction. See database documentation for more details about the behavior of this SQL statement. Note for example that IBM® Informix® IDS will also release any savepoint that has been declared between the specified savepoint and the `RELEASE SAVEPOINT` instruction.

Example

In the next example, the `RELEASE SAVEPOINT` instruction cancels the `UPDATE` and `INSERT` statements and destroys the sp1 and sp2 savepoints. Only the `DELETE` statement will take effect at the end of the transaction:

```
MAIN
  DATABASE stock
  BEGIN WORK
  DELETE FROM items
  SAVEPOINT sp1
  INSERT INTO items VALUES ( ... )
  SAVEPOINT sp2
  UPDATE items SET ...
  RELEASE SAVEPOINT sp1
  ROLLBACK WORK TO SAVEPOINT
  COMMIT WORK
END MAIN
```

SET ISOLATION

Defines the transaction isolation level for the current connection.

Syntax

```
SET ISOLATION TO
  { DIRTY READ
  | COMMITTED READ [LAST COMMITTED] [RETAIN UPDATE LOCKS]
  | CURSOR STABILITY
  | REPEATABLE READ }
```

Usage

The `SET ISOLATION` instruction sets the transaction isolation level for the current connection. See database concepts in your database server documentation for more details about isolation levels and concurrency management.

When possible, the underlying database driver sets the corresponding transaction isolation level. If the isolation level cannot be set, the runtime system generates an exception.

When using the `DIRTY READ` isolation level, the database server might return a phantom row, which is an uncommitted row that was inserted or modified within a transaction that has subsequently rolled back. No other isolation level allows access to a phantom row.

On most database servers, the default isolation level is `COMMITTED READ`, which is appropriate to portable database programming.

The `LAST COMMITTED` and `RETAIN UPDATE LOCKS` options have been added to the language syntax for conformance with IBM® Informix® IDS 11. The `LAST COMMITTED` option can be turned on implicitly with a server configuration parameter, saving unnecessary code changes.

Example

```
MAIN
  DATABASE stock
  SET ISOLATION TO COMMITTED READ
  ...
END MAIN
```

SET LOCK MODE

Defines the behavior of the program that tries to access a locked row or table.

Syntax

```
SET LOCK MODE TO { NOT WAIT | WAIT[ seconds ] }
```

Usage

The `SET LOCK MODE` instruction defines the timeout for lock acquisition for the current connection.

When possible, the underlying database driver sets the corresponding connection parameter to define the timeout for lock acquisition. But some database servers may not support setting the lock timeout parameter. In this case, the runtime system generates an exception.

When using the `NOT WAIT` clause, the timeout is set to zero. If the resource is locked, the database server ends the operation immediately and raises an exception with the SQL error.

seconds defines the number of seconds to wait for lock acquisition. If the resource is locked, the database server ends the operation after the elapsed time and raises an exception with the SQL error.

When using the `WAIT` clause without a number of seconds, the database server waits for lock acquisition for an infinite time.

With most database servers, the default is to wait for locks to be released.

Make sure that the database server and corresponding database driver both support a lock acquisition timeout option, otherwise the program will raise an exception.

Example

```
MAIN
  DATABASE stock
  SET LOCK MODE TO WAIT 20
  ...
END MAIN
```

Static SQL statements

Describes static SQL statements supported in the language.

- Understanding static SQL statements on page 487
- Using program variables in static SQL on page 487
- Table and column names in static SQL on page 488
- SQL texts generated by the compiler on page 488
- INSERT on page 489
- DELETE on page 492

- UPDATE on page 490
- SELECT on page 493
- SQL ... END SQL on page 495
- CREATE SEQUENCE on page 496
- ALTER SEQUENCE on page 496
- DROP SEQUENCE on page 497
- CREATE TABLE on page 497
- ALTER TABLE on page 497
- DROP TABLE on page 498
- CREATE INDEX on page 498
- ALTER INDEX on page 499
- DROP INDEX on page 499
- CREATE VIEW on page 499
- DROP VIEW on page 499
- CREATE SYNONYM on page 499
- DROP SYNONYM on page 499
- RENAME on page 500

Understanding static SQL statements

Static SQL statements are SQL instructions that are a part of the language syntax. Static SQL statements can be used directly in the source code as a normal procedural instruction. The static SQL statements are parsed and validated at compile time. At runtime, these SQL statements are automatically prepared and executed by the runtime system.

Program variables can be used inside static SQL statements; Variabales are detected by the compiler and handled as SQL parameters at runtime.

The following example defines two variables that are directly used in an `INSERT` statement:

```
MAIN
  DEFINE iref INTEGER, name CHAR(10)
  DATABASE stock
  LET iref = 65345
  LET name = "Kartopia"
  INSERT INTO item ( item_ref, item_name ) VALUES ( iref, name )
  SELECT item_name INTO name
    FROM item WHERE item_ref = iref
END MAIN
```

Become it is integrated in the language syntax, static SQL statement usage clarifies the source code, but the SQL text is hard-coded and cannot be modified at runtime as it is possible with `PREPARE` / `EXECUTE` instructions.

Limited SQL syntax is part of the language, only common SQL statements such as `INSERT`, `UPDATE`, `DELETE`, `SELECT` are supported.

The compiler supports also `SQL ... END SQL` blocks to write free SQL text in your programs.

Using program variables in static SQL

The syntax of static SQL statements supports the usage of program variables directly as SQL parameters. This gives a better understanding of the source code and requires less lines as when using SQL parameters in dynamic SQL statements.

```
MAIN
  DEFINE c_num INTEGER
  DEFINE c_name CHAR(10)
```

```
  DATABASE stock
  SELECT cust_name INTO c_name FROM customer WHERE cust_num = c_num
END MAIN
```

If a database column name conflicts with a program variable, you can use the @ sign as the column prefix. The compiler will treat the identifier following the @ as a table column:

```
MAIN
  DEFINE cust_name CHAR(10)
  DEFINE cnt INTEGER
  DATABASE stock
  SELECT COUNT(*) INTO cnt FROM customer WHERE @cust_name = cust_name
END MAIN
```

The @ sign will not figure in the resulting SQL statement stored in the .42m compiled module.

Table and column names in static SQL

In static SQL statements, table and column names will be converted to lowercase by the fglcomp compiler. The SQL keywords are always converted to uppercase.

For example:

```
UPDATE CUSTOMER set CUST_name = 'undef' WHERE cust_name is null
```

Will be converted to:

```
UPDATE customer SET cust_name = 'undef' WHERE cust_name IS NULL
```

While SQL keywords are not case sensitive for database servers, table names and column names can be case-sensitive.

You can dump the static SQL statement texts with the `-S` option of fglcomp.

SQL texts generated by the compiler

The fglcomp compiler parses the static SQL statements and modifies them before writing the resulting SQL text to the .42m module.

You can extract all static SQL statements from the source by using the `-S` option of fglcomp:

Example

```
MAIN
  DEFINE c_name CHAR(10)
  DEFINE cnt INTEGER
  DATABASE stock
  SELECT COUNT(*) INTO cnt FROM customer WHERE
 customer.cust_name = c_name
END MAIN
```

```
$ fglcomp -S test.4gl
test.4gl^5^SELECT COUNT(*) FROM customer WHERE cust_name = ?
```

INSERT

Creates a new row in a database table.

Syntax 1:

This is the most standard syntax, working with all type of database engines.

```
INSERT INTO table-specification [ ( column [,...] ) ]
{
 VALUES ( { variable | sql-expression } [,...] )
|
 select-statement
}
```

Syntax 2:

The fglcomp compiler will automatically generate a standard INSERT statement with the complete list of members of the record. The generated SQL will depend from the definition of the record.

```
INSERT INTO table-specification VALUES ( record.* )
```

Syntax 3:

This syntax requires a database schema specification with the SCHEMA instruction, and the corresponding database schema file.

```
INSERT INTO table-specification VALUES record.*
```

where *table-specification* is:

```
[dbname[@dbserver]:][owner.]table
```

1. *dbname* identifies the database name.
2. *dbserver* identifies the database server (INFORMIXSERVER).
3. *owner* identifies the owner of the table, with optional double quotes.
4. *table* is the name of the database table.
5. *column* is a name of a table column.
6. *variable* is a program variable, a record member or an array member used as a parameter buffer to provide values.
7. *sql-expression* is an expression supported by the database server, this can be a literal or NULL for example.
8. *select-statement* is a static SELECT statement with or without parameters as variables.
9. *record* is the name of a record (followed by dot star in this syntax).

Usage

The INSERT SQL statement can be used to create a row i specified database table.

The *dbname*, *dbserver* and *owner* prefix of the table name should be avoided for maximum SQL portability.

When using the VALUES clause, the statement inserts a row in the table with the values specified in variables, as literals, or with NULL. If a record is available, you can specify all record members with the star notation (record.*).

The third syntax can be used to avoid serial column usage in the value list: The record member corresponding to a column defined as SERIAL, SERIAL8 or BIGSERIAL in the schema file will be removed

by the compiler. This is useful when using databases like Microsoft™ SQL Server, where IDENTITY columns must be omitted in `INSERT` statements.

When using a *select-statement*, the statement insert all rows returned in the result set of the `SELECT` statement. The columns returned by the result set must match the column number and data types of the target table. For SQL portability, it is not recommended that you use this syntax.

Example

```
MAIN
   DEFINE myrec RECORD
             key INTEGER,
             name CHAR(10),
             cdate DATE,
             comment VARCHAR(50)
          END RECORD
   DATABASE stock
   LET myrec.key     = 123
   LET myrec.name    = "Katos"
   LET myrec.cdate   = TODAY
   LET myrec.comment = "xxxxxx"
   INSERT INTO items VALUES ( 123, 'Practal', NULL,
 myrec.comment )
   INSERT INTO items VALUES ( myrec.* )
   INSERT INTO items VALUES myrec.*  -- without serial (if one
 is used)
   INSERT INTO items SELECT * FROM histitems WHERE name =
 myrec.name
END MAIN
```

UPDATE

Modifies rows of a database table.

Syntax 1:

This is the most standard syntax, working with all type of database engines.

```
UPDATE table-specification
   SET
       column = { variable | sql-expression }
       [,...]
   [  sql-condition ]
```

Syntax 2:

This syntax is not standard, but will be converted by compiler to a portable UPDATE syntax.

```
UPDATE table-specification
   SET ( column [,...] )
     = ( { variable | sql-expression } [,...] )
   [  sql-condition ]
```

Syntax 3:

This syntax is not portable, and is not converted by the compiler.

```
UPDATE table-specification
   SET [table.]*
```

```
      = ( { variable | sql-expression } [,...] )
   [  sql-condition ]
```

Syntax 4:

The last syntax requires a database schema specification with SCHEMA instruction, and the corresponding database schema file.

```
UPDATE table-specification
   SET { [table.]* | ( column [,...] ) }
     = record.*
   [  sql-condition ]
```

where *table-specification* is:

```
[dbname[@dbserver]:][owner.]table
```

And *sql-condition* is:

```
WHERE { condition | CURRENT OF cursor }
```

1. *dbname* identifies the database name.
2. *dbserver* identifies the database server (INFORMIXSERVER).
3. *owner* identifies the owner of the table, with optional double quotes.
4. *table* is the name of the database table.
5. *column* is a name of a table column.
6. *variable* is a program variable, a record member or an array member used as a parameter buffer to provide values.
7. *sql-expression* is an expression supported by the database server, this can be a literal or NULL for example.
8. *record* is the name of a record (followed by dot star in this syntax).
9. *condition* is an SQL expression to select the rows to be updated.
10. *cursor* is the identifier of a database cursor.

Usage

The UPDATE SQL statement can be used to modify one or more rows in the specified database table.

The *dbname*, *dbserver* and *owner* prefix of the table name should be avoided for maximum SQL portability.

The third syntax should be avoided, this syntax is not standard and will not work will all database types.

The fourth syntax can be used if the database schema file has been generated with the correct data types. This is especially important when using SERIAL columns or equivalent auto-incremented columns. The fglcomp compiler will automatically extend the SQL text with the columns identified by the record variable. The columns defined in the database schema file as SERIAL (code 262) will be omitted in the generated column list.

column with a subscript expression (`column[a,b]`) is not recommended because most database servers do not support this notation.

For more details about the `WHERE CURRENT OF` clause, see Positioned updates/deletes on page 514.

Example

```
MAIN
   DEFINE myrec RECORD
             key INTEGER,
             name CHAR(10),
```

```
            cdate DATE,
            comment VARCHAR(50)
         END RECORD
   DATABASE stock
   LET myrec.key     = 123
   LET myrec.name    = "Katos"
   LET myrec.cdate   = TODAY
   LET myrec.comment = "xxxxxx"
   UPDATE items SET
        name    = myrec.name,
        cdate   = myrec.cdate,
        comment = myrec.comment
    WHERE key = myrec.key
END MAIN
```

DELETE

Removes rows from a database table.

Syntax

```
DELETE FROM table-specification
   [ WHERE { condition | CURRENT OF cursor } ]
```

where *table-specification* is:

```
[dbname[@dbserver]:][owner.]table
```

1. *dbname* identifies the database name.
2. *dbserver* identifies the database server (INFORMIXSERVER).
3. *owner* identifies the owner of the table, with optional double quotes.
4. *table* is the name of the database table.
5. *condition* is an SQL expression to select the rows to be deleted.
6. *cursor* is the identifier of a database cursor.

Usage

The `DELETE` SQL statement can be used to delete one or more rows from the specified database table.

The *dbname*, *dbserver* and *owner* prefix of the table name should be avoided for maximum SQL portability.

If you do not specify the `WHERE` clause, all rows in the table will be deleted. No warning will be generated by the compiler.

For more details about the `WHERE CURRENT OF` clause, see Positioned updates/deletes on page 514.

Example

```
MAIN
   DATABASE stock
   DELETE FROM items WHERE name LIKE 'A%'
END MAIN
```

SELECT

Produces a result set from a query on database tables.

Syntax

```
select-statement [ UNION [ALL] select-statement
] [...]
```

where *select-statement* is:

```
SELECT [subset-clause] [duplicates-option] { * | select-list }
  [ INTO variable [,...] ]
  FROM table-list [,...]
  [ WHERE condition ]
  [ GROUP BY column-list [ HAVING condition ]]
  [ ORDER BY column [{ASC|DESC}] [,...] ]
```

where *subset-clause* is:

```
[ SKIP { integer | variable }]
[ {FIRST|MIDDLE|LIMIT} { integer | variable ]
```

where *duplicates-option* is:

```
{ ALL
| DISTINCT
| UNIQUE
}
```

where *select-list* is:

```
{ [@]table-specification.*
| [table-specification.]column
| literal
} [ [AS] column-alias ]
[,...]
```

where *table-list* is:

```
{ table-name
| OUTER table-name
| OUTER ( table-name [,...] )
}
[,...]
```

where *table-name* is:

```
table-specification [ [AS] table-alias]
```

where *table-specification* is:

```
[dbname[@dbserver]:][owner.]table
```

where *column-list* is:

```
column-name [,...]
```

where *column-name* is:

```
[table.]column
```

1. *dbname* identifies the database name.
2. *dbserver* identifies the database server (INFORMIXSERVER).
3. *owner* identifies the owner of the table, with optional double quotes.
4. *table* is the name of the database table.
5. *table-alias* defines a new name to reference the *table* in the rest of the statement.
6. *integer* is an integer constant.
7. *variable* is a program variable.
8. *column* is a name of a table column.
9. *column-alias* defines a new name to reference the *column* in the rest of the statement.
10. *condition* is an SQL expression to select the rows to be deleted.

Usage

The *dbname*, *dbserver* and *owner* prefix of the table name should be avoided for maximum SQL portability.

If the SELECT statement returns only one row of data, you can write it directly as a procedural instruction. However, you must use the INTO clause to provide the list of variables where column values will be fetched. The INTO clause provides the list of fetch buffers. This clause is not part of the SQL language sent to the database server; it is extracted from the statement by the compiler.

```
MAIN
   DEFINE myrec RECORD
            key INTEGER,
            name CHAR(10),
            cdate DATE,
            comment VARCHAR(50)
         END RECORD
   DATABASE stock
   LET myrec.key = 123
   SELECT name, cdate
     INTO myrec.name, myrec.cdate
     FROM items
     WHERE key=myrec.key
END MAIN
```

If the SELECT statement returns more than one row of data, you must declare a database cursor to process the result set.

```
MAIN
   DEFINE myrec RECORD
            key INTEGER,
            name CHAR(10),
            cdate DATE,
            comment VARCHAR(50)
         END RECORD
   DATABASE stock
   LET myrec.key = 123
   DECLARE c1 CURSOR FOR
     SELECT name, cdate
       FROM items
       WHERE key=myrec.key
   OPEN c1
   FETCH c1 INTO myrec.name, myrec.cdate
   CLOSE c1
END MAIN
```

The SELECT statement can include the INTO clause, but it is strongly recommended that you use that clause in the FETCH instruction only.

The SELECT INTO TEMP statement creates temporary tables. Such statement does not return a result set.

SQL ... END SQL

Performs an SQL that is not part of the static SQL syntax.

Syntax

```
SQL
 sql-statement
END SQL
```

where *sql-statement* is:

```
  sql-keyword
| identifier
| INTO $host-variable [,...]
| $host-variable
| {+ sql-directive }
| --+ sql-directive
| --# fgl-comment
[...]
```

1. *sql-keyword* is any keyword of the SQL language.
2. *identifier* is a regular SQL identifier such as a table or column name.
3. *host-variable* is a program variable defined in the current scope.
4. *sql-directive* is a special comment to be kept in the SQL statement.
5. *fgl-comment* defines a comment that will be interpreted as a regular syntax element.

Usage

SQL blocks provide a convenient way to execute specific SQL statements that are not supported in the language as static SQL statements.

SQL blocks start with the SQL keyword and end with the END SQL keywords. The content of the SQL block is parsed by the fglcomp compiler to extract host variables, but the SQL statement syntax is not checked. This is actually the main purpose of SQL blocks, compared to regular static SQL statements; with SQL blocks, you can use any recent SQL statement introduced by the latest version of your database server. Note however, that you can achieve the same result using dynamic SQL instructions.

Only one SQL statement can be included in an SQL block. Using the ; semicolon statement separator is forbidden.

Program variables can be used inside the SQL statement. However, unlike static SQL statements, each host variable must be identified with a $ dollar prefix. The list of fetch targets must be preceded by the INTO keyword, as in static SELECT statements. Complete records can be used in SQL blocks by using the dot star notation ($record.*), you can also use the THROUGH or THRU keywords), as well as array elements.

SQL blocks can also be used to declare a cursor with the DECLARE mycursor CURSOR FOR SQL ... END SQL syntax.

SQL directives can be used inside SQL blocks as special comments with the {+} or --+ syntax. The SQL directives will be kept in the SQL text that will be executed by the database server. You typically write optimizer hints with the SQL directives syntax.

The `--#` specific comment is supported for backward compatibility. The SQL text following this marker will be parsed as regular SQL text, but will be ignored by other compilers. It is not recommended to use this feature.

You can check the resulting SQL statement after parsing by using the `-S` option of fglcomp.

Example

```
MAIN
   DEFINE myrec RECORD
             key INTEGER,
             name CHAR(10)
          END RECORD
   DATABASE stock
   LET myrec.key = 123
   SQL
     SELECT (+EXPLAIN) items.* INTO $myrec.*
        FROM items WHERE key=$myrec.key
   END SQL
END MAIN
```

CREATE SEQUENCE

Creates a new sequence object in the database.

Syntax:

```
CREATE SEQUENCE [ IF NOT EXISTS ] sequence-name
[ INCREMENT BY integer
| START WITH integer
| NOMAXVALUE
| MAXVALUE integer
| NOMINVALUE
| MINVALUE integer
| CYCLE
| NOCYCLE
| CACHE integer
| NOCACHE
| ORDER
| NOORDER
]
```

ALTER SEQUENCE

Modifies the definition of an existing sequence in the database.

Syntax:

```
ALTER SEQUENCE sequence-name
[ INCREMENT BY integer
| RESTART WITH integer
| NOMAXVALUE
| MAXVALUE integer
| NOMINVALUE
| MINVALUE integer
| CYCLE
| NOCYCLE
| CACHE integer
| NOCACHE
| ORDER
```

```
| NOORDER
]
```

DROP SEQUENCE

Drops a sequence object from the database.

Syntax:

```
DROP SEQUENCE [ IF EXISTS ] sequence-name
```

CREATE TABLE

Creates a new table object in the database.

Syntax:

```
CREATE [TEMP] TABLE [ IF NOT EXISTS ] table-specification
(
[ column-name data-type
       [ DEFAULT default-value ] [ NOT NULL ]
       [ PRIMARY KEY [ contraint-name ]
       | UNIQUE [ contraint-name ]
       | CHECK ( sql-condition ) [ contraint-name ]
       | REFERENCES table-name
             [ ( column-name [,...] ) ]
             [ ON DELETE CASCADE ]
             [ contraint-name ]
       ]
| PRIMARY KEY ( column-name [,...] ) [ contraint-name ]
| UNIQUE ( column-name [,...] ) [ contraint-name ]
| CHECK ( sql-condition ) [ contraint-name ]
| FOREIGN KEY ( column-name [,...] )
    REFERENCES table-name
             [ ( column-name [,...] ) ]
             [ ON DELETE CASCADE ]
             [ contraint-name ]
] [,...]
)
[ WITH NO LOG ]
[ IN tablespace-name ]
[ EXTENT SIZE integer ]
[ NEXT SIZE integer ]
[ LOCK MODE { PAGE | ROW } ]
```

ALTER TABLE

Modifies the definition of an existing table in the database.

Syntax:

```
ALTER TABLE table-specification
(
[ DROP ( column-name [,...] )
| ADD ( column-name data-type
          [ DEFAULT default-value ] [ NOT NULL ]
          [ PRIMARY KEY [ contraint-name ]
          | UNIQUE [ contraint-name ]
          | CHECK ( sql-condition ) [ contraint-name ]
          | REFERENCES table-name
```

```
                [ ( column-name [,...] ) ]
                [ ON DELETE CASCADE ]
                [ contraint-name ]
          ]
          [ BEFORE column-name
          [,...]
        )
| MODIFY ( column-name data-type
          [ DEFAULT default-value ] [ NOT NULL ]
          [ PRIMARY KEY [ contraint-name ]
          | UNIQUE [ contraint-name ]
          | CHECK ( sql-condition ) [ contraint-name ]
          | REFERENCES table-name
                [ ( column-name [,...] ) ]
                [ ON DELETE CASCADE ]
                [ contraint-name ]
          ]
          [,...]
        )
| DROP CONSTRAINT constraint-name
| ADD CONSTRAINT
    { PRIMARY KEY ( column-name [,...] ) [ contraint-name ]
    | UNIQUE ( column-name [,...] ) [ contraint-name ]
    | CHECK ( sql-condition ) [ contraint-name ]
    | FOREIGN KEY ( column-name [,...] )
         REFERENCES table-name
             [ ( column-name [,...] ) ]
             [ ON DELETE CASCADE ]
             [ contraint-name ]
    }
| LOCK MODE ( { PAGE | ROW } )
| MODIFY NEXT SIZE integer
] [,...]
)
```

DROP TABLE

Drops a table object from the database.

Syntax:

```
DROP TABLE [ IF EXISTS ] table-specification
```

CREATE INDEX

Creates a new index object in the database.

Syntax:

```
CREATE [ UNIQUE | CLUSTER | UNIQUE CLUSTER ] INDEX
       [ IF NOT EXISTS ] index-name
 ON table-specification
    ( column-name [ ASCENCDING | DESCENDING ]  [,...] )
```

ALTER INDEX

Modifies the definition of an existing index in the database.

Syntax:

```
ALTER INDEX index-name TO [ NOT ] CLUSTER
```

DROP INDEX

Drops an index object from the database.

Syntax:

```
DROP INDEX [ IF EXISTS ] index-name
```

CREATE VIEW

Creates a new view object in the database.

Syntax:

```
CREATE VIEW [ IF NOT EXISTS ] view-name
[ ( column-alias-name [,...] ) ]
    AS sub-query
[ WITH CHECK OPTION ]
```

where *sub-query* is a limited syntax of the `SELECT` statement.

DROP VIEW

Drops a view object from the database.

Syntax:

```
DROP VIEW [ IF EXISTS ] view-name
```

CREATE SYNONYM

Creates a new synonym object in the database.

Syntax:

```
CREATE SYNONYM [ IF NOT EXISTS ] synonym-name
   FOR table-specification
```

DROP SYNONYM

Drops a synonym object from the database.

Syntax:

```
DROP SYNONYM [ IF EXISTS ] synonym-name
```

RENAME

Renames an object in the database.

Syntax:

```
RENAME { TABLE | COLUMN | INDEX | SEQUENCE }
    old-name TO new-name
```

Dynamic SQL management

Explains how to execute and manage SQL statements at runtime.

- Understanding dynamic SQL on page 500
- PREPARE (SQL statement) on page 501
- EXECUTE (SQL statement) on page 502
- FREE (SQL statement) on page 503
- EXECUTE IMMEDIATE on page 504

Understanding dynamic SQL

Basic SQL instructions are part of the language syntax as static SQL statements, but only a limited number of SQL instructions are supported this way. *Dynamic SQL* management allows you to execute any kind of SQL statement, hard coded or created at runtime, with or without SQL parameters, returning or not returning a result set.

In order to execute an SQL statement dynamically, you must first prepare the SQL statement to initialize a *statement handle*, then you execute the prepared statement one or more times:

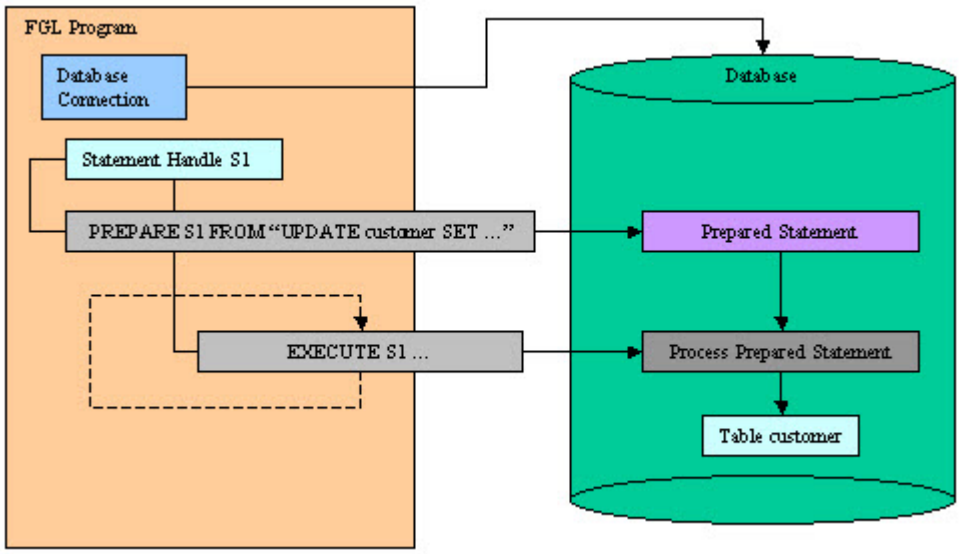

Figure 23: Dynamic SQL management diagram

When you no longer need the prepared statement, you can free the statement handle to release allocated resources:

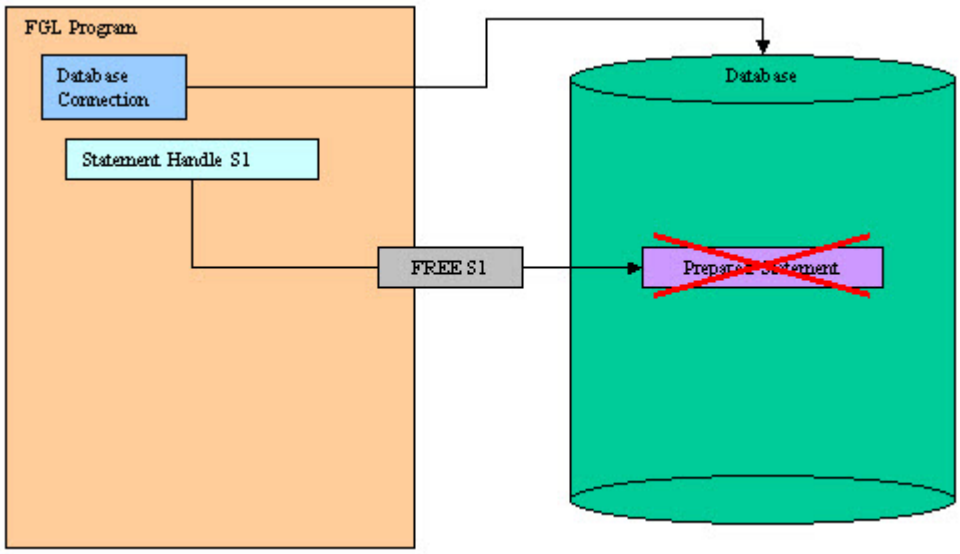

Figure 24: FREE statement diagram

When using insert cursors or SQL statements that produce a result set (like `SELECT`), you must declare a cursor with a prepared statement handle.

Prepared SQL statements can contain SQL parameters by using ? placeholders in the SQL text. In this case, the `EXECUTE` or `OPEN` instruction supplies input values in the `USING` clause.

To increase performance efficiency, you can use the `PREPARE` instruction, together with an `EXECUTE` instruction in a loop, to eliminate overhead caused by redundant parsing and optimizing. For example, an `UPDATE` statement located within a `WHILE` loop is parsed each time the loop runs. If you prepare the `UPDATE` statement outside the loop, the statement is parsed only once, eliminating overhead and speeding statement execution.

PREPARE (SQL statement)

Prepares an SQL statement for execution.

Syntax

```
PREPARE sid FROM sqltext
```

1. *sid* is an identifier to handle the prepared SQL statement.
2. *sqltext* is a string expression containing the SQL statement to be prepared.

Usage

The `PREPARE` instruction allocates resources for an SQL statement handle, in the context of the current database connection. The SQL text is sent to the database server for parsing, validation and to generate the execution plan.

Prepared SQL statements can be executed with the `EXECUTE` instruction, or, when the SQL statement generates a result set, the prepared statement can be used to declare cursors with the `DECLARE` instruction.

A statement identifier (*sid*) can represent only one SQL statement at a time. You can execute a new `PREPARE` instruction with an existing statement identifier if you wish to assign the text of a different SQL statement to the statement identifier. The scope of reference of the *sid* statement identifier is local to the module where it is declared. That is, the identifier of a statement that was prepared in one module cannot be referenced from another module.

The SQL statement can have parameter placeholders, identified by the question mark (?) character. You cannot directly reference a variable in the text of a prepared SQL statement. You cannot use question mark (?) placeholders for SQL identifiers such as a table name or a column name; you must specify these identifiers in the statement text when you prepare it.

Resources allocated by PREPARE can be released later by the FREE instruction.

The number of prepared statements in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the prepared statement.

Some database servers support multiple SQL statement preparation in a unique PREPARE instruction, but most database servers deny multiple statements. You should only prepare one SQL statement at a time.

Example

```
FUNCTION deleteOrder(n)
  DEFINE n INTEGER
  PREPARE s1 FROM "DELETE FROM order WHERE key=?"
  EXECUTE s1 USING n
  FREE s1
END FUNCTION
```

See EXECUTE for more code examples.

EXECUTE (SQL statement)

This instruction runs an SQL statement previously prepared.

Syntax

```
EXECUTE sid
     [ USING pvar {IN|OUT|INOUT} [,...] ]
     [ INTO fvar [,...] ]
```

1. *sid* is an identifier to handle the prepared SQL statement.
2. *pvar* is a variable containing an input value for an SQL parameter.
3. *fvar* is a variable used as fetch buffer.

Usage

The EXECUTE instruction performs the execution of a prepared SQL statement. Once prepared, an SQL statement can be executed as often as needed.

If the SQL statement has (?) parameter placeholders, you must specify the USING clause to provide a list of variables as parameter buffers. Parameter values are assigned by position.

If the SQL statement returns a result set with one row, you can specify the INTO clause to provide a list of variables to receive the result set column values. Fetched values are assigned by position. If the SQL statement returns a result set with more than one row, the instruction raises an exception.

The IN, OUT or INOUT options can only be used for simple variables, you cannot specify those options for a complete record with the record.* notation.

The IN, OUT or INOUT options can be used to call stored procedures having input / output parameters. Use the IN, OUT or INOUT options to indicate if a parameter is respectively for input, output or both.

You cannot execute a prepared SQL statement based on database tables if the table structure has changed (ALTER TABLE) since the PREPARE instruction; you must re-prepare the SQL statement.

Example

```
MAIN
  DEFINE var1 CHAR(20)
  DEFINE var2 INTEGER

  DATABASE stores

  PREPARE s1 FROM "UPDATE tab SET col=? WHERE key=?"
  LET var1 = "aaaa"
  LET var2 = 345
  EXECUTE s1 USING var1, var2

  PREPARE s2 FROM "SELECT col FROM tab WHERE key=?"
  LET var2 = 564
  EXECUTE s2 USING var2 INTO var1

  PREPARE s3 FROM "CALL myproc(?,?)"
  LET var1 = 'abc'
  EXECUTE s3 USING var1 IN, var2 OUT

END MAIN
```

FREE (SQL statement)

Releases the resources allocated to a prepared statement.

Syntax

```
FREE sid
```

1. *sid* is the identifier of the prepared SQL statement.

Usage

The FREE instruction takes the name of a statement as parameter.

All resources allocated to the SQL statement handle are released.

After resources are released, the statement identifier cannot be referenced by a cursor, or by the EXECUTE statement, until you prepare the statement again.

Free the statement if it is not needed anymore, this saves resources on the database client and database server side.

Example

```
FUNCTION update_customer_name( key, name )
  DEFINE key INTEGER
  DEFINE name CHAR(10)
  PREPARE s1 FROM "UPDATE customer SET name=? WHERE
 customer_num=?"
  EXECUTE s1 USING name, key
  FREE s1
END FUNCTION
```

EXECUTE IMMEDIATE

Performs a simple SQL execution without SQL parameters or result set.

Syntax

```
EXECUTE IMMEDIATE sqltext
```

1. *sqltext* is a string expression containing the SQL statement to be executed.

Usage

The `EXECUTE IMMEDIATE` instruction passes an SQL statement to the database server for execution in the current database connection.

The SQL statement used by `EXECUTE IMMEDIATE` must be a single statement without SQL parameters and must not produce a result set.

This instruction is equivalent to `PREPARE`, `EXECUTE` and `FREE` in one step.

Example

```
MAIN
  DATABASE stores
  EXECUTE IMMEDIATE "UPDATE tab SET col='aaa' WHERE key=345"
END MAIN
```

Result set processing

Shows how to fetch rows from a database query.

- Understanding database result sets on page 504
- DECLARE (result set cursor) on page 506
- OPEN (result set cursor) on page 509
- FETCH (result set cursor) on page 510
- CLOSE (result set cursor) on page 511
- FREE (result set cursor) on page 512
- FOREACH (result set cursor) on page 512

Understanding database result sets

A *database result set* is a group of rows produced by an SQL statement such as `SELECT`. The result set is maintained by the database server. In a program, you handle a result set with a *database cursor*.

First you must declare the database cursor with the `DECLARE` instruction. This instruction sends the SQL statement to the database server for parsing, validation and to generate the execution plan.

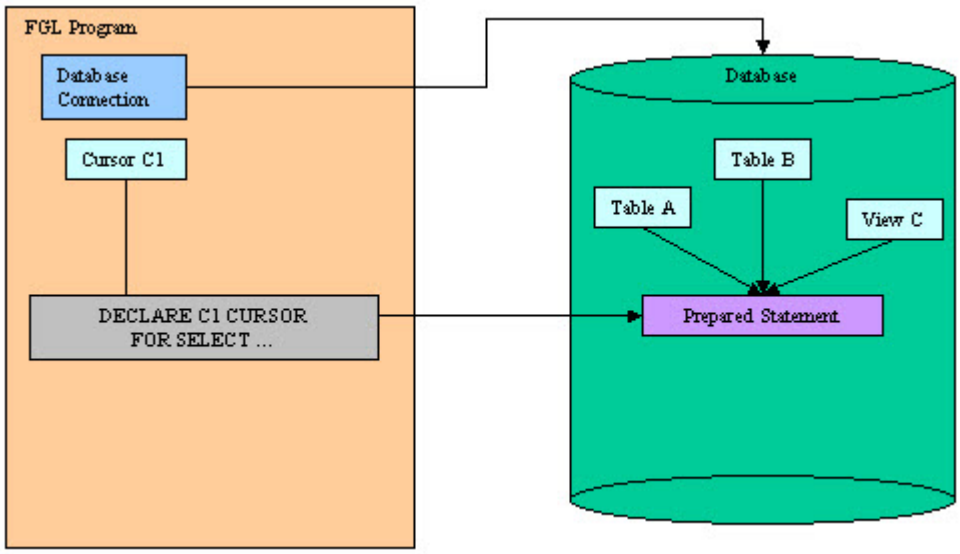

Figure 25: Database result set

The result set is produced after execution of the SQL statement, when the database cursor is associated with the result set by the OPEN instruction. At this point, no data rows are transmitted to the program. You must use the FETCH instruction to retrieve data rows from the database server.

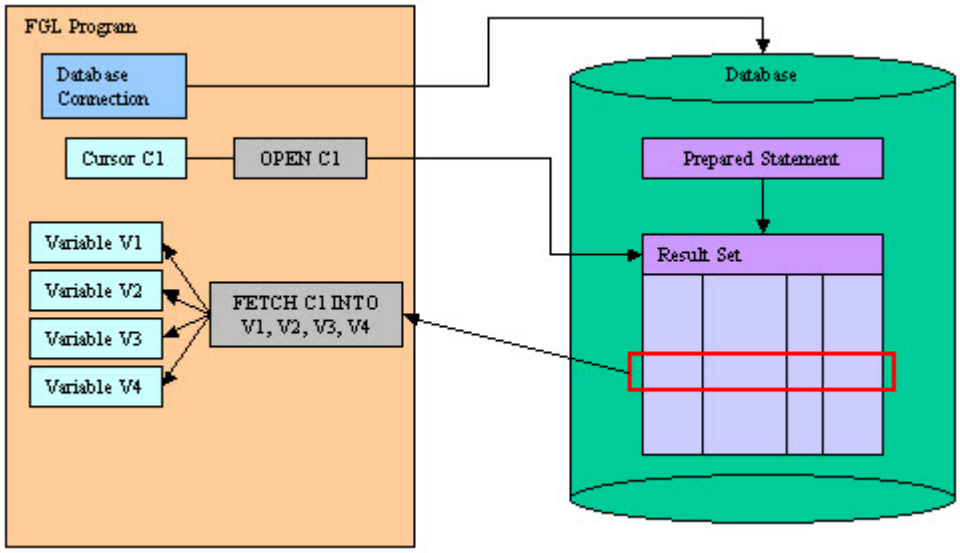

Figure 26: FETCH instruction

When finished with the result set processing, you must CLOSE the cursor to release the resources allocated for the result set on the database server. The cursor can be reopened if needed. If the SQL statement is no longer needed, you can free the resources allocated to statement execution with the FREE instruction.

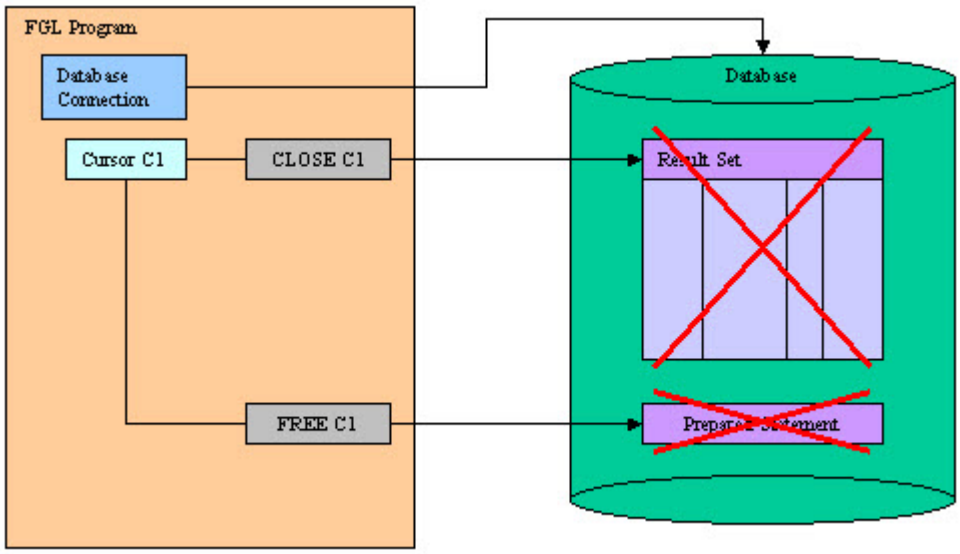

Figure 27: FREE instruction

The scope of reference of a database cursor is local to a module, so a cursor that was declared in one source file cannot be referenced in a statement in another file.

The language supports *sequential cursors* and *scrollable cursors*. Sequential cursors, which are unidirectional, are used to retrieve rows for a `REPORT`, for example. Scrollable cursors allow you to move backwards or to an absolute or relative position in the result set. Specify whether a cursor is scrollable with the `SCROLL` option of the `DECLARE` instruction.

DECLARE (result set cursor)

Associates a database cursor with an SQL statement producing a result set.

Syntax 1: Cursor declared with a static SQL statement.

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR select-statement
```

Syntax 2: Cursor declared with a prepared statement.

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR sid
```

Syntax 3: Cursor declared with a string expression.

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FROM expr
```

Syntax 4: Cursor declared with an SQL Block.

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR SQL sql-statement END SQL
```

1. *cid* is the identifier of the database cursor.
2. *select-statement* is a `SELECT` statement defined in static SQL.
3. *sid* is the identifier of a prepared SQL statement.
4. *expr* is any expression that evaluates to a string.
5. *sql-statement* is a statement defined in an SQL block.

Usage

The DECLARE instruction allocates resources for an SQL statement handle, in the context of the current connection. The SQL text is sent to the database server for parsing, validation and to generate the execution plan.

After declaring the cursor, you can use the OPEN instruction to execute the SQL statement and produce the result set.

DECLARE must precede any other statement that refers to the cursor during program execution.

The scope of reference of the *cid* cursor identifier is local to the module where it is declared.

Resources allocated by the DECLARE *cursor-name* can be released later by the FREE *cursor-name* instruction.

The static *select-statement* used in the DECLARE can contain ? (question mark) parameter placeholders, that can be bound to program variables with the USING clause of the OPEN instruction.

The maximum number of declared cursors in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the declared cursor.

When declaring a cursor with a static *select-statement*, the statement can include an INTO clause. However, to be consistent with prepared statements you better omit the INTO clause in the SQL text and use the INTO clause of the FETCH statement to retrieve the values from the result set.

You can add the FOR UPDATE clause in the SELECT statement to declare an update cursor. You can use the update cursor to modify (update or delete) the current row.

You should use the WITH HOLD option with care, because this feature is specific to IBM® Informix® servers. Other database servers do not behave as Informix® does with this type of cursor. For example, if the SELECT is not declared FOR UPDATE, most database servers keep cursors open after the end of a transaction, but IBM® DB2® automatically closes all cursors when the transaction is rolled back.

Forward only cursors

If you use only the DECLARE CURSOR keywords, you create a *sequential cursor*, which can fetch only the next row in sequence from the result set. The sequential cursor can read through the result set only once each time it is opened. If you are using a sequential cursor for a select cursor, on each execution of the FETCH statement, the database server returns the contents of the current row and locates the next row in the result set.

Cursors can be declare with a static SELECT statement:

```
MAIN
   DATABASE stores
   DECLARE c1 CURSOR FOR SELECT * FROM customer
END MAIN
```

Cursors can also be declared with a SELECT statement defined in a character string:

```
MAIN
  DEFINE key INTEGER
  DEFINE cust RECORD
            num INTEGER,
            name CHAR(50)
         END RECORD
  DATABASE stores
  PREPARE s1
     FROM "SELECT customer_num, cust_name FROM customer WHERE
 customer_num>?"
  DECLARE c1 CURSOR FOR s1
  LET key=101
  FOREACH c1 USING key INTO cust.*
```

```
     DISPLAY cust.*
  END FOREACH
END MAIN
```

Scrollable cursors

Use the `DECLARE SCROLL CURSOR` keywords to create a *scrollable cursor*, which can fetch rows of the result set in any sequence. Until the cursor is closed, the database server retains the result set of the cursor in a static data set (for example, in a temporary table like Informix®). You can fetch the first, last, or any intermediate rows of the result set as well as fetch rows repeatedly without having to close and reopen the cursor. On a multiuser system, the rows in the tables from which the result set rows were derived might change after the cursor is opened and a copy of the row is made in the static data set. If you use a scroll cursor within a transaction, you can prevent copied rows from changing, either by setting the isolation level to `REPEATABLE READ` or by locking the entire table in share mode during the transaction. Scrollable cursors cannot be declared `FOR UPDATE`.

With most database servers, scrollable cursors take quite a few resources to hold a static copy of the result set. Therefore you should consider optimizing scrollable cursor usage by fetching only the primary keys of rows, and execute a secondary `SELECT` statement to fetch other fields for each row that must be displayed.

The `DECLARE [SCROLL] CURSOR FROM` syntax allows you to declare a cursor directly with a string expression, so that you do not have to use the `PREPARE` instruction. This simplifies the source code and speeds up the execution time for non-Informix databases, because the SQL statement is not parsed twice.

```
MAIN
  DEFINE key INTEGER
  DEFINE cust RECORD
            num INTEGER,
            name CHAR(50)
        END RECORD
  DATABASE stores
  DECLARE c1 SCROLL CURSOR
     FROM "SELECT customer_num, cust_name FROM customer WHERE
 customer_num>?"
  LET key=101
  FOREACH c1 USING key INTO cust.*
     DISPLAY cust.*
  END FOREACH
END MAIN
```

Hold cursors

Use the `WITH HOLD` option with Informix® databases to create a *hold cursor*. A hold cursor allows uninterrupted access to a set of rows across multiple transactions. Ordinarily, all cursors close at the end of a transaction. A hold cursor does not close; it remains open after a transaction ends. A hold cursor can be either a sequential cursor or a scrollable cursor. Hold cursors are only supported by Informix® database engines.

You can use the ? question mark place holders with prepared or static SQL statements, and provide the parameters at execution time with the `USING` clause of the `OPEN` or `FOREACH` instructions.

```
MAIN
  DEFINE key INTEGER
  DEFINE cust RECORD
            num INTEGER,
            name CHAR(50)
        END RECORD
  DATABASE stores
  DECLARE c1 CURSOR WITH HOLD
```

```
     FOR SELECT customer_num, cust_name FROM customer WHERE customer_num > ?
  LET key=101
  FOREACH c1 USING key INTO cust.*
     BEGIN WORK
     UPDATE cust2 SET name=cust.cust_name WHERE num=cust.num
     COMMIT WORK
  END FOREACH
END MAIN
```

OPEN (result set cursor)

Executes the SQL statement with result set associated to the specified database cursor

Syntax

```
OPEN cid
   [ USING pvar {IN|OUT|INOUT} [,...] ]
   [ WITH REOPTIMIZATION ]
```

1. *cid* is the identifier of the database cursor.
2. *pvar* is a variable containing an input value for an SQL parameter.

Usage:

The `OPEN` instruction executes the SQL statement of a declared cursor. The result set is produced on the server side and rows can be fetched.

The `USING` clause is required to provide the SQL parameters as program variables, if the cursor was declared with a prepared statement that includes (?) question mark placeholders.

A subsequent `OPEN` statement closes the cursor and then reopens it. When the database server reopens the cursor, it creates a new result set, based on the current values of the variables in the `USING` clause. If the variables have changed since the previous `OPEN` statement, reopening the cursor can generate an entirely different result set.

The `IN`, `OUT` or `INOUT` options can be used to call stored procedures having input / output parameters and generating a result set. Use the `IN`, `OUT` or `INOUT` options to indicate if a parameter is respectively for input, output or both.

Sometimes, query execution plans need to be re-optimized when SQL parameter values change. Use the `WITH REOPTIMIZATION` clause to indicate that the query execution plan has to be re-optimized on the database server (this operation is normally done during the `DECLARE` instruction). If this option is not supported by the database server, it is ignored.

In a IBM® Informix® database that is ANSI-compliant, you receive an error code if you try to open a cursor that is already open. **Informix® only!**

A cursor is closed with the `CLOSE` instruction, or when the parent connection is terminated (typically, when the program ends). By using the `CLOSE` instruction explicitly, you release resources allocated for the result set in the db client library and on the database server.

The database server evaluates the values that are named in the `USING` clause of the `OPEN` statement only when it opens the cursor. While the cursor is open, subsequent changes to program variables in the `OPEN` clause do not change the result set of the cursor; you must re-open the cursor to re-execute the statement.

If you release cursor resources with a `FREE` instruction, you cannot use the cursor unless you declare the cursor again.

The `IN`, `OUT` or `INOUT` options can only be used for simple variables, you cannot specify those options for a complete record with the record.* notation.

Example

```
MAIN
   DEFINE k INTEGER
   DEFINE n VARCHAR(50)
   DATABASE stores
   DECLARE c1 CURSOR FROM "SELECT cust_name FROM customer WHERE
 cust_id > ?"
   LET k = 102
   OPEN c1 USING k
   FETCH c1 INTO n
   LET k = 103
   OPEN c1 USING k
   FETCH c1 INTO n
END MAIN
```

FETCH (result set cursor)

Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

Syntax

```
FETCH [ direction ] cid
   [ INTO fvar [,...] ]
```

where *direction* is one of:

```
{
  NEXT
| { PREVIOUS | PRIOR }
| CURRENT
| FIRST
| LAST
| ABSOLUTE position
| RELATIVE offset
}
```

1. *cid* is the identifier of the database cursor.
2. *fvar* is a variable used as fetch buffer.
3. *direction* options different from `NEXT` can only be used with scrollable cursors.
4. *position* is an positive integer expression.
5. *offset* is a positive or negative integer expression.

Usage

The `FETCH` instruction retrieves a row from a result set of an opened cursor. The cursor must be opened before using the `FETCH` instruction.

The `INTO` clause can be used to provide the fetch buffers that receive the result set column values.

A sequential cursor can fetch only the next row in sequence from the result set.

The `NEXT` clause (the default) retrieves the next row in the result set. If the row pointer was on the last row before executing the instruction, the SQL code is set to 100 (`NOTFOUND`), and the row pointer remains on the last row. (if you issue a `FETCH PREVIOUS` at this time, you get the next-to-last row).

The `PREVIOUS` clause retrieves the previous row in the result set. If the row pointer was on the first row before executing the instruction, the SQL code is set to 100 (`NOTFOUND`), and the row pointer remains on the first row. (if you issue a `FETCH NEXT` at this time, you get the second row).

The CURRENT clause retrieves the current row in the result set.

The FIRST clause retrieves the first row in the result set.

The LAST clause retrieves the last row in the result set.

The ABSOLUTE clause retrieves the row at *position* in the result set. If the *position* is not correct, the SQL code is set to 100 (NOTFOUND). Absolute row positions are numbered from 1.

The RELATIVE clause moves *offset* rows in the result set and returns the row at the current position. The offset can be a negative value. If the *offset* is not correct, the SQL code is set to 100 (NOTFOUND). If *offset* is zero, the current row is fetched.

Fetching rows can have specific behavior when the cursor was declared FOR UPDATE to perform a positioned update or delete.

Example

```
MAIN
   DEFINE cust_rec RECORD
            cnum INTEGER,
            cname CHAR(20)
        END RECORD
   DATABASE stores
   DECLARE c1 SCROLL CURSOR FOR SELECT customer_num, cust_name
 FROM customer
   OPEN c1
   FETCH c1 INTO cust_rec.*
   FETCH LAST c1 INTO cust_rec.*
   FETCH PREVIOUS c1 INTO  cust_rec.*
   FETCH FIRST c1 INTO cust_rec.*
   FETCH LAST c1 -- INTO clause is optional
   FETCH FIRST c1 -- INTO clause is optional
END MAIN
```

CLOSE (result set cursor)

Closes a database cursor and frees resources allocated on the database server for the result set.

Syntax

```
CLOSE cid
```

1. *cid* is the identifier of the database cursor.

Usage

The CLOSE instruction releases the resources allocated for the result set on the database server.

After using the CLOSE instruction, you must reopen the cursor with OPEN before retrieving values with FETCH.

You should close the cursor when the result set is no longer used, this saves resources on the database client and database server side.

Example

```
MAIN
   DATABASE stores
   DECLARE c1 CURSOR FOR SELECT * FROM customer
   OPEN c1
```

```
   CLOSE c1
   OPEN c1
   CLOSE c1
END MAIN
```

FREE (result set cursor)

Releases SQL cursor resources allocated by the DECLARE instruction.

Syntax

```
FREE cid
```

1. *cid* is the identifier of the database cursor.

Usage

The FREE instruction takes the name of a cursor as parameter.

All resources allocated to the database cursor are released.

If not done, the cursor is automatically closed when doing a FREE.

When cursor resources are released with FREE, the cursor must be declared again before usage.

Free the cursor when the result set is no longer used by the program; this saves resources on the database client and database server side.

Example

```
MAIN
   DEFINE i, j INTEGER
   DATABASE stores
   FOR i=1 TO 10
       DECLARE c1 CURSOR FOR SELECT * FROM customer
       FOR j=1 TO 10
           OPEN c1
           FETCH c1
           CLOSE c1
       END FOR
       FREE c1
   END FOR
END MAIN
```

FOREACH (result set cursor)

Processes a series data rows returned from a database cursor.

Syntax

```
FOREACH cid
   [ USING pvar {IN|OUT|INOUT} [,...] ]
   [ INTO fvar [,...] ]
   [ WITH REOPTIMIZATION ]
       {
         statement
       | CONTINUE FOREACH
       | EXIT FOREACH
       }
```

```
        [...]
END FOREACH
```

1. *cid* is the identifier of the database cursor.
2. *pvar* is a variable containing an input value for an SQL parameter.
3. *fvar* is a variable used as fetch buffer.

Usage

Use the FOREACH instruction to retrieve and process database rows that were selected by a query. This instruction is equivalent to using the OPEN, FETCH and CLOSE cursor instructions:

1. Open the specified cursor
2. Fetch the rows selected
3. Close the cursor (after the last row has been fetched)

You must declare the cursor (by using the DECLARE instruction) before the FOREACH instruction can retrieve the rows. A compile-time error occurs unless the cursor was declared prior to this point in the source module. You can reference a sequential cursor, a scroll cursor, a hold cursor, or an update cursor, but FOREACH only processes rows in sequential order.

The FOREACH statement performs successive fetches until all rows specified by the SELECT statement are retrieved. Then the cursor is automatically closed. It is also closed if a WHENEVER NOT FOUND exception handler within the FOREACH loop detects a NOTFOUND condition.

After a FOREACH loop, STATUS and SQLCA.SQLCODE will not be set to NOTFOUND(100) if no rows are returned by the query: If no error occurred, these registers will hold the value zero.

The USING clause is required to provide the SQL parameter buffers, if the cursor was declared with a prepared statement that includes (?) question mark placeholders.

The IN, OUT or INOUT options can be used to call stored procedures having input / output parameters and generating a result set. Use the IN, OUT, or INOUT options to indicate if a parameter is respectively for input, output, or both.

The INTO clause can be used to provide the fetch buffers that receive the row values.

Use the WITH REOPTIMIZATION clause to indicate that the query execution plan has to be re-optimized.

The CONTINUE FOREACH instruction interrupts processing of the current row and starts processing the next row. The runtime system fetches the next row and resumes processing at the first statement in the block.

The EXIT FOREACH instruction interrupts processing and ignores the remaining rows of the result set.

The IN, OUT, or INOUT options can only be used for simple variables; you cannot specify those options for a complete record with the record.* notation.

Example

```
MAIN
   DEFINE clist ARRAY[200] OF RECORD
            cnum INTEGER,
            cname CHAR(50)
          END RECORD
   DEFINE i INTEGER
   DATABASE stores
   DECLARE c1 CURSOR FOR SELECT customer_num, cust_name FROM
 customer
   LET i=0
   FOREACHc1 INTO clist[i+1].*
      LET i=i+1
      DISPLAY clist[i].*
```

```
   END FOREACH
   DISPLAY "Number of rows found: ", i
END MAIN
```

Positioned updates/deletes

Describes row modification based on a FOR UPDATE cursor.

- Understanding positioned update or delete on page 514
- DECLARE (SELECT ... FOR UPDATE) on page 515
- UPDATE ... WHERE CURRENT OF on page 516
- DELETE ... WHERE CURRENT OF on page 517
- Examples on page 517

Understanding positioned update or delete

When declaring a database cursor with a `SELECT` statement using a unique table and ending with the `FOR UPDATE` keywords, you can update or delete database rows by using the `WHERE CURRENT OF` keywords in the `UPDATE` or `DELETE` statements. Such an operation is called *positioned update* or *positioned delete*.

Some database servers do not support **hold** cursors (`WITH HOLD`) declared with a `SELECT` statement including the `FOR UPDATE` keywords. The SQL standards require *for update cursors* to be automatically closed at the end of a transaction. Therefore, it is strongly recommended that you use positioned updates in a transaction block.

Do not confuse positioned update with the use of `SELECT FOR UPDATE` statements that are not associated with a database cursor. Executing `SELECT FOR UPDATE` statements is supported by the language, but you cannot perform positioned updates since there is no cursor identifier associated to the result set.

To perform a positioned update or delete, you must declare the database cursor with a `SELECT FOR UPDATE` statement.

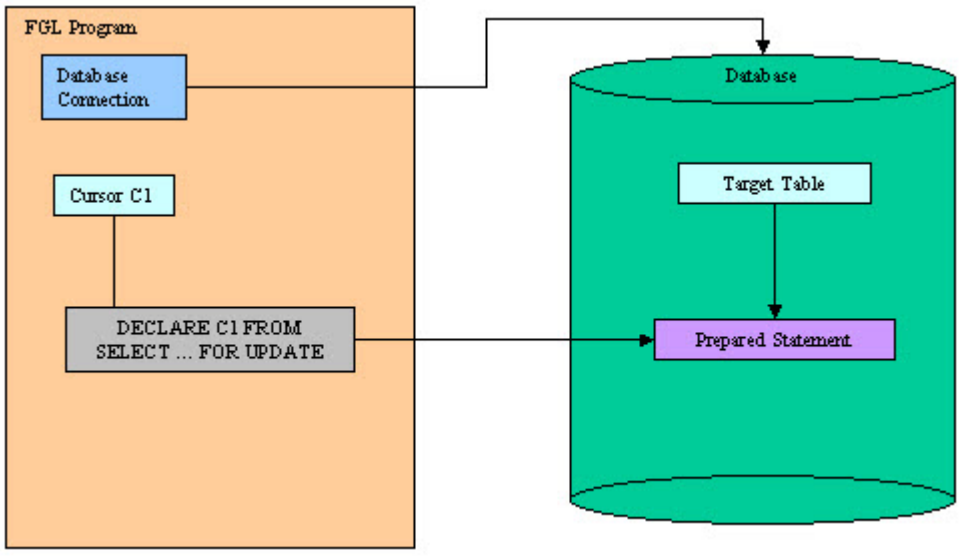

Figure 28: SELECT FOR UPDATE statement

Then, start a transaction, open the cursor and fetch a row.

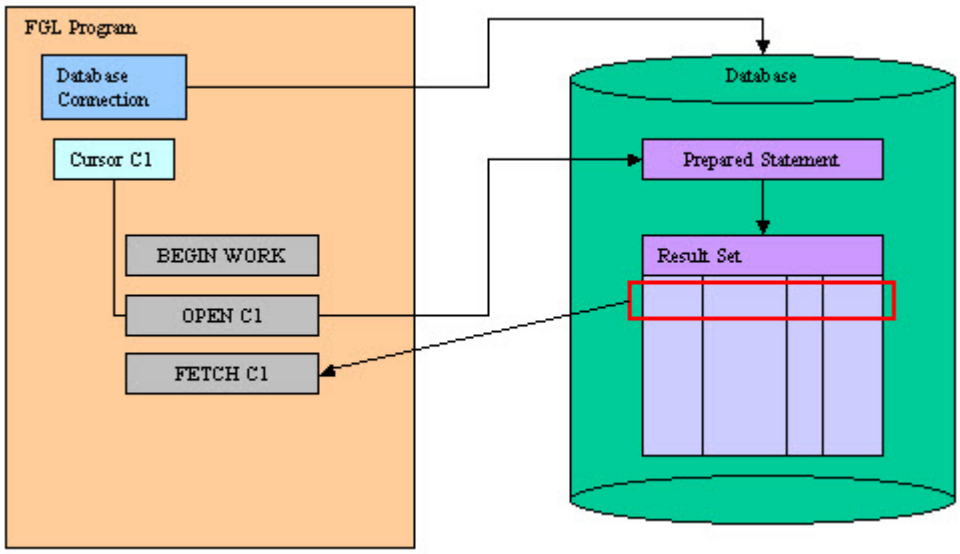

Figure 29: Open a cursor

Finally, you update or delete the current row and you commit the transaction.

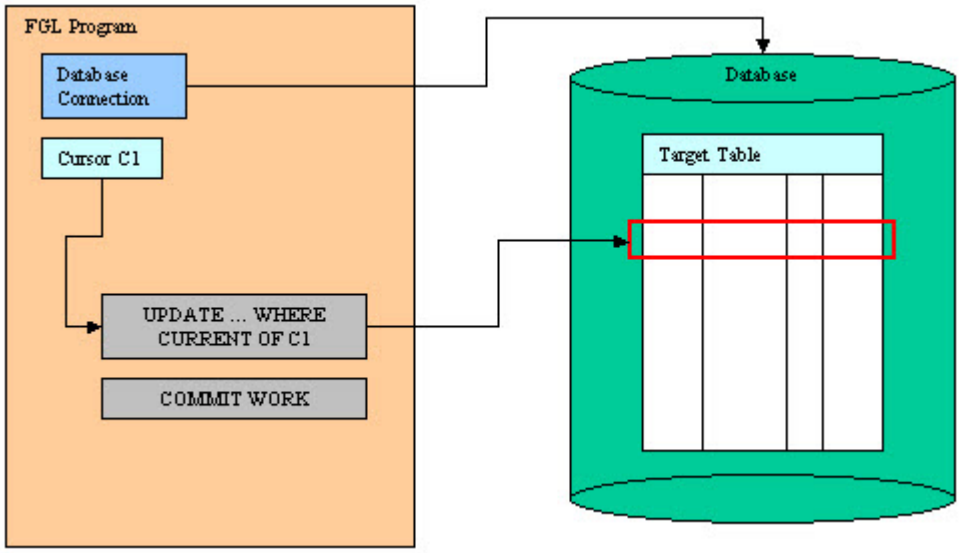

Figure 30: Delete the row

DECLARE (SELECT ... FOR UPDATE)

Associate a database cursor with a SELECT statement to perform positioned updates and deletes

Syntax

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD]
    FOR { select-statement | sid }
```

1. *cid* is the identifier of the database cursor.
2. *select-statement* is a SELECT statement defined in static SQL, with the FOR UPDATE keywords.
3. *sid* is the identifier of a prepared SELECT statement including the FOR UPDATE keywords.

Usage

DECLARE ... FOR UPDATE will define a cursor that can be used to do positioned updates and deletes with the WHERE CURRENT OF clause.

DECLARE must precede any other statement that refers to the cursor during program execution.

To perform positioned updates, the *select-statement* must include the FOR UPDATE keywords.

The scope of reference of the *cid* cursor identifier is local to the module where it is declared. Therefore, you must execute the DECLARE, UPDATE or DELETE instructions in the same module.

The static *select-statement* used in the DECLARE can contain ? (question mark) parameter placeholders, that can be bound to program variables with the USING clause of the OPEN instruction.

Use the WITH HOLD option carefully, because this feature is specific to IBM® Informix® servers. Other database servers do not behave as Informix® does with such cursors. For example, if the SELECT is not declared FOR UPDATE, most database servers keep cursors open after the end of a transaction, but IBM® DB2® automatically closes all cursors when the transaction is rolled back.

UPDATE ... WHERE CURRENT OF

Updates the current row in a result set of a database cursor declared for update.

Syntax

```
UPDATE table-specification
   SET
       column = { variable | sql-expression }
       [,...]
   WHERE CURRENT OF cid
```

1. *table-specification* identifies the target table (see UPDATE for more details).
2. *column* is a name of a table column.
3. *variable* is a program variable, a record member or an array member used as a parameter buffer to provide values.
4. *sql-expression* is an expression supported by the database server, this can be a literal or NULL for example.
5. *cid* is the identifier of the database cursor declared for update.

Usage

Use UPDATE ... WHERE CURRENT OF to modify the values of the row currently pointed by the associated FOR UPDATE cursor.

The UPDATE statement does not advance the cursor to the next row, so the current row position remains unchanged.

The scope of reference of the *cid* cursor identifier is local to the module where it is declared. Therefore, you must execute the DECLARE,UPDATE or DELETE instructions in the same module.

There must be a current row in the result set. Make sure that the SQL status returned by the last FETCH is equal to zero.

If the DECLARE statement that created the cursor specified one or more columns in the FOR UPDATE clause, you are restricted to updating only those columns in a subsequent UPDATE ... WHERE CURRENT OF statement.

DELETE ... WHERE CURRENT OF

Deletes the current row in a result set of a database cursor declared for update.

Syntax

```
DELETE FROM table-specification
   WHERE CURRENT OF cid
```

1. *table-specification* identifies the target table
2. *cid* is the identifier of the database cursor declared for update.

Usage

Use `DELETE ... WHERE CURRENT OF` to remove the row currently pointed by the associated `FOR UPDATE` cursor.

After the deletion, no current row exists; you cannot use the cursor to delete or update a row until you reposition the cursor with a FETCH statement.

The scope of reference of the *cid* cursor identifier is local to the module where it is declared. Therefore, you must execute the `DECLARE`, `UPDATE` or `DELETE` instructions in the same module.

There must be a current row in the result set. Make sure that the SQL status returned by the last `FETCH` is equal to zero.

Examples

Example 1: Positioned UPDATE statement

```
MAIN
  DEFINE pname CHAR(30)
  DATABASE stock
  DECLARE uc CURSOR FOR
    SELECT name FROM item WHERE key=123 FOR UPDATE
  BEGIN WORK
    OPEN uc
    FETCH uc INTO pname
    IF sqlca.sqlcode=0 THEN
      LET pname = "Dummy"
      UPDATE item SET name=pname WHERE CURRENT OF uc
    END IF
    CLOSE uc
  COMMIT WORK
  FREE uc
END MAIN
```

SQL insert cursors

Explains how to insert a log of rows into a table efficiently.

- Understanding SQL insert cursors on page 518
- DECLARE (insert cursor) on page 520
- OPEN (insert cursor) on page 521
- PUT (insert cursor) on page 521
- FLUSH (insert cursor) on page 521
- CLOSE (insert cursor) on page 522
- FREE (insert cursor) on page 522

- Examples on page 522

Understanding SQL insert cursors

An *insert cursor* is a database cursor declared with a restricted form of the `INSERT` statement, designed to perform buffered row insertion in database tables.

The insert cursor simply inserts rows of data; it cannot be used to fetch data. When an insert cursor is opened, a buffer is created in memory to hold a block of rows. The buffer receives rows of data as the program executes `PUT` statements. The rows are written to disk only when the buffer is full. You can use the `CLOSE` , `FLUSH` , or `COMMIT WORK` statement to flush the buffer when it is less than full. You must close an insert cursor to insert any buffered rows into the database before the program ends. You can lose data if you do not close the cursor properly.

When the database server supports buffered inserts, an insert cursor increases processing efficiency (compared with embedding the `INSERT` statement directly). This process reduces communication between the program and the database server and also increases the speed of the insertions.

Before using the insert cursor, you must declare it with the `DECLARE` instruction using an `INSERT` statement.

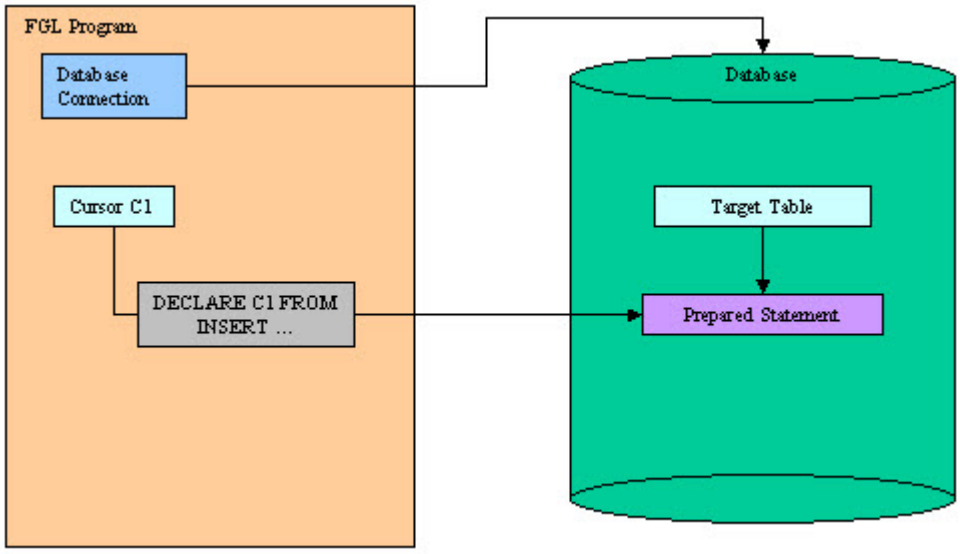

Figure 31: Declaring a cursor

Once declared, you can open the insert cursor with the `OPEN` instruction. This instruction prepares the insert buffer. When the insert cursor is opened, you can add rows to the insert buffer with the `PUT` statement.

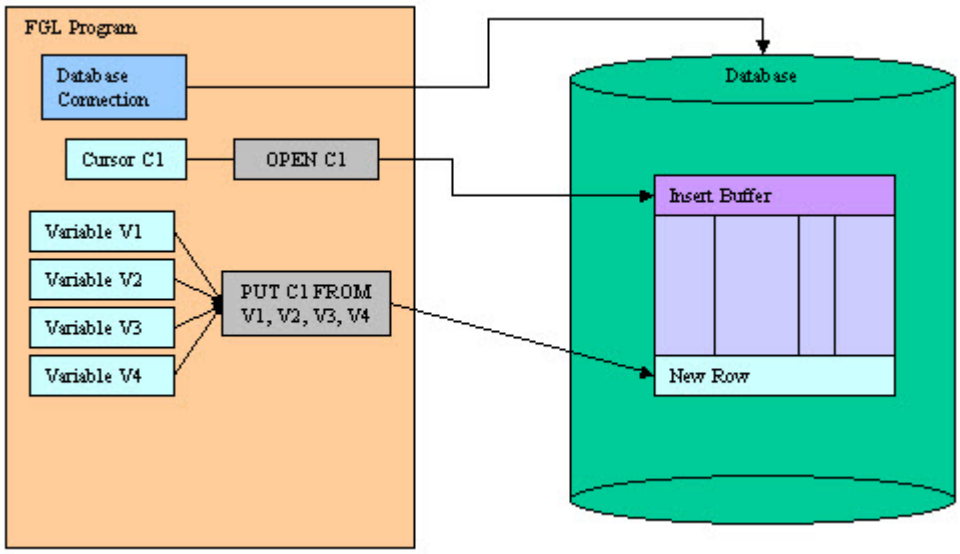

Figure 32: OPEN and PUT statements

Rows are automatically added to the database table when the insert buffer is full. To force row insertion in the table, you can use the FLUSH instruction.

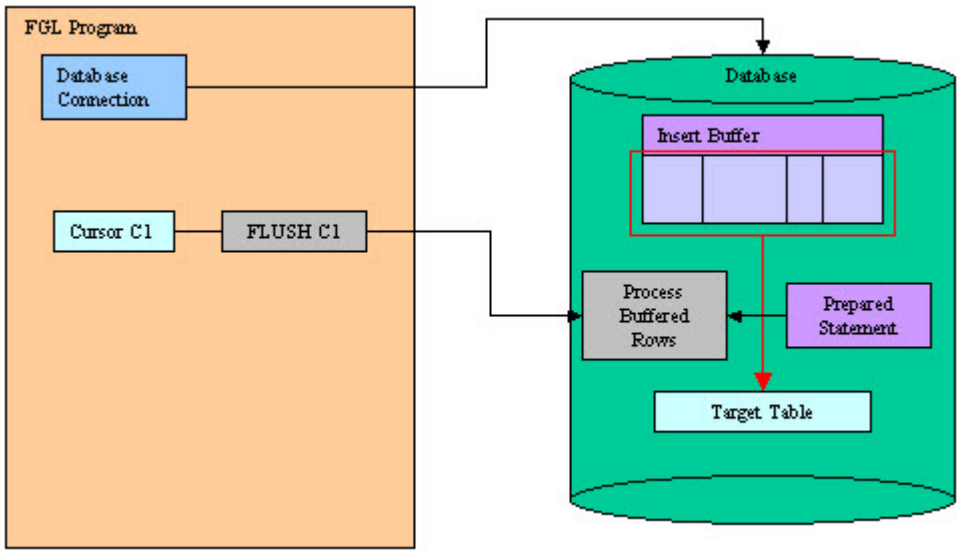

Figure 33: FLUSH statement

Finally, when all rows are added, you can CLOSE the cursor and if you no longer need it, you can de-allocate resources with the FREE instruction.

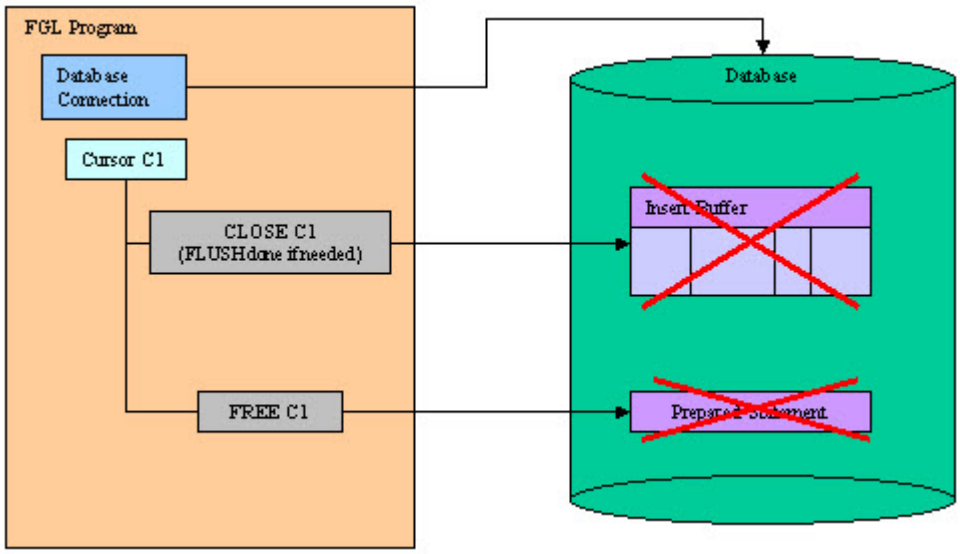

Figure 34: CLOSE and FREE statements

By default, insert cursors must be opened inside a transaction block, with `BEGIN WORK` and `COMMIT WORK`, and they are automatically closed at the end of the transaction. If needed, you can declare insert cursors with the `WITH HOLD` clause, to allow uninterrupted row insertion across multiple transactions.

DECLARE (insert cursor)

The `DECLARE` with an `INSERT` instruction defines an insert cursor.

Syntax

```
DECLARE cid CURSOR [WITH HOLD] FOR { insert-statement | sid }
```

1. *cid* is the identifier of the insert cursor.
2. *insert-statement* is an `INSERT` statement defined in static SQL.
3. *sid* is the identifier of a prepared `INSERT` statement.

Usage

Use the `DECLARE` instruction with an `INSERT` instruction to define a new insert cursor in the current database session.

The `INSERT` statement is parsed, validated and the execution plan is created.

`DECLARE` must precede any other statement that refers to the cursor during program execution.

The scope of reference of the *cid* cursor identifier is local to the module where it is declared.

The static *insert-statement* statement can include a list of variables in the `VALUES` clause. These variables are automatically read by the `PUT` statement; you do not have to provide the list of variables in that statement. As an alternative, use the ? (question mark) SQL parameter placeholder in the `VALUE` clause to bind program variables provided in the `FROM` clause of the `PUT` instruction.

When declaring a cursor with a prepared *sid* statement, the statement can include ? (question mark) placeholders for SQL parameters. In this case you must provide a list of variables in the `FROM` clause of the `PUT` statement.

Use the `WITH HOLD` option to declare cursors that have uninterrupted inserts across multiple transactions.

Resources allocated by the `DECLARE` can be released later by the `FREE` instruction.

The number of declared cursors in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the declared insert cursor.

The identifier of a cursor that was declared in one module cannot be referenced from another module.

OPEN (insert cursor)

Initializes an insert cursor.

Syntax

```
OPEN cid
```

1. *cid* is the identifier of the insert cursor.

Usage

The `OPEN` statement initializes the insert cursor if the specified cursor was declared with an `INSERT` statement.

Once the insert cursor is opened, you can add rows with the `PUT` statement.

When used with an insert cursor, the `OPEN` instruction cannot include a `USING` clause.

A subsequent `OPEN` statement closes the cursor and then reopens it.

If the insert cursor was not declared `WITH HOLD` option, the`OPEN` instruction generates an SQL error if there is no current transaction started.

If you release cursor resources with a `FREE` instruction, you cannot use the cursor unless you declare the cursor again.

PUT (insert cursor)

Adds a new row to the insert cursor buffer.

Syntax

```
PUT cid FROM pvar [,...]
```

1. *cid* is the identifier of the insert cursor.
2. *pvar* is a variable containing an input value for the new row.

Usage

The `PUT` instruction adds a row to the insert cursor buffer.

If the insert cursor was not declared `WITH HOLD` option, the `PUT` instruction generates an SQL error if there is no current transaction started.

If the insert buffer has no room for the new row when the statement executes, the buffered rows are written to the database in a block, and the buffer is emptied. As a result, some `PUT` statement executions cause rows to be written to the database, and some do not.

FLUSH (insert cursor)

Flushes the buffer of an insert cursor.

Syntax

```
FLUSH cid
```

1. *cid* is the identifier of the insert cursor.

Usage

When flushing an insert cursor, all buffered rows are inserted into the target database table and the insert buffer is cleared.

The insert buffer may be automatically flushed by the runtime system if there no room when a new row is added with the PUT instruction.

CLOSE (insert cursor)

Flushes and closes an insert cursor.

Syntax

```
CLOSE cid
```

1. *cid* is the identifier of the insert cursor.

Usage

If rows are present in the insert buffer, they are inserted into the target table.

Closing the insert cursor releases the resources allocated for the insert buffer on the database server.

After using the CLOSE instruction, you must reopen the cursor with OPEN before adding new rows with PUT/FLUSH.

FREE (insert cursor)

Releases resources allocated for an insert cursor.

Syntax

```
FREE cid
```

1. *cid* is the identifier of the insert cursor.

Usage

After executing the FREE statement, all resources allocated to the insert cursor are released.

The cursor should be explicitly closed before it is freed.

If you release cursor resources with this instruction, you cannot use the cursor unless you declare the cursor again.

Examples

Example 1: Insert Cursor declared with a Static INSERT

```
MAIN
   DEFINE i INTEGER
   DEFINE rec RECORD
            key INTEGER,
            name CHAR(30)
          END RECORD
   DATABASE stock
   DECLARE ic CURSOR FOR
     INSERT INTO item VALUES (rec.*)
```

```
   BEGIN WORK
     OPEN ic
     FOR i=1 TO 100
         LET rec.key = i
         LET rec.name = "Item #" || i
         PUT ic
         IF i MOD 50 = 0 THEN
             FLUSH ic
         END IF
     END FOR
     CLOSE ic
   COMMIT WORK
   FREE ic
END MAIN
```

Example 2: Insert Cursor declared with an SQL text

```
MAIN
   DEFINE i INTEGER
   DEFINE rec RECORD
           key INTEGER,
           name CHAR(30)
         END RECORD
   DATABASE stock
   DECLARE ic CURSOR FROM "INSERT INTO item VALUES (?,?)"
   BEGIN WORK
     OPEN ic
     FOR i=1 TO 100
         LET rec.key = i
         LET rec.name = "Item #" || i
         PUT ic FROM rec.*
         IF i MOD 50 = 0 THEN
             FLUSH ic
         END IF
     END FOR
     CLOSE ic
   COMMIT WORK
   FREE ic
END MAIN
```

Example 3: Insert Cursor declared with 'hold' option

```
MAIN
   DEFINE name CHAR(30)
   DATABASE stock
   DECLARE ic CURSOR WITH HOLD FOR
     INSERT INTO item VALUES (1,name)
   OPEN ic
   LET name = "Item 1"
   PUT ic
   BEGIN WORK
     UPDATE refs SET name="xyz" WHERE key=123
   COMMIT WORK
   PUT ic
   PUT ic
   FLUSH ic
   CLOSE ic
   FREE ic
END MAIN
```

SQL load and unload

Describes the instructions to export/import information from/to a database.

- LOAD on page 524
- UNLOAD on page 527

LOAD

Inserts data from a file into an existing database table.

Syntax

```
LOAD FROM filename [ DELIMITER delimiter]
{
  INSERT INTO table-specification [ ( column [,...]) ]
|
  insert-string
}
```

where *table-specification* is:

```
[dbname[@dbserver]:][owner.]table
```

1. *filename* is a string expression containing the name of the file the data is read from.
2. *delimiter* is the character used as the value delimiter.
3. The `INSERT` clause is a pseudo `INSERT` statement (without the `VALUES` clause), where you can specify the list of columns in braces.
4. *dbname* identifies the database name.
5. *dbserver* identifies the database server (INFORMIXSERVER).
6. *owner* identifies the owner of the table, with optional double quotes.
7. *table* is the name of the database table.
8. *column* is a name of a table column.
9. *insert-string* is a string expression containing the pseudo-INSERT statement.

Usage

The `LOAD` instruction reads serialized data from an input file and inserts new rows in a database table specified in the `INSERT` clause. A file created by the `UNLOAD` statement can be used as input for the `LOAD` statement if its values are compatible with the schema of *table*.

The `LOAD` statement must include a pseudo-`INSERT` statement (either directly or as text in a variable) to specify where to store the data. `LOAD` appends the new rows to the specified table, synonym, or view, but does not overwrite existing data. It cannot add a row that has the same key as an existing row.

The *dbname*, *dbserver* and *owner* prefix of the table name should be avoided for maximum SQL portability.

The number and the order of columns in the `INSERT` statement must match the values of the input file.

The `LOAD` instruction cannot be prepared with a `PREPARE` statement, however `LOAD` can take a string literal as parameter, that allows to build the `INSERT` statement at runtime.

The variable or string following the `LOAD FROM` keywords must specify the name of a file of ASCII characters (or characters that are valid for the current locale) that holds the data values that are to be inserted.

Each set of data values in *filename* that represents a new row is called an input record. Each input record must contain the same number of delimited data values. If the `INSERT` clause has no list of columns, the

sequence of values in each input record must match the columns of *table* in number and order. Each value must have the literal format of the column data type, or of a compatible data type.

If LOAD is executed within a transaction block (BEGIN WORK / COMMIT WORK), the rows inserted by the LOAD instruction are part of the transaction. With some database servers the insert rows remain locked until the COMMIT WORK or ROLLBACK WORK statement terminates the transaction. Consider locking the whole table to

If the database does not support transactions, a failing LOAD statement cannot remove any rows that were loaded before the failure occurred. You must manually remove the already loaded records from either the load file or from the receiving table, repair the erroneous records, and rerun LOAD.

If the database supports transactions, you can do the following actions:

- Run LOAD as a singleton transaction, so that any error causes the entire LOAD statement to be automatically rolled back.
- Run LOAD within an explicit BEGIN WORK / COMMIT WORK transaction block, so that a data error merely stops the LOAD statement in place with the transaction still open.

A single character delimiter instructs LOAD to read data in the default format. When using "CSV" as delimiter specification, the LOAD instruction will read the data in CSV format. If the DELIMITER clause is not specified, the delimiter is defined by the DBDELIMITER environment variable. If the DBDELIMITER environment variable is not set, the default is a | pipe. The field delimiter can be a blank character. It cannot be backslash or any hexadecimal digit (0-9, A-F, a-f). If the delimiter specified in the LOAD command is NULL, the runtime system will use the default delimiter or DBDELIMITER if the variable is defined.

At this time, data type description of the input file fields is implicit; in order to create the SQL parameter buffers to hold the field values for inserts, the LOAD instruction uses the current database connection to get the column data types of the target table. Those data types depend on the type of database server. For example, IBM® Informix® DATE columns do not store the same data as the Oracle DATE data type. Therefore, be careful when using the LOAD/UNLOAD instructions; if the application connects to different kinds of database servers, it can result data conversion errors.

Pay attention to numeric (DECIMAL, MONEY) and date/time values (DATE, DATETIME): These must match the current format settings (DBMONEY, DBDATE). As a general programming pattern, use simple INSERT statements to load default and configuration data into your database, in order to be independent from the numeric and date format settings.

Default LOAD format

The next table describes how data values should be represented in the input file used by the LOAD instruction. Values must be serialized with a character string following the SQL data type of the receiving column of the table.

Table 158: Data representation for the default LOAD format

Data type	Input Format
CHAR, VARCHAR, TEXT	Values can have more characters than the declared maximum length of the column, but any extra characters are ignored. A backslash (\ ) is required before any literal backslash or any literal delimiter character, and before any NEWLINE character anywhere in character value. Blank values can be represented as one or more blank characters between delimiters, but leading blanks must not precede other CHAR, VARCHAR, or TEXT values.
DATE	In the default locale, values must be in month/day/year format unless another format is specified by DBDATE environment variable. The day and month must be a 2-digit number, and the year must be a 4-digit number.
DATETIME	DATETIME values must be in the format:

Data type	Input Format
	`year-month-day hour:minute:second.fraction` or a contiguous subset, without the `DATETIME` keyword or qualifiers. Time units outside the declared column precision can be omitted. The `year` must be a four-digit number; all other time units (except `fraction`) require two digits.

`INTERVAL`	`INTERVAL` values must be formatted:
	`year-month`
	or
	`day hour:minute:second.fraction`
	or a contiguous subset thereof, without the `INTERVAL` keyword or qualifiers. Time units outside the declared column precision can be omitted. All time units (except `year` and `fraction`) require two digits.

`DECIMAL`, `MONEY`	Values must use the decimal separator defined by DBFORMAT/DBMONEY. For `MONEY`, values can include currency symbols, but these are not required.
`BYTE`	Values must be ASCII-hexadecimals; no leading or trailing blanks.
`SERIAL`, `BIGSERIAL`, `SERIAL8`	Values can be represented as 0 to tell the database server to supply a new serial value. You can specify a literal integer greater than zero, but if the column has a unique index, an error results if this number duplicates an existing value.

The NEWLINE character must terminate each input record in *filename*. Specify only values that the language can convert to the data type of the database column. For database columns of character data types, inserted values are truncated from the right if they exceed the declared length of the column.

NULL values of any data type must be represented by consecutive delimiters in the input file; you cannot include anything between the delimiter symbols.

The `LOAD` statement expects incoming data in the format specified by environment variables like `DBFORMAT`, `DBMONEY`, `DBDATE`, `GL_DATE`, and `GL_DATETIME`. The precedence of these format specifications is consistent with forms and reports. If there is an inconsistency, an error is reported and the `LOAD` is canceled.

The backslash symbol (`\`) serves as an escape character in the input file to indicate that the next character in a data value is a literal. The `LOAD` statement scans for backslash escaped elements to read special characters in the following contexts:

- The backslash character appears anywhere in the value.
- The delimiter character appears anywhere in the value.
- The NEWLINE character appears anywhere in a value.

CSV LOAD format

The CSV (comma separated values) format is similar to the default format when using a simple comma delimiter, with the following differences:

- Input values might be surrounded with " double quotes.
- If an input value contains a comma or a NEWLINE, it is not escaped be the value must be quoted in the file.
- Double-quote characters in input values are doubled and will be converted to a unique " character; the value must be quoted.
- Backslash characters are not escaped in the input file and are read as; the value must be quoted.
- Leading and trailing blanks are kept (no truncation).
- No ending delimiter is expected at the end of the input record.

Example

```
MAIN
  DATABASE stores
  BEGIN WORK
  DELETE FROM items
  LOAD FROM "items01.unl" INSERT INTO items
  LOAD FROM "items02.unl" INSERT INTO items
  COMMIT WORK
END MAIN
```

UNLOAD

Copies data from the database tables into a file.

Syntax

```
UNLOAD TO filename [ DELIMITER delimiter]
{
  select-statement
|
  select-string
}
```

1. *filename* is a string expression containing the name of the file the data is written to.
2. *delimiter* is the character used as the value delimiter.
3. *select-statement* is static SELECT statement.
4. *select-string* is string expression containing the SELECT statement.

Usage

The UNLOAD instruction serializes into a file the SQL data produced by a SELECT statement.

You cannot use the PREPARE statement to pre-process an UNLOAD statement, you can however use a string literal to build the SELECT statement at runtime.

The *filename* after the TO keyword identifies an output file in which to store the rows retrieved from the database by the SELECT statement. In the default (U.S. English) locale, this file contains only ASCII characters. (In other locales, output from UNLOAD can contain characters from the codeset of the locale.)

The UNLOAD statement must include a SELECT statement (directly, or in a variable) to specify what rows to copy into *filename*. UNLOAD does not delete the copied data.

A single character delimiter instruct UNLOAD to write data in the default format. When using "CSV" as delimiter specification, the UNLOAD instruction will write the data in CSV format. If the DELIMITER clause is not specified, the delimiter is defined by the DBDELIMITER environment variable. If the DBDELIMITER environment variable is not set, the default is a | pipe. The field delimiter can be a blank character. It cannot be backslash or any hexadecimal digit (0-9, A-F, a-f). If the delimiter specified in the UNLOAD command is NULL, the runtime system will use the default delimiter or DBDELIMITER if the variable is defined.

When using a *select-string* , do not attempt to substitute question marks (?) in place of host variables to make the SELECT statement dynamic, because this usage has binding problems.

At this time, data type description of the output file fields is implicit; in order to create the fetch buffers to hold the column values, the UNLOAD instruction uses the current database connection to get the column data types of the generated result set. Those data types depend on the type of database server. For example, IBM® Informix® INTEGER columns are 4-bytes integers, while the Oracle INTEGER data type

is actually a `NUMBER(10,0)` type. Therefore, you should take care when using this instruction; if your application connects to different kinds of database servers, you may get data conversion errors.

Default UNLOAD format

A set of values in output representing a row from the database is called an *output record*. A NEWLINE character (ASCII 10) terminates each output record.

The `UNLOAD` statement represents each value in the output file as a character string by using the current locale, according to the data type of the database column:

Table 159: Default UNLOAD format

Data type	Output Format
`CHAR, VARCHAR, TEXT`	Trailing blanks are dropped from `CHAR` and `TEXT` (but not from `VARCHAR`) values. A backslash (`\`) is inserted before any literal backslash or delimiter character and before a NEWLINE character in a character value.
`DECIMAL, FLOAT, INTEGER, MONEY, SMALLFLOAT, SMALLINT`	Values are written as literals with no leading blanks. `MONEY` values are represented with no leading currency symbol. Zero values are represented as 0 for `INTEGER` or `SMALLINT` columns, and as 0.00 for `FLOAT`, `SMALLFLOAT`, `DECIMAL`, and `MONEY` columns.
`DATE`	Values are written in the format `month/day/year` unless some other format is specified by the `DBDATE` environment variable.
`DATETIME`	`DATETIME` values are formatted `year-month-day hour:minute:second.fraction` or a contiguous subset, without `DATETIME` keyword or qualifiers. Time units outside the declared precision of the database column are omitted.

`INTERVAL`	INTERVAL values are formatted
	`year-month`
	or
	`day hour:minute:second.fraction`
	or a contiguous subset, without `INTERVAL` keyword or qualifiers. Time units outside the declared precision of the database column are omitted.

`BYTE`	`BYTE` Values are written in ASCII hexadecimal form, without any added blank or NEWLINE characters. The logical record length of an output file that contains `BYTE` values can be very long, and thus might be very difficult to print or to edit.

NULL values of any data type are represented by consecutive delimiters in the output file, without any characters between the delimiter symbols.

The backslash symbol (`\`) serves as an escape character in the output file to indicate that the next character in a data value is a literal. The `UNLOAD`statement automatically inserts a preceding backslash to prevent literal characters from being interpreted as special characters in the following contexts:

- The backslash character appears anywhere in the value.
- The delimiter character appears anywhere in the value.
- The NEWLINE character appears anywhere in a value.

CVS UNLOAD format

The CSV (comma separated values) format is similar to the standard format when using a simple comma delimiter, with the following differences:

- A comma character generates a quoted output value, and the comma is written as is (not escaped).
- A " double-quote character generate quoted output value and the quote in the value is doubled.
- NEWLINE characters generate a quoted output value, and the NEWLINE is written as is (not escaped).
- Backslash characters are written as is in the output value (i.e. not escaped).
- Leading and trailing blanks are not truncated in the output value.
- No ending delimiter is written at the end of the output record.

Example

```
MAIN
  DEFINE var INTEGER
  DATABASE stores
  LET var = 123
  UNLOAD TO "items.unl"
    SELECT * FROM items WHERE item_num > var
END MAIN
```

SQL adaptation guides

This section includes the SQL adaptation guides for various supported databases. The adaptation guides provide you with information about installation and configuration requirements, as well as details on what is and is not supported when using database-specific SQL.

- SQL guide for IBM Informix database servers 5.x, 7.x, 8.x, 9.x, 10.x, 11.x on page 529
- SQL adaptation guide for IBM DB2 UDB 10.x on page 540
- SQL adaptation guide for IBM Netezza 6.x on page 572
- SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014 on page 592
- SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x on page 625
- SQL adaptation guide for Oracle Database 11, 12 on page 643
- SQL adaptation guide for PostgreSQL 9.x on page 683
- SQL adaptation guide for SQLite 3.x on page 709
- SQL adaptation guide for SAP Sybase ASE 16.x on page 723
- SQL adaptation guide for SAP HANA DB (SPS09+)

SQL guide for IBM® Informix® database servers 5.x, 7.x, 8.x, 9.x, 10.x, 11.x

Purpose of the Informix® SQL guide

This section contains information to configure your Genero runtime system to work with an Informix® database engine, and describes the IBM® Informix® SQL features that are not supported (or partially supported) by Genero BDL.

Understand that Genero BDL was designed to work with IBM® Informix® databases, so most of the IBM® Informix® SQL features are supported. However, new features implemented in recent server versions need modifications in the Genero BDL compilers and runtime system to be supported.

Some topics show an enhancement reference note with a number, identifying the request id as filed in our internal "TODO" database. If the SQL feature is mission critical for your application, contact the support center and mention the enhancement identifier.

Installation (Runtime Configuration)
ODI adaptation guide Installation topics.
Supported IBM® Informix® server and CSDK versions

1. Genero BDL is certified with all IBM® Informix® servers from version **5.x** to the latest **11.x** version, including the Standard Engine, On-Line and IDS server families, as long as the IBM® Informix® Client SDK is compatible with the server.
2. Genero BDL is certified with IBM® Informix® SDK version **3.50** or higher.

Install IBM® Informix® and create a database - database configuration/design tasks

1. Install the IBM® Informix® database software (IDS for example) on your database server.
2. Install the IBM® Informix® Software Development Kit (SDK) on your application server.

   With some IBM® Informix® distributions (IDS 11), this package is included in the server bundle. You should check the IBM® web site for SDK upgrades or patches. Genero BDL is certified with IBM® Informix® SDK version 3.50 or higher.
3. Setup the IDS server (onconfig file, etc)
   a) Starting with IDS version 11, the `TEMPTAB_NOLOG` is set to 1 by default.

      Consider setting this parameter to 0, if you want to log temporary table changes. This can affect the behavior of programs expecting that a ROLLBACK WORK cancels changes done on a temporary table.
4. Define a database user dedicated to your application: the application administrator.

   This user will manage the database schema of the application (all tables will be owned by it). With IBM® Informix®, database users reference Operating System users, and must be part of the IBM® Informix® group. See IBM® Informix® documentation.
5. Connect to the server as IBM® Informix® user (for example with the dbaccess tool) and give all requested database administrator privileges to the application administrator.

```
GRANT CONNECT TO appadmin;
GRANT RESOURCE TO appadmin;
GRANT DBA TO appadmin;
```

6. Define the database locale before creating the database.

   According to the language(s) supported in your application, consider using UTF-8 locale by setting the Informix environment variables defining the locale for the database server and data: CLIENT_LOCALE, DB_LOCALE, SERVER_LOCALE.
7. Connect as application administrator and create an IBM® Informix® database entity, for example with the following SQL statement:

   `CREATE DATABASE` *`dbname`* `WITH BUFFERED LOG;`
8. Create the application tables.

Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® Informix®, you must have a database driver "dbmifx" in FGLDIR/dbdrivers.
2. Make sure the IBM® Informix® client environment variables are properly set.

   Check for example INFORMIXDIR (the path to the installation directory), INFORMIXSERVER (the name of the server defined in the sqlhosts list), etc. For more details, see the IBM® Informix® documentation.
3. In order to connect to an IBM® Informix® server, you must define a line in the `$INFORMIXDIR/etc/sqlhosts` file, referencing the server name specified in the INFORMIXSERVER environment variable.

   On Windows™ platforms, the sqlhost entries are defined in the registry database. See IBM® Informix® documentation.
4. Verify the environment variable defining the search path for IBM® Informix® SDK database client shared libraries.

Table 160: Shared library environment setting for IBM® Informix® SDK version

IBM® Informix® SDK version	Shared library environment setting
All versions	*UNIX*™: Add $INFORMIXDIR/lib, $INFORMIXDIR/lib/esql, $INFORMIXDIR/lib/tools and $INFORMIXDIR/lib/cli to LD_LIBRARY_PATH (or its equivalent). *Windows*™ : Add %INFORMIXDIR%\bin to PATH.

5. Check the database client locale settings (CLIENT_LOCALE, DB_LOCALE, etc).

   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

6. To verify if the IBM® Informix® client environment is correct, you can start the SQL command interpreter:

```
$ dbaccess - -
> CONNECT TO "dbname" USER "appadmin";
ENTER PASSWORD: password
```

7. Set up the fglprofile entries for database connections.

   Important: Make sure that you are using the ODI driver corresponding to the database client and server version.

Fully supported IBM® Informix® SQL features
Fully supported IBM® Informix® SQL features.
What are the supported IBM® Informix® SQL features?

Genero BDL was first designed for IBM® Informix® databases. The answer to this question is: Every SQL feature that is not listed in the other sections of this chapter.

The following list gives an idea of the IBM® Informix® SQL elements you can use with Genero BDL:

- Database connection control instructions (DATABASE, CONNECT). See Connections.
- Transaction control instructions and concurrency settings (BEGIN WORK, SET ISOLATION). See Transactions.
- Basic, portable data types (INT, BIGINT, DECIMAL, CHAR, VARCHAR, DATE, DATETIME, TEXT, BYTE, etc). See data types.
- Common Data Definition Language statements (CREATE TABLE, DROP TABLE, etc). See Static SQL.
- Common Data Manipulation Language statements (SELECT, INSERT, UPDATE, DELETE, etc). See Static SQL.
- Result set handling with cursors (DECLARE / OPEN / FETCH / CLOSE / FREE). See Result Sets.
- Positioned UPDATEs and DELETEs (UPDATE/DELETE WHERE CURRENT OF). See Positioned Updates.
- Cursors to insert rows (DECLARE / OPEN / PUT / FLUSH). See Insert Cursors.
- Stored procedure calls. See SQL Programming.
- SQL execution status and error messages (SQLCA, SQLSTATE). See Connections.
- Global Language Support with single and multibyte character sets for CHAR/ VARCHAR data storage. See Localization.
- LOAD and UNLOAD utility statements. See I/O SQL instructions.
- Database schema extraction to define program variables LIKE database columns. See Database Schema.

Partially supported IBM® Informix® SQL features

Partially supported IBM® Informix® SQL features.

The BIGSERIAL / SERIAL8 data types

IBM® Informix® database supports the BIGSERIAL and SERIAL8 data types for auto-generated 64 bit integer sequences.

The BIGINT data type can be used to store data from BIGSERIAL SERIAL8 values.

Note however that SQLCA.SQLERRD[2] is defined as an INTEGER and therefore cannot be used to get the last generated serial. To retrieve the last generated BIGSERIAL or SERIAL8, you must use the `dbinfo()` SQL function as in the following code example:

```
MAIN
  DEFINE new_val BIGINT
  INSERT INTO mytable VALUES ( 0, 'aaaa' )
  SELECT dbinfo('bigserial') INTO new_val
    FROM systables WHERE tabid=1
  DISPLAY new_val
END MAIN
```

The NCHAR / NVARCHAR data types

IBM® Informix® supports the standard NCHAR and NVARCHAR data types. These types are equivalent to CHAR and VARCHAR (the same character set is used), except that the collation order is locale specific with NCHAR/NVARCHAR types.

With Genero BDL, you can handle character strings of NCHAR/NVARCHAR database columns by using program variables defined with the CHAR/VARCHAR types. Since the character set is identical for NCHAR/NVARCHAR and CHAR/VARCHAR, not specific consideration needs to be given for the "N" character types.

When extracting a database schema with fgldbsch, NCHAR/NVARCHAR types will be identified in the .sch file by the native Informix® type codes 15 and 16. When compiling .4gl or .per sources referencing NCHAR/NVARCHAR columns in the schema file, the compilers will automatically use the CHAR and VARCHAR Genero BDL types for the type codes 15 and 16.

However, Genero BDL is missing full support of NCHAR and NVARCHAR types as it is not possible to declare program variables directly with the NCHAR / NVARCHAR keywords. Further, sorting features of Genero should follow the same collation order as the IBM® Informix® database when using "N" character types.

Enhancement reference: 20004

The LVARCHAR data type

IBM® Informix® supports the LVARCHAR type as a "large" VARCHAR type. The LVARCHAR type was introduced to bypass the 255 bytes size limitation of the standard VARCHAR type. Starting with IDS version 9.4, the LVARCHAR size limit is 32739 bytes. In older versions the limit was 2048 bytes.

Genero BDL does not support the LVARCHAR type natively, but it has the VARCHAR type which can hold up to 65535 bytes. IBM® Informix® LVARCHAR values can be inserted or fetched by using the BDL VARCHAR type.

Static SQL statements such as CREATE TABLE can include the LVARCHAR column type.

When extracting a schema with fgldbsch, LVARCHAR(N) columns will by default be converted to VARCHAR2(N) in the schema file. VARCHAR2 is a Genero BDL-only pseudo type identified with the type code 201, and allows define VARCHAR variables with a size that can be greater than 255 bytes.

Enhancement reference: 3464

DISTINCT data types

IBM® Informix® supports DISTINCT data types as User Defined Types based on a source data type, but with different casts and functions than those on the source data type.

Genero BDL partially supports the IBM® Informix® DISTINCT data types:

The fgldbsch schema extractor can extract columns defined with a distinct type and write the distinct type code in the .sch schema file. For more details, see the list of distinct types in the Column Definition File (.sch) on page 358

However, there are some restrictions you must be aware of:

- It is not possible to define BDL variables explicitly with the name of a distinct type. Variables must be defined indirectly with the schema by using the DEFINE LIKE statement.
- The static SQL syntax does not support OPAQUE-related syntax elements:
  - The DDL statements CREATE DISTINCT TYPE, DROP TYPE, CREATE CAST, and DROP CAST are not allowed,
  - In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  - The :: cast operator is not supported.

Enhancement reference: 20003

Stored Procedures

With IBM® Informix® database servers, you can write stored procedures with the SPL (Stored Procedure Language) or with an external language in C or JAVA.

If you plan to support different types of database servers, you must be aware that each DB vendor has defined its own stored procedure language. In such cases, you may consider writing most of your business logic in BDL, and implementing only some stored procedures in the database, mainly to get better performance or to use database features that only exist with stored procedures.

Genero BDL partially supports SP creation, but has full support of SP invocation:

- The Genero BDL static SQL syntax does not include CREATE FUNCTION and CREATE PROCEDURE with a body block. However, you can create stored procedures with an body block by using dynamic SQL (EXECUTE IMMEDIATE), or with CREATE PROCEDURE and the FROM *filename* clause, which is supported by Genero BDL static SQL.
- The EXECUTE FUNCTION or EXECUTE PROCEDURE instruction is not allowed in the static SQL syntax. To invoke a stored procedure with Informix®, you must use the PREPARE instruction, followed by EXECUTE or OPEN. The PREPARE instruction must initiate the EXECUTE FUNCTION/ PROCEDURE instruction.

For more details about stored procedure invocation, see SQL Programming.

Database Triggers

Triggers can be created for IBM® Informix® database tables with the CREATE TRIGGER instruction.

If you plan to support different types of database servers, you must be aware that each DB vendor has defined its own trigger creation syntax and stored procedure language. In such cases, you may consider writing most your business logic in BDL, and implementing only some triggers in the database, mainly to get better performance or use database features that only exist with stored procedures.

Genero BDL partially supports trigger creation:

- The Genero BDL static SQL syntax does not include the CREATE TRIGGER and DROP TRIGGER instructions. However, you can create database triggers by using dynamic SQL (EXECUTE IMMEDIATE).

Optimizer directives

IBM® Informix® SQL allows you to specify query optimization directives to force the query optimizer to use a different path than the implicit plan. With IBM® Informix®, optimizer directives are specified with the following SQL comment markers followed by a plus sign:

```
/*+ optimizer-directives */
{+  optimizer-directives }
--+ optimizer-directives
```

Genero BDL partially supports optimizer directives:

- The static SQL syntax does not allow the C-style optimizer syntax.
- The curly-brace and dash-dash optimizer directive syntaxes cannot be used in static SQL statements, because these correspond to the 4GL language comments.
- However, you can execute queries with optimization directives with Dynamic SQL.

  Tip: Optimization directives are not portable. If you plan to use different types of database servers, you should avoid the usage of query plan hints.

XML publishing support

IBM® Informix® IDS 11.10 introduced a set of XML built-in functions when the **idsxmlvp** virtual processor is turned on. Built-in XML functions are of two types: Those returning LVARCHAR values, and those returning CLOB values. For example, *genxml()* returns an LVARCHAR(32739), while *genxmlclob()* returns a CLOB. XML data is typically stored in LVARCHAR or CLOB columns.

Genero BDL partially supports XML functions:

- Because Genero BDL does not support BLOB/CLOB types, functions returning CLOB values cannot be used. You can however use the XML functions returning LVARCHAR values, and fetch the result into a VARCHAR variable of the appropriate size.
- Some of the XML functions such as genxml() take ROW() values as parameters. Because literal unnamed ROW() expressions are like regular function calls, you can use XML functions in static SQL statements.

Example:

```
FUNCTION get_cust_data(id)
   DEFINE id INT, v VARCHAR(5000)
   SELECT genxml(ROW(cust_name, cust_address), "custdata") INTO v
      FROM customers WHERE cust_id = id
   RETURN v
END FUNCTION
```

DataBlade® modules

IBM® Informix® IDS provides several database extensions implemented with the DataBlade® Application Programming Interface, such as MQ Messaging, Large OBjects management, Text Search DataBlades, Spatial DataBlade® Module, etc.

Genero BDL partially supports DataBlade® modules:

- DataBlade® extensions are based on User Defined Functions and User Defined Types. It is not possible to define program variables with specific User Defined Types. For example, you cannot define a program variable with the ST_Point type implemented by the Spatial DataBlade® module.
- The static SQL grammar does not support DataBlade® specific syntax. For example, it is not possible to create a Basic Text Search index with the USING bts clause of the CREATE INDEX statement.

However, as long as the syntax of the DataBlade® functions follows basic SQL expressions, it can be used in static SQL statements. For example, the next query uses the bts_contains() function of the Basic Text Search extension:

```
SELECT id FROM products WHERE bts_contains( brands, 'standard' )
```

You can also use Dynamic SQL to perform queries with a syntax that is not allowed in the static SQL grammar.

Specific CREATE INDEX clauses

In addition to the standard index-key specification using a column list, the CREATE INDEX statement supported by IBM® Informix® SQL allows specific clauses, for example to define storage options.

Genero BDL partially supports the CREATE INDEX statement; the following are not supported in static SQL grammar:

- The IF NOT EXISTS clause.
- Functional index specification is now allowed in the index-key list.
- Storage options such as IN *dbspace*, EXTEND SIZE, NEXT SIZE.
- The index mode clauses such as FILTERING WITH/WITHOUT ERROR.
- The USING clause.
- The HASH ON clause.
- The FILLFACTOR clause.

You can use Dynamic SQL to execute CREATE INDEX statements with clauses that are not allowed in the static SQL grammar.

Other SQL instructions

Genero BDL static SQL syntax implements common Data Manipulation Statements such as SELECT, INSERT, UPDATE and DELETE. Data Definition Language statements such as CREATE TABLE, CREATE INDEX, CREATE SEQUENCE and their corresponding ALTER and DROP statements are also part of the static SQL grammar. These are supported with a syntax limited to the standard SQL clauses. For example, Genero BDL might not support the most recent CREATE TABLE storage options supported by IBM® Informix® SQL.

Since the first days of the 4GL language the SQL language has been extended, and it has become so large that it's impossible to embed all the existing new statements without introducing grammar conflicts with the 4GL language. In addition, each DB vendor has improved the standard SQL language with proprietary SQL statements that are not portable; it would not be a good idea to use these specific instructions if you plan to make your application run with different types of database engines.

However, the Genero BDL static SQL is constantly improved with standard SQL syntax that works with most types of database servers. For example, Genero BDL supports the ANSI outer join syntax, constraints definition in DDL statements, sequence instructions, BIGINT and BOOLEAN data types, and there is more to come.

If a statement is unsupported in static SQL, that does not mean that you cannot execute it. If you want to execute an SQL instruction that is not part of the static SQL grammar, you can use Dynamic SQL as follows:

- Use PREPARE + EXECUTE for statements that do not generated a result set
- Use (PREPARE/) DECLARE + OPEN for statements returning a result set
- Use EXECUTE IMMEDIATE if no SQL parameters are required and no result set is generated

Dynamic SQL instructions take a string as the input, so there is no limitation regarding the SQL text you can execute; however, only one statement can be executed at a time. It is better, however, to write your SQL statements directly in static SQL when possible, because it makes the code more readable and the syntax is checked at compiled time.

For more details about statements supported in the static SQL syntax, see Static SQL.

Below is a list of the IBM® Informix® SQL statements that are not allowed in the static SQL syntax (last updated from IDS **11.50** SQL instructions). The IBM® Informix® SQL Syntax manual includes ESQL/C specific statements such as ALLOCATE DESCRIPTOR, which are not part of the basic SQL statements supported by the engines. ESQL/C specific statements are not listed here:

```
ALTER ACCESS_METHOD
ALTER FRAGMENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER ROUTINE
ALTER SECURITY LABEL COMPONENT
CREATE ACCESS_METHOD
CREATE AGGREGATE
CREATE CAST
CREATE DISTINCT TYPE
CREATE EXTERNAL TABLE Statement
CREATE FUNCTION (with body)
CREATE OPAQUE TYPE

Unsupported IBM® Informix® SQL features
Unsupported IBM® Informix® SQL features.
CLOB and BLOB data types

In addition to the TEXT and BYTE data types (known as Simple Large Objects), IBM® Informix® servers support the CLOB and BLOB types to store large objects. CLOB/BLOB are known as Smart Large Objects. The main difference is that Smart Large Objects support random access to the data - seek, read and write through the LOB as if it was a OS file.

Genero BDL does not support the CLOB and BLOB types:

- It is not possible to define BDL variables with the CLOB or BLOB types, so you cannot manipulate CLOB/BLOB objects within programs.
- Defining a TEXT / BYTE variable to hold CLOB / BLOB column data is not supported; you will get error -609 (Illegal attempt to use a Text/Byte host variable).
- The static SQL syntax for DDL statements like CREATE TABLE does not allow the CLOB / BLOB keywords for column types.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a CLOB or BLOB column.

You can, however:

- Create a table with CLOB/BLOB columns by using Dynamic SQL.
- Use the Smart Large Object functions FILETOBLOB(), FILETOCLOB(), LOCOPY(), LOTOFILE() in static SQL statements.

Enhancement reference: 476

The LIST data type

In IBM® Informix® databases, the LIST type is a collection type that can store ordered elements of a specific base type. Unlike the MULTISET type, the elements of a LIST have ordinal positions. Elements can be duplicated.

Genero BDL does not support the IBM® Informix® LIST data type.

- It is not possible to define BDL variables with the LIST type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the LIST keyword for column types,
  - The collection-derived notation `TABLE( )` is not allowed,
  - The `INSERT AT` *`position`* instruction is not supported,
  - The `LIST { }` literal syntax is not allowed.
  - The *`value`* `IN` *`identifier`* syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a LIST column.

The MULTISET data type

The MULTISET IBM® Informix® data type is a collection type that can store non-ordered elements of a specific base type. Unlike the LIST type, the elements of a MULTISET have no ordinal positions. Elements can be duplicated.

Genero BDL does not support the IBM® Informix® MULTISET data type:

- It is not possible to define BDL variables with the MULTISET type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the MULTISET keyword for column types,
  - The collection-derived notation `TABLE( )` is not allowed,
  - The `MULTISET { }` literal syntax is not allowed.
  - The *`value`* `IN` *`identifier`* syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a MULTISET column.

The SET data type

The SET IBM® Informix® data type is a collection type that stores non-ordered unique elements of a specific base type. Unlike the LIST type, the elements of a LIST have no ordinal positions. Elements cannot be duplicated.

Genero BDL does not support the IBM® Informix® SET data type:

- It is not possible to define BDL variables with the SET type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the SET keyword for column types,
  - The collection-derived notation `TABLE( )` is not allowed,
  - The `SET { }` literal syntax is not allowed.
  - The *`value`* `IN` *`identifier`* syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a SET column.

The ROW data types

IBM® Informix® supports the named and unnamed ROW data types. A ROW type is a complex type that combines several table columns. You create a ROW type with the CREATE ROW TYPE instruction, and then you can reuse the type definition for a table column.

Genero BDL does not support the IBM® Informix® ROW data types:

- It is not possible to define BDL variables with a named ROW type. The equivalent would be a RECORD variable, but data is not mapped directly from a structured ROW column, you must list individual fields of the ROW column.
- The static SQL syntax does not support ROW-related syntax elements:
  - The DDL statements CREATE ROW TYPE, DROP ROW TYPE, CREATE CAST and DROP CAST are not allowed,
  - In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  - The :: cast operator is not supported when specifying a ROW() literal. However, the CAST() expressions are allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a column defined with a ROW type.

However:

- Static SQL allows multilevel single-dot notation, so you can, for example, identify a ROW field as *employee.address.city*.
- Dynamic SQL can be used to insert or update rows with ROW type columns.

- Individual ROW column fields can be fetched to BDL program variables, as long as the basic types match.

Enhancement reference: 19159

OPAQUE data types

Opaque User Defined Types can be implemented in IBM® Informix® with the CREATE OPAQUE TYPE statement. The storage structure of an OPAQUE type is unknown to the database server, data can only be accessed through user-defined routines.

Genero BDL does not support the IBM® Informix® OPAQUE data types:

- It is not possible to define BDL variables with an opaque type.
- The static SQL syntax does not support OPAQUE-related syntax elements:
  - The DDL statements CREATE OPAQUE TYPE, DROP TYPE, CREATE CAST and DROP CAST are not allowed,
  - In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  - The :: cast operator is not supported. However, the CAST() expressions are allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a column defined with a OPAQUE type.

The :: cast operator

IBM® Informix® SQL implements the :: cast operator and the CAST() expressions to do an explicit cast of a value:

```
CREATE TABLE tab ( v INTEGER )
INSERT INTO tab VALUES ( 123456::INTEGER )
SELECT 'abcdef'::CHAR(20)||'.' FROM tab
SELECT CAST('abcdef' AS CHAR(20))||'.' FROM tab
```

Genero BDL does not support the :: cast operator in the static SQL grammar. However, the CAST() expressions are allowed. If you need to use the :: cast operator, you must use Dynamic SQL to perform such queries.

Enhancement reference: 19190

Table inheritance

IBM® Informix® SQL allows you to define a table hierarchy through named row types. Table inheritance allows a table to inherit the properties of the supertable in the meaning of constraints, storage options, triggers. You must first create the types with CREATE ROW TYPE, then you can create the tables with the UNDER keyword to define the hierarchy relationship.

```
CREATE ROW TYPE person_t ( name VARCHAR(50) NOT NULL,
 address VARCHAR(200), birthdate DATE )
CREATE ROW TYPE employee_t ( salary INTEGER, manager VARCHAR(50) )
CREATE TABLE person OF TYPE person_t
CREATE TABLE employee OF TYPE employee_t UNDER person
```

A table hierarchy allows you to do SQL queries whose row scope is the supertable and its subtables. For example, after inserting one row in the person table and another one in the employee table, if you UPDATE the name column without a WHERE clause, it will update all rows from both tables. To limit the set of rows affected by the statement to rows of the supertable, you must use the ONLY keyword:

```
UPDATE ONLY(person) SET birthdate = NULL
SELECT * FROM ONLY(person)
```

Genero BDL static SQL grammar does not include the syntax elements related to table hierarchy management. You can however use Dynamic SQL to perform such queries.

SQL adaptation guide for IBM® DB2® UDB 10.x

Installation (Runtime Configuration)
IBM® DB2® related installation topics.
Install DB2® and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the IBM® DB2® Universal Server on your database server.
2. Create a DB2® database entity: *dbname*

   To create the database entity in DB2, use the graphical tool provided by IBM® called "DB2 Data Studio", or from the command line, use the `db2` command interpreter in a DB2 operating system user session (db2inst). Consider creating your database with the correct database locale (codeset and territory), for example:

   ```
   $ db2
   ...
   db2 => CREATE DATABASE dbname
            AUTOMATIC STORAGE YES
            USING CODESET UTF-8 TERRITORY EN_US
   DB20000I  The CREATE DATABASE command completed successfully.
   ```
3. Connect to the new created database with the DB2 administrator user.

   Open a database connect in the DB2 Data Studio, or use the `db2` command interpreter as in the following example:

   ```
   db2 => connect to dbname

      Database Connection Information

    Database server        = DB2/LINUX 10.1.0
    SQL authorization ID   = DB2INST
    Local database alias   = dbname
   ```
4. Declare a database user dedicated to your application: the application administrator. This user will manage the database schema of the application (all tables will be owned by it).

   Create the user with the DB2 Data Studio, or use the `db2` command interpreter as follows:

   ```
   db2 => GRANT CONNECT ON DATABASE TO USER appadmin
   DB20000I  The SQL command completed successfully.
   ```
5. Give all requested database administrator privileges to the application administrator.

   Grant the privileges to the new created user in the DB2 Data Studio, or use the `db2` command interpreter as follows:

   ```
   db2 => GRANT CREATETAB ON DATABASE TO USER appadmin
   DB20000I  The SQL command completed successfully.
   ```
6. If you plan to use temporary table emulation, you must setup the database for DB2® global temporary tables (create a user temporary tablespace and grant privileges to all users).

   See Temporary tables on page 560.
7. Connect as the application administrator:

   Open a new database connect in the DB2 Data Studio, or use the `db2` command interpreter as follows:

   ```
   db2 => connect to dbname user appadmin using password
   ```

```
  Database Connection Information

Database server        = DB2/LINUX 10.1.0
SQL authorization ID   = DB2INST
Local database alias   = dbname
```

8. Create the application tables with `CREATE TABLE` statements.

   Convert Informix® data types to DB2® data types. See issue Data Type Conversion Table for more details.

9. If you plan to use SERIAL column emulation, you must prepare the database.

   See SERIAL data types on page 551.

Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® DB2®, you must have the database driver "`dbmdb2`" in `FGLDIR/dbdrivers`.
2. If you want to connect to a remote DB2® server, the "IBM® DB2® Client Application Enabler" must be installed and configured on the computer running the BDL applications.

   You must declare the data source set up as follows:

   a) Login as root.

      1. Create a user dedicated to the db2 client instance environment, for example, "db2cli1".
      2. Create a client instance environment with the `db2icrt` tool as in following example:

         ```
         # db2dir /instance/db2icrt -a server -s client instance-user
         ```

   b) Login as the instance user (environment should be set automatically, verify DB2DIR).

      1. Catalog the remote server node:

         ```
         # db2 "catalog tcpip node db2node remote hostname server tcp-service"
         ```

      2. Catalog the remote database:

         ```
         # db2 "catalog database datasource at node db2node authentication
          server"
         ```

      3. Test the connection to the remote database:

         ```
         # db2 "connect to datasource user dbuser using password"
         ```

         (where *dbuser* is a database user declared on the remote database server)

   See IBM® DB2® documentation for more details.

3. **Important:** If you have a non-English environment, you may need to set the `PATCH2=15` configuration parameter in the `DB2CLI.INI` file to ensure that DECIMAL values will be properly inserted or fetched:

   ```
   [datasource]
   PATCH2=15
   ```

   For more details, see the DB2® README.TXT file in the SQLLIB directory.

4. Make sure that the DB2® client environment variables are properly set.

   Check variables such as DB2DIR (the path to the installation directory), DB2INSTANCE (the name of the DB2® instance), INSTHOME (the path to the home directory of the instance owner). On UNIX™, you will find environment settings in the file `$INSTHOME/sqllib/db2profile`. See IBM® DB2® documentation for more details.

5. Check the database client locale settings (DB2CODEPAGE, etc).

The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

6. Verify the environment variable defining the search path for DB2 CLI database client shared libraries (libdb2.so on UNIX™, DB2CLI.DLL on Windows™).

Table 161: Shared library environment setting for DB2® UDB version

DB2® UDB version	Shared library environment setting
DB2® UDB 9.x and higher	*UNIX*™: Add $DB2DIR/lib32 (for 32 bit) or $DB2DIR/lib64 (for 64 bit) to LD_LIBRARY_PATH (or its equivalent). *Windows*™: Add %DB2DIR%\bin to PATH.

7. To verify if the DB2® client environment is correct, you can, for example, start the db2 command interpreter and connect to the server:

```
$ db2
db2 => CONNECT TO dbname USER username USING password
```

8. Setup the **fglprofile** entries for database connections.
   a) Define the IBM DB2 database driver:

```
dbi.database.dbname.driver = "dbmdb2"
```

   b) The "source" parameter defines the name of the IBM DB2 database name.

```
dbi.database.dbname.source = "test1"
```

   c) Define the database schema selection if needed:

   Use the following entry to define the database schema to be used by the application. The database interface will automatically perform a SET SCHEMA *name* instruction to switch to a specific schema:

```
dbi.database.dbname.db2.schema = 'name'
```

   Here *dbname* identifies the database name used in the BDL program (DATABASE *dbname*) and *name* is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no "SET SCHEMA" instruction is executed and the current schema defaults to the user's name.

Database concepts
IBM® DB2® related database concept topics.
Database concepts

As with Informix®, an IBM® DB2® database server can handle more than one database entity. Informix® servers have an ID (INFORMIXSERVER) and databases are identified by name. IBM® DB2® instances are identified by the DB2INSTANCE environment variable and databases have to be cataloged as data sources (see IBM® DB2® documentation for more details).

Data storage concepts

An attempt should be made to preserve as much of the storage information as possible when converting from Informix® to IBM® DB2®. Most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be reused for the IBM® DB2® database.

Storage concepts are quite similar in Informix® and in IBM® DB2®, but the names are different.

These tables compares Informix® storage concepts to IBM® DB2® storage concepts:

Table 162: Physical units of storage (Informix® vs. DB2®)

Informix®	IBM® DB2®
The largest unit of physical disk space is a "**chunk**", which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (=UNIX partition, I/O is controlled by the database engine). A "dbspace" uses at least one "chunk" for storage. You must add "chunks" to "dbspaces" in order to increase the size of the logical unit of storage.	One or more "**containers**" are created for each "tablespace" to physically store the data of all logical structures. Like Informix® "chunks", "containers" can be an OS file or a raw device. You can add "containers" to a "tablespace" in order to increase the size of the logical unit of storage or you can define EXTEND options.
A "**page**" is the smallest physical unit of disk storage that the engine uses to read from and write to databases. A "chunk" contains a certain number of "pages". The size of a "page" must be equal to the operating system's block size.	At the finest level of granularity, IBM® DB2® stores data in "**data blocks**" with size corresponding to a multiple of the operating system's block size. You set the "data block" size when creating the database.
An "**extent**" consists of a collection of contiguous "pages" that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, "extents" can be located in different "chunks" of the same "dbspace".	An "**extent**" is a specific number of contiguous "data blocks", obtained in a single allocation. When creating a table, you can specify the first extent size and the size of future extents with the STORAGE() option. For a single table, "extents" can be located in different "data files" of the same "tablespace".

Table 163: Logical units of storage (Informix® vs. DB2®)

Informix®	IBM® DB2®
A "**table**" is a logical unit of storage that contains rows of data values.	Same concept as Informix®.
A "**database**" is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges.	Same concept as Informix®. An IBM® DB2® instance can manage several databases.
Database tables are created in a specific "**dbspace**", which defines a logical place to store data. If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.	Database tables are created in a specific "**tablespace**", which defines a logical place to store data. The main difference with Informix® "dbspaces", is that IBM® DB2® tablespaces belong to a "database", while Informix® "dbspaces" are external to a database.

Table 164: Other storage concepts (Informix® vs. DB2®)

Informix®	IBM® DB2®
When initializing an Informix® engine, a "**root dbspace**" is created to store information about all databases, including storage information (chunks used, other dbspaces, etc.).	Each IBM® DB2® database uses a set of "**control files**" to store internal information. These files are located in a dedicated directory: ".../$DB2INSTANCE/NODEnnnn"
The "**physical log**" is a set of continuous disk pages where the engine stores "before-images" of data that has been modified during processing. The "**logical log**" is a set of "**logical-log files**" used to record logical operations during on-line processing. All transaction information is stored in the logical log files if a database has been created with transaction log. Informix® combines "physical log" and "logical log" information when doing fast recovery. Saved "logical logs" can be used to restore a database from tape.	DB2® uses "**database log files**" to record SQL transactions.

Data consistency and concurrency

Data consistency involves readers that want to access data currently modified by writers and *concurrency data access* involves several writers accessing the same data for modification. *Locking granularity* defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to manage data consistency and concurrency. When a process modifies data with UPDATE, INSERT or DELETE, an exclusive lock is set on the affected rows. The lock is held until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks according the isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:

- Isolation level: SET ISOLATION TO ...
- Lock wait mode: SET LOCK MODE TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit locking: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is **read committed**.
- The default lock wait mode is "not wait".
- The default locking granularity is on per page.

IBM® DB2®

As in Informix®, IBM® DB2® uses locks to manage data consistency and concurrency. The database manager sets exclusive locks on the modified rows and shared locks when data is read, according to the isolation level. The locks are held until the end of the transaction. When multiple processes want to access the same data, the latest processes must wait until the first finishes its transaction. The lock granularity is at the row or table level. For more details, see DB2's Administration Guide, "Application Consideration".

Control:

- Lock wait mode: Always WAIT. Only the Lock Timeout can be changed, but this is a global database parameter.
- Isolation level: Can be set through an API function call or with a database client configuration parameter.
- Locking granularity: Row level or Table level.
- Explicit locking: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is Cursor Stability (readers cannot see uncommitted data, no shared lock is set when reading data).

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by an ODBC API call setting the SQL_ATTR_TXN_ISOLATION connection attribute. The next table shows the isolation level mappings done by the database driver:

Table 165: Isolation level mappings done by the IBM® DB2® UDB database driver

SET ISOLATION instruction in program	ODBC SQL_ATTR_TXN_ISOLATION connection attribute
SET ISOLATION TO DIRTY READ	SQL_TXN_READ_UNCOMMITTED
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	SQL_TXN_READ_COMMITTED
SET ISOLATION TO CURSOR STABILITY	SQL_TXN_REPEATABLE_READ
SET ISOLATION TO REPEATABLE READ	SQL_TXN_SERIALIZABLE

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

See Informix® and IBM® DB2® documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and IBM® DB2® handle transactions differently. The differences in the transactional models can affect the program logic.

- Informix® native mode (non ANSI):
  - DDL statements can be executed (and canceled) in transactions.
  - Transactions must be started with `BEGIN WORK`. Statements executed outside of a transaction are automatically committed.
- IBM® DB2®:
  - DDL statements can be executed (and canceled) in transactions.
  - Beginning of transactions are implicit; two transactions are delimited by `COMMIT` or `ROLLBACK`.

Transactions in stored procedures:

Avoid using transactions in stored procedures to allow the client applications to handle transactions, in accordance with the transaction model.

Savepoints:

- Informix® version 11.50 introduces **savepoints** with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

- IBM® DB2® supports **savepoints** too. However, there are differences:

1. Savepoints must be declared with the `ON ROLLBACK RETAIN CURSORS` clause
2. Rollback must always specify the savepoint name

Solution

The Informix® behavior is simulated with an autocommit mode in the IBM® DB2® interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with IBM® DB2®.

> **Note:** If you want to use savepoints, always specify the savepoint name in `ROLLBACK TO SAVEPOINT`.

See also SELECT FOR UPDATE

Database users

Until version 11.70.xC2, Informix® database users had to be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

IBM® DB2® users are operating system users with a specific DB2® environment. The database administrator must grant the CONNECT authority to these users.

- Database *authorities* involve actions on a database as a whole. When a database is created, some authorities are automatically granted to anyone who accesses the database. For example, CONNECT, CREATETAB, BINDADD and IMPLICIT_SCHEMA authorities are granted to all users.
- Database *privileges* involve actions on specific objects within the database. When a database is created, some privileges are automatically granted to anyone who accesses the database. For example, SELECT privilege is granted on catalog views and EXECUTE and BIND privilege on each successfully bound utility is granted to all users.

Together, privileges and authorities act to control access to an instance and its database objects. Users can access only those objects for which they have the appropriate authorization, that is, the required privilege or authority.

> **Note:** As in Informix®, DB2® user names that connect to the database server must be a maximum of **eight** characters long.

Solution

Set up the IBM® DB2® environment for each user as described in the documentation.

Setting privileges

Informix® and IBM® DB2® user privileges management is quite similar.

- IBM® DB2® provides user groups to define.
- IBM® DB2® users must have at least the CONNECT authority to access the database.

  `GRANT CONNECT ON DATABASE TO (PUBLIC|user|group)`
- Informix® users must have at least the CONNECT privilege to access the database:

  `GRANT CONNECT TO (PUBLIC|user)`

Solution

Make sure DB2® users have the right privileges to access the database.

See also Temporary Tables

Data dictionary
IBM® DB2® related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way: As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

IBM® DB2® 9.x does not implement a BOOLEAN SQL type.

Solution

The DB2® database interface converts BOOLEAN type to CHAR(1) columns and stores '1' or '0' values in the column.

CHARACTER data types

Informix® supports the following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

IBM® DB2® implements the following character data types:

- CHAR(N) with N<= 254 bytes
- VARCHAR(N) with N <= 32672 bytes
- GRAPHIC(N) with N <= 127 characters
- VARGRAPHIC(N) with N <=16336 characters

Like Informix®, IBM® DB2® uses Byte Length Semantics to define the length of CHAR/VARCHAR columns. However, GRAPHIC and VARGRAPHIC lengths are specified in characters (i.e. max number of double-byte characters).

The character set used by DB2® to store CHAR and VARCHAR data is defined in the database locale section when creating a new database. If your application uses UTF-8, consider creating the DB2 database with the UTF-8 codeset.

DB2® can automatically convert from/to the client and server characters sets. In the client applications, you define the character set with the DB2CODEPAGE profile variable.

Solution

Informix® CHAR(N) types must be mapped to DB2® CHAR(N) types, and Informix® VARCHAR(N) or LVARCHAR(N) columns must be mapped to DB2® VARCHAR(N).

Important:

- DB2® does not support NCHAR/NVARCHAR types. If your programs create tables with these types, you must review your code. The DB2® driver does not automatically convert the NCHAR/NVARCHAR Informix® types to GRAPHIC/VARGRAPHIC, because the meaning of the length is different.
- Check that your database schema does not use CHAR or VARCHAR types with a length exceeding the DB2® limits. Especially, the Informix® CHAR type has a very long size limit compared to DB2® CHAR.

When using a multibyte character set (such as UTF-8), if the DB2 database was created with the appropriate codeset (UTF-8), you can use the CHAR/VARCHAR columns, and user byte length semantics in programs. If the database code set is non multi-byte, you must use the GRAPHIC and VARGRAPHIC data types to store multi-byte character data, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a DB2® database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in DB2® database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

NUMERIC data types

Informix® provides the following data types to store numbers:

Table 166: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)
DEC(p) / DECIMAL(p)	Floating-point decimal number
DEC(p,s) / DECIMAL(p,s)	Fixed-point decimal number
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

Most data types supported by IBM® DB2® UDB are compatible to Informix® data types. DB2® V 9.1 introduces the DECFLOAT(16) and DECFLOAT(34) floating point decimal types to store large decimals. The next table lists the Informix® types and DB2® equivalents.

Table 167: Informix® numeric data types and DB2® equivalents

Informix® data type	IBM® DB2® equivalent
INT8	Use BIGINT instead
DECIMAL(p)	With DB2® **V9.1**, DECIMAL(p<=16) can be stored in DECFLOAT(16) and DECIMAL(p>16) can be stored in DECFLOAT(34). With older versions of DB2®, we can use DECIMAL(p*2,p), but with a limitation of 15 for the original Informix® DECIMAL precision.
DECIMAL(32,s)	DB2® decimals maximum precision is 31 digits!
MONEY	DECIMAL(16,2)
MONEY(p)	DECIMAL(p,2)
MONEY(p,s)	DECIMAL(p,s)
SMALLFLOAT	REAL
FLOAT[(n)]	FLOAT[(n)] (DOUBLE)

Solution

SQL scripts to create databases must be converted manually. Tables created from BDL programs do not have to be converted; the database interface detects the MONEY data type and uses the DECIMAL type for DB2®.

The maximum precision for DB2® decimals is 31 digits, while Informix® supports 32 digits.

- When using DB2® V8 and prior:

  There is no DB2® equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use DB2® compatible types. To workaround the DB2® limitation, the DB2® database drivers convert DECIMAL(p) types to a DECIMAL(2*p, p), to store all possible numbers an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 15 ((2*15) = 30), since DB2® maximum DECIMAL precision is 31. If the original precision is bigger than 15, a CREATE TABLE statement executed from a Genero program will fail with a DB2® SQLSTATE 42611.
- When using DB2® V9.1 and higher:

  The DECIMAL(p) data type is converted to DECFLOAT(16) (for p<=16) or DECFLOAT(34) (for p>16) to store floating point decimals. If you create tables with DECFLOAT columns, you will lose the original DECIMAL precision when extracting the schema with fgldbsch, because IBM® DB2® supports only two precision specifications (16 or 34). Note also the DECFLOAT(34) will be extracted as DECIMAL(32), since the Genero DECIMAL type has a maximum precision of 32 digits.

DATE and DATETIME data types

Informix® provides two data types to store date and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

IBM® DB2® provides following data type to store dates:

- DATE = for year, month, day storage.
- TIME = for hour, minute, second storage.

- TIMESTAMP = for year, month, day, hour, minute, second, fraction storage.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string content matches environment parameters (i.e. DBDATE, GL_DATETIME). As Informix®, IBM® DB2® can convert quoted strings to dates, times or timestamps. Only one format is possible: 'yyyy-mm-dd' for dates, 'hh:mm:ss' for times and'yyyy-mm-dd hh:mm:ss:f' for timestamps.

Date time arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used and an INTERVAL value if a DATETIME is used in the expression.
- In IBM® DB2®, the result of an arithmetic expression involving DATE values is a NUMBER of days, the decimal part is the fraction of the day (0.5 = 12H00, 2.00694444 = (2 + (10/1440)) = 2 days and 10 minutes)).
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. IBM® DB2® does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in IBM® DB2®.

Solution

DB2® has the same DATE data type as Informix® DATE columns.

DB2® TIME data type can be used to store Informix® DATETIME HOUR TO SECOND values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION(5) can be stored in DB2® TIMESTAMP columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the DB2® TIMESTAMP value will be "1900-01-01 11:45:00.0".

Important:

- Using integers as a number of days in an expression with dates is not supported by IBM® DB2®. Check your code to detect where you are using integers with DATE columns.
- Literal DATETIME and INTERVAL expressions (i.e. DATETIME (1999-10-12) YEAR TO DAY) are not converted.
- It is strongly recommended that you use BDL variables in dynamic SQL statements instead of quoted strings representing DATEs. For example:

  ```
  LET stmt = "SELECT ... FROM customer WHERE creat_date >'", adate,"'"
  ```

  is not portable, use a question mark place holder instead and OPEN the cursor USING adate:

  ```
  LET stmt = "SELECT ... FROM customer WHERE creat_date > ?"
  ```
- DATE arithmetic expressions using SQL parameters (USING variables) are not fully supported. For example:

  `"SELECT ... WHERE datecol < ? +1" generates an error at PREPARE time.`
- SQL Statements using expressions with TODAY / CURRENT / EXTEND must be reviewed and adapted to the native syntax.

INTERVAL data type

Informix® INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

DB2® does not provide a data type corresponding the Informix® INTERVAL data type.

Solution

The INTERVAL data type is not well supported because the database server has no equivalent native data type. However, BDL INTERVAL values can be stored into and retrieved from CHAR columns.

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a `SELECT dbinfo('bigserial')` query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERTs that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

IBM® DB2® version 7.1 supports IDENTITY columns:

```
CREATE TABLE tab ( k INTEGER GENERATED ALWAYS AS IDENTITY);
```

To get the last generated IDENTITY value after an INSERT, DB2® provides the following function:

```
IDENTITY_VAL_LOCAL()
```

IBM® DB2® version 8.1 supports SEQUENCES:

```
CREATE SEQUENCE sq1 START WITH 100;
```

To create a new sequence number, you must use the "NEXTVAL FOR" operator:

```
INSERT INTO table VALUES ( NEXTVAL FOR sq1, ... )
```

To get the last generated sequence number, you must use the "PREVVAL FOR" operator:

```
SELECT PREVVAL FOR sq1 ...
```

Solution

To emulate Informix® serials with IBM® DB2®, you can use IDENTITY columns (1), or insert triggers using sequences (2). The first solution is faster, but does not allow explicit serial value specification in insert statements; the second solution is slower but allows explicit serial value specification.

> **Important:** The trigger-based solution is provided to simplify the conversion from Informix, but is slower as the solution using identity columns. We strongly recommend that you use native IDENTITY columns instead to get best performances.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation = {"native"|"trigseq"}
```

- native: uses IDENTITY columns.
- trigseq: uses insert triggers with sequences.

The default emulation technique is "`native`".

This entry must be used in conjonction with:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial = {true|false}`

If the `datatype.serial` entry is set to false, the emulation method is ignored.

Using the `native` serial emulation

In database creation scripts, all SERIAL[(n)] data types must be converted by hand to:

```
INTEGER GENERATED ALWAYS AS IDENTITY[( START WITH n, INCREMENT BY 1)]
```

while the SERIAL8 and BIGSERIAL[(n)] types must be converted to:

```
BIGINT GENERATED ALWAYS AS IDENTITY[( START WITH n, INCREMENT BY 1)]
```

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to an IDENTITY specification.

In BDL, the new generated SERIAL value is available from the SQLCA.SQLERRD[2] variable. This is supported by the database interface which performs a call to the IDENTITY_VAL_LOCAL() function. However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must use the IDENTITY_VAL_LOCAL() function.

Since IBM® DB2® does not allow you to specify the value of IDENTITY columns, it is mandatory to convert all INSERT statements to remove the SERIAL column from the list. For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES (0, p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

must be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

Using the `trigseq` serial emulation

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, SERIAL8/BIGSERIAL must be converted to BIGINT, and you must create a sequence and a trigger for each table using a SERIAL. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native SQL commands to create the sequence and the trigger.

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the sequence and the insert trigger.

Note:

IBM® DB2® performs NOT NULL data controls before the execution of triggers. If the serial column must be NOT NULL (for example, because it is part of the primary key), you cannot specify a NULL value for that column in INSERT statements.

For example, the following statement:

```
INSERT INTO tab VALUES (NULL,p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Important:

- IBM® DB2® triggers are not automatically dropped when the corresponding table is dropped. They become ***inoperative*** instead. Database administrators must take care of this behavior when managing schemas.
- With IBM® DB2®, INSERT statements using NULL for the SERIAL column will produce a new serial value:

  ```
  INSERT INTO tab ( col_serial, col_data ) VALUES ( NULL, 'data' )
  ```

  This behavior is mandatory in order to support INSERT statements which do not use the serial column:

  ```
  INSERT INTO tab (col_data) VALUES ('data')
  ```

  Check if your application uses tables with a SERIAL column that can contain a NULL value.
- With DB2®, trigger creation is not allowed on temporary tables. Therefore, the "**trigseq**" method cannot work with temporary tables using serials.

ROWIDs

When creating a table, Informix® automatically adds a "ROWID" integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

IBM® DB2® ROWID columns were introduced in version 9.7. Unlike Informix® integer row ids, DB2® row ids are based on VARCHAR(16) FOR BIT DATA (128 bit integer) that are usually represented as a 32 char hexadecimal representation of the value. The IBM® DB2® ROWID is actually an alternative syntax for RID_BIT(), and a qualified reference to ROWID like *tablename*.ROWID is equivalent to RID_BIT(*tablename*).

For example: `x'070000000000000000000065CE770000'`

In DB2® SQL, to find a row with a rowid, you must specify the rowid value as an hexadecimal value:

```
SELECT * FROM customer WHERE ROWID = x'070000000000000000000065CE770000'
```

or convert the ROWID to an hexadecimal representation and then you can compare to a simple string:

```
SELECT * FROM customer WHERE HEX(ROWID) ='070000000000000000000065CE770000'
```

With Informix®, SQLCA.SQLERRD[6] contains the ROWID of the last INSERTed or UPDATEd row. This is not supported with DB2 because DB2 are not INTEGERs.

Solution

If the BDL application uses ROWIDs, the program logic should be reviewed in order to use the real primary keys (usually, serials which can be supported).

The DB2® database driver will convert the ROWID keyword to HEX(ROWID), so it can be used as a VARCHAR(32) with the hexadecimal representation of the BIT DATA. You need however to replace all INTEGER variable definitions by VARCHAR(32) or CHAR(32).

To emulate Informix® integer ROWIDs, you can also use the DB2® GENERATE_UNIQUE built-in function, or the IDENTITY attribute of the INTEGER or BIGINT data types.

All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last INSERTed or UPDATEd row when using the IBM® DB2® interface.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

IBM® DB2® supports the LONG VARCHAR/CLOB and BLOB/VARGRAPHIC/DBCLOB types for large objects storage

Solution

The DB2® database interface can convert BDL TEXT data to CLOB and BYTE data to BLOB. Note that DB2® CLOB and BLOB columns are created with a size of 500K, while Genero TEXT/BYTE program variables have a limit of 2 gigabytes; make sure that the large object data does not exceed this limit.

Constraints

Constraint naming syntax

Both Informix® and DB2® support primary key, unique, foreign key, default and check constraints. But the constraint naming syntax is different: DB2® expects the "CONSTRAINT" keyword **before** the constraint specification, and Informix® expects it **after** .

UNIQUE constraint example:

Table 168: UNIQUE constraint example (Informix® vs IBM® DB2®)

Informix®	**IBM® DB2®**

`CREATE TABLE emp (`
`  ...`
`  emp_code CHAR(10) UNIQUE`
`  CONSTRAINT pk_emp,`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  CONSTRAINT pk_emp UNIQUE,`
	`  ...`

Primary keys

Like Informix®, DB2® creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using "CREATE UNIQUE INDEX" to define unique constraints is obsolete (use primary keys or a secondary key instead).

> **Note:** DB2® primary key constraints do not allow NULLs; make sure your tables do not contain NULLs in the primary key columns.

Unique constraints

Like Informix®, DB2® creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

> **Note:** DB2® unique constraints do not allow NULLs; make sure your tables do not contain NULLs in the unique columns.

Foreign keys

Both Informix® and DB2® support the ON DELETE CASCADE option.

Check constraints

The check condition may be any valid expression that can be evaluated to TRUE or FALSE,including functions and literals. You must verify that the expression is not Informix-specific.

Null constraints

Informix® and DB2® support NOT NULL constraints, but Informix® does not allow you to give a name to "NOT NULL" constraints.

Solution

Constraint naming syntax: The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for DB2®.

Triggers

Informix® and IBM® DB2® provide triggers with similar features, but the trigger creation syntax and the programming languages are totally different.

Informix® triggers define which stored procedures must be called when a database event occurs (before | after insert | update | delete ...), while IBM® DB2® triggers can hold a procedural block.

IBM® DB2® provides specific syntax to define triggers. See documentation for more details.

Solution

Informix® triggers must be converted to IBM® DB2® triggers "by hand".

Stored procedures

Both Informix® and IBM® DB2® support stored procedures and user functions, but the programming languages are totally different.

Solution

Informix® stored procedures must be converted to IBM® DB2® "by hand".

See SQL Programming for more details about executing stored procedures with DB2®.

Name resolution of SQL objects

Case sensitivity in object names:

- Informix® database object names are not **case-sensitive** in non-ANSI databases.

```
CREATE TABLE Tab1 ( Key INT, Col1 CHAR(20) )
SELECT COL1 FROM TAB1
```

- IBM® DB2® database object names are case-sensitive. When a name is used without double quotes, it is automatically converted to uppercase letters. When using double quotes, the names are not converted:

```
CREATE TABLE tab1 ( Key INT, Col1 CHAR(20) )
-- Table name is "TAB1", column names are "KEY" and "COL1"
CREATE TABLE "Tab1" ( "Key" INT, "Col1" CHAR(20) )
-- Table name is "Tab1", column names are "Key" and "Col1"
```

The DB2® schema concept:

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement.

`SELECT ... FROM table-name WHERE ...`

In an IBM® DB2® database, tables always belong to a database **schema**. When executing a SQL statement, a schema name must be used as the high-order part of a two-part object name, unless the current schema corresponds to the table's schema.

The default (implicit) schema is the current user's name but it can be changed with the "SET SCHEMA" instruction.

Example: The table "TAB1" belongs to the schema "SCH1". User "MARK" (implicit schema is "MARK") wants to access "TAB1" in a SELECT statement:

```
SELECT ... FROM TAB1 WHERE ...
-- Error "MARK"."TAB1" is an undefined name. SQLSTATE=42704
SELECT ... FROM SCH1.TAB1 WHERE ...
-- OK.
SET SCHEMA SCH1
-- Changes the current schema to SCH1.
SELECT ... FROM TAB1 WHERE ...
-- OK.
```

> **Note:** When executing the "SET SCHEMA" instruction, the database interface does not use double quotes around the schema name (= name is converted to uppercase letters). Make sure that the schema name is created with uppercase letters in the database.

DB2® provides "**aliases**", but they cannot be used to make a database object name public because aliases belong to schemas also.

Solution

Case sensitivity in object names:

Avoid the usage of double quotes around the database object names. All names will be converted to uppercase letters.

The DB2® schema concept:

After a connection, the database interface can automatically execute a `SET SCHEMA name` instruction if the following FGLPROFILE entry is defined:

`dbi.database.dbname.db2.schema= "name"`

Here *dbname* identifies the database name used in the BDL program (DATABASE *dbname*) and *name* is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no "SET SCHEMA" instruction is executed and the current schema defaults to the user's name.

Examples:

```
dbi.database.stores.db2.schema= "STORES1"
dbi.database.accnts.db2.schema= "ACCSCH"
```

> **Note:** DB2® does not check the schema name when the SET SCHEMA instruction is executed. Setting a wrong schema name results in "undefined name" errors when performing subsequent SQL instructions like SELECT, UPDATE, INSERT.

In accordance with this automatic schema selection, you must create a DB2® schema for your application:

1. Connect as a user with the DBADM authority.
2. Create an administrator user dedicated to your application. For example, "STORESADM". Make sure this user has the IMPLICIT_SCHEMA privilege (this is the default in DB2®).
3. Connect as the application administrator "STORESADM" to create all database objects (tables, indexes, ...). In our example, a "STORESADM" schema will be created implicitly and all database objects will belong to this schema.

As a second option you can create a specific schema with the following SQL command:

```
CREATE SCHEMA "name" AUTHORIZATION "appadmin"
```

See the IBM® DB2® manuals for more details about schemas.

The ALTER TABLE instruction

Informix® and IBM® DB2® use different implementations of the ALTER TABLE instruction. For example:

- Informix® allows you to use multiple ADD clauses separated by commas. DB2® does not expect parentheses and the comma separator:

  Informix®:

  ```
  ALTER TABLE customer ADD(col1 INTEGER), ADD(col2 CHAR(20))
  ```

  IBM® DB2®:

  ```
  ALTER TABLE customer ADD col1 INTEGER ADD col2 CHAR(20)
  ```

- Depending on the values currently stored, Informix® can change the data type of a column, while DB2® only supports changing the size of CHAR and VARCHAR columns:

  Informix®:

  ```
  ALTER TABLE customer MODIFY ( col1 INTEGER )
  ```

  IBM® DB2®:

  ```
  ALTER TABLE customer ALTER COLUMN col1 SET data type VARCHAR(200)
  ```

Solution

No automatic conversion is done by the database interface. Read the SQL documentation and review the SQL scripts or the BDL programs in order to use the database server specific syntax for ALTER TABLE.

Data type conversion table: Informix to DB2

Table 169: Data type conversion table (Informix to DB2 UDB)

Informix® data types	**DB2® data types (V<9.1)**	**DB2® data types (V>=9.1)**
CHAR(n)	CHAR(n) (limit = 254c!)	CHAR(n) (limit = 254c!)
VARCHAR(n[,m])	VARCHAR(n) (limit = 32672c!)	VARCHAR(n) (limit = 32672c!)
LVARCHAR(n)	VARCHAR(n) (limit = 32672c!)	VARCHAR(n) (limit = 32672c!)
NCHAR(n)	N/A	N/A
NVARCHAR(n[,m])	N/A	N/A
BOOLEAN	CHAR(1)	CHAR(1)
SMALLINT	SMALLINT	SMALLINT
INT / INTEGER	INTEGER	INTEGER
BIGINT	BIGINT	BIGINT
INT8	BIGINT	BIGINT
SERIAL[(start)]	INTEGER (see note 1)	INTEGER (see note 1)
BIGSERIAL[(start)]	BIGINT (see note 1)	BIGINT (see note 1)
SERIAL8[(start)]	BIGINT (see note 1)	BIGINT (see note 1)

Informix® data types	**DB2® data types (V<9.1)**	**DB2® data types (V>=9.1)**
DOUBLE PRECISION / FLOAT[(n)]	FLOAT[(n)] / DOUBLE	FLOAT[(n)] / DOUBLE
REAL / SMALLFLOAT	REAL	REAL
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s) (limit = 31 digits)	DECIMAL(p,s) (limit = 31 digits)
NUMERIC / DEC / DECIMAL(p) with p<=15	DECIMAL(2*p,p)	DECFLOAT(16)
NUMERIC / DEC / DECIMAL(p) with p>15	N/A	DECFLOAT(16) if p=16, DECFLOAT(34) if p>16
NUMERIC / DEC / DECIMAL	N/A	DECFLOAT(34)
MONEY(p,s)	DECIMAL(p,s) (limit = 31 digits)	DECIMAL(p,s) (limit = 31 digits)
MONEY(p)	DECIMAL(p,2) (limit = 31 digits)	DECIMAL(p,2) (limit = 31 digits)
MONEY	DECIMAL(16,2)	DECIMAL(16,2)
DATE	DATE	DATE
DATETIME HOUR TO SECOND	TIME	TIME
DATETIME q1 TO q2 (different from above)	TIMESTAMP	TIMESTAMP
INTERVAL q1 TO q2	CHAR(50)	CHAR(50)
TEXT	CLOB(500K)	CLOB(500K)
BYTE	BLOB(500K)	BLOB(500K)

Notes:

1. For more details about serial emulation, see SERIAL data types on page 551.

Data manipulation
IBM® DB2® related data manipulation topics.
Reserved words

Even if IBM® DB2® allows SQL reserved keywords as SQL object names ("create table table (column int)"), you should take care in your existing database schema and check that you do not use DB2® SQL words. An example of a common word which is part of DB2® SQL grammar is '**alias** '.

Solution

See IBM® DB2® documentation for reserved keywords.

Outer joins

The original OUTER join syntax of Informix® is different from the IBM® DB2® outer join syntax:

- In Informix® SQL, outer tables are defined in the FROM clause with the **OUTER** keyword:

```
SELECT ... FROM cust, OUTER(order)
 WHERE cust.key = order.custno

SELECT ... FROM cust,OUTER(order,OUTER(item))
 WHERE cust.key = order.custno
    AND order.key = item.ordno
    AND order.accepted = 1
```

- IBM® DB2® supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
                     ON cust.key = order.custno

SELECT ...
  FROM cust LEFT OUTER JOIN order
                 LEFT OUTER JOIN item
                 ON order.key = item.ordno
              ON cust.key = order.custno
 WHERE order.accepted = 1
```

See the IBM® DB2® SQL reference for a complete description of the syntax.

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The IBM® DB2® interface can convert most Informix® OUTER specifications to IBM® DB2® outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item and the outer tables must figure from left to right in the order of outer levels. Example which does not work: "FROM OUTER(tab2), tab1".
2. The outer join in the WHERE clause must use the table name as prefix. Example: "WHERE tab1.col1 = tab2.col2".

Restrictions:

1. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: `"... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10"`
2. Statements composed by 2 or more SELECT instructions using OUTERs are not supported.

   Example: `"SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"`

   Note:

   - Table aliases are detected in OUTER expressions.

     `OUTER example with table alias: "OUTER( tab1 alias1)"`
   - In the outer join, *outer table.column-name* can be placed on both right or left sides of the equal sign.

     `OUTER join example with table on the left: "WHERE outertab.col1 = maintab.col2 "`
   - Table names detection is not case-sensitive.

     Example: `"SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2"`
   - Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and IBM® DB2® handle transactions differently. The differences in the transactional models can affect the program logic.

- Informix® native mode (non ANSI):
  - DDL statements can be executed (and canceled) in transactions.
  - Transactions must be started with `BEGIN WORK`. Statements executed outside of a transaction are automatically committed.
- IBM® DB2®:

- DDL statements can be executed (and canceled) in transactions.
- Beginning of transactions are implicit; two transactions are delimited by `COMMIT` or `ROLLBACK`.

Transactions in stored procedures:

Avoid using transactions in stored procedures to allow the client applications to handle transactions, in accordance with the transaction model.

Savepoints:

- Informix® version 11.50 introduces **savepoints** with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

- IBM® DB2® supports **savepoints** too. However, there are differences:

1. Savepoints must be declared with the `ON ROLLBACK RETAIN CURSORS` clause
2. Rollback must always specify the savepoint name

Solution

The Informix® behavior is simulated with an autocommit mode in the IBM® DB2® interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with IBM® DB2®.

> **Note:** If you want to use savepoints, always specify the savepoint name in `ROLLBACK TO SAVEPOINT`.

See also SELECT FOR UPDATE

Temporary tables

Informix® temporary tables are created through the `CREATE TEMP TABLE` DDL instruction or through a `SELECT ... INTO TEMP` statement. Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

> **Note:** BDL reports create a temporary table when the rows are not sorted externally (by the source SQL statement).

IBM® DB2® 7 supports the DECLARE GLOBAL TEMPORARY TABLE instruction. Native DB2® temporary tables are quite similar to Informix® temporary tables with some exceptions:

- A 'user temporary table space' must exist for the database.
- Users must have 'USE' privilege on a 'user temporary table space'.
- For usage, the temporary table name must be prefixed by 'SESSION'.
- No constraints or indexes can be created on temporary tables.

For more details, see the DB2® documentation.

Solution

In accordance with some prerequisites, temporary tables creation in BDL programs can be supported by the database interface.

How does it work ?

- Informix-specific statements involving temporary table creation are automatically converted to IBM® DB2® "DECLARE GLOBAL TEMPORARY TABLE" statements.
- Once the temporary table has been created, all other SQL statements performed in the current SQL session are parsed to add the SESSION prefix to the table name automatically.

Prerequisites

- Fulfill the DB2® prerequisites to create global temporary tables, at minimum you must create a user temporary table space and grant the usage to database users:

  ```
  CREATE USER TEMPORARY TABLESPACE tempspace01 MANAGED BY AUTOMATIC STORAGE
  GRANT USE OF TABLESPACE tempspace01 TO PUBLIC
  ```

  See DB2® documentation for more details.

Limitations

- Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using a temp table name for other database objects, like columns. The following example illustrates this limitation:

  ```
  CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) )
  SELECT tmp1 FROM table_x WHERE ...
  ```

- Only the 'native' serial emulation mode is supported with temporary tables. See the issue about SERIALs for more details.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R'   -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

IBM® DB2® provides different functions (SUBSTR, SUSTR2, SUBSTRING), to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTR(col1,2,2) = 'RO'
SELECT SUBSTR('Some text',6,3) ...
SELECT SUBSTRING(col,1,3,CODEUNITS32) ...
```

Solution

You must replace all Informix® `col[x,y]` expressions by `SUBSTRING(col,x,y-x+1,CODEUNITS32)`.

Important:

- In UPDATE instructions, setting column values through subscripts will produce an error with IBM® DB2®:

  `UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...`

  is converted to:

  `UPDATE tab1 SET SUBSTR(col1,2,3-2+1) = 'RO' WHERE ...`

- Column subscripts in ORDER BY expressions produce an error with IBM® DB2®:

  `SELECT ... FROM tab1 ORDER BY col1[1,3]`

is converted to:

```
SELECT ... FROM tab1 ORDER BY SUBSTR(col1,1,3-1+1)
```

String delimiters

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE "tabname"."colname" = 'string'`

Informix® allows double quotes as string delimiters, but IBM® DB2® doesn't. This is important since many BDL programs use that character to delimit the strings in SQL commands.

This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

Solution

The IBM® DB2® database interface can automatically replace all double quotes by single quotes. However, we recommend that you use only single quotes to enforce portability.

Escaped string delimiters can be used inside strings as in the following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: """
"This is a double quote: \""
```

Database object names cannot be delimited by double quotes because the database interface cannot determine the difference between a database object name and a quoted string!

For example, if the program executes the SQL statement:

`WHERE "tabname"."colname" = "string"`

replacing all double quotes by single quotes would produce:

`WHERE 'tabname'.'colname' = 'string'`

This would produce an error since '*tabname*'.'*colname*' is not allowed by IBM® DB2®.

Getting one row with SELECT

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

With IBM® DB2®, you have to do this:

```
SELECT user FROM SYSIBM.SYSTABLES WHERE NAME='SYSTABLE'
```

Solution

Check the BDL sources for `"FROM systables WHERE tabid=1"` and use dynamic SQL to resolve this problem.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements, while IBM® DB2® supports the LIKE statement only.

MATCHES requires * and ? wild-card characters, and LIKE uses the % and _ wild-cards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows you to use brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The IBM® DB2® LIKE operator has no operator for `[ ]` brackets character ranges.

With IBM® DB2® , columns defined as CHAR(N) are blank padded, and trailing blanks are significant in the LIKE expressions. As result, with a CHAR(5) value such as `'abc '` (with 2 trailing blanks), the expression `(colname LIKE 'ab_')` will not match. To workaround this behavior, you can do `(RTRIM(colname) LIKE '`*`pattern`*`')`. However, consider adding the condition `AND (colname LIKE '`*`patten`*`%')` to force the DB server to optimize the query of the column is indexed. The `CONSTRUCT` instruction uses this technique when the entered criteria does not end with a * star wildcard.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no `[ ]` bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

SQL functions

Both Informix® and DB2® provide numerous built-in SQL functions. Most Informix® SQL functions have the same name and purpose in DB2® (DAY(), MONTH(), YEAR(), UPPER(), LOWER(), LENGTH()).

Table 170: Informix® and IBM® DB2® built-in SQL functions

Informix®	IBM® DB2®
today	current date
current hour to second	current time
current year to fraction(5)	current timestamp
trim([leading | trailing | both "char" FROM] "string")	ltrim() and rtrim()
pow(x,y)	power(x,y)

Solution

You must review the SQL statements using TODAY / CURRENT / EXTEND expressions.

You can create user defined functions (UFs) in the DB2® database.

Querying system catalog tables

As in Informix®, IBM® DB2® provides system catalog tables (systables, syscolumns, etc.) in each database, but the table names and their structures are quite different.

Solution

No automatic conversion of Informix® system tables is provided by the database interface.

The GROUP BY clause

Informix® allows you to use column numbers in the GROUP BY clause

```
SELECT ord_date, sum(ord_amount) FROM order GROUP BY 1
```

IBM® DB2® does not support column numbers in the GROUP BY clause.

Solution

Use column names instead:

```
SELECT ord_date, sum(ord_amount) FROM order GROUP BY ord_date
```

The star (asterisk) in SELECT statements

Informix® allows you to use the star character in the select list along with other expressions:

```
SELECT col1, * FROM tab1 ...
```

IBM® DB2® does not support this. You must use the table name as a prefix to the star:

```
SELECT col1, tab1.* FROM tab1 ...
```

Solution

Always use the table name with stars.

The LENGTH() function

Informix® provides the LENGTH() function:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

IBM® DB2® has a equivalent function with the same name, but there is some difference:

- Informix® does not count the trailing blanks neither for CHAR not for VARCHAR expressions, while IBM® DB2® counts the trailing blanks.
- With the IBM® DB2® LENGTH function, when using a CHAR column, values are always blank padded, so the function returns the size of the CHAR column. When using a VARCHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

Solution

You must check if the trailing blanks are significant when using the LENGTH()function.

If you want to count the number of characters by ignoring the trailing blanks, you must use the RTRIM() function:

```
SELECT LENGTH(RTRIM(col1)) FROM table
```

BDL programming

IBM® DB2® related programming topics.

Informix® specific SQL statements in BDL

The BDL compiler supports several Informix-specific SQL statements that have no meaning when using IBM® DB2®:

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and remove all static SQL statements that are Informix-specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® databases with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

IBM® DB2® does not support insert cursors.

Solution

Insert cursors are emulated by the IBM® DB2® database interface.

Cursors WITH HOLD

Informix® provides the WITH HOLD option to prevent cursors being closed when a transaction ends.

This feature is well supported when using the DB2® interface, except when a transaction is canceled with a ROLLBACK, because DB2® automatically closes all cursors when you rollback a transaction.

Solution

Check that your source code does not use WITH HOLD cursors after transactions canceled with ROLLBACK.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to prevent several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

In both Informix® and DB2®, locks are released when closing the cursor or when the transaction ends; DB2's locking granularity is at the row level.

To control the behavior of the program when locking rows:

- Informix® provides a specific instruction to set the wait mode:

  ```
  SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
  ```

  The default mode is NOT WAIT. This as an Informix-specific SQL statement.
- DB2® has no equivalent for "SET LOCK MODE TO NOT WAIT". The "**Lock timeout**" can be changed but this is a database parameter (global to all processes)!

Solution

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

You must review the program logic if you use pessimistic locking because it is based on the NOT WAIT mode which is not supported by IBM® DB2®.

SQL parameters limitation

The IBM® DB2® SQL parser does not allow some uses of the '?' SQL parameter marker.

The following SQL expressions are not supported:

```
? IS [NOT] NULL
? operator ?
function( ? )
```

SQL instructions containing these expressions raise an error during the statement preparation.

Solution

Check that your BDL programs do not use these types of conditional expressions.

If you really need to test a BDL variable during the execution of a SQL statement, you must use the CAST() function for DB2® only:

```
WHERE CAST( ? AS INTEGER ) IS NULL
```

See the DB2® documentation for more details.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into an text file, and the LOAD instruction inserts rows from an text file into a database table.

IBM® DB2® does not provide LOAD and UNLOAD instructions.

Solution

LOAD and UNLOAD instructions are supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

DB2® UDB 9 supports SQL Interruption in a similar way as Informix®. The db client must issue an SQLCancel() ODBC call to interrupt a query.

Solution

The DB2® database driver supports SQL interruption and converts the native SQL error code -952 to the Informix® error code -213.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

DB2® UDB supports native scrollable cursors.

Solution

The DB2® database driver uses the native DB2® scrollable cursors by setting the CLI statement attribute SQL_ATTR_CURSOR_TYPE to SQL_CURSOR_STATIC.

Connecting to DB2® OS/400®

> **Note:** Some of the following actions can be taken via the OS/400® Operations Navigator.

DB2® Architecture on OS/400®

On OS/400® machines, the DB2 Universal Database™ is integrated to the operating system. Therefore, some concepts change. For example, the physical organization of the database is quite different from UNIX™ or Windows™ platforms.

Table 171: Common terms for the physical organization of the database with DB2® OS/400®

SQL Terms	DB2® OS/400® Terms
Table	Physical file
Row	Record
Column	Field
Index	Keyed logical file, access path
View	Non keyed logical file
Schema	Library, Collection, Schema (OS/400® V5R1 only)
Log	Journal
Isolation Level	Commitment control level

A Collection is a library containing a Journal, Journal Receivers, Views on the database catalogs.

Login to the AS/400® server

First, login to the AS/400® machine with a 5250 display emulation. All the commands are executed in the 5250 display emulation (or telnet connection).

Collection (Schema) Creation

A collection or library in DB2® for OS/400® is equivalent to a schema in DB2® for UNIX™.

1. Launch "Interactive SQL"

   ```
   STRSQL COMMIT(*NONE)
   ```
2. Create a Collection

   CREATE COLLECTION

   Press F4

   Enter field values:

   LIBRARY: name of the collection (Schema)

   ASP: 1

   WITH DATA DICTIONARY: Y

   Press ENTER

   Press F3 to quit (choose Option 1 (save and exit)).

   > **Note:** The name of the Schema should not begin with “Q”; libraries beginning with “Q” are system libraries.

This procedure creates:

- A library for your new database,
- A catalog with a data dictionary,
- A journal (QSQJRN),
- A journal receiver (QSQJRN0001).

Source Physical File Creation

Each table in the database is stored in a Physical file. They can be created in the control center with SQL scripts (CREATE TABLE), or with OS/400® commands.

The table creation script file must be copied in the library in the form: *library/sourcefile.member*

Creation of a physical file:

Type:

CRTSRCPF

Enter field values:

FILE = name of the table (10 characters max).

LIBRARY = name of the library in which the table is created (schema).

RECORD LENGTH = length of the script creation file (in bytes)

MEMBER = *FILE

Execution of the SQL creation script:

Type

RUNSQLSTM

Press F10 for additional parameters

Enter field values:

SOURCE FILE = name of the source file of the script creation file

LIBRARY = name of the library (schema)

SOURCE MEMBER = name of the member of the script creation file

NAMING FIELD = *SQL (SQL Naming convention library.table)

COMMITMENT CONTROL = *NONE

IBM® SQL FLAGGING FIELD = *FLAG

If errors occur, you can use WRKSPLF to display error information saved in the spool file. Use option 5 in the Opt Field on the line of the script file you tried to execute.

Trigger Creation

With DB2® on OS/400®, triggers need to be external programs written in a high level language such as C, COBOL, RPG, or PL/I.

To create a trigger, use the following steps:

1. Create an OS/400® Source file for the trigger programs

   Create a source physical file on your AS/400® for the trigger programs. Each trigger program will be stored in a separate member within this source file.

   Type:

   CRTSRCPF FILE(*library*/*file*)

   where:

   - *library*: name of the library you created for your new database
   - *file*: name you want to call the trigger source physical file

   The file name should be ten characters or fewer.
2. Create a member for each trigger program

   Create a source file member for each trigger program. After the creation of trigger programs (in the next step), the programs will be forwarded to these members.

   Type:

   ADDPFM

Enter field values:

FILE = name of the source file you just created

LIBRARY = name of the library you created for your database

MEMBER = name you want to give the trigger source member

Repeat this operation for each trigger.

3. Create trigger programs in an OS/400® supported high level language

   The OS/400-compatible languages include: ILE C/400®, ILE COBOL, ILE RPG, COBOL, PL/I, and RPG.

   The script creation file of the trigger should be send via FTP into *library/sourcefile.member,* where *sourcefile* and member are the values specified in the previous step.

4. Compile the trigger programs

   Once the trigger programs are in AS/400® members, you can compile them. Use whichever compiler is appropriate for the language you used to create the trigger program.

5. Bind the trigger programs

   After you compile the trigger programs, "bind" each compiled program file. Binding will establish a relationship between the program and any tables or views the program specifies.

   Type:

   CRTPGM PGM (*library*/*program*) ACTGRP(*CALLER)

   where:

   library is the name of the library you created for your new database

   program is the name of the compiled trigger program

   Repeat this operation for each trigger.

6. Add the trigger programs to physical files

   The final step for migrating triggers is to add each program to a physical file. This will tie the trigger program to the table that calls it.

   Type:

   ADDPFTRG

   Enter field values:

   PHYSICAL FILE = name of the table you want to attach the trigger to

   PHYSICAL FILE LIBRARY = name of the database library

   TRIGGER TIME = either *BEFORE or *AFTER.

   TRIGGER EVENT = *INSERT, *DELETE, or *UPDATE.

   PROGRAM = name of the compiled program file

   PROGRAM LIBRARY = name of the database library.

   REPLACE TRIGGER = *YES.

   ALLOW REPEATED CHANGES = *YES.

   Note: The trigger program should be in the same library as the database.

The trigger program is now tied to the table specified in the *Physical File* field and will be called each time the database action you specified occurs. The trigger program may be called from interactive SQL, another AS/400® program, or an ODBC insert, delete, update, or procedure call.

Permission Definition

On OS/400®, database security is managed at the operating system level, not at the database level. When you set up permissions for the database, you determine the degree of access (read, add, delete, etc.) individual users, groups, and authorization lists may have. This operation can easily be done via Operation Navigator.

The privileges must include the following system authorities:

- *USE to the Create Physical File (CRTPF) command.
- *EXECUTE and *ADD to the library into which the table is created.
- *OBJOPR and *OBJMGT to the journal.
- *CHANGE to the data dictionary if the library into which the table is created is an SQL collection with a data dictionary.

To define a foreign key, the privileges must include the following on the parent table:

- The REFERENCES privilege or object management authority for the table.
- The REFERENCES privilege on each column of the specified parent key.
- Ownership of the table.

The REFERENCES privilege on a table consists of:

- Being the owner of the table.
- Having the REFERENCES privilege to the table.
- Having the system authorities of either *OBJREF or *OBJMGT to the table.

The REFERENCES privilege on a column consists of:

- Being the owner of the table.
- Having the REFERENCES privilege to the column.
- Having the system authority of *OBJREF to the column or the system authority of *OBJMGT to the table.

To EXECUTE a user-defined function, the privilege consists of:

- Being owner of the user-defined function.
- Having EXECUTE privilege to the user-defined function.
- Having the system authorities of *OBJOPR and *EXECUTE to the user-defined function.

Relational DB Directory Entry Creation

The relational database directory is equivalent to the database directory of the DB2® client. This is necessary to access the database with DRDA® clients (Distributed Relational Database Architecture™) like DB2® client.

Use the WRKRDBDIRE tool to add the entry in the database directory:

- Type

  WRKDBDIRE
- Type Option 1 (add)
- Enter field values:

  ADDRESS = *LOCAL

  TYPE = *IP

Start the DDM server on the OS/400® which listens on the DRDA® 446 port:

- Type STRTCPSVR *DDM

Start the database server:

- Type STRHOSTSVR

- Enter field values:

  SERVER TYPE = *DATABASE

  REQUIRED PROTOCOL: *ANY

The DDM/DRDA server that listens on TCP/IP port 446 handles requests from a DRDA® client (examples are DB2 Connect™ or another AS/400®).

The database server is not needed for DRDA® clients, but it is needed for Client Access.

If a TCP/IP connection is desired, then your AS/400® server cannot have a release prior to V4R2 installed.

To manually configure the connection via the DB2® command line, you will need to enter catalog commands:

```
> db2 catalog tcpip node <node-name> remote <as400-adress> server 446
> db2 catalog db <db-name-alias> at node <node-name> authentication dcs
> db2 catalog dcs db <db-name-alias> as <local-RDB-name-of-AS400>
```

If you catalogue the DB2® UDB for iSeries® server incorrectly, you may get an SQL5048N error message. SQL7008N is another common error in that the DB2® UDB for iSeries® tables being accessed on the server are not being journaled. To correct the SQL7008N error, you need to start journaling your tables or change the isolation level to No Commit.

The proper CCSID value (normally 37 for US English customers) is needed for any tables on the iSeries® accessed via DB2 Connect™. You can view the CCSID value with the DSPFD CL command or Operations Navigator. CCSID values can be changed with the ALTER TABLE statement or CHGPF CL command. Furthermore, to successfully connect, you may need to change one of the following: the CCSID of the job, the CCSID of the user profile used, or the system CCSID value (QCCSID) if it's the default 65535.

DB2® Client Configuration on Windows™

To configure a DB2® client on Windows™ platforms, use the Client Configuration Assistant. This tool is available only under Microsoft™ Windows™. Under UNIX™, you have to use the command line as described in the previous chapter.

1. Source:
   - Select “Manually configure a connection to a database”.
2. Protocol:
   - Select “TCP/IP”.
   - Check “The database physically resides on a host or AS/400® System”.
3. TCP/IP:
   - Host Name: AS/400® system name.
   - Port Number: Port where DDM/DRDA server is listening (default: 446).
4. Database:
   - Database name: name defined in the relational database directory entries (with WRKRDBDIRE).
5. ODBC:
   - You can register the database as an ODBC data source. Not needed for DRDA® connection used by ODI.
6. Node Options:
   - Optional, but needed to access the database via the control center.
   - System name: AS/400® system name.
   - Instance name: not used for a connection to AS400 (because only one instance is running on an AS/400®).
   - Operating System: OS/400®.

7. Security Options:
   - Optional.
8. Host or AS400 Options:
   - Optional.

Differences Between DB2® UNIX™ & DB2® OS/400®

Some of the differences between DB2® for UNIX™ / Windows™ and DB2® for OS/400® are:

- There is only one database on a system; you can not create two instances on the same database server. The database is a single system-wide database. The database name used for the connect statement is the name of the system. Schemas (Collections) can be used to manage different logical databases on the same OS/400® machine.
- There is no TABLESPACE concept on DB2® for iSeries®. All the storage is controlled by the database manager and operating system.
- The identity column is not supported (for serial emulation).
- The SET SCHEMA SQL command is not supported.
- NUMERIC data type is defined as zoned decimal on DB2® for iSeries® and packed decimal on other platforms.
- The FLOAT data type does not use the same storage. For portability across platforms, do not use FLOAT(n).
- Not all features of the CREATE FUNCTION statement are supported on each platform (see documentation).
- iSeries® prior to V5R1 requires the statement to be processed by a special schema processor. iSeries® as of V5R1 would require this only if the statement includes other DDL statements.
- OS/400® supports “SET DEFAULT” clause ON DELETE.
- OS/400® supports DROP statement with CASCADE behavior.
- Syntaxes of CREATE, ALTER and RENAME TABLE are different on the two systems.

Naming Conventions

The naming convention defines how database tables are identified.

DB2® OS/400® can use two kinds of naming conventions:

- The ***SQL** naming convention.

  The table has to be qualified with the name of the collection (schema) which must be the same name as the user connected to the database. All tables have to be in the same database.
- The ***SYS** naming convention.

  If a table is unqualified, it will be searched for in the *CURLIB collection. You can change the library list with the ADDLIBLE command. You may create a small CL program attached to the profile that will change the library list on sign on. You can also globally change the user portion of the library list using the QUSRLIBL system variable, but this would affect all users on the system.

SQL adaptation guide for IBM® Netezza® 6.x

Installation (Runtime Configuration)
IBM® Netezza® related installation topics.
Install IBM® Netezza® and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. An IBM® Netezza® appliance (the server) must be available.
2. Install the IBM® Netezza® client software with the IBM® Netezza® ODBC driver on the application server.
3. Create an IBM® Netezza® database with the `nzsql` utility.

You must connect to the "system" database:

```
$ nzsql -h hostname system username password
```

4. Create your database with the following SQL command:

```
CREATE DATABASE mydatabase ...
```

5. Create a database user dedicated to the administration of the new database and grant privileges:

```
CREATE USER myadmin WITH PASSWORD 'password' ...
GRANT ALL PRIVILEGES on mydatabase TO myadmin
```

6. Create the application tables.

   Convert Informix® data types to Netezza® data types. See Data type conversion table: Informix to Netezza on page 584 for more details.

7. If you plan to use the SERIAL emulation, you must prepare the database.

   See SERIAL data types on page 581 for more details.

Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® Netezza®, you must have the "`dbmntz`" driver in `FGLDIR/dbdrivers`.
2. The IBM® Netezza® client software with ODBC driver is required to connect to a server.

   Check if the ODBC client library (`libnzodbc.*`) is installed on the machine where the BDL programs run.
3. Make sure that the IBM® Netezza® client environment variables are properly set.

   Check for example NZ_DIR (the path to the installation directory), NZ_ODBC_INI_PATH (the path to the ODBC data source file), etc. See IBM® Netezza® documentation for more details.
4. Verify the environment variable defining the search path for Netezza database client shared libraries (libnzodbc.so on UNIX™, ODBC32.DLL on Windows™).

   Table 172: Shared library environment setting for IBM® Netezza®

IBM® Netezza® version	Shared library environment setting
IBM® Netezza® 6 and higher	*UNIX*™: Add $NZ_DIR/lib (for 32 bit) or $NZ_DIR/lib64 (for 64 bit) to LD_LIBRARY_PATH (or its equivalent). *Windows*™: Add %NZ_DIR%\bin to PATH.

5. Check the database client locale settings.

   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).
6. You can test the client environment by trying to connect to the server with the SQL command line tool:

```
$ nzsql -h hostname system username password
```

7. Set up the fglprofile entries for database connections.
   a) Define the Netezza database driver:

```
dbi.database.dbname.driver = "dbmntz"
```

   b) The "`source`" parameter defines the name of the ODBC source.

```
dbi.database.dbname.source = "test1"
```

Database concepts
IBM® Netezza® related database concepts topics.
Database concepts

Like Informix® servers, Netezza® can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.

Solution

Create a Netezza® database for each Informix® database.

Data consistency and concurrency

Data consistency involves readers that want to access data currently modified by writers, and *concurrency data access* involves several writers accessing the same data for modification. *Locking granularity* defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks** according to the **isolation level**. In the case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is read committed.
- The default lock wait mode is "not wait".
- The default locking granularity is per page.

Netezza®

Netezza® servers are designed for Data Warehouse applications, not for OLTP applications: Concurrent data access is not the best thing that a Netezza® server can do. There are a bunch of limitations that you must be aware of. You must not expect to be able to migrate an existing OLTP application running against Informix® or Oracle to a Netezza® database server. The purpose of a Netezza-based application is mostly to do queries, with few insert or updates. Typically a Netezza® database is fed with data by using tools such as nzload, not by Genero BDL programs.

Some limitations of Netezza®:

- An application can only execute one cursor (or statement handle) at a time.
- Singular data modification statements (INSERT, UPDATE, DELETE) are much slower than with traditional OLTP database servers. Netezza® is, however, very good when it comes to loading a huge amount of data with special tools like the nzload utility.
- SELECT ... FOR UPDATE is not supported. Regular SELECTs never lock rows.
- Locks can only be set for an entire table with LOCK TABLE.
- A maximum of 31 concurrent INSERT processes are allowed (Netezza® V6), and there must be only INSERTs in a transaction block.

- UPDATE/DELETE statements lock the entire table, but don't prevent SELECTs. Other processes doing UPDATEs/DELETEs will wait until the first session has committed.
- Netezza® (V6) understands the SET TRANSACTION ISOLATION statement, but currently implements only the SERIALIZABLE level.
- There is no way to define the LOCK WAIT mode. With Netezza®, processes always wait for locks to be released.

Solution

Understand that the main difference with Informix® is that Netezza® is not good at concurrent data modification. Note also that readers do not have to wait for writers in Netezza®.

Genero applications should mainly do queries against a Netezza® server. You must review your program logic that modifies data, having in mind that only one process can modify a table at the time. Note however, that if you write short transactions this is not visible to the end users, except that an INSERT / UPDATE / DELETE of a single row takes more time than with another database server.

The SET ISOLATION TO ... Informix® syntax is replaced by SET TRANSACTION ISOLATION LEVEL ... in Netezza®. However, only the REPEATABLE READ level is supported with Netezza®.

The next table shows the isolation level mappings done by the Netezza® database driver:

Table 173: Isolation level mappings done by the Netezza® database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	**Not supported (SQL Error)**
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	**Not supported (SQL Error)**
SET ISOLATION TO CURSOR STABILITY	**Not supported (SQL Error)**
SET ISOLATION TO REPEATABLE READ	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE

> **Important:** Since Netezza® does not support the **lock wait** mode, you must check that your programs do not include a SET LOCK MODE instruction. This instruction will fail with error -6370 if it is executed when connected to Netezza®.

See the Informix® and Netezza® documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Compared to Informix®, Netezza® has some limitations regarding transactions and concurrent data access.

Informix® native mode (non-ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Netezza®:

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.
- A transaction must only contain INSERTs if you want concurrent processes to insert rows at the same time (UPDATEs/DELETEs lock the whole table).
- Only the SERIALIZABLE isolation level is implemented by Netezza®.

  Note: Netezza® cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
SELECT FROM unexisting WHERE key = 123   -- unexisting table = sql error
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With Netezza®, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction.

Solution

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Netezza®: Informix® transaction handling commands are automatically converted to Netezza® instructions to start, validate or cancel transactions. However, since Netezza® is not designed for OLTP applications, you must review any code doing complex data modifications. See the concurrency topic for more details.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. To get the same behavior in case of error when connected to a different database than Netezza®, you must issue a ROLLBACK to cancel all the SQL statements that succeeded in the transaction, for example with a TRY/CATCH block.

```
TRY
  BEGIN WORK
  ...
  COMMIT WORK
CATCH
  ROLLBACK WORK
END TRY
```

Database users

Until version 11.70.xC2, Informix® database users must be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers. Any database user must have sufficient privileges to connect and use the resources of the database; user rights are defined with the GRANT command.

Netezza® users must be registered in the database with the CREATE USER command, for example:

`CREATE USER` *`name`* `WITH PASSWORD '`*`pswd`*`' IN GROUP ...`

See the Netezza® documentation for more details about user creation and database access/security.

Solution

According to the application logic (is it a multiuser application?), you have to create one or several Netezza® users.

Data dictionary
IBM® Netezza® related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values; Genero BDL implements the BOOLEAN data type in a different way. As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

Netezza® supports the BOOLEAN data type and stores 't' or 'f' values for TRUE and FALSE representation. It is not possible to insert the integer values 1 or 0: Values must be true, false, 't', 'f', '1' or '0'.

Solution

The Netezza® database interface supports the BOOLEAN data type, and converts the BDL BOOLEAN integer values to a CHAR(1) of '1' or '0'.

CHARACTER data types

Informix® supports the following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases.)

Netezza® supports the following character data types:

- CHAR(N) with N <= 64000 characters
- VARCHAR(N) with N <= 64000 characters
- NCHAR(N) with N <= 16000 characters
- NVARCHAR(N) with N <= 16000 characters

Netezza® stores single-byte character data in CHAR/VARCHAR columns, and stores UNICODE (UTF-8 encoded) character strings in NCHAR/NVARCHAR columns. You cannot store UTF-8 strings in CHAR/VARCHAR columns.

NCHAR/NVARCHAR data is always stored in UTF-8. The database character defines the encoding for CHAR and VARCHAR columns and is defined when creating the database with the CREATE DATABASE command; the default is latin9. Note that, at the time of writing these lines, Netezza® V6 does not yet support a different database character set than latin9.

No automatic character set conversion is done by the Netezza® software, this means that the application/client character set must match the database character set.

Solution

If your application uses a single-byte character set (i.e. latin9), you can create tables with the CHAR and VARCHAR types. However, if you want to store UNICODE (UTF-8) strings, you must use the NCHAR/ NVARCHAR types instead when creating tables. In program sources you can use CHAR/VARCHAR; these types can hold single and multibyte character sets, according to the C POSIX locale.

> **Important:** Netezza® (V6 while writing these lines) supports only the latin9 database character set for CHAR / VARCHAR types. Since character set conversion is not supported, you can only implement either latin9 or UTF-8 based applications.

When using a multibyte character set (such as UTF-8), define database columns as NCHAR and NVARCHAR, with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a Netezza® database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in Netezza® database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

NUMERIC data types

Informix® supports several data types to store numbers:

Table 174: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)
DEC / DECIMAL(p)	Floating-point exact decimal number, with p significant digits
DEC / DECIMAL(p,s)	Fixed-point exact decimal number, with p significant digits as s decimals
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

Solution

Netezza® supports the following data types to store numbers:

Table 175: Netezza® numeric data types

Netezza® data type	Description
BYTEINT	8-bit value with the range -128 to 127
SMALLINT	16 bit signed integer
INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
NUMERIC(p,s) / DECIMAL(p,s)	Exact decimal number with p significant digits and s decimals (1<=p<=38)
NUMERIC(p) / DECIMAL(p)	Integer with precision p (1<=p<=38)
NUMERIC / DECIMAL	Integer, same as NUMERIC(18,0)
FLOAT(p) with 1 <= p <= 6	16 bit approx floating point (C float)
FLOAT(p) with 7 <= p <= 15	32 bit approx floating point (C double)
REAL	same as FLOAT(6)
DOUBLE PRECISION	same as FLOAT(15)

Important:

There is no Netezza® equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application uses such data types, you must review the database schema in order to use Netezza® compatible types.

To workaround the Netezza® limitation, the NTZ database drivers converts DECIMAL(p) types to a DECIMAL(2*p, p), to store all possible numbers that an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since the Netezza® maximum DECIMAL precision is 38(2*19). If the original precision is bigger than 19, a CREATE TABLE statement executed from a Genero program will fail with an SQL error.

DATE and DATETIME data types

Informix® provides two data types to store dates and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

Netezza® provides the following data type to store date and time information:

- DATE = for year, month, day storage.
- TIME = for hour, minute, second, fraction with (6 decimal positions).
- TIME WITH TIME ZONE / TIMETZ = same as TIME, with time zone information.
- TIMESTAMP = for year, month, day, hour, minute, second, fraction (with 6 decimal positions).

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contents matches environment parameters (i.e. DBDATE, GL_DATETIME). As in Informix®, Netezza® can convert quoted strings to date time data. Netezza® accepts different date formats, including ISO date time strings, and you can specify the cast operator (::date, ::time, ::timestamp) after the string literal.

Date arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used and an INTERVAL value if a DATETIME is used in the expression.
- In Netezza®, the result of an arithmetic expression involving DATE values is an INTEGER representing a number of days.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. Netezza® does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in Netezza®.

Using DATE/DATETIME variables in SQL statements

Informix® supports implicit DATE/DATETIME conversions, for example you can use a DATE variable when the target column is a DATETIME. This is not possible with Netezza®: The type of the SQL parameter must match the type of the column in the database table.

Solution

Netezza® has the same DATE data type as Informix® (year, month, day). So you can use Netezza® DATE data type for Informix® DATE columns.

Netezza® TIME data type can be used to store Informix® DATETIME HOUR TO SECOND values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION(5) can be stored in Netezza® TIMESTAMP columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the Netezza® TIMESTAMP value will be "1900-01-01 11:45:00.0".

Note:

- Make sure that you are using the same type for the SQL parameter and the target column, DATE/DATETIME implicit conversion is not supported by Netezza®.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix® INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

Netezza® implements the INTERVAL data type in a different way than Informix® does.

- Netezza® allows you to specify interval qualifiers (YEAR, MONTH, DAY, ...) but internally it always uses the same base type, storing values of any combination of units. Thus, there is no way to distinguish year-month intervals and day-time intervals with Netezza®.
- The precision of Netezza® intervals includes fraction of seconds with up to 6 significant digits. However, it is not possible to specify the scale of a Netezza® interval as with the Informix® FRACTION(N) qualifier.
- With Netezza®, interval literals must be include the units, as "-923 days 11 hours 22 minutes", while Informix® interval literals have the form INTERVAL(999-99...) qualifier1 TO qualifier2.
- Netezza® normalizes all INTERVAL values to units of seconds, and considers a month to be thirty days for the purpose of interval comparisons. This approximation can lead to inaccuracies.

Solution

The Informix® INTERVAL types of the day-time class can be mapped to the native Netezza® INTERVAL type, for day to second time interval storage.

Since Netezza® does not clearly distinguish year-month interval class, such types are converted to CHAR(50) by the Netezza® driver.

> **Important:** Netezza® (V6 at the time of writing) has several bugs regarding the INTERVAL type; we do not recommend using this type until Netezza® has fixed these problems.

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

However, Netezza® does not have a SERIAL data type. Version 6 of the database supports SEQUENCEs, but not triggers. The lack of triggers support makes it impossible to emulate Informix® SERIALs.

Solution

If you are using Informix® SERIALs or BIGSERIALs, you must review the application logic and database schema to replace SERIAL/BIGSERIAL columns with INTEGER/BIGINT columns, and generate the new keys from a SEQUENCE as described in the SQL Programming page.

ROWIDs

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

Netezza® implements ROWIDs like Informix®, except that the rowids are stored in a 64 bit integer in Netezza®.

Solution

ROWIDs can be used with Netezza® as with Informix®, as long as you fetch rowid values into a BIGINT variable. But you should avoid ROWID-based code and use primary key constraints instead.

The SQLCA.SQLERRD[6] register cannot be supported, because Netezza® rowids are 64 bit integers (BIGINT) while SQLCA.SQLERRD[6] is a 32 bit integer (INTEGER). Therefore, all references to SQLCA.SQLERRD[6] must be removed because this variable will not contain the ROWID of the last INSERTed or UPDATEd row.

Indexes

Like most database servers, Informix® supports index creation on table columns. Indexes can be used to make the server find rows rapidly:

```
CREATE INDEX cust_ix1 ON customer (cust_name)
```

Netezza® does not support index creation on tables. There is no need for indexes in a Netezza® database because performance is achieved by distributing data rows over several disks. Netezza® tracks min/max values of each column per disk extent to ignore extents which do not contain the values the query is looking for. See Netezza® documentation for more details.

Solution

You must remove all CREATE INDEX instructions from your programs and SQL scripts that create database tables.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

Netezza® (V6) does not support large objects in the database.

Solution

If your application need to store large objects with TEXT and BYTE data types, you cannot use a Netezza® server.

Constraints

Constraint naming syntax

Both Informix® and Netezza® support primary key, unique, foreign key, default and check constraints, but the constraint naming syntax is different. Netezza® expects the "CONSTRAINT" keyword **before** the constraint specification and Informix® expects it **after**.

UNIQUE constraint example

Table 176: UNIQUE constraint example (Informix® vs Netezza®)

Informix®	Netezza®

`CREATE TABLE emp (`
`  ...`
`  emp_code CHAR(10) UNIQUE`
`  CONSTRAINT pk_emp,`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  CONSTRAINT pk_emp UNIQUE,`
	`  ...`

> **Important:** Netezza® allows you to create tables with the UNIQUE and PRIMARY KEY and FOREIGN KEY syntax, but the constraints are not enforced.

Solution

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint-naming clauses for Netezza®.

Since Netezza® does not enforce constraints, you must test for unique values and foreign key references at the program level.

Triggers

Informix® supports triggers on database tables.

Netezza® does not support triggers.

Solution

Informix® triggers must be re-written in 4GL.

Stored procedures

Informix® supports stored procedures with the SPL language, and with Java/ C as User Defined Routines.

Netezza® supports stored procedures with the NZPLSQL language.

In Netezza® (V6), a stored procedure must always return a value (see the RETURNS clause). The value returned from a stored procedure can be either a simple scalar value, or a result set (REFTABLE). Netezza® has a limited support for stored procedures producing result sets (you must use dynamic SQL in the stored procedure). See the Netezza® documentation for more details.

> **Note:** Netezza® does not support OUTPUT parameters for stored procedures, only one single value or a result set can be returned.

Solution

Informix® stored procedures must be re-written in the Netezza® language, and the call from programs is slightly different from Informix®.

To call a stored procedure returning a simple scalar value, do following:

```
PREPARE s1 FROM "SELECT myproc(?,?,?)"
EXECUTE s1 USING var1, var2, var3 INTO res
```

To call a stored procedure returning a result set:

```
PREPARE s1 FROM "SELECT myproc(?,?,?)"
OPEN s1 USING var1, var2, var3
FETCH s1 INTO record.*
FETCH s1 INTO record.*
...
```

See SQL Programming for more details about executing stored procedures with Netezza.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

```
[database[@dbservername]:][{owner|"owner"}.]identifier
```

With Netezza®, an object name takes the following form:

```
[database.[schema].]identifier
```

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Data type conversion table: Informix to Netezza

Table 177: Data type conversion table (Informix to Netezza)

Informix® data types	Netezza® data types
CHAR(n)	CHAR(n) or NCHAR(n) if UTF-8
VARCHAR(n[,m])	VARCHAR(n) or NVARCHAR if UTF-8
NCHAR(n)	NCHAR(n) (UTF-8)
NVARCHAR(n[,m])	NVARCHAR(n) (UTF-8)
BOOLEAN	BOOLEAN
SMALLINT	SMALLINT
INT / INTEGER	INTEGER
BIGINT	BIGINT
INT8	BIGINT
SERIAL[(start)]	N/A (see note 1)
BIGSERIAL[(start)]	N/A (see note 1)
SERIAL8[(start)]	N/A (see note 1)
DOUBLE PRECISION / FLOAT[(n)]	DOUBLE
REAL / SMALLFLOAT	REAL
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL(p)	DECIMAL(p*2,p)
NUMERIC / DEC / DECIMAL	DECIMAL(32,16)
MONEY(p,s)	DECIMAL(p,s)
MONEY(p)	DECIMAL(p,2)
MONEY	DECIMAL(16,2)
TEXT	N/A
BYTE	N/A
DATE	DATE
DATETIME HOUR TO SECOND	TIME
DATETIME YEAR TO FRACTION(p)	TIMESTAMP
INTERVAL YEAR[(p)] TO MONTH	CHAR(50)
INTERVAL YEAR[(p)] TO YEAR	CHAR(50)
INTERVAL MONTH[(p)] TO MONTH	INTERVAL
INTERVAL DAY[(p)] TO FRACTION(n)	INTERVAL
INTERVAL DAY[(p)] TO SECOND	INTERVAL
INTERVAL DAY[(p)] TO MINUTE	INTERVAL
INTERVAL DAY[(p)] TO HOUR	INTERVAL

Informix® data types	**Netezza® data types**
INTERVAL DAY[(p)] TO DAY	INTERVAL
INTERVAL HOUR[(p)] TO FRACTION(n)	INTERVAL
INTERVAL HOUR[(p)] TO SECOND	INTERVAL
INTERVAL HOUR[(p)] TO MINUTE	INTERVAL
INTERVAL HOUR[(p)] TO HOUR	INTERVAL
INTERVAL MINUTE[(p)] TO FRACTION(n)	INTERVAL
INTERVAL MINUTE[(p)] TO SECOND	INTERVAL
INTERVAL MINUTE[(p)] TO MINUTE	INTERVAL
INTERVAL SECOND[(p)] TO FRACTION(n)	INTERVAL
INTERVAL SECOND[(p)] TO SECOND	INTERVAL
INTERVAL FRACTION[(p)] TO FRACTION(n)	INTERVAL

Notes:

1. For more details about serial emulation, see SERIAL data types on page 581.

Data manipulation
IBM® Netezza® related data manipulation topics.
Reserved words

Informix® allows the use of SQL language keywords for database object names (tables, columns):

```
CREATE TABLE table ( int INT, date DATE )
```

In Netezza®, SQL object names like table and column names cannot be SQL reserved keywords.

Solution

Table or column names which are Netezza® reserved keywords must be renamed.

See the Netezza® SQL Reference guide for a list of reserved keywords.

Outer joins

In Informix® SQL, outer tables can be defined in the FROM clause with the **OUTER** keyword:

```
SELECT ... FROM a, OUTER (b)
 WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c))
 WHERE a.key = b.akey
   AND b.key1 = c.bkey1
   AND b.key2 = c.bkey2
```

Netezza® supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
                     ON cust.key = order.custno
SELECT ...
  FROM cust LEFT OUTER JOIN order
                 LEFT OUTER JOIN item
                 ON order.key = item.ordno
            ON cust.key = order.custno
```

```
WHERE order.cdate > current date
```

See the Netezza® reference for a complete description of the syntax.

Solution

For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The Netezza® interface can convert most Informix® OUTER specifications to ANSI outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item, and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work: `"FROM OUTER(tab2), tab1"`
2. The outer join in the WHERE part must use the table name as prefix.

   Example: c_fgl_odiagntz_009.dita.

Restrictions:

1. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: `"... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10"`
2. Statements composed of 2 or more SELECT instructions using OUTERs are not supported.

   Example: `"SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"`

Remarks:

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias: `"OUTER( tab1 alias1)"`
2. In the outer join, <outer table>.<col> can be placed on both right or left sides of the equal sign.

   OUTER join example with table on the left: `"WHERE outertab.col1 = maintab.col2 "`
3. Table names detection is not case-sensitive.

   Example: `"SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2"`
4. Temporary tables are supported in OUTER specifications.

Transactions handling

Compared to Informix®, Netezza® has some limitations regarding transactions and concurrent data access.

Informix® native mode (non-ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Netezza®:

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Statements executed outside of a transaction are automatically committed.

- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.
- A transaction must only contain INSERTs if you want concurrent processes to insert rows at the same time (UPDATEs/DELETEs lock the whole table).
- Only the SERIALIZABLE isolation level is implemented by Netezza®.

  Note: Netezza® cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
SELECT FROM unexisting WHERE key = 123   -- unexisting table = sql error
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With Netezza®, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction.

Solution

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Netezza®: Informix® transaction handling commands are automatically converted to Netezza® instructions to start, validate or cancel transactions. However, since Netezza® is not designed for OLTP applications, you must review any code doing complex data modifications. See the concurrency topic for more details.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. To get the same behavior in case of error when connected to a different database than Netezza®, you must issue a ROLLBACK to cancel all the SQL statements that succeeded in the transaction, for example with a TRY/CATCH block.

```
TRY
  BEGIN WORK
  ...
  COMMIT WORK
CATCH
  ROLLBACK WORK
END TRY
```

Temporary tables

Informix® temporary tables are created through the CREATE TEMP TABLE DDL instruction or through a SELECT ... INTO TEMP statement. Temporary tables are automatically dropped when the SQL session ends, but they can be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

Netezza® support temporary tables as Informix® does, with a little syntax difference in the SELECT INTO TEMP instruction.

Solution

Temporary tables are well supported with native Netezza® temp tables.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R'   -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

Netezza® provides the SUBSTRING(... from ... to ...) function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTRING(col1 from 2 for 2) = 'RO'
SELECT SUBSTRING('Some text' from 6 for 3) ... -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions by SUBSTRING(col from x for (y-x+1)).

Note:

- In UPDATE instructions, setting column values through subscripts will produce an error with PostgreSQL:

  `UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...`

  is converted to:

  `UPDATE tab1 SET SUBSTRING(col1 from 2 for (3-2+1)) = 'RO' WHERE ...`
- Column subscripts in ORDER BY expressions are also converted and produce an error with PostgreSQL:

  `SELECT ... FROM tab1 ORDER BY col1[1,3]`

  is converted to:

  `SELECT ... FROM tab1 ORDER BY SUBSTRING(col1 from 1 for(3-1+1))`

The LENGTH() function

In Informix®, the LENGTH() function counts the number of bytes of a string expression by ignoring the trailing blanks.

Netezza® supports LENGTH() and CHARACTER_LENGTH() functions, but these count the number of characters (not bytes), and trailing blanks are significant.

Netezza® returns NULL if the LENGTH() parameter is NULL. Informix® returns zero instead.

Solution

The Netezza® database interface cannot simulate the behavior of the Informix® LENGTH() SQL function. Review the program logic and make sure you do not pass NULL values to the LENGTH() SQL function.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

`[database[@dbservername]:][{owner|"owner"}.]identifier`

With Netezza®, an object name takes the following form:

`[database.[schema].]identifier`

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

String delimiters

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE "tabname"."colname" = 'string'`

Informix® allows double quotes as string delimiters, but Netezza® doesn't. This is important since many BDL programs use that character to delimit the strings in SQL commands.

> **Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

Solution

The Netezza® database interface can automatically replace all double quotes by single quotes.

Escaped string delimiters can be used inside strings like following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: """
"This is a double quote: \""
```

> **Important:** Database object names cannot be delimited by double quotes because the database interface cannot determine the difference between a database object name and a quoted string!

For example, if the program executes the SQL statement:

`WHERE "tabname"."colname" = "string"`

replacing all double quotes by single quotes would produce:

`WHERE 'tabname'.'colname' = 'string'`

This would produce an error since 'tabname'.'colname' is not allowed by Netezza®.

Although double quotes are replaced automatically in SQL statements, you should use only single quotes to enforce portability.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements. Netezza® supports the LIKE statement as in Informix®, plus the ~ operators that are similar but different from the Informix® MATCHES operator.

MATCHES requires * and ? wildcard characters, and LIKE uses the % and _ wildcards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The Netezza® LIKE operator has no operator for `[ ]` brackets character ranges.

The Netezza® ~ operator expects regular expressions as follows: `( col ~ 'a.*' )`

With Netezza® , columns defined as CHAR(N) are blank padded, and trailing blanks are significant in the LIKE expressions. As result, with a CHAR(5) value such as `'abc '` (with 2 trailing blanks), the expression

`(colname LIKE 'ab_')` will not match. To workaround this behavior, you can do `(RTRIM(colname) LIKE 'pattern')`. However, consider adding the condition `AND (colname LIKE 'patten%')` to force the DB server to optimize the query of the column is indexed. The `CONSTRUCT` instruction uses this technique when the entered criteria does not end with a * star wildcard.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no `[ ]` bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

Querying system catalog tables

As in Informix®, Netezza® provides system catalog tables (actually, system views). But the table names and their structure are quite different.

Solution

No automatic conversion of Informix® system tables is provided by the database interface.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

```
UPDATE table SET ( col-list ) = ( val-list )
```

or

```
UPDATE table SET table.* = myrecord.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column = value [,...]
```

BDL programming
IBM® Netezza® related programming topics.
UPDATE limitations in Netezza

Netezza® has some limitations regarding the UPDATE statement:

- Like DELETE, an UPDATE statement locks the entire table.
- It is not possible to UPDATE *distribution columns*:
  - Netezza® database tables get distributed across all of the nodes using the distribution column. You can specify the distribution column(s) when you create the table. See Netezza® documentation for more details.
  - If you try to update a distribution column, you get error 46 "Attempt to UPDATE a distribution column".

Solution

Review the program logic if the UPDATE statements in your programs use distribution columns, and keep in mind that an UPDATE will lock the entire table.

Informix® specific SQL statements in BDL

The BDL compiler supports several Informix-specific SQL statements that have no meaning when using Netezza®.

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and review all SQL statements which are Informix-specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement.

- When this type of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.
- For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

Netezza® does not support insert cursors.

Solution

Insert cursors are emulated by the Netezza® database interface.

Cursors WITH HOLD

Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the DECLARE instruction.

With Netezza®, cursors can be kept open when a transaction ends. However, cursors declared with a SELECT FOR UPDATE are not supported with Netezza®.

Solution

Since WITH HOLD cursors are usually declared with SELECT FOR UPDATE and because Netezza® does not support SELECT FOR UPDATE, you must review the program logic if you are using cursors declared WITH HOLD.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to avoid several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

In both Informix® and Netezza®, locks are released when closing the cursor or when the transaction ends.

Netezza® does not support SELECT FOR UPDATE statements.

Solution

You must review the program logic if you use SELECT FOR UPDATE statements. Actually Netezza® systems are designed for data warehouse applications, not for OLTP applications. In a DW context, concurrent data access is not required or a priority.

UPDATE/DELETE WHERE CURRENT OF

Informix® allows positioned UPDATEs and DELETEs with the "`WHERE CURRENT OF cursor`" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

Netezza® servers do no support SELECT FOR UPDATE, and does not set locks. Thus, positioned UPDATEs/DELETEs with the WHERE CURRENT OF<cursor> clause cannot be supported with Netezza®.

Solution

You must review the program logic and rewrite all positioned UPDATEs/DELETEs with a WHERE condition based on primary keys or rowids.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instructions insert rows from a text file into a database table.

Netezza® does not provide LOAD and UNLOAD instructions, but provides external tools like the nzload utility.

Solution

LOAD and UNLOAD instructions are supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

Netezza® supports SQL Interruption in a way similar to Informix®. However, when the statement is interrupted, Netezza® rolls the transaction back and returns a "Transaction rolled back by user", SQL error number 46.

Solution

The Netezza® database driver supports SQL interruption and converts the native SQL error 46 to the Informix® error code -213.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

Netezza® does support native scrollable cursors.

Solution

The Netezza® database driver emulates scrollable cursors by fetching rows in a temporary file.

See Scrollable cursors on page 422 for more details about scroll cursor emulation.

SQL adaptation guide for SQL SERVER 2005, 2008, 2012, 2014

Installation (Runtime Configuration)
Microsoft™ SQL Server related installation topics.
Install SQL SERVER and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the Microsoft™ SQL SERVER on your computer.

   Important: Make sure that you select the correct collation when installing SQL Server: The default collation will apply to the tempdb database and will also be used for temporary tables, instead of inheriting the collation of the current database. If the default server collation does not match the collation of the current database, you will experience character set conflicts between permanent tables and temporary tables (SQL Server error message 468).
2. Create a SQL SERVER database entity with the SQL SERVER Management Studio.

   In the database properties:

   a) Choose the right code page / collation to get a case-sensitive database; this cannot be changed later.

   Remember collation defines the character set for CHAR/VARCHAR columns, while NCHAR/NVARCHAR columns are always storing UNICODE (UCS-2) characters. Informix® collation order is codeset based for CHAR/VARCHAR/TEXT columns. If you want to get the same sort order with SQL Server, you will need to use a binary collation such as Latin1_General_BIN.

   b) Make sure the "ANSI NULL Default" option is true if you want to have the same default NULL constraint as in Informix® (i.e. a column created without a NULL constraint will allow null values, users must specify NOT NULL to deny nulls).

   c) Make sure the "Quoted Identifiers Enabled" option is false to use database object names without quotes as in Informix®.
3. Create and declare a database user dedicated to your application: the application administrator .
4. If you plan to use SERIAL emulation based on triggers using a registration table, create the SERIALREG table and create the serial triggers for all tables using a SERIAL.

   See SERIAL data types on page 606.
5. Create the application tables.

   Convert Informix® data types to SQL SERVER data types. See Data type conversion table: Informix to SQL Server on page 615. In order to make application tables visible to all users, make sure that the tables are created with the 'dbo' owner.

Prepare the runtime environment - connecting to the database

1. Genero BDL provides several database drivers based on different ODBC clients. This list describes each of them:

   - For Windows™ platforms, use the SNC database driver based on SQL Native Client ODBC driver (SQLNCLI*.DLL) for Microsoft™ SQL SERVER 2005 and higher. Make sure that the dbmsnc* driver matches the SQNCLI*.DLL.

     The SNC driver is supported starting from Genero 2.10.
   - For Unix platforms, Genero supports the FTM driver is based on the FreeTDS ODBC client (www.freetds.org).

     This driver can be used with FreeTDS to connect from a UNIX™ platform to a Windows™ platform running SQL SERVER.

     You need at least FreeTDS version 0.83, recommended version is 0.95 to connect to recent SQL Server versions such as 2014.

     The FTM driver is supported starting from Genero 2.11.
   - For Unix platforms, Genero supports the ESM driver is based on the EasySoft ODBC driver for SQL Server (www.easysoft.com).

     This driver can be used with EasySoft to connect from a UNIX™ platform to a Windows™ platform running SQL SERVER.

     You need at least EasySoft version 1.2.3.

The ESM driver is supported starting from Genero 2.21.

2. Check that the Genero distribution package has installed the SQL SERVER database driver you need (i.e. a "dbmsnc", "dbmftm" or "dbmesm" driver must exist in `FGLDIR/dbdrivers`.
3. An ODBC data source must be configured to allow the BDL program to establish connections to SQL SERVER.

   Make sure you select the correct ODBC driver (SNC = "SQL Native Client", FTM = "FreeTDS", ESM = "EasySoft").

   > **Important:** When using the FTM (FreeTDS) or ESM (EasySoft) database driver, you have to define the ODBCINI and ODBCINST environment variable to point to the odbc.ini and odbcinst.ini files.

4. Install and configure the database client software:

   a) When using the SNC database driver, you must have the "Microsoft™ SQL SERVER Native Client" software installed on the computer running Genero applications.

   Since the SNC driver is using ODBC32.DLL, there is no need to set the PATH environment variable to a specific database client library path.

   The database client **locale** is defined by the regional settings of the application server and must match the locale used by the BDL application. Character set conversion (current code set <=> Wide-Char) is done by the SNC ODI driver according to the LANG environment variable. If the LANG environment variable is not defined, the application character set defaults to the ANSI code page (ACP).

   b) When using the FTM database driver, you must install FreeTDS (www.freetds.org).

   Make sure the FreeTDS environment variables are properly set. Check for example FREETDS (the path to the configuration file). See FreeTDS documentation for more details.

   With the FTM driver, there is no need to install a driver manager like unixODBC: The FTM database driver is linked directly with the `libtdsodbc.so` shared library. Verify the environment variable defining the search path for that database client shared library (LD_LIBRARY_PATH or equivalent).

   You must create the odbc.ini and odbcinst.ini files to defined the data source.

   Do not forget to define the client character set for FreeTDS (`client charset` parameter in freetds.conf or `ClientCharset` parameter in odbc.ini). You may need to link FreeTDS with the libiconv library to support character set conversions.

   > **Important:** You must set the TDS protocol version according to the SQL Server version (2005, 2008, etc), by setting the `tds version` parameter in freetds.conf or `TDS_Version` in `odbc.ini`. For example, when using SQL Server 2005, you must use the TDS protocol version 7.1. For SQL Server version 2008, 2012 and 2014, use `TDS_Version=7.3`.

   See FreeTDS documentation for more details about installation and data source configuration in ODBC files.

   c) When using the ESM database driver, you must install EasySoft ODBC for SQL Server (www.easysoft.com).

   Make sure the EasySoft environment variables are properly set. Check for example EASYSOFT_ROOT (the path to the installation directory). See FreeTDS documentation for more details.

   With the ESM driver, there is no need to install a driver manager like unixODBC: The ESM database driver is linked directly with the `libessqlsrv.so` shared library. Verify the environment variable defining the search path for that database client shared library (LD_LIBRARY_PATH or equivalent)

   You must create the odbc.ini and odbcinst.ini files to defined the data source.

   Do not forget to define the client character set for EasySoft with the `Client_CSet` parameter in odbc.ini. The client character set is an iconv name and must match the locale of your Genero application.

When using CHAR/VARCHAR types in the database and when the database collation is different from the client locale, you must also set the `Server_CSet` parameter to an iconv name corresponding to the database collation. For example, if `Client_CSet=BIG5` and the db collation is `Chinese_Taiwan_Stroke_BIN`, you must set `Server_CSet=BIG5HKSCS`, otherwise invalid data will be returned from the server.

You must also set the following DSN parameters:

```
AnsiNPW=Yes
Mars_Connection=No
QuotedId=No
```

See EasySoft documentation for more details about installation and data source configuration in ODBC files.

5. On Windows™ platforms, BDL programs are executed in a CONSOLE environment, not a GUI environment. CONSOLE and GUI environments may use different code pages on your system. Start the "SQL SERVER Configuration Manager" to setup your client environment and make sure no wrong character conversion occurs. See Microsoft™ SQL SERVER documentation for more details.
6. Set up the fglprofile entries for database connections.
   a) Define the SQL Server database driver according to the database client used:

   ```
   dbi.database.dbname.driver = { "dbmsnc" | "dbmesm" | "dbmftm" }
   ```

   b) The "`source`" parameter defines the name of the ODBC source.

   ```
   dbi.database.dbname.source = "test1"
   ```

   c) With the SNC driver you might consider setting the `snc.widechar` FGLPROFILE parameter to false if your database columns are defined with the CHAR/VARCHAR/TEXT types (by default the driver is prepared to work with the "UNICODE" types NCHAR/NVARCHAR/NTEXT). See CHARACTER data types on page 600 for more details.

   ```
   dbi.database.dbname.snc.widechar = false
   ```

   d) If required, define the serial emulation method to "trigseq", when the INSERT statements use all columns of the table, including the serial column. For more details, see SERIAL data types on page 606.

   ```
   dbi.database.dbname.ifxemul.datatype.serial.emulation = "trigseq"
   ```

Database concepts
Microsoft™ SQL Server related database concepts topics.
Database concepts

As in Informix®, an SQL SERVER engine can manage multiple database entities. When creating a database object like a table, Microsoft™ SQL SERVER allows you to use the same object name in different databases.

Data storage concepts

An attempt should be made to preserve as much of the storage information as possible when converting from Informix® to Microsoft™ SQL SERVER. Most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be reused in an SQL SERVER database.

Storage concepts are quite similar in Informix® and in Microsoft™ SQL SERVER, but the names are different.

These table compares Informix® storage concepts to Microsoft™ SQL SERVER storage concepts:

Table 178: Physical units of storage

Informix®	**Microsoft™ SQL SERVER**
The largest unit of physical disk space is a "**chunk**", which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (= UNIX™ partition, I/O is controlled by the database engine). A "dbspace" uses at least one "chunk" for storage. You must add "chunks" to "dbspaces" in order to increase the size of the logical unit of storage.	SQL SERVER uses "**filegroups**", based on Windows NT™ operating system files and therefore define the physical location of data.
A "**page**" is the smallest physical unit of disk storage that the engine uses to read from and writeto databases. A "chunk" contains a certain number of "pages". The size of a "page" must be equal to the operating system's block size.	As in Informix®, SQL SERVER stores data in "**pages**" with a size fixed at 2Kb in V6.5 and 8Kb in V7 and later.
An "**extent**" consists of a collection of continuous "pages" that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, "extents" can be located in different "chunks" of the same "dbspace".	An "**extent**" is a specific number of 8 contiguous pages, obtained in a single allocation. Extents are allocated in the filegroup used by the database.

Table 179: Logical units of storage

Informix®	**Microsoft™ SQL SERVER**
A "**table**" is a logical unit of storage that contains rows of data values.	Same concept as Informix®.
A "**database**" is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges.	Same concept as Informix®. When creating a "**database**", you must specify which "database devices" (V6.5) or "filegroup" (V7) has to be used for physical storage.
Database tables are created in a specific "**dbspace**", which defines a logical place to store data. If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.	Database tables are created in a database based on "database devices" (V6.5) or a "filegroup" (V7), which defines the physical storage.
The total disk space allocated for a table is the "**tblspace**", which includes "pages" allocated for data, indexes, blobs, tracking page usage within table extents.	No equivalent.

Table 180: Other concepts relating to storage

Informix®	**Microsoft™ SQL SERVER**
When initializing an Informix® engine, a "**root dbspace**" is created to store information about all databases, including storage information (chunks used, other dbspaces, etc.).	SQL SERVER uses the "**master**" database to hold system stored procedures, system messages, SQL SERVER logins, current activity information, configuration parameters of other databases.
The "**physical log**" is a set of continuous disk pages where the engine stores "before-images" of data that has been modified during processing. The "**logical log**" is a set of "**logical-log files**" used to record logical operations during on-line processing. All transaction information is stored in the logical log files if a database has been created with transaction log. Informix® combines "physical log" and "logical log" information when doing fast recovery. Saved "logical logs" can be used to restore a database from tape.	Each database has its own "**transaction log**" that records all changes to the database. The "transaction log" is based on a "database device" (V6.5) or "filegroup" (V7) which is specified when creating the database. SQL SERVER checks the "transaction logs" for automatic recovery.

Data consistency and concurrency

Data consistency involves readers which want to access data currently modified by writers and *concurrency data access* involves several writers accessing the same data for modification. *Locking granularity* defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to manage data consistency and concurrency. When a process modifies data with UPDATE, INSERT or DELETE, an exclusive lock is set on the affected rows. The lock is held until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks according to the isolation level . In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode .

Control:

- Isolation level: SET ISOLATION TO ...
- Lock wait mode: SET LOCK MODE TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit locking: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is READ COMMITTED.
- The default lock wait mode is NOT WAIT.
- The default locking granularity is per page.

SQL SERVER

As in Informix®, SQL SERVER uses locks to manage data consistency and concurrency. The database manager sets exclusive locks on the modified rows and shared locks or update locks when data is read, according to the isolation level . The locks are held until the end of the transaction. When multiple

processes want to access the same data, the latest processes must wait until the first finishes its transaction or the lock timeout occurred. The locking strategy of SQL SERVER is row locking with possible promotion to page or table locking. SQL SERVER dynamically determines the appropriate level at which to place locks for each Transact-SQL statement.

Starting with SQL Server 2005, you can enhance concurrency by turning on snapshot isolation level, to make SQL Server use a copy of the row when it is changed by a transaction. To turn this feature on, you must set the database property ALLOW_SNAPSHOT_ISOLATION ON. Setting the READ_COMMITTED_SNAPSHOT ON option allows access to versioned rows under the default READ COMMITTED isolation level (otherwise, snapshot isolation must be specified by every SQL Session).

Control:

- Lock wait mode: SET LOCK_TIMEOUT <milliseconds> (returns error 1222 on time out).
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Locking granularity: Row, Page or Table level (Automatic - See Dynamic Locking).
- Explicit locking: SELECT ... FROM ... WITH (UPDLOCK) (See Locking Hints)

Defaults:

- The default isolation level is READ COMMITTED (readers cannot see uncommitted data).
- The default LOCK_TIMEOUT is -1 (indicates no timeout period, wait forever).

Solution

The SET ISOLATION TO ... in programs is converted to SET TRANSACTION ISOLATION LEVEL ...for SQL Server. The next table shows the isolation level mappings done by the database driver:

Table 181: Isolation level mappings done by the Microsoft™ SQL Server database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	SET TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO CURSOR STABILITY	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ
SET ISOLATION TO REPEATABLE READ	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

When using `SET LOCK MODE ...` in the programs, it will be converted to a `SET LOCK_TIMEOUT` instruction for SQL SERVER:

Table 182: SET LOCK MODE as handled by the Microsoft™ SQL Server database driver

SET LOCK MODE instruction in program	Native SQL command
SET LOCK MODE TO WAIT	SET LOCK_TIMEOUT -1 (wait forever)
SET LOCK MODE TO WAIT *seconds*	SET LOCK_TIMEOUT *seconds* * 1000 (wait N milliseconds)
SET LOCK MODE TO NOT WAIT	SET LOCK_TIMEOUT 0 (do not wait)

See Informix® and SQL SERVER documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and Microsoft™ SQL SERVER handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Microsoft™ SQL SERVER supports named and nested transactions:

- Transactions are started with BEGIN TRANSACTION [*name*].
- Transactions are validated with COMMIT TRANSACTION [*name*].
- Transactions are canceled with ROLLBACK TRANSACTION [*name*].
- Savepoints can be placed with SAVE TRANSACTION *name*.
- Transactions can be rolled back to a savepoint with ROLLBACK TRANSACTION TO *name*.
- Savepoints can not be released.
- Statements executed outside of a transaction are automatically committed (autocommit mode). This behavior can be changed with "SET IMPLICIT_TRANSACTION ON".
- DDL statements are not supported in transactions blocks.

Transactions in stored procedures: avoid using transactions in stored procedure to allow the client applications to handle transactions, according to the transaction model.

Solution

Informix® transaction handling commands are automatically converted to Microsoft™ SQL SERVER instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Microsoft™ SQL SERVER.

> **Important:** If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Database users

Until version 11.70.xC2, Informix® database users must be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

Before a user can access an SQL SERVER database, the system administrator (SA) must add the user's **login** to the SQL SERVER Login list and add a **user name** for that database. The user name is a name that is assigned to a login ID for the purpose of allowing that user to access a specified database. Database users are members of a **user group**; the default group is 'public'.

Microsoft™ SQL SERVER offers two authentication modes: The **SQL SERVER authentication mode**, which requires a login name and a password, and the **Windows NT™ authentication mode**, which uses the security mechanisms within Windows NT™ when validating login connections. With this mode, user

do not have to enter a login ID and password - their login information is taken directly from the network connection.

Solution

Both SQL SERVER and Windows NT™ authentication methods can be used to allow BDL program users to connect to Microsoft™ SQL SERVER and access a specific database.

If you don't specify the `USER/USING` clause in the `CONNECT TO` instruction, operating system authentication takes place.

See SQL SERVER documentation for more details on database logins and users.

Setting privileges

Informix® and Microsoft™ SQL SERVER user privileges management are quite similar.

Microsoft™ SQL SERVER provides **user groups** to grant or revoke permissions to more than one user at the same time.

Data dictionary
Microsoft™ SQL Server related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way: As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

SQL SERVER provides the BIT data type to store boolean values.

Solution

The SQL SERVER database interfaces converts BOOLEAN type to BIT columns and stores 1 or 0 values in the column.

CHARACTER data types

Informix® supports following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

SQL Server provides the following data types to store character data:

- CHAR(N) with N<= 8000 bytes (single or multibyte charset)
- VARCHAR(N) with N<= 8000 bytes (single or multibyte charset)
- VARCHAR(MAX) with a limit of 2^31-1 bytes (single or multibyte charset)
- NCHAR(N) with N<= 4000 (Unicode/UCS-2) characters
- NVARCHAR(N) with N<= 4000 (Unicode/UCS-2) characters
- NVARCHAR(MAX) with a limit of 2^31-1 bytes (Unicode/UCS-2)

To store large text data (LOBs), Microsoft™ SQL Server version 2005 introduced the VARCHAR(MAX) type as a replacement for the old TEXT type.

The use of NCHAR, NVARCHAR character types is the same as CHAR, VARCHAR, TEXT respectively, except:

- The encoding is UCS-2 (an UTF-16 subset).
- The length N in N[VAR]CHAR(N) defines a number of characters, not bytes.
- Since each character occupies 2 bytes, twice the space is needed to store the same strings as with CHAR/VARCHAR.
- The maximum size of NCHAR and NVARCHAR column is 4000 characters, compared to 8000 chars for CHAR/VARCHAR using a single-byte character set.
- Unicode string literals are specified with a leading N. For example: N'###'
- The LIKE statement behaves differently with CHAR and NCHAR columns when using the N prefix before the search pattern.

Note that SQL Server uses Byte Length Semantics to define the size of CHAR/VARCHAR columns, while NCHAR and NVARCHAR sizes are expressed in character units.

SQL Server defines the character encoding for CHAR and VARCHAR columns with the database collation. The database collation can be specified when creating a new database. Character strings are always stored in the UCS-2 encoding for NCHAR/NVARCHAR columns.

Automatic charset conversion is supported by SQL Server between the client application and the server. The client charset is defined by the Windows™ operating system, in the language settings for non-Unicode applications.

Solution

According to the character set used by your application, you must either use CHAR/VARCHAR or NCHAR/NVARCHAR columns with SQL Server. If the charset is single-byte , you can use CHAR/VARCHAR columns. If the charset set is multibyte or Unicode (i.e. UTF-8), you must use NCHAR/NVARCHAR columns in SQL Server.

See also the section about Localization.

Make sure that the regional language settings for non-Unicode applications corresponds to the locale used by Genero programs.

Check that your database tables does not use CHAR or VARCHAR types with a length exceeding the SQL SERVER limit.

When using a multibyte character set (such as UTF-8), define database columns as NCHAR and NVARCHAR, with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a SQL Server database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a NCHAR(10 (characters)) column a in SQL Server database, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

Using the SNC driver

The SNC driver can work in *char* or in *wide-char* mode. The character size mode can be controlled by the following FGLPROFILE entry:

```
dbi.database.dbname.snc.widechar= { true | false }
```

By default the **SNC** database driver works in Wide Char mode (true).

Using SNC driver in char mode

The *char* mode can be used with applications defining character string columns with CHAR/VARCHAR/TEXT types. It is not mandatory (i.e. the *wide-char* mode could be used), but it appears that SQL Server behaves in different ways when wide-char bindings are used for CHAR/VARCHAR/TEXT columns.

When defining CHAR(*n*)/VARCHAR(*n*) columns in SQL Server, you specify *n* as a number of bytes, therefore you should use byte length semantics (the default) in Genero programs, with FGL_LENGTH_SEMANTICS=BYTE.

Using SNC driver in wide-char mode

NCHAR / NVARCHAR and NTEXT SQL Server column data types must be used to store Unicode data. The *wide-char* mode should be used for applications using these types. And in such case, the runtime system must use a UTF-8 locale, with character length semantics (FGL_LENGTH_SEMANTICS=CHAR).

In *wide-char* mode, all string literals of an SQL statement are automatically changed to get the N prefix. Thus, you don't need to add the N prefix by hand in all of your programs. This solution makes your Genero code portable to other databases.

Using the ESM driver

When using the ESM (EasySoft) database driver, string literals get the N prefix only if the current locale (LANG / LC_ALL) defines a multibyte code set such as .big5 or .utf8. String literals are not touched if the locale uses a single-byte character set.

When using the ESM (EasySoft) database driver, SQL Statements are prepared with SQLPrepare(), by using the current character set. EasySoft takes in charge the conversion from the client charset to UCS-2 before sending the SQL text to the server. ODBC SQL parameters with character string data are bound (SQLBindParameter) with the C type SQL_C_CHAR and with the SQL type SQL_W[VAR]CHAR (=UNICODE) type. As a result, the necessary character set conversion is taken in charge by EasySoft. However, it is critical to declare the correct client character set in EasySoft configuration files. The EasySoft client character set is defined by the "Client_CSet" parameter in odbc.ini.

Using the FTM driver

When using the FTM (FreeTDS) database driver, string literals get the N prefix only if the current locale (LANG / LC_ALL) defines a multibyte code set such as .big5 or .utf8. String literals are not touched if the locale uses a single-byte character set.

With the FTM (FreeTDS) database driver, SQL Statements are prepared with SQLPrepare(), by using the current character set. FreeTDS takes in charge the conversion from the client charset to UCS-2 before sending the SQL text to the server. ODBC SQL parameters with character string data are bound (SQLBindParameter) with the C type SQL_C_CHAR and with the SQL type SQL_W[VAR]CHAR (=UNICODE) or with SQL_[VAR]CHAR, according to the current locale. The SQL_W[VAR]CHAR type is used if the current locale is a multibyte encoding. When using a single-byte encoding, parameters are bound with the SQL_[VAR]CHAR type. As a result, the necessary character set conversion is taken in charge by FreeTDS and is optimized when using a single-byte character set.

> **Important:** It is critical to declare the correct client character set in FreeTDS configuration files.

The FreeTDS client character set is defined with "ClientCharset" parameter in odbc.ini.

NUMERIC data types

Microsoft™ SQL SERVER offers numeric data types which are quite similar to Informix® numeric data types. This table shows general conversion rules for numeric data types:

Table 183: Numeric data types (Informix® vs. Microsoft™ SQL Server)

Informix®	**Microsoft™ SQL SERVER**
SMALLINT	SMALLINT
INTEGER (synonym: INT)	INTEGER (synonym: INT)
BIGINT	BIGINT
INT8	BIGINT
DECIMAL[(p[,s])] (synonyms: DEC, NUMERIC) DECIMAL(p,s) defines a fixed point decimal where p is the total number of significant digits and s the number of digits that fall on the right of the decimal point. DECIMAL(p) defines a floating point decimal where p is the total number of significant digits. The precision p can be from 1 to 32. DECIMAL is treated as DECIMAL(16).	DECIMAL[(p[,s)] (synonyms: DEC, NUMERIC) DECIMAL[(p[,s])] defines a fixed point decimal where p is the total number of significant digits and s the number of digits that fall on the right of the decimal point. The maximum precision is 38. Without any decimal storage specification, the precision defaults to 18 and the scale defaults to zero: • DECIMAL in SQL SERVER = DECIMAL(18,0) in Informix® • DECIMAL(p) in SQL SERVER = DECIMAL(p,0) in Informix®
MONEY[(p[,s])	SQL SERVER provides the MONEY and SMALLMONEY data types, but the currency symbol handling is quite different. Therefore, Informix® MONEY columns should be implemented as DECIMAL columns in SQL SERVER.
SMALLFLOAT (synonyms: REAL)	REAL
FLOAT[(n)] (synonyms: DOUBLE PRECISION) The precision (n) is ignored.	FLOAT(n) (synonyms: DOUBLE PRECISION) Where n must be from 1 to 15.

Solutions

In BDL programs

When creating tables from BDL programs, the database interface automatically converts Informix® numeric data types to corresponding Microsoft™ SQL SERVER data types.

> **Important:** There is no SQL Server equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use SQL Server compatible types. To workaround the SQL Server limitation, the SQL Server database drivers convert DECIMAL(p) types to a DECIMAL(2*p, p), to store all possible numbers an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since SQL Server maximum DECIMAL precision is 38(2*19). If the original precision is bigger as 19, a CREATE TABLE statement executed from a Genero program will fail with an SQL Server error 2750.

In database creation scripts

- SMALLINT, INTEGER and BIGINT columns do not have to use another data type in SQL SERVER.
- For DECIMALs, check the precision limit. Always use a precision and a scale.

- Convert MONEY columns to DECIMAL(p,s) columns. Always use a precision and a scale.
- Convert SMALLFLOAT columns to REAL columns.
- Since FLOAT precision is ignored in Informix®, convert this data type to FLOAT(15).

DATE and DATETIME data types

Informix® provides two data types to store dates and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

Microsoft™ SQL SERVER provides two data type to store dates:

- DATETIME = for year, month, day, hour, min, second, fraction(3) storage (from January 1, 1753 through December 31, 9999). Values are rounded to increments of .000, .003, or .007 seconds.
- SMALLDATETIME = for year, month, day, hour, minutes storage (from January 1, 1900, through June 6, 2079). Values with 29.998 seconds or lower are rounded down to the nearest minute; values with 29.999 seconds or higher are rounded up to the nearest minute.

Starting with Microsoft™ SQL SERVER 2008, following new date data types are available:

- DATE = for year, month, day storage as Informix® DATEs.
- TIME(n) = for hour, minute, second and fraction(7) storage. Here n defines the precision of fractional seconds.
- DATETIME2(n) = for year, month, day, hour, minute, second and fraction(7) storage. Here n defines the precision of fractional seconds.
- DATETIMEOFFSET(n) = for year, month, day, hour, minute, second, fraction(7) and time zone information storage. Here n defines the precision of fractional seconds.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contents matches environment parameters (i.e. DBDATE, GL_DATETIME). As in Informix®, Microsoft™ SQL SERVER can convert quoted strings to DATETIME data. The CONVERT() SQL function allows you to convert strings to dates.

Date time arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used and an INTERVAL value if a DATETIME is used in the expression.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. Microsoft™ SQL SERVER does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in Microsoft™ SQL SERVER.
- Microsoft™ SQL SERVER does not allow direct arithmetic operations on datetimes; the date handling SQL functions must be used instead (DATEADD & DATEDIFF).
- The SQL SERVER provides equivalent functions for YEAR(), MONTH() and DAY(). Be careful with the DAY(*n*) function on SQL SERVER because it begins from January 1, 1900 while Informix® begins from December 31, 1899.

Table 184: Select first day example (Informix® vs. Microsoft™ SQL Server)

Informix®	Microsoft™ SQL SERVER

`SELECT day(0), month(0), year(0)`
`  FROM systables WHERE tabid=1;`
`------ ------ ------`
	`SELECT day(0), month(0), year(0)`
	`----------- ----------- -----------`

Informix®	Microsoft™ SQL SERVER
31 12 1899	1 1 1900

- The SQL SERVER equivalent for WEEKDAY() is the DATEPART(dw,<date>) function. The weekday date part depends on the value set by SET DATEFIRST *n*, which sets the first day of the week (1=Monday ... 7=Sunday (default)).
- SQL SERVER uses a different basis for the day of the week. In SQL SERVER, Sunday is day 7 and Monday is day 1 while Informix® defines Sunday as the day 0 (zero) and Monday as 1.

Solution

The SQL SERVER database drivers will automatically map Informix® date/time types to native SQL SERVER type, according the server version. Conversions are described in this table:

Table 185: Date/time mapping between Informix® and Microsoft™ SQL Server

Informix® date/time type	Microsoft™ SQL SERVER date/time type before SQL SERVER 2008	Microsoft™ SQL SERVER date/time type since SQL SERVER 2008
DATE	DATETIME	DATE
DATETIME HOUR TO SECOND	DATETIME (filled with 1900-01-01)	TIME(0)
DATETIME HOUR TO FRACTION(n)	DATETIME (filled with 1900-01-01)	TIME(n)
DATETIME YEAR TO SECOND	DATETIME	DATETIME2(0)
Any other sort of DATETIME type	DATETIME (filled with 1900-01-01)	DATETIME2(n)

With SQL SERVER 2005 and lower, Informix® DATETIME with any precision from YEAR to FRACTION(3) is stored in SQL SERVER DATETIME columns.

For heterogeneous DATETIME types like DATETIME HOUR TO MINUTE, the database interface fills missing date or time parts to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the SQL SERVER datetime value will be "1900-01-01 11:45:00.0".

Important:

- SQL SERVER SMALLDATETIME can store dates from January 1, 1900, through June 6, 2079. Therefore, we do not recommend using this data type.
- With SQL SERVER 2005 and lower, the fractional second part of a SQL SERVER DATETIME has a precision of 3 digits while Informix® has a precision up to 5 digits. Do not try to insert a datetime value in a SQL SERVER DATETIME with a precision more than 3 digits or a conversion error could occur. You can use the MS SUBSTRING() function to truncate the fraction part of the Informix® datetimes or another BDL solution. The fraction part of a SQL SERVER DATETIME is an approximate value. For example, when you insert a datetime value with a fraction of 111, the database actually stores 110. This may cause problems because Informix® DATETIMEs with a fraction part are exact values with a precision up to 5 digits. Starting with SQL SERVER 2008, the DATETIME2 native type will be used. This new type can store fraction of seconds with a precision of 7 digits, so Informix® DATETIME values can be stored without precision lost.
- When migrating to SQL SERVER 2008, you must pay attention if the database has DATETIME columns used to store Informix® DATETIME HOUR TO SECOND or DATETIME HOUR TO FRACTION(n) types: Before version 2008, those types were stored in SQL SERVER DATETIME

columns (filling missing date part with 1900-01-01). The SNC database driver for SQL SERVER 2008 maps now DATETIME HOUR TO SECOND / FRACTION(n) to a TIME data type, which is not compatible with an SQL SERVER DATETIME type. To solve this problem, SQL SERVER DATETIME columns used to store DATETIME HOUR TO SECOND/FRACTION(n) must be converted to TIME columns (ALTER TABLE).

- When fetching a TIME or DATETIME2 with a precision that is greater as 5 (the DATETIME precision limit), the database interface will allocate a buffer of VARCHAR(16) for the TIME and VARCHAR(27) for the DATETIME2 column. As a result, you can fetch such data into a CHAR or VARCHAR variable.
- Review the program logic if you are using the Informix® WEEKDAY() function because SQL SERVER uses a different basis for the days numbers (Monday = 1).
- Use the SQL SERVER's GETDATE() function to get the system current date.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix's INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

SQL SERVER does not provide a data type corresponding to the Informix® INTERVAL data type.

Solution

The INTERVAL data type is not well supported because the database server has no equivalent native data type. However, you can store into and retrieve from CHAR columns BDL INTERVAL values.

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERTs that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

Microsoft™ SQL SERVER IDENTITY columns:

- When creating a table, the IDENTITY keyword must be specified after the column data type:

  ```
  CREATE TABLE tab1 ( k integer identity, c char(10) )
  ```

- You can specify a start value and an increment with "identity(start,incr)".

  ```
  CREATE TABLE tab1 ( k integer identity(100,2), ...
  ```

- A new number is automatically created when inserting a new row:

```
INSERT INTO tab1 ( c ) VALUES ( 'aaa' )
```

- To get the last generated number, Microsoft™ SQL SERVER provides following function:

  ```
  SELECT SCOPE_IDENTITY()
  ```

  The @@IDENTITY global T-SQL variable is not recommended, as it is scope-less.
- To put a specific value into a IDENTITY column, the SET command must be used:

```
SET IDENTITY_INSERT tab1 ON
INSERT INTO tab1 ( k, c ) VALUES ( 100, 'aaa' )
SET IDENTITY_INSERT tab1 OFF
```

Informix® SERIALs and MS SQL SERVER IDENTITY columns are quite similar; the main difference is that MS SQL SERVER does not allow you to use the zero value for the identity column when inserting a new row.

Starting with version 2012, Microsoft™ SQL SERVER supports sequences:

```
-- To create a sequence object:
CREATE SEQUENCE myseq START WITH 100 INCREMENT BY 1;

-- To get a new sequence value:
SELECT NEXT VALUE FOR myseq;

-- To find the current sequence value (last generated)
SELECT convert(bigint, current_value) FROM sys.sequences WHERE name =
 'myseq';

-- To reset the sequence with a new start number:
ALTER SEQUENCE myseq START WITH 100;
```

Solution

To emulation Informix® serials with SQL SERVER, you can use three different solutions:

1. Native SQL SERVER IDENTITY columns.
2. Insert triggers based on sequences (requires SQL SERVER 2012 and +).
3. Insert triggers based on the SERIALREG table (for SQL SERVER prior to 2012).

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial.emulation = {"native"|"trigseq"|"regtable"}`

1. `native`: uses IDENTITY columns.
2. `trigseq`: uses insert triggers with SEQUENCEs.
3. `regtable`: uses insert triggers with the SERIALREG table.

The default emulation technique is "`native`".

This entry must be used in conjonction with:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial = {true|false}`

If the `datatype.serial` entry is set to false, the emulation method is ignored.

The native IDENTITY-based solution is faster, but does not allow explicit serial value specification in insert statements; the others solution are slower but allow explicit serial value specification in INSERT statements.

> **Important:** The trigger-based solutions are provided to simplify the conversion from Informix, but are slower as the solution using IDENTITY columns. To get best performances, we strongly recommend that you use native IDENTITY columns instead of triggers.

1. Using the `native` serial emulation

Make sure that the following FGLPROFILE entry is not defined, in order to use the default "native" emulation:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation ...
```

In database creation scripts, all SERIAL[(n)] data types must be converted by hand to INTEGER IDENTITY[(n,1)] data types, while BIGSERIAL[(n)] data types must be converted by hand to BIGINT IDENTITY[(n,1)] data types.

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER IDENTITY[(n,1)]".

In BDL, the new generated SERIAL value is available from the SQLCA.SQLERRD[2] variable. This is supported by the database interface which performs a "SELECT SCOPE_IDENTITY()". However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must retrieve the last generated serial with the SCOPE_IDENTITY() SQL function.

By default (see SET IDENTITY_INSERT), MS SQL SERVER does not allow you to specify the IDENTITY column in INSERT statements; You must convert all INSERT statements to remove the identity column from the list.

For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES (0, p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file (`DEFINE rec LIKE tab.*`) must also be reviewed:

```
INSERT INTO tab VALUES (rec.*) -- will use the serial column
```

must be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

Since 2.10.06, SELECT * FROM table INTO TEMP with original table having an IDENTITY column is supported: The database driver converts the Informix® SELECT INTO TEMP to the following sequence of statements:

1. `SELECT` *`selection-items`* `INTO` *`#table`* `FROM ... WHERE 1=2`
2. `SET IDENTITY_ INSERT` *`#table`* `ON`
3. `INSERT INTO` *`#table`* `(` *`column-list`* `) SELECT` *`original select clauses`*
4. `SET IDENTITY_ INSERT` *`#table`* `OFF`

See also temporary tables.

2. Using the `trigseq` serial emulation (SQL SERVER 2012 and +)

In order to use the serial emulation based on triggers and sequences, make sure that all database users creating tables in program have permissions to create/drop sequences and triggers.

Define the FGLPROFILE entry to enable "trigseq" serial emulation:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation = "trigseq"
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL must be converted to BIGINT and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command using a sequence.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers. When using BIGSERIAL[(n)], the column is converted to a BIGINT.

Important:

- SQL SERVER does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.
- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER. Similarly, a BIGSERIAL column becomes BIGINT.
- When a table is dropped, all associated triggers are also dropped.
- INSERT statements using NULL for the SERIAL column will produce a new serial value, instead of using NULL:

  ```
  INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
  ```

  This behavior is mandatory in order to support INSERT statements which do not use the serial column:

  ```
  INSERT INTO tab (col2) VALUES ('data')
  ```

  Check if your application uses tables with a SERIAL column that can contain a NULL value.

3. Using the `regtable` serial emulation (SQL SERVER versions prior to 2012)

Note: This solution is supported for SQL SERVER versions prior to 2012, if your server is a SQL SERVER 2012 or +, consider using the "trigseq" emulation instead.

In order to use the serial emulation based on triggers and the SERIALREG table, make sure that all database users creating tables in program have permissions to create/drop triggers.

Then, prepare the database and create the SERIALREG table as follows:

```
CREATE TABLE serialreg (
    tablename VARCHAR(50) NOT NULL,
    lastserial BIGINT NOT NULL,
    PRIMARY KEY ( tablename )
)
```

The SERIALREG table and columns have to be created with lower case names, since the SQL SERVER database is created with case sensitive names, because triggers are using this table in lower case.

Define the FGLPROFILE entry to enable "regtable" serial emulation:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation = "regtable"
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL must be converted to BIGINT and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column.

Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command using the SERIALREG table.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers. When using BIGSERIAL[(n)], the column is converted to a BIGINT.

Important:

- The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.
- SQL SERVER does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.
- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER. Similarly, a BIGSERIAL column becomes BIGINT.
- When a table is dropped, all associated triggers are also dropped.
- INSERT statements using NULL for the SERIAL column will produce a new serial value, instead of using NULL:

  ```
  INSERT INTO tab (col1,col2) VALUES ( NULL,'data')
  ```

  This behavior is mandatory in order to support INSERT statements which do not use the serial column:

  ```
  INSERT INTO tab (col2) VALUES ('data')
  ```

  Check if your application uses tables with a SERIAL column that can contain a NULL value.

SQL Server UNIQUEIDENTIFIER data type

SQL Server supports a special type named UNIQUEIDENTIFIER, which can be used to store "Globally Unique Identifiers" (GUIDs). UNIQUEIDENTIFIER values can be generated with the NEWID() function. When creating a table, you typically define a UNIQUEIDENTIFIER column with a DEFAULT clause where the value is produced from a NEWID() call:

```
CREATE TABLE mytab ( k INT, id UNIQUEIDENTIFIER DEFAULT NEWID(), c
 VARCHAR(10) )
```

The UNIQUEIDENTIFIER type is based on the BINARY(16) SQL Server type. The Genero language does not have an equivalent type for BINARY(16). However, BINARY values can be represented as hexadecimal strings in CHAR or VARCHAR variables.

A UNIQUEIDENTIFIER value is usually represented as a GUID identifier, with the following hexadecimal format:

```
XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX (where X can be 0-9, A-F )
```

You typically fetch UNIQUEIDENTIFIER data into a CHAR(36) Genero variable. The resulting value will be expressed in hexadecimal string using the format. You can then reuse that value in an SQL statement, but you have to convert the CHAR(36) hexadecimal string value back to a UNIQUEIDENTIFIER value with the CONVERT() SQL Server function, as shown in this example:

```
DEFINE pi CHAR(36)
CREATE TABLE mytab ( k INT, i UNIQUEIDENTIFIER DEFAULT NEWID(), c
 VARCHAR(10) )
INSERT INTO mytab ( k, c ) VALUES ( 1, 'aaa' )
SELECT i INTO pi FROM mytab WHERE k = 1
UPDATE mytab SET c = 'xxx' WHERE i = CONVERT(UNIQUEIDENTIFIER, pi)
```

When extracting a database schema, UNIQUEIDENTIFIER columns can be clearly distinguished from BINARY(N) columns. The fgldbsch tool will produce a CHAR(36) type code in the .sch file for UNIQUEIDENTIFIER columns.

You can also exclude the UNIQUEIDENTIFIER columns from the table definition in the schema file, by using the x character at the appropriate position of the string passed with the -cv data type conversion option of fgldbsch.

SQL Server ROWVERSION data type

SQL Server provides a special type named ROWVERSION, to stamp row modifications. The ROWVERSION data type replaces the old TIMESTAMP column definition. When you define a column with the ROWVERSION, SQL Server will automatically increment the version column when the row is modified. ROWVERSION is just an incrementing number, it does not preserve date or time information. It be used to control concurrent access to the same rows.

The ROWVERSION type is based on the BINARY(8) SQL Server type. The Genero language does not have an equivalent type for BINARY(8). Therefore, you must fetch ROWVERSION data into a CHAR(16) variable. The resulting value will be expressed in hexadecimal. You can then reuse that value in an UPDATE statement to check that the row was not modified by another process, but you have to convert the CHAR(16) hexadecimal value back to a BINARY(8) value with the CONVERT() SQL Server function, as shown in this example:

```
DEFINE pv CHAR(16)
CREATE TABLE mytab ( k INT, v ROWVERSION, c VARCHAR(10) )
INSERT INTO mytab VALUES ( 1, NULL, 'aaa' )
SELECT v INTO pv FROM mytab WHERE k = 1
UPDATE mytab SET c = 'xxx' WHERE k = 1 AND v =CONVERT(BINARY(8), pv, 2)
```

With SQL Server 2005, the CONVERT() function does not properly transform the hexadecimal string to a binary value. Therefore, you should only use ROWVERSION as SQL parameter starting with SQL Server 2008. ROWVERSION values can however be fetched with SQL Server versions prior to 2008, for example if you have to define record variables based on the table schema, including the ROWVERSION column.

Since ROWVERSION is a synonym for BINARY(8), ROWVERSION columns cannot be clearly identified in ODBC. Therefore, the following conversion rule applies when fetching data from the server:

- If the column is defined as BINARY(N), with N<=128, the data will be fetched as a CHAR(N*2), as an hexadecimal string.
- If the column is defined as BINARY(N), with N>128, the data will be fetched as a BYTE, as a regular binary value.

When extracting a database schema, ROWVERSION columns are identified as TIMESTAMP columns and can be clearly distinguished from BINARY(N) columns. The fgldbsch tool will produce a CHAR(16)type code in the .sch file for ROWVERSION or TIMESTAMP columns.

ROWIDs

When creating a table, Informix® automatically adds a "ROWID" integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

Microsoft™ SQL SERVER tables have no ROWIDs.

Solution

If the BDL application uses ROWIDs, the program logic should be reviewed in order to use the real primary keys (usually, serials which can be supported).

However, if your existing Informix® application depends on using ROWID values, you can use the IDENTITY property of the DECIMAL, INT, NUMERIC, SMALLINT, BIGINT, or TINYINT data types, to simulate this functionality.

All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last INSERTed or UPDATEd row when using the Microsoft™ SQL SERVER interface.

Case sensitivity

In Informix®, database object names like table and column names are not case sensitive:

```
CREATE TABLE Customer ( Custno INTEGER, ... )
SELECT CustNo FROM cuSTomer ...
```

In SQL SERVER, database object names and character data are case-insensitive by default:

```
CREATE TABLE Customer ( Custno INTEGER, CustName CHAR(20) )
INSERT INTO CUSTOMER VALUES ( 1, 'TECHNOSOFT' )
SELECT CustNo FROM cuSTomer WHERE custname = 'techNOSoft'
```

The installation program of SQL SERVER allows you to customize the **sort order**. The sort order specifies the rules used by SQL SERVER to collate, compare, and present character data. **It also specifies whether SQL SERVER is case-sensitive**.

Genero compilers convert table and column names to lower case. For example, when writing following static SQL statement:

```
SELECT COUNT(*) FROM CUSTOMER WHERE CUSTNAME LIKE 'S%'
```

The SQL text stored in the pcode module will be:

```
SELECT COUNT(*) FROM customer WHERE custname LIKE 'S%'
```

Solution

Select the case-sensitive sort order when installing SQL SERVER to make queries case-sensitive.

Define the database tables and columns in lower case only, because Genero compilers convert them to lower case.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

Microsoft™ SQL SERVER 2005 and higher provides the VARCHAR(MAX), NVARCHAR(MAX) and VARBINARY(MAX) data types to store large object data. The text, ntext and image data types still exist, but are considered as obsolete and will be removed in a future version.

In SQL Server, the VARCHAR(MAX), NVARCHAR(MAX) and VARBINARY(MAX) types have a limit of 2 gigabytes (2^31 -1 actually). The old text, ntext and image types have the same limit.

Solution

In Genero programs connecting to SQL SERVER, the TEXT and BYTE data types of DDL statements such as CREATE TABLE are respectively converted to VARCHAR(MAX) and VARBINARY(MAX) types.

SQL SERVER database drivers make the appropriate bindings to use TEXT and BYTE Genero types as SQL parameters and fetch buffers, and can be used for SQL SERVER text, image or VARCHAR(MAX), NVARCHAR(MAX) and VARBINARY(MAX) columns.

Genero TEXT/BYTE program variables and the SQL SERVER large object types have the same a limit of 2 gigabytes.

> **Note:** When using a stored procedure that has SET/IF statements and produces a result set with LOBs, the LOB columns must appear at the end of the SELECT list. If LOB columns are followed by

other columns with regular types, the fetching rows will fail. Using SET NOCOUNT ON in the stored procedure does not help, because the cursor type is changed from a server cursor to a default result set cursor.

The ALTER TABLE instruction

Informix® and MS SQL SERVER use different implementations of the ALTER TABLE instruction. For example, Informix® allows you to use multiple ADD clauses separated by comma. This is not supported by SQL SERVER:

Informix®:

```
ALTER TABLE customer ADD(col1 INTEGER), ADD(col2 CHAR(20))
```

SQL SERVER:

```
ALTER TABLE customer ADD col1 INTEGER, col2 CHAR(20)
```

Solution

No automatic conversion is done by the database interface. There is even no real standard for this instruction (that is, no common syntax for all database servers). Read the SQL documentation and review the SQL scripts or the BDL programs in order to use the database server-specific syntax for ALTER TABLE.

Constraints

Constraint naming syntax

Both Informix® and Microsoft™ SQL SERVER support primary key, unique, foreign key, default and check constraints. But the constraint naming syntax is different: SQL SERVER expects the "CONSTRAINT" keyword **before** the constraint specification and Informix® expects it **after**.

Table 186: UNIQUE constraint example (Informix® vs. Microsoft™ SQL Server)

Informix®	Microsoft™ SQL SERVER

`CREATE TABLE emp(`
`  ...`
`  emp_code CHAR(10) UNIQUE`
`  [CONSTRAINT pk_emp],`
`  ...`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  [CONSTRAINT pk_emp] UNIQUE,`
	`  ...`

Important: SQL SERVER does not produce an error when using the Informix® syntax of constraint naming.

The NULL / NOT NULL constraint

Note: Microsoft™ SQL SERVER creates columns as NOT NULL by default, when no NULL constraint is specified (`colname datatype {NULL | NOT NULL}`). A special option is provided to invert this behavior: ANSI_NULL_DFLT_ON. This option can be enabled with the SET command, or in the database options of SQL SERVER Management Studio.

Solutions

Constraint naming syntax

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for Microsoft™ SQL SERVER.

The NULL / NOT NULL constraint

Before using a database, you must check the "ANSI NULL Default" option in the database properties if you want to have the same default NULL constraint as in Informix® databases.

Triggers

Informix® and Microsoft™ SQL SERVER provide triggers with similar features, but the programming languages are totally different.

Microsoft™ SQL SERVER does not support "BEFORE" triggers.

Microsoft™ SQL SERVER does not support row-level triggers.

Solution

Informix® triggers must be converted to Microsoft™ SQL SERVER triggers "by hand".

> **Important:** To ensure that SQL SERVER generates only necessary result sets in triggers, use the SET NOCOUNT ON at the beginning of your triggers. See SQL SERVER documentation for more details about SET NOCOUNT ON.

Stored procedures

Both Informix® and Microsoft™ SQL SERVER support stored procedures, but the programming languages are totally different.

Solution

Informix® stored procedures must be converted to Microsoft™ SQL SERVER "by hand".

See SQL Programming for more details about executing stored procedures with SQL SERVER.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

```
[database[@dbservername]:][{owner|"owner"}.]identifier
```

With Microsoft™ SQL SERVER, an object name takes the following form:

```
[[database.]owner.]identifier
```

Object names are limited to 128 characters in SQL SERVER and cannot start with one of the following characters: @ (local variable) # (temp object).

To support double quotes as string delimiters in SQL SERVER, you can switch **OFF** the database option "Use quoted identifiers" in the database properties panel. But quoted table and column names are not supported when this option is OFF.

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Check for single or double quoted table or column names in your source and remove them.

Data type conversion table: Informix to SQL Server

Table 187: Data type conversion table (Informix to SQL Server)

Informix® data types	**SQL SERVER data types (<2008)**	**SQL SERVER data types (>=2008)**
CHAR(n)	CHAR(n) (limit = 8000b!)	CHAR(n) (limit = 8000b!)
VARCHAR(n[,m])	VARCHAR(n) (limit = 8000b!)	VARCHAR(n) (limit = 8000b!)
LVARCHAR(n)	VARCHAR(n) (limit = 8000b!)	VARCHAR(n) (limit = 8000b!)
NCHAR(n)	NCHAR(n) (UNICODE, limit = 4000c!)	NCHAR(n) (UNICODE, limit = 4000c!)
NVARCHAR(n[,m])	NVARCHAR(n) (UNICODE, limit = 4000c!)	NVARCHAR(n) (UNICODE, limit = 4000c!)
BOOLEAN	BIT	BIT
SMALLINT	SMALLINT	SMALLINT
INT / INTEGER	INTEGER	INTEGER
BIGINT	BIGINT	BIGINT
INT8	BIGINT	BIGINT
SERIAL[(start)]	INTEGER (see note 1)	INTEGER (see note 1)
BIGSERIAL[(start)]	BIGINT (see note 1)	BIGINT (see note 1)
SERIAL8[(start)]	BIGINT (see note 1)	BIGINT (see note 1)
DOUBLE PRECISION / FLOAT[(n)]	FLOAT(n)	FLOAT(n)
REAL / SMALLFLOAT	REAL	REAL
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL(p) with p<=19	DECIMAL(2*p,p)	DECIMAL(2*p,p)
NUMERIC / DEC / DECIMAL(p) with p>19	N/A	N/A
NUMERIC / DEC / DECIMAL	DECIMAL(32,16)	DECIMAL(32,16)
MONEY(p,s)	DECIMAL(p,s)	DECIMAL(p,s)
MONEY(p)	DECIMAL(p,2)	DECIMAL(p,2)
MONEY	DECIMAL(16,2)	DECIMAL(16,2)
DATE	DATETIME	DATE
DATETIME HOUR TO MINUTE	DATETIME	TIME(0)
DATETIME HOUR TO FRACTION(n)	DATETIME	TIME(n)
DATETIME YEAR TO SECOND	DATETIME	DATETIME2(0)
DATETIME q1 TO q2 (different from above)	DATETIME	DATETIME2(n)

Informix® data types	**SQL SERVER data types (<2008)**	**SQL SERVER data types (>=2008)**
INTERVAL q1 TO q2	CHAR(50)	CHAR(50)
TEXT	VARCHAR(MAX)	VARCHAR(MAX)
BYTE	VARBINARY(MAX)	VARBINARY(MAX)

Notes:

1. For more details about serial emulation, see SERIAL data types on page 606.

Data manipulation
Microsoft™ SQL Server related data manipulation topics.
Reserved words

Microsoft™ Transact-SQL does not allow you to use reserved words as database object names (tables, columns, constraint, indexes, triggers, stored procedures, ...). An example of a common word which is part of SQL SERVER grammar is '**go**' (see the 'Reserved keywords' section in the SQL SERVER Documentation).

Solution

Database objects having a name which is a Transact-SQL reserved word must be renamed.

All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™ 'grep' or 'awk' tools. Most modifications can be automatically done with UNIX™ tools like 'sed' or 'awk'.

You can use SET QUOTED_IDENTIFIER ON with double-quotes to enforce the use of keywords in the database objects naming, but it is not recommended.

Outer joins

The original OUTER join syntax of Informix® is different from Microsoft™ SQL SERVER outer join syntax:

In Informix® SQL, outer tables can be defined in the **FROM** clause with the **OUTER** keyword:

```
SELECT ... FROM cust, OUTER(order)
  WHERE cust.key = order.custno

SELECT ... FROM cust, OUTER(order,OUTER(item))
  WHERE cust.key = order.custno
    AND order.key = item.ordno
    AND order.accepted = 1
```

Microsoft™ SQL SERVER supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
                     ON cust.key = order.custno

SELECT ...
  FROM cust LEFT OUTER JOIN order
            ON cust.key = order.custno
            LEFT OUTER JOIN item
            ON order.key = item.ordno
 WHERE order.accepted = 1
```

Remark: The old way to define outers in SQL SERVER looks like the following:

```
SELECT ... FROM a, b WHERE a.key *= b.key
```

See the SQL SERVER reference manual for a complete description of the syntax.

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The Microsoft™ SQL SERVER interface can convert simple Informix® OUTER specifications to Microsoft™ SQL SERVER ANSI outer joins.

Prerequisites:

1. The outer join in the WHERE part must use the table name as prefix. Example: "WHERE tab1.col1 = tab2.col2 ".
2. Additional conditions on outer table columns cannot be detected and therefore are not supported: Example: "... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10".
3. Statements composed of 2 or more SELECT instructions using OUTERs are not supported. Example : "SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"

Remarks:

1. Table aliases are detected in OUTER expressions. OUTER example with table alias: "OUTER(tab1 alias1)".
2. In the outer join, <outer table>.<col> can be placed on both right or left sides of the equal sign. OUTER join example with table on the left: "WHERE outertab.col1 = maintab.col2 ".
3. Table names detection is not case-sensitive. Example: "SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2".
4. Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and Microsoft™ SQL SERVER handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Microsoft™ SQL SERVER supports named and nested transactions:

- Transactions are started with BEGIN TRANSACTION [*name*].
- Transactions are validated with COMMIT TRANSACTION [*name*].
- Transactions are canceled with ROLLBACK TRANSACTION [*name*].
- Savepoints can be placed with SAVE TRANSACTION *name*.
- Transactions can be rolled back to a savepoint with ROLLBACK TRANSACTION TO *name*.
- Savepoints can not be released.
- Statements executed outside of a transaction are automatically committed (autocommit mode). This behavior can be changed with "SET IMPLICIT_TRANSACTION ON".
- DDL statements are not supported in transactions blocks.

Transactions in stored procedures: avoid using transactions in stored procedure to allow the client applications to handle transactions, according to the transaction model.

Solution

Informix® transaction handling commands are automatically converted to Microsoft™ SQL SERVER instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Microsoft™ SQL SERVER.

> **Important:** If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Temporary tables

Informix® temporary tables are created through the **CREATE TEMP TABLE** DDL instruction or through a **SELECT ... INTO TEMP** statement. Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

Remark: BDL reports create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

Microsoft™ SQL SERVER provides local (SQL session wide) or global (database wide) temporary tables by using the '#' or '##' characters as table name prefix. No 'TEMP' keyword is required in CREATE TABLE, and the INTO clause can be used within a SELECT statement to create and fill a temporary table in one step:

```
CREATE TABLE #temp1 ( kcol INTEGER, .... )
SELECT * INTO #temp2 FROM customers WHERE ...
```

Unfortunately, SQL Server temporary tables are created by default with the collation of the tempdb database, instead of inheriting the collation of the current database you are connected to.

Solution

In BDL, Informix® temporary tables instructions are converted to generate native SQL SERVER temporary tables.

Microsoft™ SQL SERVER does not support scroll cursors based on a temporary table.

You must install SQL Server with the same collation as your database, see Installation for more details.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

Microsoft™ SQL SERVER provides the SUBSTR() function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTRING(col1,2,2) = 'RO'
SELECT SUBSTRING('Some text',6,3) FROM tab1 -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions with SUBSTRING(col,x,y-x+1).

In UPDATE instructions, setting column values through subscripts will produce an error with Microsoft™ SQL SERVER:

```
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
```

is converted to:

```
UPDATE tab1 SET SUBSTRING(col1,2,3-2+1) = 'RO' WHERE ...
```

Column subscripts in ORDER BY expressions are also converted and produce an error with Microsoft™ SQL SERVER:

```
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

is converted to:

```
SELECT ... FROM tab1 ORDER BY SUBSTRING(col1,1,3-1+1)
```

String delimiters

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE "tabname"."colname" = 'string'`

Informix® allows double quotes as string delimiters, but SQL SERVER doesn't. This is important, since many BDL programs use that character to delimit the strings in SQL commands.

> **Note:** This problem concerns only double quotes within SQL statements. Double quotes used in BDL string expressions are not subject of SQL compatibility problems.

National character strings:

With SQL SERVER, all UNICODE strings must be prefaced with an N character:

```
UPDATE cust SET cust_name =N'###' WHERE cust_id=123
```

If you don't specify the N prefix, SQL SERVER will convert the characters from the current system locale to the database locale. If the string is prefixed with N, the server can recognize a UNICODE string and use it as is to insert into NCHAR or NVARCHAR columns.

Solution

The SQL SERVER database interface can automatically replace all double quotes by single quotes.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: """
"This is a double quote: \""
```

> **Important:** Database object names cannot be delimited by double quotes because the database interface cannot determine the difference between a database object name and a quoted string !

For example, if the program executes the SQL statement:

`WHERE "tabname"."colname" = "string"`

replacing all double quotes by single quotes would produce:

`WHERE 'tabname'.'colname' = 'string'`

This would produce an error since 'tabname'.'colname' is not allowed by ORACLE.

Although double quotes are replaced automatically in SQL statements, you should use only single quotes to enforce portability.

National character strings

When using the **SNC** database driver, all string literals of an SQL statement are automatically changed to get the N prefix. Thus, you don't need to add the N prefix by hand in all of your programs. This solution makes by the way your Genero code portable to other databases.

With the **SNC** database driver, character string data is converted from the current Genero BDL locale to Wide Char (Unicode UCS-2), before is it used in an ODBC call such as SQLPrepareW or SQLBindParameter(SQL_C_WCHAR). When fetching character data, the **SNC** database driver converts from Wide Char to the current Genero BDL locale. The current Genero BDL locale is defined by LANG, and if LANG is not defined, the default is the ANSI Code Page of the Windows™ operating system. See CHARACTER data types for more details.

When using the **FTM** (FreeTDS) or the **ESM** (EasySoft) database driver on UNIX™, string literals get the N prefix if the current locale is a multibyte encoding like BIG5, EUC-JP or UTF-8. If the current locale is a single-byte encoding like ISO-8859-1, no prefix will be added to the string literals.

Getting one row with SELECT

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

With SQL SERVER, you can omit the FROM clause to generate one row only:

```
SELECT user
```

Solution

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements, while Microsoft™ SQL SERVER supports the LIKE statement only.

The MATCHES operator of Informix® uses the star (*), question mark (?) and square braces ([ ]) wildcard characters. The LIKE operator of SQL SERVER offers the percent (%), underscore (_) and square braces ([ ]) wildcard characters:

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x[a-z]' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x[a-z]' )
```

The LIKE operator of SQL Server does not evaluate to true with CHAR/NCHAR columns, if the LIKE pattern is provided as a UNICODE string literal (with the N prefix) and the search pattern matches the value in the column (without an ending % wildcard for example). See the following test:

```
CREATE TABLE mytable ( k INT, nc NCHAR(20) )
INSERT INTO mytable VALUES ( 1, N'abc' )
SELECT * FROM mytable WHERE nc = 'abc' -- one row is returned
SELECT * FROM mytable WHERE nc = N'abc' -- one row is returned
SELECT * FROM mytable WHERE nc LIKE 'abc' -- one row is returned
```

```
SELECT * FROM mytable WHERE nc LIKE N'abc' -- no rows are found
SELECT * FROM mytable WHERE nc LIKE N'abc%' -- one row is returned
```

This can be an issue because the SQL Server driver will by default automatically add an N prefix before all string literals in SQL statements. See Microsoft™ SQL Server documentation for more details about the LIKE semantics regarding blank padding and see also CHARACTER data types for the N prefix usage: You might consider setting the **snc.widechar** FGLPROFILE parameter to false if you are using CHAR/VARCHAR types.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no `[ ]` bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

Pay attention to UNICODE string prefixes N'...' in the LIKE expressions when used with CHAR/NCHAR columns. You might want to always add a % wildcard at the end of the LIKE condition, or use the equal operator when doing a query with exact values.

See also: MATCHES and LIKE operators on page 438.

Querying system catalog tables

As in Informix®, Microsoft™ SQL SERVER provides system catalog tables (sysobjects, syscolumns, etc.) in each database, but the table names and their structure are quite different.

Solution

> **Note:** No automatic conversion of Informix® system tables is provided by the database interface.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

`UPDATE` *`table`* `SET ( col-list ) = ( val-list )`

or

`UPDATE table SET` *`table`*`.* = myrecord.*`

`UPDATE table SET * =` *`myrecord`*`.*`

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

`UPDATE` *`table`* `SET` *`column = value`* `[,...]`

The LENGTH() function

Informix® provides the LENGTH() function:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Microsoft™ SQL SERVER has a equivalent function called LEN().

Do not confuse LEN() with DATALEN(), which returns the data size used for storage (number of bytes).

Both Informix® and SQL SERVER ignore trailing blanks when computing the length of a string.

Solution

You must adapt the SQL statements using LENGTH() and use the LEN() function.

Note:

If you create a user function in SQL SERVER as follows:

```
create function length(@s varchar(8000))
 returns integer
as
begin
   return len(@s)
end
```

You must qualify the function with the owner name:

```
SELECT dbo.length(col1) FROM table
```

String concatenation operator

The Informix® concatenation operator is the double pipe (||):

```
SELECT firstname || ' ' || lastname FROM employee
```

The Microsoft™ SQL SERVER concatenation operator is the plus sign:

```
SELECT firstname + ' ' + lastname FROM employee
```

Solution

The database interface detects double-pipe operators in SQL statements and converts them to a plus sign automatically.

BDL programming
Microsoft™ SQL Server related programming topics.
Executing SQL statements

The database driver for Microsoft™ SQL SERVER is based on ODBC. The ODBC driver implementation provided with SQL SERVER uses system stored procedures to prepare and execute SQL statements (You can see this with the Profiler).

Some Transact-SQL statements like SET DATEFORMAT have a local execution context effect (for example, when executed in a stored procedure, it is reset to the previous values when procedure execution is finished).

To support such statements in BDL programs, the database driver uses the SQLExecDirect() ODBC API function when the SQL statement is not a SELECT, INSERT, UPDATE or DELETE. This way the SET statement is executed 'directly', without using the system stored procedures. The result is that the SET statement has the expected effect (i.e. a permanent effect).

However, if the SQL statement uses parameters, the ODBC driver forces the use of system stored procedures to execute the statement.

See the MSDN for more details about system stored procedures used by Microsoft™ APIs.

Informix® specific SQL statements in BDL

The BDL compiler supports several Informix® specific SQL statements that have no meaning when using Microsoft™ SQL SERVER.

Examples:

- CREATE DATABASE dbname **IN dbspace WITH BUFFERED LOG**
- **START DATABASE** (SE only)
- **ROLLFORWARD DATABASE**
- CREATE TABLE ... **IN dbspace WITH LOCK MODE ROW**

Solution

Review your BDL source and remove all static SQL statements that are Informix-specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

Microsoft™ SQL SERVER does not support insert cursors.

Solution

Insert cursors are emulated by the Microsoft™ SQL SERVER database interface.

Cursors WITH HOLD

Informix® automatically closes opened cursors when a transaction ends unless the WITH HOLD option is used in the DECLARE instruction.

Microsoft™ SQL SERVER does not close cursors when a transaction ends. You can change this behavior using the SET CURSOR_CLOSE_ON_COMMIT ON.

Solution

BDL cursors that are not declared "WITH HOLD" are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed by the BDL program.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to avoid several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

- A transaction must be started before opening cursors declared for update.
- The row must be fetched in order to set the lock.
- The lock is released when the transaction ends (if the cursor is not declared "WITH HOLD") or when the cursor is closed.

Microsoft™ SQL SERVER allows individual and exclusive row locking by using the (UPDLOCK) hint after the table names in the FROM clause:

```
SELECT ... FROM tab1 WITH (UPDLOCK) WHERE ...
```

The FOR UPDATE clause is not mandatory; the (UPDLOCK) hint is important.

- Individual locks are acquired when fetching the rows.

- When the cursor (WITH HOLD) is opened outside a transaction, locks are released when the cursor is closed.
- When the cursor is opened inside a transaction, locks are released when the transaction ends.

SQL SERVER's locking granularity is at the row level, page level or table level (the level is automatically selected by the engine for optimization).

To control the behavior of the program when locking rows, Informix® provides a specific instruction to set the wait mode:

```
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
```

The default mode is NOT WAIT. This as an Informix® specific SQL statement.

Solution

The SQL SERVER database driver for MS SQL SERVER uses the SCROLL LOCKS concurrency options for cursors (SQL_ATTR_CONCURRENCY = SQL_CONCUR_LOCK).

This option implements pessimistic concurrency control, in which the application attempts to lock the underlying database rows at the time they are read into the cursor result set.

When using server cursors, an update lock is placed on the row when it is read into the cursor. If the cursor is opened within a transaction, the transaction update lock is held until the transaction is either committed or rolled back; the cursor lock is dropped when the next row is fetched.

If the cursor has been opened outside a transaction, the lock is dropped when the next row is fetched.

Therefore, a cursor should be opened in a transaction whenever the user wants full pessimistic concurrency control.

An update lock prevents any other task from acquiring an update or exclusive lock, which prevents any other task from updating the row.

An update lock, however, does not block a shared lock, so it does not prevent other tasks from reading the row unless the second task is also requesting a read with an update lock.

SELECT FOR UPDATE statements are well supported in BDL as long as they are used inside a transaction. Avoid cursors declared WITH HOLD.

> **Note:** The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

The SELECT FOR UPDATE statement cannot contain an ORDER BY clause if you want to perform positioned updates/deletes with WHERE CURRENT OF.

Cursors declared with SELECT ... FOR UPDATE using the "WITH HOLD" clause cannot be supported with SQL SERVER.

You must review the program logic if you use pessimistic locking because it is based on the NOT WAIT mode which is not supported by SQL SERVER.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instruction inserts rows from a text file into a database table.

Microsoft™ SQL SERVER has LOAD and UNLOAD instructions, but those commands are related to database backup and recovery. Do not confuse with Informix® commands.

Solution

LOAD and UNLOAD instructions are supported; note the following;

- The LOAD instruction does not work with tables using emulated SERIAL columns because the generated INSERT statement holds the "SERIAL" column which is actually a IDENTITY column in SQL SERVER. See the limitations of INSERT statements when using SERIALs.
- With Microsoft™ SQL SERVER versions prior to 2008, Informix® DATE data is stored in DATETIME columns, but DATETIME columns are similar to Informix® DATETIME YEAR TO FRACTION(3) columns. Therefore, when using LOAD and UNLOAD, those columns are converted to text data with the format "YYYY-MM-DD hh:mm:ss.fff". However, since SQL SERVER 2008, Informix® DATE data is stored in SQL SERVER DATE columns, so the result of a LOAD or UNLOAD statement is equivalent when using a DATE column with SQL SERVER 2008.
- With Microsoft™ SQL SERVER versions prior to 2008, Informix® DATETIME data is stored in DATETIME columns, but DATETIME columns are similar to Informix® DATETIME YEAR TO FRACTION(3) columns. Therefore, when using LOAD and UNLOAD, those columns are converted to text data with the format "YYYY-MM-DD hh:mm:ss.fff". With SQL SERVER 2008, Informix® DATETIME data is stored in SQL SERVER DATETIME2(n<=5) or TIME(n<=5) columns. Concerning DATETIME2(n<=5) columns, the result of LOAD and UNLOAD is equivalent to Informix® DATETIME columns, as long as the original Informix® type starts with the YEAR qualifier. The text data will be "YYYY-MM-DD hh:mm:ss.<*fraction-digits*>", where *fraction-digits* depends on the precision (n) of the DATETIME2(n) column. Concerning TIME(n) columns, the type is converted to an Informix® DATETIME HOUR TO SECOND or FRACTION(n). The text data will be "hh:mm:ss.<*fraction-digits*>", where *fraction-digits* depends on the precision (n) of the TIME(n) column.
- When using an Informix® database, simple dates are unloaded with the DBDATE format (ex:"23/12/1998"). Therefore, unloading from an Informix® database for loading into a Microsoft™ SQL SERVER database is not supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

SQL SERVER 2005 supports SQL Interruption in a similar way as Informix®. The db client must issue an SQLCancel() ODBC call to interrupt a query.

Solution

The SQL Server `SNC` and `ESM` database drivers support SQL interruption and return the Informix® error code **-213** if the statement is interrupted.

> **Important:** Make sure you have SQL SERVER 2005 or higher installed and that you use the **SNC** or **ESM** database driver.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

SQL Server supports native scrollable cursors.

Solution

All the SQL SERVER database drivers use the native SQL Server scrollable cursors by setting the ODBC statement attribute SQL_ATTR_CURSOR_SCROLLABLE to SQL_SCROLLABLE.

SQL adaptation guide for Oracle MySQL 5.x, MariaDB 10.x

> **Note:** Genero programs can connect to Oracle MySQL and it's open source equivalent MariaDB, by using the same database driver (dbmmys).

Installation (Runtime Configuration)
Oracle MySQL related installation topics.
Install MySQL/MariaDB and create a database - database configuration/design tasks

1. Install the MySQL Server (or MariaDB) on your computer.

2. Configure the server with the appropriate storage engine.

   In order to have transaction support by default, you must use a storage engine that supports transactional tables, such as INNODB. In recent versions of MySQL, this is the default storage engine.
3. Consider setting the `sql-mode` configuration parameter to get the appropriate behavior of the MySQL server:
   a) When the STRICT_TRANS_TABLES mode is used, you will get a -1406 error (data too long) when inserting a character string that is too large for the target column.

      If you don't use the STRICT_TRANS_TABLES mode, you get a -1265 warning (data truncated) when the value is too large.
   b) Blank padding of fetched CHAR data can be controlled with the PAD_CHAR_TO_FULL_LENGTH.

      You can use this parameter to get CHAR values padded with blanks to their full length, but the result of the SQL LENGTH() function will be different since trailing blanks are significant for that function in MySQL.
4. The **mysqld** process must be started to listen to database client connections. See MySQL documentation for more details about starting the database server process.
5. Create a database user dedicated to your application, the application administrator.

   Connect as the MySQL root user and GRANT all privileges to this user:

```
$ mysql -u root
...
mysql> grant all privileges on *.*
            to 'myuser'@'localhost'
            identified by 'password'
...
```

6. Connect as the application administrator and create a MySQL database with the CREATE DATABASE statement, and specify the character set to be used for this database:

```
$ mysql -u mysuser
...
mysql> create database mydatabase
             default character set utf8;
```

7. Create the application tables.

   Do not forget to convert Informix® data types to MySQL data types. See Data type conversion table: Informix to MySQL on page 636 for more details.

Prepare the runtime environment - connecting to the database

1. In order to connect to MySQL, you must have a MySQL database driver "`dbmmys`" in `FGLDIR/dbdrivers`.
2. The MySQL client software is required to connect to a database server.

   Check if the MySQL client library (`libmysqlclient.*`) is installed on the system. The shared library version of the MySQL client library must match the libmysqlclient library version linked to the dbmmys.so ODI driver.
3. Make sure that the MySQL client environment variables are properly set.

   Check for example MYSQL_HOME (the path to the installation directory), DATADIR (the path to the data files directory), etc. See MySQL documentation for more details about client environment variables to be set.
4. Check the MySQL client configuration options in the my.cnf file. The driver will read the options defined in the [client] group. Note that your can specify a particular configuration file with the `dbi.database.`*`dbname`*`.mys.optionsfile` FGLPROFILE configuration parameter.
5. Check the database client locale settings (`default-character-set` option in the my.cnf configuration file).

The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

6. Verify the environment variable defining the search path for the database client shared library (libmysqlclient.so on UNIX™, LIBMYSQL.dll on Windows™).

   Table 188: Shared library environment setting for MySQL

MySQL version	Shared library environment setting
MySQL 5.1 and higher	*UNIX™* : Add $MYSQL_HOME/lib to LD_LIBRARY_PATH (or its equivalent). *Windows™ :* Add %MYSQL_HOME%\bin to PATH.

7. To verify if the MySQL client environment is correct, you can start the MySQL command interpreter:

```
$ mysql dbname -u appadmin -p
```

8. Set up the fglprofile entries for database connections.
   a) Define the MySQL database driver:

```
dbi.database.dbname.driver = "dbmmys"
```

   b) The "source" parameter defines the name of the MySQL database.

```
dbi.database.dbname.source = "test1"
```

Database concepts
Oracle MySQL related database concepts topics.
Database concepts

Like Informix® servers, MySQL can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.

Solution

Create a MySQL database for each Informix® database.

Data storage concepts

An attempt should be made to preserve as much of the storage information as possible when converting from Informix® to MySQL. Most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be reused for the MySQL database.

Storage concepts are quite similar in Informix® and in MySQL, but the names are different.

Data consistency and concurrency

Data consistency involves readers which want to access data currently modified by writers and *concurrency data access* involves several writers accessing the same data for modification. *Locking granularity* defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks** according to the **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same

row for modification or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is read committed.
- The default lock wait mode is "not wait".
- The default locking granularity is per page.

MySQL

When data is modified, **exclusive locks** are set and held until the end of the transaction. For data consistency, MySQL uses a **locking mechanism**. Readers must wait for writers as in Informix®.

Control:

- No lock wait mode control is provided.
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is Read Committed.
- The default locking granularity is per table (pre page when using BDB tables).

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by SET SESSION TRANSACTION ISOLATION LEVEL ... in MySQL. The next table shows the isolation level mappings done by the MySQL database driver:

Table 189: Isolation level mappings done by the MySQL database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO CURSOR STABILITY	SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO REPEATABLE READ	SET SESSION TRANSACTION ISOLATION LEVEL REPEATABLE READ

For portability, it is recommended that you work with Informix® in the read committed isolation level, make processes wait for each other (lock mode wait), and create tables with the "lock mode row" option.

See Informix® and MySQL documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and MySQL handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

MySQL:

- Transactions are started with START TRANSACTION.
- Transactions are validated with COMMIT [WORK].
- Transactions are canceled with ROLLBACK [WORK].
- Savepoints can be placed with SAVEPOINT *name*.
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO [SAVEPOINT] *name*.
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Solution

Informix® transaction handling commands are automatically converted to MySQL instructions to start, validate or cancel transactions.

MySQL does not support transactions by default. You must set the server system parameter **table_type=InnoDB**.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with MySQL, as long as you have a transaction manager installed with MySQL.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Database users

Until version 11.70.xC2, Informix® database users must be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

MySQL users must be registered in the database. They are created with the **GRANT** SQL instruction:

```
$ mysql -u root -pmanager --host orion test
mysql>  GRANT ALL PRIVILEGES ON * TO mike IDENTIFIED BY 'pswd';
```

Solution

According to the application logic (is it a multiuser application?), you have to create one or several MySQL users.

Data dictionary
Oracle MySQL related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way: As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

MySQL supports the BOOLEAN data type and stores 1 or 0 integer values for TRUE and FALSE.

Solution

The MySQL database interface supports the BOOLEAN data type and stores 1 or 0 values in the column..

CHARACTER data types

Informix® supports following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

MySQL supports the following character data types:

- CHAR(N) with N<= 255 characters
- VARCHAR(N) with N<= 65535 characters
- NCHAR(N) with N<= 255 characters
- NVARCHAR(N) with N<= 65535 characters
- TEXT (a LOB data type)

With MySQL version 4, CHAR/VARCHAR with a size exceeding 255 characters are silently converted to TEXT columns. With later versions, you now get an SQL error when trying to define a CHAR or VARCHAR column with a size greater than the limit. Also, before version MySQL 5.0.3, VARCHAR limit was 255 characters, starting with 5.0.3 the limit is 65535 characters.

MySQL uses character length semantics to define the size of CHAR/VARCHAR columns, while Informix® and Genero use Byte Length Semantics.

MySQL can support multiple character sets, you can run the SHOW CHARACTER SET statement to list supported encodings. There are different configuration levels to define the character set used by MySQL to store data. The server character set defines the default for database character sets if not specified in the CREATE DATABASE command. You can even define a specific character set at the table and column level, but this is not recommended with Genero applications. The database character set is used to store CHAR and VARCHAR columns. The NCHAR and NATIONAL VARCHAR types use a predefined character set which can be different from the database character set. In MySQL the national character set is UTF-8.

MySQL can automatically convert from/to the client and server characters sets. In the client applications, you define the character set with the SET NAMES instruction.

Note that by default, when fetching CHAR columns from MySQL, trailing blanks are trimmed. This does not matter as long as you fetch CHAR columns into CHAR variables, but this non-standard behavior will

impact CHAR fetch into VARCHAR, or other SQL areas such as string concatenation for example. You can control the behavior of CHAR trailing blanks trimming with the PAD_CHAR_TO_FULL_LENGTH sql-mode parameter. But when this mode is used, the result of the SQL LENGTH() function will be different since trailing blanks are significant for that function in MySQL.

Solution

Informix® CHAR(N) types must be mapped to MySQL CHAR(N) types. Informix® VARCHAR(N) or LVARCHAR(N) columns must be mapped to MySQL VARCHAR(N).

You can store single-byte or multibyte character strings in MySQL CHAR, VARCHAR and TEXT columns.

MySQL uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics. When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a MySQL database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in MySQL database using the UTF8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

Review your database schema when using CHAR columns with a size exceeding the MySQL limits: If you need to store CHAR character strings larger as the MySQL CHAR limit, you can use the MySQL TEXT type. However, as of MySQL version 5.0.3 (supporting large VARCHAR sizes), as long as you use short sizes for CHAR (<100c), the character types can be used as is in MySQL.

The CHAR(N>255) types are converted by the SQL Translator to a MySQL TEXT type, because MySQL CHAR type has a limit of 255 characters. When designing a database, you should consider to use CHAR only for short character string data storage (<50c), and use VARCHAR for larger character string data storage (name, address, comments).

> **Note:** For each TEXT column fetched from MySQL, the MySQL database driver needs to allocate a temporary string buffer of 65535 bytes. The memory used by this temporary buffer is freed when freeing the cursor.

When using VARCHAR types, the SQL Translator leaves the type definition as is, even for N > 255, assuming that the target MySQL server version is at least 5.0.3 (supporting VARCHAR(N) up to 65535 characters).

See also the section about Localization.

NUMERIC data types

Informix® supports several data types to store numbers:

Table 190: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)

Informix® data type	**Description**
DEC(p) / DECIMAL(p)	Floating-point decimal number
DEC(p,s) / DECIMAL(p,s)	Fixed-point decimal number
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

Solution

MySQL supports the following data types to store numbers:

Table 191: MySQL numeric data types

MySQL data type	**Description**
DECIMAL(p)	Stores whole numeric numbers up to p digits (not floating point)
DECIMAL(p,s)	Maximum precision depends on MySQL Version, see documentation.
FLOAT[(M,D)]	4 bytes variable precision
DOUBLE[(M,D)]	8 bytes variable precision
SMALLINT	16 bit signed integer
INTEGER	32 bit signed integer
BIGINT	64 bit signed integer

> **Note:** Before MySQL 5.0.3, the maximum range of DECIMAL values is the same as for DOUBLE. Since MySQL 5.0.3, DECIMAL can store real precision numbers as in Informix®. However, the maximum number of digits depends on the version of MySQL, see documentation for more details. We strongly recommend that you make tests (INSERT+SELECT) to check whether large decimals are properly inserted and fetched back.

DATE and DATETIME data types

Informix® provides two data types to store dates and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

MySQL provides the following data type to store dates:

- DATE = for year, month, day storage.
- TIME[(N)] = for hour, minute, second and fraction of second storage.
- DATETIME[(N)] = for year, month, day, hour, minute, second and fraction of second storage.
- TIMESTAMP = Lilke DATETIME, but can automatically updated when row is touched.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contents matches environment parameters (i.e. DBDATE, GL_DATETIME). As in Informix®, MySQL can convert quoted strings to datetime data according the ISO datetime format (YYYY-MM-DD hh:mm:ss').

Date arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used and an INTERVAL value if a DATETIME is used in the expression.
- In MySQL, the result of an arithmetic expression involving DATE values is an INTEGER representing a number of days.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. MySQL does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in MySQL.

Solution

MySQL has the same DATE data type as Informix® (year, month, day). So you can use MySQL DATE data type for Informix® DATE columns.

The SQL Translator of the MySQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to MySQL TIME (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to MySQL TIME.
- DATETIME HOUR TO FRACTION(N) is converted to MySQL TIME(N).
- DATETIME YEAR TO MINUTE is converted to MySQL DATETIME (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to MySQL DATETIME.
- DATETIME YEAR TO FRACTION(N) is converted to MySQL DATETIME(N).

Other DATETIME types will be mapped to MySQL DATETIME(N) columns. Missing date or time parts default to 1900-01-01 00:00:00.

> **Important:** MySQL version older than 5.6.4 and MariaDB versions older than 5.3.0 do not support fractional part of DATETIME. If you try to store a DATETIME x TO FRACTION(P) with such old server version, the fractional part is lost.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix® INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals .

MySQL provides an INTERVAL data type, but it is totally different from the Informix® INTERVAL type. For example, you specify an INTERVAL literal as follows:

```
25 years 2 months 23 days
```

Solution

The INTERVAL data type is not well supported because the database server has no equivalent native data type. However, you can store into and retrieve from CHAR columns BDL INTERVAL values.

SERIAL data type

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

MySQL supports the AUTO_INCREMENT column definition option as well as the SERIAL keyword:

- In CREATE TABLE, you specify a auto-incremented column with the AUTO_INCREMENT attribute
- Auto-incremented columns have the same behavior as Informix® SERIAL columns
- You define a start value with ALTER TABLE tabname AUTO_INCREMENT = value
- The column must be the primary key.
- When using the InnoDB engine, AUTO_INCREMENTED columns might reuse unused sequences after a server restart. Actually, when the server restarts, it issues a SELECT MAX(auto_increment_column) on each table with such as column to identify the next sequence to be generated. If you insert rows that generate the numbers 101, 102 and 103, then you delete rows 102 and 103; When the server is restarted next generated number will be 101 + 1 = 102.
- SERIAL is a synonym for BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE.

Solution

The Informix® SERIAL data type is emulated with MySQL AUTO_INCREMENT option. After an insert, SQLCA.SQLERRD[2] holds the last generated serial value. However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT auto incremented columns. If you are using BIGINT auto incremented columns, you must use the LAST_INSERT_ID() SQL function.

AUTO_INCREMENT columns must be primary keys. This is handled automatically when you create a table in a BDL program.

Like Informix®, MySQL allows to specify a zero for auto-incremented columns, however, for SQL portability, INSERT statements should be reviewed to remove the SERIAL column from the list.

For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES ( 0, p_value)
```

can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.* ) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

ROWIDs

When creating a table, Informix® automatically adds a "ROWID" integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

MySQL does not have an equivalent for the Informix® ROWID pseudo-column.

Solution

ROWIDs are not supported. You must review the code using ROWIDs and use primary key columns instead.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

MySQL provides TINYTEXT, TEXT, MEDIUMTEXT, LONGTEXT, TINYBLOB, BLOB, MEDIUMBLOB and LONGBLOB data types.

Solution

Starting with MySQL version 5.0, the database interface can convert BDL TEXT data to LONGTEXT and BYTE data to LONG BLOB.

Genero TEXT/BYTE program variables have a limit of 2 gigabytes, make sure that the large object data does not exceed this limit.

Because MySQL CHAR and VARCHAR cannot exceed 255 bytes, we recommend that you use the MySQL TEXT type to store CHAR/VARCHAR values with a size larger than 255 bytes. When fetching TEXT columns from a MySQL database, these will be treated as CHAR/VARCHAR types by the MySQL database driver. See CHAR/VARCHAR types for more details.

Constraints

Constraint naming syntax

Both Informix® and MySQL support primary key, unique, foreign key and default, but the constraint naming syntax is different: MySQL expects the "CONSTRAINT" keyword **before** the constraint specification and Informix® expects it **after**.

UNIQUE constraint example

Table 192: UNIQUE constraint example (Informix® vs. MySQL)

Informix®	MySQL

`CREATE TABLE emp(`
`  ...`
`  emp_code CHAR(10) UNIQUE`
`  CONSTRAINT pk_emp,`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  CONSTRAINT pk_emp UNIQUE,`

Informix®	MySQL
`...`	`...`

Primary keys

Like Informix®, MySQL creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using "CREATE UNIQUE INDEX" to define unique constraints is obsolete (use primary keys or a secondary key instead).

In MySQL, the name of a PRIMARY KEY is PRIMARY.

Unique constraints

Like Informix®, MySQL creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

When using a unique constraint, Informix® allows only one row with a NULL value, while MySQL allows several rows with NULL! Using CREATE UNIQUE INDEX is obsolete.

Foreign keys

Both Informix® and MySQL support the ON DELETE CASCADE option. In MySQL, foreign key constraints are checked immediately, so NO ACTION and RESTRICT are the same.

Check constraints

Check constraints are not yet supported in MySQL.

Solution

Constraint naming syntax

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for MySQL.

Name resolution of SQL objects

Informix® uses the following form to identify a SQL object:

```
[database[@dbservername]:][{owner|"owner"}.]identifier
```

With MySQL, an object name takes the following form:

```
[database.]identifier
```

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Data type conversion table: Informix to MySQL

Table 193: Data type conversion table (Informix to MySQL)

Informix® data types	MySQL data types
CHAR(n)	CHAR(n) or TEXT (see note 1)
VARCHAR(n[,m])	VARCHAR(n)

Informix® data types	**MySQL data types**
LVARCHAR(n)	VARCHAR(n)
NCHAR(n)	NCHAR(n)
NVARCHAR(n[,m])	NVARCHAR(n)
BOOLEAN	BOOLEAN
SMALLINT	SMALLINT
INT / INTEGER	INTEGER
BIGINT	BIGINT
INT8	BIGINT
SERIAL[(start)]	INTEGER (see note 2)
BIGSERIAL[(start)]	BIGINT (see note 2)
SERIAL8[(start)]	BIGINT (see note 2)
DOUBLE PRECISION / FLOAT[(n)]	DOUBLE
REAL / SMALLFLOAT	FLOAT
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL(p) with p<=15	DECIMAL(p*2,p)
NUMERIC / DEC / DECIMAL(p) with >15	N/A
NUMERIC / DEC / DECIMAL	DECIMAL(32,16) (unsupported!)
MONEY(p,s)	DECIMAL(p,s)
MONEY(p)	DECIMAL(p,2)
MONEY	DECIMAL(16,2)
DATE	DATE
DATETIME HOUR TO MINUTE	TIME
DATETIME HOUR TO SECOND	TIME
DATETIME HOUR TO FRACTION(p)	TIME(p) (see note 3)
DATETIME YEAR TO MINUTE	DATETIME
DATETIME YEAR TO SECOND	DATETIME
DATETIME YEAR TO FRACTION(p)	DATETIME(p) (see note 3)
DATETIME q1 TO q2 (others than above)	DATETIME(p) (see note 3)
INTERVAL q1 TO q2	CHAR(50)
TEXT	MEDIUMTEXT / LONGTEXT (using <= 2Gb!)
BYTE	MEDIUMBLOB / LONGBLOB (using <= 2Gb!)

Notes:

1. The CHAR types with a size > 255 are converted TEXT types. For more details, see CHARACTER data types on page 630.
2. For more details about serial emulation, see SERIAL data type on page 634.

3. Only with MySQL >= 5.6.4 and MariaDB >= 5.3.0, for older versions DATETIME cannot use a frational part.

Data manipulation
Oracle MySQL related data manipulation topics.
Reserved words

SQL object names like table and column names cannot be SQL reserved words in MySQL.

Solution

Table or column names which are MySQL reserved words must be renamed.

Outer joins

In Informix® SQL, outer tables can be defined in the **FROM** clause with the **OUTER** keyword:

```
SELECT ... FROM a, OUTER(b)
 WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c))
 WHERE a.key = b.akey    AND b.key1 = c.bkey1
   AND b.key2 = c.bkey2
```

MySQL 3.23 supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
                     ON cust.key = order.custno
SELECT ...
  FROM cust LEFT OUTER JOIN order
                 LEFT OUTER JOIN item
                 ON order.key = item.ordno
             ON cust.key = order.custno
 WHERE order.cdate > current date
```

See the MySQL reference for a complete description of the syntax.

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The MySQL interface can convert most Informix® OUTER specifications to ANSI outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item and the outer tables must figure from left to right in the order of outer levels.

   Example which does not work: "FROM OUTER(tab2), tab1".
2. The outer join in the WHERE part must use the table name as prefix.

   Example: "WHERE tab1.col1 = tab2.col2".

Restrictions:

1. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: "... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10".
2. Statements composed by 2 or more SELECT instructions using OUTERs are not supported.

   Example: "SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"

   Note:

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias: "OUTER(tab1 alias1)".
2. In the outer join, <outer table>.<col> can be placed on both right or left side of the equal sign.

   OUTER join example with table on the left: "WHERE outertab.col1 = maintab.col2 ".
3. Table names detection is not case-sensitive.

   Example: "SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2".
4. Temporary tables

   are supported in OUTER specifications.

Transactions handling

Informix® and MySQL handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

MySQL:

- Transactions are started with START TRANSACTION.
- Transactions are validated with COMMIT [WORK].
- Transactions are canceled with ROLLBACK [WORK].
- Savepoints can be placed with SAVEPOINT *name*.
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO [SAVEPOINT] *name*.
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Solution

Informix® transaction handling commands are automatically converted to MySQL instructions to start, validate or cancel transactions.

MySQL does not support transactions by default. You must set the server system parameter **table_type=InnoDB**.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with MySQL, as long as you have a transaction manager installed with MySQL.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Temporary tables

Informix® temporary tables are created through the **CREATE TEMP TABLE** DDL instruction or through a **SELECT ... INTO TEMP** statement. Temporary tables are automatically dropped when the SQL session ends, but they can be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

MySQL support temporary tables with the following syntax:

```
CREATE TEMPORARY TABLE tablename ( coldef [,...] )
```

and:

```
CREATE TEMPORARY TABLE tablename LIKE other-table
```

Solution

In BDL, Informix® temporary tables instructions are converted to generate native SQL Server temporary tables.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3]= 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

MySQL provides the SUBSTRING() function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTRING(col1,2,3) = 'RO'
SELECT SUBSTRING('Some text',6,3) ... -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions by SUBSTRING(col,x,y-x+1).

In UPDATE instructions, setting column values through subscripts will produce an error with MySQL:

```
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
```

is converted to:

```
UPDATE tab1 SET SUBSTRING(col1,2,(3-2+1)) = 'RO' WHERE ...
```

Column subscripts in ORDER BY expressions are also converted and produce an error with MySQL:

```
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

is converted to:

```
SELECT ... FROM tab1 ORDER BY SUBSTRING(col1,1,(3-1+1))
```

Database object name delimiters

Informix® identifies database object names with double quotes, while MySQL does not use the double quotes as database object identifiers.

Solution

Check your programs for database object names having double quotes:

```
WHERE "tabname"."colname" = "string"
```

should be written as follows:

```
WHERE tabname.colname = 'string'
```

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements. MySQL supports the LIKE statement as in Informix®, plus the ~ operators that are similar but different from the Informix® MATCHES operator.

MATCHES requires * and ? wildcard characters, and LIKE uses the % and _ wildcards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The MySQL LIKE operator has no operator for [ ] brackets character ranges.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

```
UPDATE table SET ( col-list ) = ( val-list )
```

or

```
UPDATE table SET table.* = myrecord.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column = value [,...]
```

BDL programming

Oracle MySQL related programming topics.

Informix-specific SQL statements in BDL

The BDL compiler supports several Informix® specific SQL statements that have no meaning when using MySQL:

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and remove all static SQL statements that are Informix-specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

MySQL does not support insert cursors.

Solution

Insert cursors are emulated by the MySQL database interface.

Cursors WITH HOLD

Informix® closes opened cursors automatically when a transaction ends unless the WITH HOLD option is used in the DECLARE instruction. In MySQL, opened cursors using SELECT statements without a FOR UPDATE clause are not closed when a transaction ends. Actually, all MySQL cursors are 'WITH HOLD' cursors unless the FOR UPDATE clause is used in the SELECT statement.

Cursors declared FOR UPDATE and using the WITH HOLD option cannot be supported with MySQL because FOR UPDATE cursors are automatically closed by MySQL when the transaction ends.

Solution

BDL cursors that are not declared "WITH HOLD" are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since MySQL automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and WITH HOLD option results in an SQL error; in the same conditions, this does not normally appear with Informix®. Review the program logic in order to find another way to set locks.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to avoid several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

MySQL locking mechanism depends upon the transaction manager. The default locking granularity is per table when you use the default non-transactional configuration. You must use the InnoDB Storage Engine to get transactions and locking mechanisms.

SELECT ... FOR UPDATE is only supported since MySQL version 6.0. Locks are released at the end of the transaction.

Solution

Check if the MySQL storage engine supports SELECT FOR UPDATE, otherwise review the program logic.

UPDATE/DELETE WHERE CURRENT OF

Informix® allows positioned UPDATEs and DELETEs with the "`WHERE CURRENT OF` *`cursor`*" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

Solution

WHERE CURRENT OF is not supported by MySQL; review your code for occurrences.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instructions insert rows from a text file into a database table.

MySQL does not provide LOAD and UNLOAD instructions.

Solution

LOAD and UNLOAD instructions are supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

MySQL provides the KILL QUERY command to interrupt a running query on the server, but the client program must open a second connection to execyte this statement.

Solution

SQL interruption is supported with MySQL. The database driver opens a second connection to the server and sends a KILL QUERY command, with the MySQL process id of the current connection.

> **Important:** Opening a second connection does not work when using Unix sockets, connect to MySQL with a host name and TCP port.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

MySQL 6.0 does not support native scrollable cursors.

Solution

The MySQL database driver emulates scrollable cursors with temporary files.

See Scrollable cursors on page 422 for more details about scroll cursor emulation.

SQL adaptation guide for Oracle Database 11, 12

Installation (Runtime Configuration)
Oracle Database related installation topics.
Install Oracle and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the ORACLE database software on your computer.
2. Create and setup the Oracle instance and database. Consider creating a multitenant database when using Oracle 12c and higher, to create several pluggable databases (PDB) in the same Oracle instance.

   Specify the database character set when creating the database instance. If you plan to create a database a multi-byte character set like UTF-8, consider using character length semantics.
3. Create a database context dedicated to your application.

   According the Oracle version, define a db user / schema to hold application tables, or create a pluggable database (starting with Oracle 12c).

   a) With Oracle version 11g and lower, group application tables in a schema by creating a dedicated database user.

Connect as system user with:

```
$ sqlplus / AS SYSDBA
```

and execute the following SQL command to create the db user:

```
CREATE USER appadmin IDENTIFIED BY password;
```

Grant privileges to the application administrator user:

```
GRANT CONNECT, RESOURCE, UNLIMITED TABLESPACE TO appadmin;
```

b) With Oracle version 12c and higher, group application tables in a pluggable database (PDB).

Connect as system user with:

```
$ sqlplus / AS SYSDBA
```

and create a pluggable database and its PDB administrator user. This is a basic PDB creation example using Oracle Managed Files, consider planing the PDB creation with the person in charge of Oracle database administration:

```
CREATE PLUGGABLE DATABASE mypdb
  ADMIN USER pdbadmin IDENTIFIED BY password ROLES = (DBA)
  DEFAULT TABLESPACE mypdb_01
     DATAFILE 'path_01' SIZE 250M AUTOEXTEND ON ;
```

For now the PDB is only mounted, it must be opened for regular usage:

```
ALTER PLUGGABLE DATABASE mypdb OPEN;
```

PDBs must be identified as separate database services (i.e. different from the CDB service). By default Oracle creates a database service with the same name as the PDB. To access the PDB through TNS, create the *mypdb* record in TNSNAMES.ORA file in addition to the default database service (`ORC*`):

```
tnsname =
 (DESCRIPTION =
    (ADDRESS = (PROTOCOL = TCP)(HOST = myhost)(PORT = 1521))
    (CONNECT_DATA =
       (SERVER = DEDICATED)
       (SERVICE_NAME = mypdb)
    )
 )
```

By default when Oracle starts, the PDBs are mounted but are not open for regular usage. With Oracle 12c, you can create a database trigger to open all PDBs automatically:

```
CREATE OR REPLACE TRIGGER open_pdbs
  AFTER STARTUP ON DATABASE
BEGIN
    EXECUTE IMMEDIATE 'ALTER PLUGGABLE DATABASE ALL OPEN';
END open_pdbs;
/
```

Re-connect as PDB administrator and create a user dedicated to application tables administration:

```
CONNECT pdbadmin/password@localhost/mypdb
CREATE USER appadmin IDENTIFIED BY password;
```

```
GRANT CONNECT, RESOURCE, UNLIMITED TABLESPACE TO appadmin;
```

4. If programs create temporary tables, you must define the type of temporary table emulation to be used.
   a) If you plan to use the default temporary table emulation, setup your database for the TEMPTABS tablespace usage.

      See Using the default temporary table emulation on page 670 for more details.
   b) If you plan to use the temporary table emulation based on Oracle global temporary tables, setup the database to use the TEMPTABS schema/user.

      See Using the global temporary table emulation on page 672 for more details.

   For more details about temporay table emulations, see Temporary tables on page 670.
5. Create the application tables by connecting to the database context as the application administrator:

   ```
   $ sqlplus appadmin/password@tnsname
   ```

   Convert Informix® data types to Oracle data types. See issue data type Conversion Tables for more details.
6. If you plan to use SERIAL emulation, you must choose a serial emulation method.

   Select the best emulation technique that matches your needs. You need to prepare the database according to the emulation type. For more details, see SERIAL data types on page 658.

Prepare the runtime environment - connecting to the database

1. In order to connect to ORACLE, you must have a database driver "dbmora" in FGLDIR/dbdrivers.
2. If you want to connect to a remote Oracle server from an application server, you must install the ORACLE Client Software on your application server and configure this.
3. Make sure that the ORACLE client environment variables are properly set.

   Check variables such as ORACLE_HOME (the path to the installation directory), ORACLE_SID (the server identifier when connecting locally), etc. See the Oracle documentation for more details.
4. Verify the environment variable defining the search path for database client shared libraries (libclntsh.so on UNIX™, OCI.DLL on Windows™)

ORACLE version	Shared library environment setting
Oracle 10g and higher	*UNIX*™: Add $ORACLE_HOME/lib to LD_LIBRARY_PATH (or its equivalent). *Windows*™: Add %ORACLE_HOME%\bin to PATH.

5. Check the database client locale settings (NLS_LANG, NLS_DATE_FORMAT, etc).

   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).
6. If you are using the TNS protocol, verify if the ORACLE listener is started on the server.
7. To test the client environment settings, you can try to connect to the ORACLE server with the SQL*Plus tool:

   ```
   $ sqlplus username/password@service
   ```

8. Set up the fglprofile entries for database connections.
   a) Set up fglprofile for the SERIAL emulation method.

      The following entry defines the SERIAL emulation method. You can use the SEQUENCE based trigger or the SERIALREG based trigger method:

      ```
      dbi.database.dbname.ifxemul.datatype.serial.emulation = "(native|
      regtable)"
      ```

The value 'native' selects the SEQUENCE based method, and the value 'regtable' selects the SERIALREG based method. This entry has no effect if `dbi.database.`*`dbname`*`.ifxemul.datatype.serial` is set to 'false'.

The default is SERIAL emulation enabled with native method (SEQUENCE-based). See issue SERIAL data types on page 658 for more details.

b) The "`source`" parameter defines the TNS name of the Oracle database.

```
dbi.database.dbname.source = "stock"
```

c) Define the database schema selection if needed.

The following entry defines the database schema to be used by the application. The database interface automatically executes an "`ALTER SESSION SET CURRENT_SCHEMA` *`owner`*" instruction to switch to a specific schema:

```
dbi.database.dbname.ora.schema = "name"
```

Here *dbname* identifies the database name used in the BDL program (DATABASE *dbname*) and *name* is the schema name to be used in the ALTER SESSION instruction. If this entry is not defined, no ALTER SESSION instruction is executed and the current schema defaults to the user's name.

d) Define pre-fetch parameters.

Oracle offers high performance by pre-fetching rows in memory. The pre-fetching parameters can be tuned with the following entries:

```
dbi.database.dbname.ora.prefetch.rows = integer
dbi.database.dbname.ora.prefetch.memory = integer # in bytes
```

These values will be applied to all application cursors.

The interface pre-fetches rows up to the prefetch.rows limit unless the prefetch.memory limit is reached, in which case the interface returns as many rows as will fit in a buffer of size prefetch.memory. By default, pre-fetching is on and defaults to 10 rows; the memory parameter is set to zero, so the memory size is not included in computing the number of rows to prefetch.

e) If needed, define a specific command to generate session identifiers with this FGLPROFILE setting:

```
dbi.database.dbname.ora.sid.command = "SELECT ..."
```

This unique session identifier will be used to create table names for temporary table emulation.

By default, the database driver will use "`SELECT USERENV('SESSIONID') FROM DUAL`".

f) If needed, define a specific command to generate session identifiers with this FGLPROFILE setting:

```
dbi.database.dbname.ora.sid.command = "SELECT ..."
```

This unique session identifier will be used to create table names for temporary table emulation.

By default, the database driver will use "`SELECT USERENV('SESSIONID') FROM DUAL`".

g) The default temporary table emulation uses regular permanent tables.

If this does not fit your needs, you can use GLOBAL TEMPORARY TABLES with this FGLPROFILE setting:

```
dbi.database.dbname.ifxemul.temptables.emulation = "global"
```

Database concepts
Oracle Database related database concepts topics.
Database concepts

Informix® servers can handle multiple database entities. By default an ORACLE instance can only handle one database entity. Starting with Oracle 12c, you can use a multi-tenant database to define several pluggable databases.

ORACLE can manage multiple schemas, but by default other users must give the owner name as prefix to the table name:

```
SELECT * FROM stores.customer
```

Solution 1: With Oracle 12c and higher

Oracle 12c introduced the multi-tenant database concept, where you can create several pluggable databases in a root container. Consider using this feature, if you need to create several copies of the same database entity, that can be accessed/seen as individual data sources.

Solution 2: With Oracle 10g and 11g

In an Oracle database, each user can manage his own database schema. You can dedicate a database user to administer each occurrence of the application database.

Any user can select the current database schema with the following SQL command:

```
ALTER SESSION SET CURRENT_SCHEMA = "schema"
```

Using this instruction, any user can access the tables without giving the owner prefix as long as the table owner has granted the privileges to access the tables.

You can make the database interface select the current schema automatically with the following fglprofile entry:

```
dbi.database.dbname.schema = "schema"
```

When using multiple database schemas, it is recommended that you create them in separated tablespaces to enable independent backups and keep logical sets of tables together. The simplest way is to define a default tablespace when creating the schema owner:

```
CREATE USER user IDENTIFIED BY password
   DEFAULT TABLESPACE deftablespace
    TEMPORARY TABLESPACE tmptablespace
```

Data storage concepts

An attempt should be made to preserve as much of the storage specification as possible when converting from Informix® to ORACLE. Most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be reused for the ORACLE database.

Storage concepts are quite similar in Informix® and in ORACLE, but the names are different.

This table compares Informix® storage concepts to ORACLE storage concepts:

Table 194: Physical units of storage

Informix®	**ORACLE**
The largest unit of physical disk space is a "**chunk**", which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (=UNIX partition, I/O is controlled by the database engine). A "dbspace" uses at least one "chunk" for storage.	One or more "**data files**" are created for each "tablespace" to physically store the data of all logical structures. Like Informix® "chunks", a "data file" can be an OS file or a raw device.

Informix®	**ORACLE**
You must add "chunks" to "dbspaces" in order to increase the size of the logical unit of storage.	You can add "data files" to a "tablespace" in order to increase the size of the logical unit of storage or you can use the AUTOEXTEND option when using OS files.
A "**page**" is the smallest physical unit of disk storage that the engine uses to read from and write to databases. A "chunk" contains a certain number of "pages". The size of a "page" must be equal to the operating system's block size.	At the finest level of granularity, ORACLE stores data in "**data blocks**" which size corresponds to a multiple of the operating system's block size. You set the "data block" size when creating the database.
An "**extent**" consists of a collection of contiguous "pages" that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, "extents" can be located in different "chunks" of the same "dbspace".	An "**extent**" is a specific number of contiguous "data blocks", obtained in a single allocation. When creating a table, you can specify the first extent size and the size of future extents with the STORAGE() option. For a single table, "extents" can be located in different "data files" of the same "tablespace".

Table 195: Logical units of storage

Informix®	**ORACLE**
A "**table**" is a logical unit of storage that contains rows of data values.	Same concept as Informix®.
A "**database**" is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges.	Same concept as Informix®, but one ORACLE instance can manage only one database, in the meaning of Informix®.
Database tables are created in a specific "**dbspace**", which defines a logical place to store data. If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.	Database tables are created in a specific "**tablespace**", which defines a logical place to store data. If no tablespace is given when creating the table, ORACLE defaults to the user's default tablespace.
The total disk space allocated for a table is the "**tblspace** ", which includes "pages" allocated for data, indexes, blobs, tracking page usage within table extents. Do not confuse the Informix® "tblspace" concept and ORACLE "tablespaces".	A "**segment**" is a set of "extents" allocated for a certain logical structure. There are four different types of segments, including data segments, index segments, rollback segments and temporary segments.

Table 196: Other concepts related to storage

Informix®	**ORACLE**
When initializing an Informix® engine, a "**root dbspace**" is created to store information about all databases, including storages information (chunks used, other dbspaces, etc.)	Each ORACLE database has a "**control file**" that records the physical structure of the database, like the database name, location and names of "data files" and "redo log" files, and time stamp of database creation.
The "**physical log**" is a set of continuous disk pages where the engine stores "before-images" of data that has been modified during processing. The "**logical log**" is a set of "**logical-log files**" used to record logical operations during online processing. All transaction information is stored in the logical log files if a database has been created with transaction log. Informix® combines "physical log" and "logical log" information when doing fast recovery. Saved "logical logs" can be used to restore a database from tape.	A "**rollback segment**" records the actions of SQL transactions that could be rolled back, and it records the data as it existed before an operation in a transaction. The "**redo log files**" hold all changes made to the database, in case the database experiences an instance failure. Each database has at least two "redo log files". Redo entries record data that can be used to reconstruct all changes made to the database, including the rollback segments stored in the database buffers of the SGA. Therefore, the online redo log also protects rollback data.

Data consistency and concurrency

Data consistency involves readers that want to access data currently modified by writers, and *concurrency data access* involves several writers accessing the same data for modification. **Locking granularity** defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks** according to the **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is read committed.
- The default lock wait mode is "not wait".
- The default locking granularity is page.

ORACLE

When data is modified, **exclusive locks** are set and held until the end of the transaction. For data consistency, ORACLE uses a **multi-version consistency model**: a copy of the original row is kept for readers before performing writer modifications. Readers do not have to wait for writers as in Informix®. The simplest way to think of Oracle's implementation of read consistency is to imagine each user accessing a private copy of the database, hence the multi-version consistency model. The **lock wait mode** cannot be changed session wide as in Informix®; the waiting behavior can be controlled with a SELECT FOR UPDATE NOWAIT only. Locks are set at the **row level** in ORACLE, and this cannot be changed.

Control:

- Lock wait mode (on SELECT only): SELECT ... FOR UPDATE NOWAIT
- Isolation level: SET TRANSACTION ISOLATION LEVEL TO ...
- Explicit exclusive lock: SELECT ... FOR UPDATE [NOWAIT]

Defaults:

- The default isolation level is Read Committed (readers cannot see uncommitted data, no shared lock is set when reading data).

The main difference between Informix® and ORACLE is that readers do not have to wait for writers in ORACLE.

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by ALTER SESSION SET ISOLATION_LEVEL ... in Oracle. The next table shows the isolation level mappings done by the database driver:

Table 197: Isolation level mappings done by the Oracle database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED
SET ISOLATION TO CURSOR STABILITY	ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED
SET ISOLATION TO REPEATABLE READ	ALTER SESSION SET ISOLATION_LEVEL = SERIALIZABLE

ORACLE does not provide a dirty read mode, the (session wide) lock wait mode cannot be changed and the locking precision is always at the row level. Based on this, it is recommended that you work with Informix® in the read committed isolation level (default), make processes wait for each other (lock mode wait), and use the default page-level locking granularity.

See the Informix® and ORACLE documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and ORACLE handle transactions differently. The differences in the transactional models can affect the program logic.

Informix® native mode (non ANSI):

- DDL statements can be executed (and canceled) in transactions.

- Transactions must be started with BEGIN WORK. Statements executed outside of a transaction are automatically committed.

ORACLE:

- Beginnings of transactions are implicit; two transactions are delimited by COMMIT or ROLLBACK.
- The current transaction is automatically committed when a DDL statement is executed.

Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, in accordance with the transaction model.

Informix® version 11.50 introduces savepoints with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

ORACLE supports savepoints too. However, there are differences:

1. Savepoints cannot be declared as UNIQUE
2. Rollback must always specify the savepoint name
3. You cannot release savepoints (RELEASE SAVEPOINT)

Solution

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with ORACLE. The Informix® behavior is simulated with an autocommit mode in the ORACLE interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program.

When executing a DDL statement inside a transaction, ORACLE automatically commits the transaction. Therefore, you must extract the DDL statements from transaction blocks.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

See also SELECT FOR UPDATE

Database users

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

Oracle users can be authenticated in different manner: as database users, as operating system users or by delegating authentication to another service, like Kerberos or LDAP.

Oracle users must be created in the database with a CREATE USER command, to create a user authenticated by the database server:

`CREATE USER username IDENTIFIED BY password`

Oracle users can also be created with the "IDENTIFIED EXTERNALLY" clause:

`CREATE USER username IDENTIFIED EXTERNALLY`

In this case, ORACLE trusts the operating system to authenticate the user. See the Oracle documentation for OS user authentication configuration, especially the `OS_AUTHENT_PREFIX` (empty string) and `REMOTE_OS_AUTHENT` (true) server parameters. Note also that the Oracle user name needs to be specified in uppercase in the CREATE USER instruction, and gets an additional prefix, according to the operating system (domain name on Windows platforms)

In ORACLE, is it also possible to define users that are defined in a central LDAP directory, with the "IDENTIFIED GLOBALLY" clause:

`CREATE USER` *`username`* `IDENTIFIED GLOBALLY AS '`*`distinguished_name`*`'`

Global users are registered and managed by an external LDAP service, and are identified by the distinguished name (DN).

Solution

Based on the application logic, you must create one or several ORACLE users. Use RDBMS or external authentication according to your needs. If you want to keep the same Informix® OS users, you must configure Oracle for OS authentication, and create users with the IDENTIFIED EXTERNALLY option. Consider however to use real RDBMS users instead, and ask for login/password when connecting a program to Oracle.

To connect to an Oracle server from a program, use the `CONNECT TO` instruction. When the `USER/USING` clause is not specified, external authentication takes place. You can check if external or rdbms authentication takes place with the FGLSQLDEBUG output (check the line containing "Credential flag").

Tester with Oracle 11.2 on a Linux system (the Linux user login name is "sf" in lowercase):

```
$ sqlplys / as sysdba

SQL> show parameter os_authent_prefix;
NAME                 TYPE            VALUE
---------------------------------------------
os_authent_prefix    string

SQL> show parameter remote_os_authent;
NAME                 TYPE            VALUE
---------------------------------------------
remote_os_authent    boolean         TRUE

SQL> create user "SF" identified externally;
User created.

SQL> grant connect, resource to "SF";
Grant succeeded.
```

To connect to Oracle as an external user declared with IDENTIFIED EXTERNALLY (authenticated by the operating system), do not specify any login/password. For example, omit the `USER/USING` clause in the `CONNECT TO` instruction:

```
CONNECT TO "orc1fox+driver='dbmora'"
```

If no db login is specified, the Oracle driver will open a database session with the OCI_CRED_EXT credentials.

An Oracle connection can also be established as SYSDBA or SYSOPER users. This is possible by specifying the following strings after the user name in the `USER` clause of the `CONNECT TO` instruction:

Table 198: Oracle connection as SYSDBA or SYSOPER

String passed to USER clause after user name	Effect as Oracle connection
`/SYSDBA`	Connection will be established as SYSDBA user.
`/SYSOPER`	Connection will be established as SYSOPER user.

Specify the user login before the /SYSDBA or /SYSOPER strings:

```
CONNECT TO "orc1fox+driver='dbmora'"
    USER "orauser/SYSDBA" USING "fourjs"
```

Setting privileges

Informix® and ORACLE user privileges management are quite similar.

ORACLE provides roles to group privileges which then can be assigned to users. Starting with version 7.20, Informix® provides roles also. But users must execute the SET ROLE statement in order to enable a role. ORACLE users do not have to explicitly set a role, they are assigned to a default privilege domain (set of roles). More than one role can be enabled at a time with ORACLE.

Informix® users must have at least the CONNECT privilege to access the database:

`GRANT CONNECT TO (PUBLIC|`*`username`*`)`

ORACLE users must have at least the CREATE SESSION privilege to access the database. This privilege is part of the CONNECT role.

`GRANT CONNECT TO (PUBLIC|`*`username`*`)`

Informix® database privileges do NOT correspond exactly to ORACLE CONNECT, RESOURCE and DBA roles. However, roles can be created with equivalent privileges.

Solution

Create a role which groups Informix® CONNECT privileges, and assign this role to the application users:

```
CREATE ROLE ifx_connect IDENTIFIED BY oracle;
GRANT CREATE SESSION, ALTER SESSION, CREATE ANY VIEW, ... TO ifx_connect;
GRANT ifx_connect TO user1;
```

Data dictionary
Oracle Database related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way: As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

Oracle does not implement a native BOOLEAN type in SQL types. However, a BOOLEAN type exists in the PL/SQL language.

Solution
The Oracle database interface converts the BOOLEAN type to CHAR(1) columns and stores '1' or '0' values in the column.
CHARACTER data types

Informix® supports the following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/

NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics; the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases.

ORACLE provides the following types to store character strings:

- CHAR(N) with N specified in bytes or characters according to the length semantics (max size is 2000 bytes)
- VARCHAR2(N) with N specified in bytes or characters according to the length semantics (max size is 4000 bytes - standard type)
- NCHAR(N) with N specified in characters (max size is 2000 bytes)
- NVARCHAR2(N) with N specified characters (max size is 4000 bytes - standard type)

  Note: Oracle 12c introduced extended character types with the MAX_STRING_SIZE=EXTENDED server parameter. You can use VARCHAR2 types with a size up to 32Kb when MAX_STRING_SIZE=EXTENDED is set. (You need to close/upgrade/alter/reopen your database, see Oracle documentation for details). However, the storage technique used by Oracle 12c for such a large string type is different from the native/standard VARCHAR2(4000) type. Large character strings will be stored as LOBs. Extended character types are not supported by Genero's Oracle database driver.

In ORACLE CHAR(N)/VARCHAR2(N) types, the size N can be specified in character or byte units, according to length semantics settings.

When comparing CHAR and VARCHAR2 values in ORACLE, the trailing blanks are significant; this is not the case when using Informix® VARCHARs. However, before comparing string values, ORACLE blank-pads CHAR(N) data to the maximum length of both operands. As result, it looks like trailing blanks are no significant in CHAR(N) comparison. For example, a column defined as CHAR(5) with the value `'abc '` (with 2 trailing blanks) will not be equal to `'abc'`, but when comparing `(col = 'abc')`, ORACLE will add 2 blanks to the right operand and values will match. Blank padding does not occur for VARCHAR2() data, as result, the expression `(col = 'abc')` will be false, if col VARCHAR2 does not exactly contain the value `'abc'`. For more details, see blank-padded and non-padded comparison semantics in ORACLE documentation.

ORACLE treats empty strings like NULL values; Informix® doesn't. See issue Empty Character Strings for more details.

With ORACLE, you can define a Database Character Set and a National Character Set: ORACLE uses the Database Character Set to store string data in the CHAR/VARCHAR2 columns, and uses the National Character Set for NCHAR/NVARCHAR2 columns.

Solution

Informix® CHAR(N) types must be mapped to ORACLE CHAR(N) types, and Informix® VARCHAR(N) or LVARCHAR(N) columns must be mapped to ORACLE VARCHAR2(N).

Check that your database tables does not use CHAR, VARCHAR or LVARCHAR types with a length exceeding the ORACLE limits of CHAR/VARCHAR2.

When using a multibyte character set (such as UTF-8), configure ORACLE to use character length semantics, define CHAR/VARCHAR2 database columns with a size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from an ORACLE database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in the database, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

The ORACLE client character set must correspond to the Genero runtime system locale (LANG/LC_ALL). You can define the ORACLE client character set with the NLS_LANG environment variable.

See also the section about Localization.

NUMERIC data types

Informix® supports several data types to store numbers:

Table 199: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)
DEC / DECIMAL(p)	Floating-point decimal number
DEC / DECIMAL(p,s)	Fixed-point decimal number
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

ORACLE supports only one data type to store numbers:

Table 200: Oracle numeric data types

ORACLE data type	Description
NUMBER(p,s) (1<=p<= 38, -84<=s<=127)	Fixed point decimal numbers.
NUMBER(p) (1<=p<= 38)	Integer numbers with a precision of p.
NUMBER(*,s)	Fixed point decimal numbers with a precision of 38 digits.
NUMBER	Floating point decimals with a precision of 38 digits.
FLOAT(b) (1<=b<= 126)	Floating point numbers with a binary precision b. This is a sub-type of NUMBER.
BINARY_FLOAT (since Oracle 10g)	32-bit floating point number.
BINARY_DOUBLE (since Oracle 10g)	64-bit floating point number.

ANSI types like SMALLINT, INTEGER are supported by ORACLE but will be converted to the native NUMBER type.

When dividing INTEGERs or SMALLINTs, Informix® rounds the result (7 / 2 = 3), while ORACLE doesn't, because it does not have a native integer data type (7 / 2 = 3.5)

Solution

We recommend that you use the following conversion rules:

Table 201: Conversion rules (Informix® vs. Oracle)

Informix® data type	ORACLE data type (before 10g)	ORACLE data type (since 10g)
DECIMAL(p,s), MONEY(p,s)	NUMBER(p,s)	NUMBER(p,s)
DECIMAL(p)	FLOAT(p * 3.32193)	FLOAT(p * 3.32193)
DECIMAL (not recommended)	FLOAT	FLOAT
SMALLINT	NUMBER(5,0)	NUMBER(5,0)
INTEGER	NUMBER(10,0)	NUMBER(10,0)
BIGINT	NUMBER(20,0)	NUMBER(20,0)
INT8	NUMBER(20,0)	NUMBER(20,0)
SMALLFLOAT	NUMBER	BINARY_FLOAT
FLOAT[(p)]	NUMBER	BINARY_DOUBLE

Avoid dividing integers in SQL statements. If you do divide an integer, use the TRUNC() function with ORACLE.

When creating a table directly in Oracle's sqlplus, using ANSI data types INTEGER, SMALLINT, you do actually create columns with the NUMBER type, which has a precision of 38 digits. As result, it is not possible to distinguish the original types used in CREATE TABLE, nor can it be possible to distinguish the columns created explicitely with the native NUMBER type, in the next example, all column with be of type NUMBER:

```
$ sqlplus ...
sql> CREATE TABLE mytab (
   col1 INTEGER,
   col2 SMALLINT,
   col3 NUMBER,
   ...
```

When extracting the database schema with fgldbsch, NUMBER, NUMBER(p>32) and NUMBER(p>32,s) types will by default give an extraction error. However, these types can be converted to DECIMAL(32) and DECIMAL(32,s) with the `-cv` option, by using the "B" character at positions 22 (for NUMBER) and 23 (for NUMBER(p>32[,s])).

> **Note:** When fetching a NUMBER[(p>32,s)] into a BDL DECIMAL(32[,s]) type, if the value stored in the NUMBER column has more than 32 digits, it will be rounded to fit into a DECIMAL(32), or the overflow error -1226 will occur when fetching into a DECIMAL(32,s). Note that it must be allowed to fetch numeric expressions such as 1/3 (=0.333333333333....) into a DECIMAL(p,s), even if such expression will produce more than 32 digits with Oracle.

When creating a table in a BDL program with DECIMAL(p), this type is converted to native Oracle FLOAT(p*3.32193). When creating a table in a BDL program with DECIMAL (without precision) this type is converted to native Oracle FLOAT. The native Oracle FLOAT[(p)] type can be extracted by fgldbsch, but Oracle's FLOAT has a higher precision than the BDL DECIMAL type, which can lead to value rounding when fetching rows.

With Oracle versions older than 10g, when creating tables in a BDL program with SMALLFLOAT or FLOAT types, these types are mapped to NUMBER (The native Oracle FLOAT(b) type could have been used, but this type is reserved to map DECIMAL(p) types). Starting with Oracle 10g, SMALLFLOAT or FLOAT types

will respectively be converted to BINARY_FLOAT and BINARY_DOUBLE native Oracle types, which can be extracted by fgldbsch and mapped back to BDL SMALLFLOAT and FLOAT respectively in the .sch file.

> **Note:** As a general recommendation, do not use DECIMAL[(p)] or SMALLFLOAT/FLOAT floating point types in business applications. These types should only be used for scientific data storage.

DATE and DATETIME data types

Informix® provides two data types to store date and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

ORACLE provides only the following data types to store date and time data:

- DATE = for year, month, day, hour, min, second storage.
- TIMESTAMP= for year, month, day, hour, min, second, fraction storage.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contains matching environment parameters (i.e. DBDATE, GL_DATETIME).

As in Informix®, ORACLE can convert quoted strings to DATE or TIMESTAMP data if the contents of the string matches the NLS date format parameters (NLS_DATE_FORMAT, NLS_TIMESTAMP_FORMAT). The TO_DATE() and TO_TIMESTAMP() SQL functions convert strings to dates or timestamps, according to a given format. The TO_CHAR() SQL function allows you to convert dates or timestamps to strings, according to a given format.

Date arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used, and an INTERVAL value if a DATETIME is used in the expression. In ORACLE, the result of an arithmetic expression involving DATE values is a NUMBER of days; the decimal part is the fraction of the day (0.5 = 12H00, 2.00694444 = (2 + (10/1440)) = 2 days and 10 minutes). The result of an expression involving Oracle TIMESTAMP data is of type INTERVAL. See the Oracle documentation for more details.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. ORACLE does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix-specific and have no equivalent in ORACLE.
- To compare dates that have time data in ORACLE, you can use the ROUND() or TRUNC() SQL functions.

Solution

Storing BDL DATE values

The ORACLE DATE type is used to store Genero BDL DATE values. However, keep in mind that the ORACLE DATE type stores also time (hh:mm:ss) information. The database interface automatically sets the time part to midnight (00:00:00) during input/output operations.

You must be very careful since manual modifications of the database might set the time part, for example:

UPDATE table SET date_col = SYSDATE

(SYSDATE is equivalent to CURRENT YEAR TO SECOND in Informix®).

After this type of update, when columns have date values with a time part different from midnight, some SELECT statements might not return all the expected rows.

When fetching ORACLE DATE values into Genero BDL DATE or DATETIME variables, the date and time information is directly set for the individual date/time parts and the conversion is straight forward. But when fetching an ORACLE DATE into a CHAR or VARCHAR variable, date to string conversion occurs. Since ORACLE DATEs are equivalent of Informix® DATETIME YEAR TO SECOND, the values are by default converted with the ISO format (YYYY-MM-DD hh:mm:ss), which is not the typical Informix® behavior where DATEs are formatted according to the DBDATE environment variable. If your application fetches DATE values into CHAR/VARCHAR and you want to get the DBDATE conversion, you must set the following FGLPROFILE entry:

```
dbi.database.dbname.ora.date.ifxfetch = true
```

Storing BDL DATETIME values

Informix® DATETIME data with any precision from YEAR to SECOND is stored in ORACLE DATE columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the ORACLE DATE value will be "1900-01-01 11:45:00".

Informix® DATETIME YEAR TO FRACTION(n) data is stored in ORACLE TIMESTAMP columns. The TIMESTAMP data type can store up to 9 digits in the fractional part, and therefore can store all precisions of Informix® DATETIME.

Important:

- Most arithmetic expressions involving dates (for example, to add or remove a number of days from a date) will produce the same result with ORACLE. But keep in mind that ORACLE evaluates date arithmetic expressions to NUMBERs (*days*.*fraction*) while Informix® evaluates to INTEGERs when only DATEs are used in the expression, or to INTERVALs if at least one DATETIME is used in the expression.
- Even if a configuration parameter exists to get the Informix® behavior, avoid to fetch date values into CHAR or VARCHAR, to bypass the DBDATE / ISO format conversion difference with ORACLE.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix's INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

ORACLE supports the INTERVAL data type similar to Informix®, with two classes (YEAR TO MONTH and DAY TO SECOND), but Oracle's INTERVAL cannot be defined with a precision different from these two classes (for example, you cannot define an INTERVAL HOUR TO MINUTE in Oracle). The class DAY TO SECOND(n) is equivalent to the Informix® INTERVAL class DAY TO FRACTION(n).

Solution

Informix® INTERVAL YEAR(n) TO MONTH data is stored in Oracle INTERVAL YEAR(n) TO MONTH columns. These data types are equivalent.

Informix® INTERVAL DAY(n) TO FRACTION(p) data is stored in Oracle INTERVAL DAY(n) TO SECOND(p) columns. These data types are equivalent.

Other Informix® INTERVAL types must be stored in CHAR() columns as with Oracle 8i, because the high qualifier precision cannot be specified with Oracle INTERVALs. For example, Informix® INTERVAL HOUR(5) TO MINUTE has no native equivalent in Oracle.

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

ORACLE provides several solutions to implement auto-incremented columns:

1. Sequence objects can be created to generate numbers (CREATE SEQUENCE, *seqname*.currval).
2. Since ORACLE 12c, it is possible to reference a sequence in DEFAULT ON NULL column clauses.
3. Since ORACLE 12c, you can define columns with the GENERATE ... AS IDENTITY clause.

Details about ORACLE sequences:

- Sequences are totally detached from tables.
- The purpose of sequences is to provide unique integer numbers.
- Sequences are identified by a sequence name.
- To create a sequence, you must use the CREATE SEQUENCE statement. Once a sequence is created, it is permanent (like a table).
- To get a new sequence value, you must use the `nextval` keyword, preceded by the name of the sequence. The *`seqname`*`.nextval` expression can be used in INSERT statements:

  ```
  INSERT INTO tab1 VALUES ( tab1_seq.nextval, ... )
  ```
- To get the last generated number, ORACLE provides the `currval` keyword:

  ```
  SELECT seqname.currval FROM DUAL
  ```
- In order to improve performance, ORACLE can handle a set of sequences in the cache (See CREATE SEQUENCE syntax in the ORACLE documentation).

Solution

The SERIAL data type can be emulated with sequences used in INSERT triggers or with the DEFAULT ON NULL clause.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation =
{"native"|"native2"|"regtable"}
```

- native: uses insert triggers with sequences.
- native2: uses DEFAULT ON NULL column clause with sequences.
- regtable: uses insert triggers with the SERIALREG table.

The default emulation technique is "`native`".

This entry must be used in conjunction with:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial = {true|false}`

If the `datatype.serial` entry is set to false, the emulation method is ignored.

> **Important:** The "`regtable`" emulation based on the SERIALREG table is provided to simplify the migration from Informix. We strongly recommend that you use the `native` or `native2` method instead. The "`native2`" method is the fastest solution when inserting a large number of rows in the database.

Notes common to all serial emulation modes

When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the Oracle interface automatically creates the additional SQL objects (column clauses, sequences or triggers) to generate numbers when an INSERT statement is performed.

Users executing programs which create tables with SERIAL columns must have the CONNECT and RESOURCE roles assigned to create triggers and sequences.

SERIAL[(n)] data types are converted to NUMBER(10,0), while SERIAL8[(n)] and BIGSERIAL[(n)] are replaced by NUMBER(20,0).

For SERIAL types, the SQLCA.SQLERRD[2] register is filled as expected with the last generated serial value. However, since SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGSERIAL (NUMBER(20,0)) auto-incremented columns. If you are using BIGSERIAL columns, you must the fetch the sequence pseudo-column CURR_VAL or fetch the LASTSERIAL column from the SERIALREG table, if used.

Check whether your application uses tables with a SERIAL column that can contain a NULL value: INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements that do not use the serial column:

```
INSERT INTO tab (col2) VALUES ('data')
```

For SQL portability, INSERT statements should be reviewed to remove the SERIAL column from the list. For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES (0, p_value)
```

can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.* INSERT INTO tab VALUES (rec.*) -- will use the serial
column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

When using the Static SQL INSERT or UPDATE syntax using record.* without braces, make sure that you database schema files contain information about serials: This information can be lost when extracting the schema from an Oracle database. See Database Schema for more details about the serial flag in column type encoding (data type code must be 6).

If the "`native`" or "`regtable`" emulation is used, inserting rows with ORACLE tools like SQL*Plus or SQL*Loader will execute the INSERT triggers. When loading big tables, you can disable triggers with `ALTER TRIGGER [ENABLE | DISABLE]` (see ORACLE documentation for more details). After reactivation of the serial triggers, the SERIAL sequences must be re-initialized (use `serialpkg.create_sequence('tab','col')`) or re-execute the PL/SQL script containing the sequence and trigger creation.

Using the `native` serial emulation

Each table having a SERIAL column needs an INSERT TRIGGER and a SEQUENCE dedicated to SERIAL generation.

To know how to write those sequences and triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native SQL commands to create the sequence and the trigger.

For temporary tables, the trigger and the sequence are dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

Using the `native2` serial emulation

With this emulation, a SERIAL type is converted to a DEFAULT ON NULL clause using a sequence is created automatically by the database driver, for example:

```
CREATE TABLE t1 ( mykey SERIAL(100), .... )
```

is converted to:

```
CREATE SEQUENCE t1_srl INCREMENT BY 1 START WITH 100
```

```
CREATE TABLE t1 (mykey NUMBER(10,0) DEFAULT ON NULL t1_srl.nextval , ...
```

For temporary tables, the sequence is dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

> **Note:** The `native2` serial emulation uses the DEFAULT ON NULL clause, supported by Oracle, starting from version 12.1.

Using the `regtable` serial emulation

Each table having a SERIAL column needs an INSERT TRIGGER which uses the SERIALREG table dedicated to SERIAL registration.

First, you must prepare the database and create the SERIALREG table as follows:

```
CREATE TABLE serialreg (
    tablename VARCHAR2(50) NOT NULL,
    lastserial NUMBER(20,0) NOT NULL,
    PRIMARY KEY ( tablename )
)
```

> **Important:** This table must exist in the database before creating the serial triggers.

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types and you must create one trigger for each table. SERIAL8/BIGSERIAL columns must be converted to NUMBER(20,0). To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at start values and you might get duplicated values.

For temporary tables, the trigger is dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

ROWIDs

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

ORACLE supports ROWIDs, but the data type is different from Informix® ROWIDs: ORACLE rowids are CHAR(18).

For example: `AAAA8mAALAAAAQkAAA`

Since ORACLE rowids are physical addresses, they cannot be used as permanent row identifiers (After a DELETE, an INSERT statement might reuse the physical place of the deleted row, to store the new row).

With Informix®, SQLCA.SQLERRD[6] contains the ROWID of the last INSERTed or UPDATEd row. This is not supported with ORACLE because ORACLE ROWID are not INTEGERs.

Solution

If the BDL application uses Informix® rowids as primary keys, the program logic should be reviewed in order to use the real primary keys (usually, serials which can be supported) or ORACLE rowids as CHAR(18) (Informix® rowids will fit in this char data type).

If you cannot avoid the use of rowids, you must change the type of the variables which hold ROWID values. Instead of using INTEGER, you must use CHAR(18). Informix® rowids (INTEGERs) will automatically fit into a CHAR(18) variable.

All references to SQLCA.SQLERRD[6] must be removed because this variable will not contain the ROWID of the last INSERTed or UPDATEd row when using the ORACLE interface.

The RAW data type

ORACLE supports the RAW data type to hold binary data. This data type is for example used to return values from the `SYS_GUID()` SQL function.

Solution

The ORACLE RAW values can be converted to a character string in the hexadecimal notation.

When fetching rows from the database, the database driver will automatically convert ORACLE RAW values to hexadecimal. On the other hand, when using SQL parameters, the database driver will convert hexadecimal VARCHAR strings to binary data.

Since each byte is represented with two characters in the hexadecimal notation, you must define a VARCHAR(N*2) variable to hold the values of a native RAW(N) column.

When extracting a database schema with the `fgldbsch` tool, the ORACLE RAW(N) type is converted to VARCHAR2(N*2).

Large OBject (LOB) types

Informix® uses the TEXT and BYTE data types to store very large texts or images. ORACLE 8 provides CLOB, BLOB, and BFILE data types. Columns of these types store a kind of pointer (lob locator). This technique allows you to use more than one CLOB / BLOB / BFILE column per a table.

Solution

The ORACLE database interface can convert BDL TEXT data to CLOB and BYTE data to BLOB.

Genero TEXT/BYTE program variables have a limit of 2 gigabytes, make sure that the large object data does not exceed this limit.

ORACLE BFILEs are not supported.

The ALTER TABLE instruction

Informix® and ORACLE have different implementations of the ALTER TABLE instruction. For example, Informix® allows you to use multiple ADD clauses separated by commas. This is not supported by ORACLE:

Informix®:

```
ALTER TABLE customer ADD(col1 INTEGER), ADD(col2 CHAR(20))
```

ORACLE:

```
ALTER TABLE customer ADD(col1 INTEGER, col2 CHAR(20))
```

Solution

No automatic conversion is done by the database interface. There is no real standard for this instruction (that is, no common syntax for all database servers). Read the SQL documentation and review the SQL scripts or the BDL programs in order to use the database server specific syntax for ALTER TABLE.

Constraints

Constraint naming syntax

Both Informix® and ORACLE support primary key, unique, foreign key, default and check constraints, but the constraint naming syntax is different: ORACLE expects the "CONSTRAINT" keyword **before** the constraint specification and Informix® expects it **after**.

UNIQUE constraint example

Table 202: UNIQUE constraint example (Informix® vs ORACLE)

Informix®	ORACLE

`CREATE TABLE emp (`
`  ...`
`  emp_code CHAR(10) UNIQUE`
`  CONSTRAINT pk_emp,`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  CONSTRAINT pk_emp UNIQUE,`
	`  ...`

Primary keys

Like Informix®, ORACLE creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using "CREATE UNIQUE INDEX" to define unique constraints is obsolete (use primary keys or a secondary key instead).

Unique constraints

Like Informix®, ORACLE creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

When using a unique constraint, Informix® allows only one row with a NULL value, while ORACLE allows several rows with NULL! Using CREATE UNIQUE INDEX is obsolete.

Foreign keys

Both Informix® and ORACLE support the ON DELETE CASCADE option. To defer constraint checking, Informix® provides the SET CONSTRAINT command while ORACLE provides the ENABLE and DISABLE clauses.

Check constraints

The check condition may be any valid expression that can be evaluated to TRUE or FALSE, including functions and literals. You must verify that the expression is not Informix® specific.

Null constraints
Informix® and ORACLE support not null constraints, but Informix® does not allow you to give a name to "NOT NULL" constraints.

Solution

Constraint naming syntax

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for ORACLE.

Triggers

Informix® and ORACLE provide triggers with similar features, but the trigger creation syntax and the programming languages are totally different.

Informix® triggers define the stored procedures to be called when a database event occurs (before | after insert | update | delete ...), while ORACLE triggers can hold a procedural block.

In ORACLE, triggers can be created with 'CREATE OR REPLACE' to keep privileges settings. With Informix®, you must drop and create again.

ORACLE V8 provides an 'INSTEAD OF' option to completely replace the INSERT, UPDATE or DELETE statement. This is provided to implement complex storage operations, for example on views that are usually read-only (you can attach triggers to views).

ORACLE allows you to create multiple triggers on the same table for the same trigger event, but it does not guarantee the execution order.

Solution

Informix® triggers must be converted to ORACLE triggers "by hand".

Stored procedures

Both Informix® and ORACLE support stored procedures, but the programming languages are totally different: **SPL** for Informix® versus **PL/SQL** for ORACLE.

In ORACLE, stored procedures and functions can be implemented in packages (similar to BDL modules). This is a powerful feature which enables structured procedural programming in the database. ORACLE itself implements system tools with packages (dbms_sql, dbms_output, dbms_lock). Procedures, functions and packages can be created with 'CREATE OR REPLACE' to keep privileges settings. With Informix®, you must drop and create again.

ORACLE uses a different privilege context when using dynamic SQL in PL/SQL; roles are not effective. Users must have direct privileges settings in order to perform DDL or DML operations inside dynamic SQL.

Solution

Informix® stored procedures must be converted to ORACLE "by hand".

Try to use ORACLE packages in order to group stored procedures into modules.

See SQL Programming for more details about executing stored procedures with ORACLE.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

```
database[@dbservername]:][{owner|"owner"}.]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "tabname"."colname").

When using double-quoted identifiers, both Informix® and ORACLE become case sensitive. Unlike Informix®, ORACLE database object names are stored in UPPERCASE in system catalogs. That means that SELECT "col1" FROM "tab1" will produce an error because those objects are identified by "COL1" and "TAB1" in ORACLE system catalogs.

in Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

With ORACLE, an object name takes the following form:

```
[(schema|"schema").](identifier|"identifier")[@database-link]
```

ORACLE has separate namespaces for different classes of objects (tables, views, triggers, indexes, clusters).

Object names are limited to 30 chars in ORACLE.

An ORACLE database schema is owned by a user (usually, the application administrator) and this user must create PUBLIC SYNONYMS to provide a global scope for his table names. PUBLIC SYNONYMS can have the same name as the schema objects they point to.

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Check that you do not use single-quoted or double-quoted table names or column names in your source. Those quotes must be removed because the database interface automatically converts double quotes to single quotes, and ORACLE does not allow single quotes as database object name delimiters.

See also the issue Database Concepts

NULLs in indexed columns

Oracle btree indexes do not store null values, while Informix® btree indexes do. This means that if you index a single column and select all the rows where that column is null, Informix® will do an indexed read to fetch just those rows, but Oracle will do a sequential scan of all rows to find them. Having an index unusable for "is null" criteria can also completely change the behavior and performance of more complicated selects without causing a sequential scan.

Solution

Declare the indexed columns as NOT NULL with a default value and change the program logic. If you do not want to change the programs, partitioning the table so that the nulls have a partition of their own will reduce the sequential scan to just the nulls (un-indexed) partition, which is relatively fast.

Data type conversion table: Informix to Oracle

Table 203: Data type conversion table (Informix to Oracle)

Informix® data types	**ORACLE data types (Versions 10.x and higher)**
CHAR(n)	CHAR(n) (limit = 2000b!)
VARCHAR(n[,m])	VARCHAR2(n)

Informix® data types	**ORACLE data types (Versions 10.x and higher)**
	(limit = 4000b!)
LVARCHAR(n)	VARCHAR2(n) (limit = 4000b!)
NCHAR(n)	NCHAR(n) (limit = 2000b!)
NVARCHAR(n[,m])	NVARCHAR2(n) (limit = 4000b!)
BOOLEAN	CHAR(1)
SMALLINT	NUMBER(5,0)
INT / INTEGER	NUMBER(10,0)
BIGINT	NUMBER(20,0)
INT8	NUMBER(20,0)
SERIAL[(start)]	NUMBER(10,0) (see note 1)
BIGSERIAL[(start)]	NUMBER(20,0) (see note 1)
SERIAL8[(start)]	NUMBER(20,0) (see note 1)
DOUBLE PRECISION / FLOAT[(n)]	BINARY_DOUBLE
REAL / SMALLFLOAT	BINARY_FLOAT
NUMERIC / DEC / DECIMAL(p,s)	NUMBER(p,s)
NUMERIC / DEC / DECIMAL(p)	FLOAT(p*3.32193)
NUMERIC / DEC / DECIMAL *(not recommended)*	FLOAT
MONEY(p,s)	NUMBER(p,s)
MONEY(p)	NUMBER(p,2)
MONEY	NUMBER(16,2)
TEXT	CLOB (using <= 2Gb!)
BYTE	BLOB (using <= 2Gb!)
DATE	DATE
DATETIME YEAR TO YEAR	DATE
DATETIME YEAR TO MONTH	DATE
DATETIME YEAR TO DAY	DATE
DATETIME YEAR TO HOUR	DATE
DATETIME YEAR TO MINUTE	DATE
DATETIME YEAR TO SECOND	DATE

Informix® data types	**ORACLE data types (Versions 10.x and higher)**
DATETIME YEAR TO FRACTION(n)	TIMESTAMP(n)
DATETIME MONTH TO MONTH	DATE
DATETIME MONTH TO DAY	DATE
DATETIME MONTH TO HOUR	DATE

INTERVAL DAY[(p)] TO FRACTION(n)	INTERVAL DAY[(p)] TO SECOND(n)
INTERVAL HOUR[(p)] TO HOUR	CHAR(50)
INTERVAL HOUR[(p)] TO MINUTE	CHAR(50)
INTERVAL HOUR[(p)] TO SECOND	CHAR(50)
INTERVAL HOUR[(p)] TO FRACTION(n)	CHAR(50)
INTERVAL MINUTE[(p)] TO MINUTE	CHAR(50)
INTERVAL MINUTE[(p)] TO SECOND	CHAR(50)
INTERVAL MINUTE[(p)] TO FRACTION(n)	CHAR(50)
INTERVAL SECOND[(p)] TO SECOND	CHAR(50)

Informix® data types	**ORACLE data types (Versions 10.x and higher)**
INTERVAL SECOND[(p)] TO FRACTION(n)	CHAR(50)
INTERVAL FRACTION[(p)] TO FRACTION	CHAR(50)

Notes:

1. For more details about serial emulation, see SERIAL data types on page 658.

Data manipulation
Oracle Database related data manipulation topics.
Reserved words

SQL object names like table and column names cannot be SQL reserved words in ORACLE.

An example of a common word which is part of the ORACLE SQL grammar is '**level**'.

Solution

Table or column names which are ORACLE reserved words must be renamed.

ORACLE reserved keywords are listed in the ORACLE documentation, or Oracle 8i provides the V $RESERVED_WORDS view to track Oracle reserved words. All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™ 'grep' or 'awk' tools. Most modifications can be done automatically with UNIX™ tools like 'sed' or 'awk'.

Outer joins

In Informix® SQL, outer joins can be defined in the **FROM** clause with the **OUTER** keyword:

```
SELECT ... FROM a, OUTER (b) WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c)) WHERE a.key = b.akey
  AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

ORACLE expects the **(+)** operator in the join condition. You must set a (+) after columns of the tables which must have NULL values when no record matches the condition:

```
SELECT ... FROM a, b WHERE a.key = b.key (+)

SELECT ... FROM a, b, c WHERE a.key = b.akey (+)>
   AND b.key1 = c.bkey1 (+)
   AND b.key2 = c.bkey2 (+)
```

When using additional conditions on outer tables, the (+) operator also has to be used. For example:

```
SELECT ... FROM a, OUTER(b) WHERE a.key = b.akey AND b.colx > 10
```

Must be converted to:

```
SELECT ... FROM a, b WHERE a.key = b.akey (+)
   AND b.colx (+) > 10
```

The ORACLE outer joins restriction:

In a query that performs outer joins of more than two pairs of tables, a single table can only be the NULL generated table for one other table. The following case is not allowed: WHERE a.col = b.col (+) AND b.col (+) = c.col

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The Oracle interface can convert most Informix® OUTER specifications to Oracle outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work: `"FROM OUTER(tab2), tab1 "`
2. The outer join in the WHERE clause must use the table name as prefix.

   Example: `"WHERE tab1.col1 = tab2.col2 "`

Restrictions:

1. Statements composed by 2 or more SELECT instructions are not supported.

   Example: `"SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"`

   Note:

   1. Table aliases are detected in OUTER expressions.

      OUTER example with table alias: "OUTER(tab1 alias1)".
   2. In the outer join, <outer table>.<col> can be placed on both right or left sides of the equal sign.

      OUTER join example with table on the left: `"WHERE outertab.col1 = maintab.col2 "`
   3. Table names detection is not case-sensitive.

      Example: `"SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2"`
   4. Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and ORACLE handle transactions differently. The differences in the transactional models can affect the program logic.

Informix® native mode (non ANSI):

- DDL statements can be executed (and canceled) in transactions.
- Transactions must be started with BEGIN WORK. Statements executed outside of a transaction are automatically committed.

ORACLE:

- Beginnings of transactions are implicit; two transactions are delimited by COMMIT or ROLLBACK.
- The current transaction is automatically committed when a DDL statement is executed.

Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, in accordance with the transaction model.

Informix® version 11.50 introduces savepoints with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

ORACLE supports savepoints too. However, there are differences:

1. Savepoints cannot be declared as UNIQUE
2. Rollback must always specify the savepoint name
3. You cannot release savepoints (RELEASE SAVEPOINT)

Solution

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with ORACLE. The Informix® behavior is simulated with an autocommit mode in the ORACLE interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program.

When executing a DDL statement inside a transaction, ORACLE automatically commits the transaction. Therefore, you must extract the DDL statements from transaction blocks.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

See also SELECT FOR UPDATE

Temporary tables

Informix® temporary tables are created through the **CREATE TEMP TABLE** DDL instruction or through a **SELECT ... INTO TEMP** statement. Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

BDL reports create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

ORACLE does not support temporary tables as Informix® does. ORACLE 8.1 provides GLOBAL TEMPORARY TABLEs which are shared among processes (only data is temporary and local to a SQL process). Informix® does not shared temp tables among SQL processes; each process can create its own temp table without table name conflicts.

Solution

In accordance with some prerequisites, temporary tables creation in BDL programs can be supported by the database interface.

The temporary table emulation can use regular tables or GLOBAL TEMPORARY tables. The way the driver converts Informix® temp table statements to Oracle regular tables or global temporary tables is driven by the following FGLPROFILE entry:

```
dbi.database.<dbname>.ifxemul.temptables.emulation = {"default" | "global" }
```

By default, the database driver uses regular tables (*default* emulation). This default emulation provides maximum compatibility with Informix® temporary tables, but requires real table creation which can be a significant overhead with Oracle. The *global* emulation uses native Oracle Global Temporary Tables, requiring only one initial table creation and thus making programs run faster. However, the *global* emulation mode has to be used carefully because of some limitations and constraints.

When creating a temporary table, you perform a Data Definition Language statement. Oracle automatically commits the current transaction when executing a DDL statement. Therefore, you must avoid temp table creation/destruction in transactions.

Using the *default* temporary table emulation

How does the *default* emulation work?

- Informix® CREATE TEMP TABLE and SELECT INTO TEMP statements are automatically converted to ORACLE "CREATE TABLE". The name of the temporary table is converted to a unique table name.
- Tables are created in the current schema.

- Temporary tables are created with the option TABLESPACE TEMPTABS so that data is stored in a dedicated tablespace named "**TEMPTABS**". Of course the TEMPTABS tablespace must exist before running programs, otherwise temporary table creation will fail. You create a tablespace with the CREATE TABLESPACE SQL command. Using a specific tablespace for temporary tables allows you to specify storage options, for example to use a physical device which can be different from the disk drive used for real data storage. Additionally, backups of permanent application tables can be performed without the data of temporary tables.
- Starting with Oracle 10g, dropped tables are saved in the recycle bin by default. You may want to avoid the recycle bin feature at the database level or session level with:

  ```
  ALTER SYSTEM SET recyclebin = OFF scope=both
  ```

  or:

  ```
  ALTER SESSION SET recyclebin = OFF
  ```

- Once the temporary table has been created, all other SQL statements performed in the current SQL session are parsed to convert the original table name to the corresponding unique table name.
- When the BDL program disconnects from the database (for example, when it ends or when a CLOSE DATABASE instruction is executed), the tables which have not been removed with an explicit "DROP TABLE" are automatically removed by the database interface. However, if the program crashes, the tables will remain in the database, so you may need to cleanup the database from time to time.

Prerequisites when using the *default* emulation

- Application users must have sufficient **privileges** to create database tables in their own schema (usually, "CONNECT" and "RESOURCE" roles).
- Create a dedicated tablespace named "**TEMPTABS**".

  The TEMPTABS tablespace must be of type "permanent", as it will hold permanent tables used to emulate Informix® temp tables.

  Make sure it is big enough to hold all the data, and check for automatic extension.

  When using a PDB, the TEMPTABS table space must be created in the context of the PDB.

  ```
  CREATE TABLESPACE temptabs
    DATAFILE 'file-path' SIZE 1M AUTOEXTEND ON;
  -- Give privileges on temptabs tablespace to other users
  ALTER USER dbuser QUOTA UNLIMITED ON TEMPTABS;
  ```

  For more details, see "CREATE TABLESPACE" in the Oracle documentation.

Limitations of the *default* emulation

- When using the default emulation, the real name of an emulated temporary table will have the following format:

  tt*number_original_name*

  Where <number> is the Oracle AUDSID session id returned by:

  ```
  SELECT USERENV('SESSIONID') FROM DUAL
  ```

  As Oracle 9i and 10g table names can't exceed 30 characters in length, and since session ids are persistent over server shutdown, you must pay attention to the names of your temporary tables. For example, if you create a temp table with the name TEMP_CUSTOMER_INVOICES (22c) it leaves 30 - (3 + 22) = 5 characters left for the session id, which gives a limit of 99999 sessions.

To workaround this limitation, you can provide your own SQL command to generate a unique session id with the following FGLPROFILE entry:

`dbi.database.`*`dbname`*`.ora.sid.command = "select ..."`

As an example, you can use the SID column value from V$SESSION:

```
SELECT SID FROM V$SESSION WHERE AUDSID = USERENV('SESSIONID')
```

- You are not allowed to use the unique table name format in your own database schema. Make sure you are not using table or column names with the following format:

  `tt`*`number_original_name`*
- Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using the temp table name for other database objects, like columns. The following example illustrates this limitation:

```
CREATE TABLE tab1 ( key INTEGER, tmp1 CHAR(20) )
CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) )
SELECT tmp1 FROM tab1 WHERE ...
```

Maintenance of *default* emulation

- If you want to list the tables created by a specific user, do this:

```
SELECT * FROM ALL_TABLES WHERE OWNER = 'user_name'
```

  As with other database object names, the user name is stored in uppercase letters if it has been created without using double quotes (`create user scott ...` = stored name is "SCOTT").

Creating indexes on temporary tables with *default* emulation

- Indexes created on temporary tables must have unique names also. The database interface detects CREATE INDEX statements which are using temporary tables and converts the index name to unique names.
- DROP INDEX statements are also detected to replace the original index name by the real name.

SERIALs in temporary table creation with *default* emulation

- You can use the SERIAL data type when creating a temporary table.

  Sequences and triggers will be created in the current schema.

  See issue about SERIALs for more details.

Using the *global* temporary table emulation

The *global* temporary table emulation is provided to get benefit of the Oracle GLOBAL TEMPORARY TABLES, by sharing the same table structure with multiple SQL sessions, reducing the cost of the CREATE TABLE statement execution. However, this emulation does not provide the same level of Informix® compatibility as the *default* emulation, and must be used carefully.

How does the *global* emulation work?

- Informix® CREATE TEMP TABLE and SELECT INTO TEMP statements are automatically converted to ORACLE "CREATE GLOBAL TEMPORARY TABLE". The original table name is kept, but it gets a "**TEMPTABS**" schema prefix, to share the underlying table structure with other database users.
- The Global Temporary Tables are created with the "ON COMMIT PRESERVE ROWS" option, to keep the rows in the table when a transaction ends.

- The Global Temporary Tables are created in a specific schema called "**TEMPTABS**". If the table exists already, error ORA-00955 will just be ignored by the database driver. This allows to do several CREATE TEMP TABLE statements in your programs with no SQL error, to emulate the Informix® behavior. This works fine as long as the table name is unique for a given structure (column count and data types must match).
- Once the Global Temporary Table has been created, all other SQL statements performed in the current SQL session are parsed to convert the original table name to TEMPTABS.*original-tablename*.
- When doing a DROP TABLE *temp-table* statement in the program, the database driver converts it to a DELETE statement, to remove all data added by the current session. A next CREATE TEMP TABLE or SELECT INTO TEMP will fail with error ORA-00955 but since this error is ignored, it will be transparent for the program. We can't use TRUNCATE TABLE because that would required at least DROP ANY TABLE privileges for all users.
- When the BDL program disconnects from the database (for example, when it ends or when a CLOSE DATABASE instruction is executed), the tables that have not been dropped by the program with an explicit DROP TABLE statement will be automatically cleaned by Oracle.

Prerequisites when using the *global* emulation

- You must create a database user (schema) dedicated to this emulation, with the name "**TEMPTABS**":

```
CREATE USER temptabs IDENTIFIED BY pswd;
```

- All database users must have sufficient privileges to use Global Temporary Tables in the **TEMPTABS** schema: If you want programs to create Global Temporary Table on the fly, you must grant a CREATE ANY TABLE + CREATE ANY INDEX system privilege to all users. But this means that all users will be able to create/drop tables in any schema (Here Oracle (10g) is missing some fine-grained system privilege to create/drop tables in a particular schema). You better "prepare" the database by creating the Global Temporary Table with the TEMPTABS user (do not forget to specify ON COMMIT PRESERVE ROWS option), and give INSERT, UPDATE, DELETE and SELECT object privileges to PUBLIC, for example:

```
CREATE GLOBAL TEMPORARY TABLE temptabs.mytable
  ( k INT PRIMARY KEY, c CHAR(10) ) ON COMMIT PRESERVE ROWS;
CREATE UNIQUE INDEX temptabs.ix1 ON temptabs.mytable ( c );
GRANT SELECT, UPDATE, INSERT, DELETE ON temptabs.mytable TO PUBLIC;
```

  For testing purpose, consider using a user with DBA privileges, to simplify the configuration.

Limitations of the *global* emulation

- Global Temporary Tables are shared by multiple users/sessions. In order to have the *global* emulation working properly with your application, each temporary table name must be unique for a given table structure, for all programs. You must for example as **tmp1**. It is recommended to use table names as follows:

```
CREATE TEMP TABLE custinfo_1 (
    cust_id INTEGER,
    cust_name VARCHAR(50)
 );
CREATE TEMP TABLE custinfo_2 (
    cust_id INTEGER,
    cust_name VARCHAR(50),
    cust_addr VARCHAR(200)
 );
```

```
CREATE TEMP TABLE custinfo_2 (
    cust_id INTEGER,
    cust_name VARCHAR(50),
```

```
    cust_addr VARCHAR(200)
);
```

- Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using the temp table name for other database objects, like columns. The following example illustrates this limitation:

```
CREATE TABLE tab1 ( key INTEGER, tmp1 CHAR(20) );
CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) );
SELECT tmp1 FROM tab1 WHERE ...
```

Creating indexes on temporary tables with *global* emulation

- Indexes created on temporary tables get also the **TEMPTABS** schema prefix.
- When executing a DROP INDEX statement on a temporary table in a program, the database driver just ignores the statement.

SERIALs in temporary table creation with *global* emulation

- You can use the SERIAL data type when creating a temporary table.

  Sequences and triggers will be created in the **TEMPTABS** schema too.

  See issue about SERIALs for more details.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

ORACLE provides the SUBSTR() function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTR(col1,2,2) = 'RO'
SELECT SUBSTR('Some text',6,3)FROM DUAL -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions by SUBSTR(col,x,y-x+1).

In UPDATE instructions, setting column values through subscripts will produce an error with ORACLE:

```
UPDATE tab1 SET col1[2,3]= 'RO' WHERE ...
```

is converted to:

```
UPDATE tab1 SET SUBSTR(col1,2,3-2+1)= 'RO' WHERE ...
```

The LENGTH() function

Informix® provides the LENGTH() function:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Oracle has a equivalent function with the same name, but there is some difference:

Informix® does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

With the Oracle LENGTH function, when using a CHAR column, values are always blank padded, so the function returns the size of the CHAR column. When using a VAR CHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

The Informix® LENGTH() function returns 0 when the given string is empty. That means, LENGTH('') is 0.

Since ORACLE handles empty strings ('') as NULL values, writing "LENGTH('')" is equivalent to "LENGTH(NULL)". In this case, the function returns NULL.

Solution

The ORACLE database interface cannot simulate the behavior of the Informix® LENGTH() function.

You must check if the trailing blanks are significant when using the LENGTH() function.

If you want to count the number of character by ignoring the trailing blanks, you must use the RTRIM() function:

```
SELECT LENGTH(RTRIM(col1)) FROM table
```

SQL conditions which verify that the result of LENGTH() is greater that a given number do not have to be changed, because the expression evaluates to false if the given string is empty (NULL>n):

```
SELECT * FROM x WHERE LENGTH(col)>0
```

Only SQL conditions that compare the result of LENGTH() to zero will not work if the column is NULL. You must check your BDL code for such conditions:

```
SELECT * FROM x WHERE LENGTH(col)=0
```

In this case, you must add a test to verify if the column is null:

```
SELECT * FROM x WHERE ( LENGTH(col)=0 OR col IS NULL )
```

In addition, when retrieving the result of a LENGTH() expression into a BDL variable, you must check that the variable is not NULL.

In ORACLE, you can use the NVL() function in order to get a non-null value:

```
SELECT * FROM x WHERE NVL(LENGTH(c),0)=0
```

Informix® Dynamic Server 7.30 supports the NVL() function, as in ORACLE. You can write the same SQL for both Informix® 7.30 and ORACLE, as shown in this example.

If the Informix® version supports stored procedures, you can create the following stored procedure in the Informix® database in order to use NVL() expressions:

```
create procedure nvl( val char(512), def char(512) )
 returning char(512);
 if val is null then return def;
 else return val;
 end if;
end procedure;
```

With this stored procedure, you can write NVL() expressions like **NVL(LENGTH(c),0)**. This should work in almost all cases and provides upward compatibility with Informix® Dynamic Server 7.30.

Empty character strings

Informix® SQL and ORACLE SQL handle empty quoted strings differently. ORACLE SQL does not distinguish between '' and NULL, while Informix® SQL treats'' (or "") as a string with a length of zero.

Using literal string values that are empty ('') for INSERT or UPDATE statements will result in the storage of NULLs with ORACLE, while Informix® would store the value as a string with a length of zero:

```
insert into tab1 ( col1, col2 ) values ( NULL, '' )
```

Using the comparison expression (col='') with ORACLE has no meaning because an empty string is equivalent to NULL; (col=NULL) expressions will always evaluate to FALSE because this is not a correct expression: The expression should be (col IS NULL).

```
select * from tab1 where col2 IS NULL
```

With Informix® 4GL and Genero BDL, when setting a variable with an empty string constant, it is automatically set to a NULL value. When using one or more space characters, the value is set to one space character:

```
define x char(10)
let x = ""
if x is null then -- evaluates to TRUE
let x = " "
if x = " " then -- evaluates to TRUE
```

Solution

The ORACLE database interface cannot automatically convert comparison expressions like (col="") to (col IS NULL) because this would require an SQL grammar parser. The interface could convert expressions like (col=""), but it would do this for the whole SQL statement:

```
UPDATE tab1 SET col1 = "" WHERE col2 = ""
```

would be converted to an incorrect SQL statement:

```
UPDATE tab1 SET col1 IS NULL WHERE col2 IS NULL
```

To increase portability, you should avoid the usage of literal string values with a length of zero in SQL statements; this would resolve storage and boolean expressions evaluation differences between Informix® and ORACLE.

NULL or program variables can be used instead. Program variables set with empty strings (let x="")are automatically converted to NULL by BDL and therefore are stored as NULL when using both Informix® or ORACLE databases.

String delimiters and object names

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE "tabname"."colname" = 'a string value'`

Informix® allows double quotes as string delimiters, but ORACLE doesn't. This is important, since many BDL programs use that character to delimit the strings in SQL commands.

This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

Solution

The ORACLE database interface can automatically replace all double quotes by single quotes.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: """
"This is a double quote: \""
```

Database object names cannot be delimited by double quotes because the database interface cannot determine the difference between a database object name and a quoted string ! For example, if the program executes the SQL statement:

`WHERE "`*`tabname`*`"."`*`colname`*`"= "a string value"`

replacing all double quotes by single quotes would produce:

`WHERE '`*`tabname`*`'.'`*`colname`*`' = 'a string value'`

This would produce an error since 'tabname'.'colname' is not allowed by ORACLE.

Although double quotes are replaced automatically in SQL statements, you should use only single quotes to enforce portability.

Getting one row with SELECT

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

Oracle provides the **DUAL** table to generate one row only.

```
SELECT user FROM DUAL
```

Solution

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements, while ORACLE supports the LIKE statement only.

MATCHES requires * and ? wildcard characters, and LIKE uses the % and _ wildcards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows you to use brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The LIKE operator has no operator for `[ ]` brackets character ranges.

With ORACLE, columns defined as CHAR(N) are blank padded, and trailing blanks as significant in the LIKE expressions. As result, with a CHAR(5) value such as `'abc '` (with 2 trailing blanks), the expression `(colname LIKE 'ab_')` will not match. To workaround this behavior, you can do `(RTRIM(colname) LIKE '`*`pattern`*`')`. However, consider adding the condition `AND (colname LIKE '`*`patten`*`%')` to force the DB server to optimize the query of the column is indexed. The `CONSTRUCT` instruction uses this technique when the entered criteria does not end with a * star wildcard.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

SQL functions

Almost all Informix® functions and SQL constants have a different name or behavior in ORACLE.

Here is a comparison list of functions and constants:

Table 204: SQL functions and constants (Informix® vs. Oracle)

Informix®	ORACLE
today	trunc(sysdate)
current year to second	sysdate
day(value)	to_number(to_char(value, 'dd'))
extend(dtvalue, first to last)	to_date(nvl(to_char(dtvalue, 'fmt-mask'), '19000101000000'), 'fmt-mask')
mdy(m,d,y)	to_date(to_char(m,'09') || to_char(d,'09') || to_char(y,'0009'), 'MMDDYYYY')
month(date)	to_number(to_char(date, 'mm'))
weekday(date)	to_number(to_char(date, 'd')) -1
year(date)	to_number(to_char(date, 'yyyy'))
date("string" | integer)	No equivalent - Depends from DBDATE in IFX
user	user *! Uppercase/lowercase: See* The User Constant
trim([leading | trailing | both "char" FROM] "string")	ltrim() and rtrim()
length(c)	length(c) *! Different behavior: See* The Length Function
pow(x,y)	power(x,y)

Solution

You must review the SQL statements using TODAY / CURRENT / EXTEND expressions.

You can define stored functions in the ORACLE database, to simulate Informix® functions. This works only for functions that are not already implemented by ORACLE:

```
create or replace function month( adate in date )
  return number
is
  v_month number;
begin
  v_month:= to_number( to_char( adate, 'mm' ) );
```

```
  return (v_month);
end month;
```

Querying system catalog tables

As in Informix®, ORACLE provides system catalog tables (actually, system views). But the table names and their structure are quite different.

Solution

No automatic conversion of Informix® system tables is provided by the database interface.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

```
UPDATE table SET ( <col-list> ) = ( <val-list> )
```

or

```
UPDATE table SET table.* = myrecord.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column=value [,...]
```

The USER constant

Both Informix® and ORACLE provide the **USER** constant, which identifies the current user connected to the database server.

Informix®:

```
SELECT USER FROM systables WHERE tabid=1
```

Oracle:

```
SELECT USER FROM DUAL
```

However, there is a difference:

- Informix® returns the user identifier as defined in the operating system, where it can be case-sensitive (UNIX™) or not (NT).
- ORACLE returns the user identifier which is stored in the database. By default ORACLE converts the user name to uppercase letters, if you do not put the user name in double quotes when creating it.

This is important if your application stores user names in database records (for example, to audit data modifications). You can, for example, connect to ORACLE with the name 'scott', and perform the following SQL operations:

```
(1) INSERT INTO mytab ( creator, comment )
    VALUES( USER, 'example' );
(2) SELECT * FROM mytab
    WHERE creator = 'scott';
```

The first command inserts 'SCOTT' (in uppercase letters) in the creator column. The second statement will not find the row.

Solution

When creating a user in ORACLE, you can put double quotes around the user name in order to force ORACLE to store the given user identifier as is:

```
CREATE USER "username" IDENTIFIED BY pswd
```

To verify the user names defined in the ORACLE database, connect as SYSTEM and list the records of the ALL_USERS table as follows:

```
SELECT * FROM ALL_USERS;

USERNAME     USER_ID      CREATED
------------------------------------------------------------
SYS                0      02-OCT-98
SYSTEM             5      02-OCT-98
DBSNMP            17      02-OCT-98
FBDL              20      03-OCT-98
Paul              21      03-OCT-98
```

The GROUP BY clause

Informix® allows you to use column numbers in the GROUP BY clause

```
SELECT ord_date, sum(ord_amount) FROM order GROUP BY 1
```

Oracle does not support column numbers in the GROUP BY clause.

Solution

Use column names instead:

```
SELECT ord_date, sum(ord_amount) FROM order GROUP BY ord_date
```

The star (asterisk) in SELECT statements

Informix® allows you to use the star character in the select list along with other expressions:

```
SELECT col1, * FROM tab1 ...
```

Oracle does not support this. You must use the table name as a prefix to the star:

```
SELECT col1, tab1.* FROM tab1 ...
```

Solution

Always use the table name before the star.

BDL programming

Oracle Database related programming topics.

Handling SQL errors when preparing statements

The ORACLE interface is implemented with the ORACLE Call Interface (OCI). This library does not provide a way to send SQL statements to the database server during the BDL PREPARE instruction, as in the Informix® interface. The statement is sent to the server only when opening the cursors or when executing the statement.

Therefore, when preparing an SQL statement with the BDL PREPARE instruction, no SQL errors can be returned if the statement has syntax errors, or if a column or a table name does not exist in the database. However, an SQL error will occur after the OPEN or EXECUTE instructions.

Solution

Make sure your BDL programs do not test the STATUS or SQLCA.SQLCODE variable just after PREPARE instructions.

Change the program logic in order to handle the SQL errors when opening the cursors (OPEN) or when executing SQL statements (EXECUTE).

Informix® specific-SQL statements in BDL

The BDL compiler supports several Informix-specific SQL statements that have no meaning when using ORACLE:

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and remove all static SQL statements which are Informix® specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

ORACLE does not support insert cursors.

Solution

Insert cursors are emulated by the ORACLE database interface.

Cursors WITH HOLD

Informix® closes opened cursors automatically when a transaction ends unless the WITH HOLD option is used in the DECLARE instruction. In ORACLE, opened cursors using SELECT statements without a FOR UPDATE clause are not closed when a transaction ends. Actually, all ORACLE cursors are 'WITH HOLD' cursors unless the FOR UPDATE clause is used in the SELECT statement.

Solution

BDL cursors that are not declared "WITH HOLD" are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since ORACLE automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and WITH HOLD results in an SQL error that does not normally appear with Informix® under the same conditions. Review the program logic in order to find another way to set locks.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to prevent several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
```

```
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

- The row must be fetched in order to set the lock.
- If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared "WITH HOLD", the lock is released when the cursor is closed.

ORACLE allows individual and exclusive row locking with:

`SELECT ... FOR UPDATE [OF col-list]`

- A lock is acquired for each selected row when the cursor is opened, before the first fetch.
- Cursors using SELECT ... FOR UPDATE are automatically closed when the transaction ends; Note that locks are **not** released **when a cursor is closed**.

ORACLE's locking granularity is at the row level.

To control the behavior of the program when locking rows, Informix® provides a specific instruction to set the wait mode:

`SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }`

The default mode is NOT WAIT. This is an Informix® specific-SQL statement.

In order to simulate the same behavior in ORACLE, your can use the NOWAIT keyword in the SELECT ... FOR UPDATE statement, as follows:

`SELECT ... FOR UPDATE [OF col-list] NOWAIT`

With this option, ORACLE immediately returns an SQL error if the row is locked by another user.

Solution

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

Cursors declared with SELECT ... FOR UPDATE using the "WITH HOLD" clause cannot be supported with ORACLE. See Cursors with Hold and UPDATE/DELETE WHERE CURRENT OF for more details.

If your BDL application uses pessimistic locking with SELECT ... FOR UPDATE, you must review the program logic for OPEN cursor and CLOSE cursor statements inside transactions (BEGIN WORK + COMMIT WORK / ROLLBACK WORK).

UPDATE/DELETE WHERE CURRENT OF

Informix® allows positioned UPDATEs and DELETEs with the "`WHERE CURRENT OF cursor`" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

UPDATE/DELETE ... WHERE CURRENT OF<cursor> is not support by the Oracle database API. However, ROWIDs can be used for positioned updates/deletes.

Solution

UPDATE/DELETE ... WHERE CURRENT OF instructions are managed by the ORACLE database interface. The ORACLE database interface replaces "WHERE CURRENT OF cursor" by "WHERE ROWID=:rid" and sets the value of the ROWID returned by the last FETCH done with the given cursor.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instructions insert rows from a text file into a database table.

ORACLE does not provide LOAD and UNLOAD instructions, but provides external tools like SQL*Plus and SQL*Loader.

Solution

In BDL programs, the LOAD and UNLOAD instructions are supported with ORACLE, with some limitations:

- There is a difference when using ORACLE DATE columns. DATE columns created in the ORACLE database are equivalent to Informix® DATETIME YEAR TO SECOND columns. In LOAD and UNLOAD, all ORACLE DATE columns are treated as Informix® DATETIME YEAR TO SECOND columns and thus will be unloaded with the "YYYY-MM-DD hh:mm:ss" format.

  The same problem appears for Informix® INTEGER and SMALLINT values, which are stored in an ORACLE database as NUMBER(?) columns. Those values will be unloaded as Informix® DECIMAL(10) and DECIMAL(5) values, that is, with a trailing dot-zero ".0".
- When using an Informix® database, simple dates are unloaded using the DBDATE format (ex:"23/12/1998"). Therefore, unloading from an Informix® database for loading into an ORACLE database is not supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

Oracle supports SQL Interruption in a similar way. The db client must issue an OCIBreak() OCI call to interrupt a query.

Solution

The ORACLE database driver supports SQL interruption and converts the native SQL error code -1013 to the Informix® error code -213.

Scrollable cursors

The Genero programming language supports scrollable cursors.

Oracle 9.0 and higher support native scrollable cursors.

Solution

By default, the Oracle database driver uses native scrollable cursors by setting the OCI_STMT_SCROLLABLE_READONLY statement attribute.

See Scrollable cursors on page 422 for more details about scroll cursor emulation.

SQL adaptation guide for PostgreSQL 9.x

Installation (Runtime Configuration)
PostgreSQL related installation topics.
Install PostgreSQL and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Compile and install the PostgreSQL Server on your computer. PostgreSQL is a free database, you can download the sources from www.postgresql.org.
2. Read PostgreSQL installation notes for details about the "`data`" directory creation with the `initdb` utility.
3. Set configuration parameters in `postgresql.conf`:
   a) PostgreSQL 9.1 and higher have by default the `standard_conforming_strings` parameter set to `on`.

      The ODI drivers for PostgreSQL 9.1 and + do no longer escape the backslash characters in string literals with a second backslash.

Start a `postmaster` process to listen to database client connections.

> **Important:** If you want to connect through TCP (for example from a Windows™ PostgreSQL client), you must start postmaster with the `-i` option and setup the "`pg_hba.conf`" file for security (trusted hosts and users).

4. Create a PostgreSQL database with the `createdb` utility, by specifying the character set of the database.

```
$ createdb -h hostname dbname --encoding encoding --locale locale
```

5. If you plan to use SERIAL emulation, you need the plpgsql procedure language, because the database interface uses this language to create serial triggers.

   Starting with PostgreSQL version 9.0, the plpgsql language is available by default. Prior to version 9.0, you must create the language in your database with the following command:

```
$ createlang -h hostname plpgsql dbname
```

6. Connect to the database as the administrator user and create a database user dedicated to your application, the application administrator:

```
dbname=# CREATE USER appadmin PASSWORD 'password';
CREATE USER
dbname=# GRANT ALL PRIVILEGES ON DATABASE dbname TO appadmin;
GRANT
dbname=# \q
```

7. Create the application tables.

   Convert Informix® data types to PostgreSQL data types. See Data type conversion table: Informix to PostgreSQL on page 698 for more details.

8. If you plan to use the SERIAL emulation, you must prepare the database.

   See SERIAL data types on page 693 for more details.

Prepare the runtime environment - connecting to the database

1. In order to connect to PostgreSQL, you must have a PostgreSQL database driver "dbmpgs" in `FGLDIR/dbdrivers`.

   On HP/UX LP64, the PostgreSQL database driver must be linked with the libxnet library if you want to use networking.

2. The PostgreSQL client software is required to connect to a database server.

   Check whether the PostgreSQL client library (`libpq.*`) is installed on the machine where the BDL programs run.

3. Make sure that the PostgreSQL client environment variables are properly set.

   Check, for example, PGDIR (the path to the installation directory), PGDATA (the path to the data files directory), etc. See the PostgreSQL documentation for more details.

4. Check the database client locale settings (for example, set the PGCLIENTENCODING environment variable).

   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

5. Verify the environment variable defining the search path for the PostgreSQL database client shared libraries (libpq.so on UNIX™, LIBPQ.DLL on Windows™).

Table 205: Shared library environment setting for PostgreSQL

PostgreSQL version	Shared library environment setting
PostgreSQL 9.0 and higher	*UNIX*™: Add $PGDIR/lib to LD_LIBRARY_PATH (or its equivalent). *Windows*™: Add %PGDIR%\bin to PATH.

6. To verify if the PostgreSQL client environment is correct, you can start the PostgreSQL command interpreter:

```
$ psql dbname -U appadmin -W
```

7. Set up the fglprofile entries for database connections.
   a) Define the PostgreSQL database driver:

```
dbi.database.dbname.driver = "dbmpgs"
```

   b) The '**source**' parameter defines the name of the PostgreSQL database, as well as additional connection parameters if needed, such as the server host name, the TCP port and specific PostgresSQL connection options.

```
dbi.database.dbname.source = "test1"
```

   The `source` parameter must have the following form:

```
dbname[@host[:port]][?options]
```

   where:

   - *dbname* defines the name of the PostgreSQL database
   - *host* defines the server host name, or IP address (IPv6 host address needs to be enclosed it in square brackets)
   - *port* defines the TCP port
   - *options* is a URI-style query string defining PostgreSQL connection parameters

   For example:

```
mydb@orion:5433?connect_timeout=10&application_name=myapp
```

Database concepts
PostgreSQL related database concepts topics.
Database concepts

Like Informix® servers, PostgreSQL can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.

Solution

Create a PostgreSQL database for each Informix® database.

Data storage concepts

An attempt should be made to preserve as much of the storage information as possible when converting from Informix® to PostgreSQL. Most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be reused for the PostgreSQL database.

Storage concepts are quite similar in Informix® and in PostgreSQL, but the names are different.

Data consistency and concurrency

Data consistency involves readers that want to access data currently modified by writers, and *concurrency data access* involves several writers accessing the same data for modification. **Locking granularity** defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks** according to the **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is read committed.
- The default lock wait mode is "not wait".
- The default locking granularity is per page.

PostgreSQL

When data is modified, **exclusive locks** are set and held until the end of the transaction. For data consistency, PostgreSQL uses a **multi-version consistency model**: A copy of the original row is kept for readers before performing writer modifications. Readers do not have to wait for writers as in Informix®. The simplest way to think of the PostgreSQL implementation of read consistency is to imagine each user operating a private copy of the database, hence the multi-version consistency model. The **lock wait** mode cannot be changed as in Informix®. Locks are set at the **row level** in PostgreSQL and this cannot be changed.

Control:

- No lock wait mode control is provided.
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is Read Committed.

The main difference between Informix® and PostgreSQL is that readers do not have to wait for writers in PostgreSQL.

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL ... in PostgreSQL. The next table shows the isolation level mappings done by the PostgreSQL database driver:

Table 206: Isolation level mappings done by the PostgreSQL database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO CURSOR STABILITY	SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED
SET ISOLATION TO REPEATABLE READ	SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL SERIALIZABLE

For portability, it is recommended that you work with Informix® in the read committed isolation level, make processes wait for each other (lock mode wait), and create tables with the "lock mode row" option.

See the Informix® and PostgreSQL documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and PostgreSQL handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

PostgreSQL supports transaction with savepoints:

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be placed with SAVEPOINT *name* .
- Transactions can be rolled back to a savepoint with ROLLBACK TO SAVEPOINT *name* .
- Savepoints can be released with RELEASE SAVEPOINT *name* .
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.

Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, according to the transaction model.

The main difference between Informix® and PostgreSQL resides in the fact that PostgreSQL cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
INSERT INTO tab1 ( 1, 'abc' )
    -- PK constraint violation = SQL Error, whole TX is aborted
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With PostgreSQL, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction. To workaround this problem in PostgreSQL you can use SAVEPOINT as described in Solution on page 688.

Solution

Informix® transaction handling commands are automatically converted to PostgreSQL instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with PostgreSQL.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. The SQL statements that can potentially raise an SQL error must be protected with a SAVEPOINT. If an error occurs, just rollback to the savepoint:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
CALL sql_protect()
INSERT INTO tab1 ( 1, 'abc' )
 -- PK constraint violation = SQL Error
CALL sql_unprotect()
COMMIT WORK
...
FUNCTION sql_protect()
  IF NOT dbtype == "PGS" THEN
     RETURN
  END IF
  SAVEPOINT _sql_protect_
END FUNCTION

FUNCTION sql_unprotect()
  IF NOT dbtype == "PGS" THEN
     RETURN
  END IF
  IF SQLCA.SQLCODE < 0 THEN
     ROLLBACK TO SAVEPOINT _sql_protect_
  ELSE
     RELEASE SAVEPOINT _sql_protect_
  END IF
END FUNCTION
```

> **Note:** If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Database users

Until version 11.70.xC2, Informix® database users had to be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

PostgreSQL users must be registered in the database. They are created by the **createuser** utility:

```
$ createuser --username=username --password
```

Solution

Based on the application logic (is it a multiuser application ?), you have to create one or several PostgreSQL users.

Setting privileges

Informix® and PostgreSQL user privileges management are quite similar.

PostgreSQL provides **user groups** to grant or revoke permissions to more than one user at the same time.

Data dictionary

PostgreSQL related data dictionary topics.

BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way; as in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

PostgreSQL supports the BOOLEAN data type and stores 't' or 'f' values for TRUE and FALSE representation. It is not possible to insert the integer values 1 or 0; values must be true, false, '1' or '0'.

Solution

The PostgreSQL database interface supports the BOOLEAN data type, and converts the BDL BOOLEAN integer values to a CHAR(1) of 't' or 'f'.

CHARACTER data types

Informix® supports the following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N)is expressed in bytes, not characters as in some other databases)

PostgreSQL provides the following character types:

- CHAR(N) with N<= 10485760 characters
- VARCHAR(N) with N<= 10485760 characters; The length specification is optional.
- TEXT with a limit of 1GB

In PostgreSQL, CHAR, VARCHAR and TEXT types store data in single byte or multibyte character sets. For CHAR and VARCHAR, the size is specified in a number of characters, not bytes. The character set used to store data for these types is defined by the database character set, which can be specified when you create the database with the *createdb* tool or the CREATE DATABASE SQL command.

> **Note:** The VARCHAR type of PostgreSQL can be used without a length specification. If no size is specified, the column accepts strings of any size. However, as Genero BDL needs to know the size of CHAR and VARCHAR columns to define fields and program variables from a schema file, you should not create tables in PostgreSQL having VARCHAR columns without size specification. If you try to extract a schema with fgldbsch, this tool will report that the VARCHAR column cannot be converted to a BDL type for the .sch file.

Automatic character set conversion between the PostgreSQL client and server is supported. You must properly specify the client character set for PostgreSQL. This can be done in different ways, with the SET CLIENT_ENCODING TO SQL command for example, or with configuration parameters. See the PostgreSQL documentation for more details.

Solution

Informix® CHAR(N) types must be mapped to PostgreSQL CHAR(N) types, and Informix® VARCHAR(N) or LVARCHAR(N) columns must be mapped to PostgreSQL VARCHAR(N).

> **Note:** When creating a table from the BDL program with NCHAR or NVARCHAR types, the type names will be left as is and produce an SQL error because these types are not supported by PostgreSQL.

You can store single-byte or multibyte character strings in PostgreSQL CHAR, VARCHAR and TEXT columns.

PostgreSQL uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics.

When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a PostgreSQL database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in PostgreSQL database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

NUMERIC data types

Informix® supports several data types to store numbers:

Table 207: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)

Informix® data type	Description
DEC / DECIMAL(p)	Floating-point decimal number
DEC / DECIMAL(p,s)	Fixed-point decimal number
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

Solution

PostgreSQL supports the following data types to store numbers:

Table 208: PostgreSQL numeric data types

PostgreSQL data type	Description
NUMERIC(p,s) / DECIMAL(p,s)	Decimals with precision and scale (fractional part)
NUMERIC(p) / DECIMAL(p)	Integers with p digits (no fractional part)
NUMERIC / DECIMAL	Floating point numbers (no limit)
FLOAT4	16 bit variable precision
FLOAT8	32 bit variable precision
INT2	16 bit signed integer
INT4	32 bit signed integer
INT8/BIGINT	64 bit signed integer

ANSI types like SMALLINT, INTEGER, FLOAT are supported by PostgreSQL as aliases to INT2, INT4 and FLOAT8 native types.

Informix® DECIMAL(p) floating point types are converted to DECIMAL without precision/scale, to store any floating point number in PostgreSQL.

DATE and DATETIME data types

Informix® provides two data types to store dates and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

PostgreSQL provides the following data type to store date and time information:

- DATE = for year, month, day storage.
- TIME [(p)] [{with|without} time zone] = for hour, minute, second and fraction of second storage.
- TIMESTAMP [(p)] [{with|without} time zone] = for year, month, day, hour, minute, second and fraction of second storage.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contents matches environment parameters (i.e. DBDATE, GL_DATETIME). As in Informix®, PostgreSQL can convert quoted

strings to date time data according to the DateStyle session parameter. PostgreSQL always accepts ISO date time strings.

Date arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used, and an INTERVAL value if a DATETIME is used in the expression.
- In PostgreSQL, the result of an arithmetic expression involving DATE values is an INTEGER representing a number of days.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. PostgreSQL does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix-specific and have no equivalent in PostgreSQL.

Solution

The DATE type of PostgreSQL is equivalent to the DATE type in Informix® (stores year, month, day). Use PostgreSQL DATE data type for Informix® DATE columns.

PostgreSQL TIME(N) WITHOUT TIME ZONE data type can be used to store DATETIME HOUR TO ??? values.

PostgreSQL TIMESTAMP(N) WITHOUT TIME ZONE data type can be used to store DATETIME YEAR TO ??? values.

The SQL Translator of the PostgreSQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to PostgreSQL TIME(0) WITHOUT TIME ZONE (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to PostgreSQL TIME(0) WITHOUT TIME ZONE.
- DATETIME HOUR TO FRACTION(N) is converted to PostgreSQL TIME(N) WITHOUT TIME ZONE.
- DATETIME YEAR TO MINUTE is converted to PostgreSQL TIMSTAMP(0) WITHOUT TIME ZONE (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to PostgreSQL TIMESTAMP(0) WITHOUT TIME ZONE.
- DATETIME YEAR TO FRACTION(N) is converted to PostgreSQL TIMESTAMP(N) WITHOUT TIME ZONE.

Other DATETIME types will be mapped to PostgreSQL TIMESTAMP(N) types. Missing date or time parts default to 1900-01-01 00:00:00.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

The Informix® INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

Starting with version 8.4, PostgreSQL provides an INTERVAL data type which is equivalent to the Informix® INTERVAL type. The following are some features of the PostgreSQL 8.4 interval type:

- It is possible to specify the interval class / precision with YEAR, MONTH, DAY, HOUR, MINUTE and SECOND[(p)] fields.
- Fractional part of seconds can be defined with up to 6 digits.
- The INTERVALs value range is from -178000000 to +178000000 years.
- Input and output format can be controlled with the SET interval style command.

Solution

Starting with Genero 2.21, database drivers dbmpgs84x and higher convert the Informix-style INTERVAL type to the native PostgreSQL INTERVAL type. See the data type conversion table for the exact conversion rules.

> **Important:** The PostgreSQL database driver forces the interval style session parameter to 'iso_8601', this is required to insert and fetch interval database with the libpq CAPI functions. You must not change this setting during program execution.

While PostgreSQL INTERVALs support up to 9 digits for the higher unit like Informix®, YEAR values range from -178000000 to +178000000 only. This limitation exists in PostgreSQL 8.4 and maybe solved in future versions.

With PostgreSQL and driver versions prior to 8.4, the INTERVAL data type is converted to CHAR(50).

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in `SQLCA.SQLERRD[2]`, while the new SERIAL8 and BIGSERIAL value must be fetched with a `SELECT dbinfo('bigserial')` query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

PostgreSQL SERIAL data type:

- PostgreSQL's SERIAL data type has the same name as in Informix®, but it behaves differently.
- You cannot define a start value (SERIAL(100)).
- You cannot specify zero as serial value to get a new serial, the PostgreSQL serial is based on default values, thus you must omit the serial column in the INSERT statement.
- When you INSERT a row with a specific value for the serial column, the underlying sequence will not be incremented. As result, the next INSERT that does not specify the serial column may get a new sequence that was already inserted explicitly.
- With some old versions of PostgreSQL, when you drop the table you must drop the sequence too.

PostgreSQL sequences:

- Sequences are totally detached from tables.
- The purpose of sequences is to provide unique integer numbers.
- Sequences are identified by a sequence name.
- To create a sequence, you must use the CREATE SEQUENCE statement.

  Once a sequence is created, it is permanent (like a table).
- To get a new sequence value, you must use the nextval() function:

```
INSERT INTO tab1 VALUES ( nextval('tab1_seq'), ... )
```

- To get the last generated number, PostgreSQL provides the currval() function:

```
SELECT currval('tab1_seq')
```

Solution

The Informix® SERIAL data type can be emulated with three different methods.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial.emulation = {"native"|"regtable"|"trigseq"}`

- native: uses the native PostgreSQL serial data type.
- regtable: uses insert triggers with the SERIALREG table.
- trigseq: uses insert triggers with sequences.

The default emulation technique is "`native`".

This entry must be used in conjonction with:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial = {true|false}`

If the `datatype.serial` entry is set to false, the emulation method is ignored.

Using the `native` serial emulation

The "`native`" mode is the default serial emulation mode, using the native PostgreSQL SERIAL data type. In this mode, the original type name will be left untouched by the SQL Translator and you will get the behavior of the PostgreSQL SERIAL column type, based on sequences.

> **Note:** INSERT statements cannot use the serial column, even with a value zero. When using a NULL value, PostgreSQL will report an non-null constraint error. Therefore, the serial column must be omitted from the INSERT statement.

The `sqlca.sqlerrd[2]` register is not set after an INSERT when using a PostgreSQL version prior to version 8.3.

See also the PostgreSQL documentation for more details about the native SERIAL type.

Using the `regtable` serial emulation

With the "`regtable`" mode, the SERIAL data type is emulated with a PostgreSQL INTEGER data type and INSERT triggers using the table SERIALREG which is dedicated to sequence production. After an insert, `sqlca.sqlerrd[2]` register holds the last generated serial value. BIGSERIAL and SERIAL8 types can be converted to BIGINT in PostgreSQL, but the `sqlca.sqlerrd[2]` register cannot be used since it is defined as an INTEGER type.

The triggers can be created manually during the application database installation procedure, or automatically from a BDL program: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL data type to INTEGER and dynamically creates the triggers.

You must create the SERIALREG table as follows:

```
CREATE TABLE SERIALREG (
   TABLENAME VARCHAR(50) NOT NULL,
   LASTSERIAL DECIMAL(20,0) NOT NULL,
   PRIMARY KEY ( TABLENAME )
)
```

> **Important:** The SERIALREG table must be created before the triggers. The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

With this emulation mode, INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements that do not use the serial column:

```
INSERT INTO tab (col2) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value. Consider removing the serial column from the INSERT statements.

Using the `trigseq` serial emulation

With "`trigseq`", the SERIAL data type is emulated with a PostgreSQL INTEGER data type and INSERT triggers using a sequence *`tablename`*`_seq`. After an insert, `sqlca.sqlerrd[2]` register holds the last generated serial value.

The triggers can be created manually during the application database installation procedure, or automatically from a BDL program: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL data type to INTEGER and dynamically creates the triggers.

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

With this emulation mode, INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```
INSERT INTO tab (col2) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value. Consider removing the serial column from the INSERT statements.

Notes common to all serial emulation modes

Since `sqlca.sqlerrd[2]` is defined as an INTEGER, it cannot hold values from BIGSERIAL (BIGINT) auto incremented columns. If you are using BIGSERIAL columns, you must query the sequence pseudo-column CURRVAL() or fetch the LASTSERIAL column from the SERIALREG table if used.

For SQL portability, INSERT statements should be reviewed to remove the SERIAL column from the list.

For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES ( 0 , p_value )
```

can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

> **Important:** When using the Static SQL INSERT and UPDATE syntax using record.* without braces, make sure that you database schema files contain information about serials: This information can be lost when extracting the schema from a PostgreSQL database which does not use native serial emulation. See Database Schema for more details about the serial flag in column type encoding (data type code must be 6)

ROWIDs

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

When the feature is enabled, PostgreSQL tables are automatically created with a OID column (Object Identifier) of type INTEGER. The behavior is equivalent to Informix® ROWID columns (see Solution).

Solution

The database automatically converts ROWID keywords to OID for PostgreSQL. You can execute "SELECT ROWID FROM" and "UPDATE .. WHERE ROWID = ?" statements as with Informix®.

> **Note:**
>
> - Starting with PostgreSQL version 8.1, OIDs are no longer supported by default. You need to define the **default_with_oid** parameter in postgresql.conf to get OID columns created for tables. See Database configuration and design tasks.
> - SQLCA.SQLERRD[6]is not supported. All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last INSERTed or UPDATEd row when using the PostgreSQL interface.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

PostgreSQL provides the TEXT and BYTEA data types for large objects storage. With these data types, large objects are handled as a whole. In fact PostgreSQL does also provide another way to store blobs, through the large objects facility based on stream-style access. The large object facility is provided as a set of C and SQL API functions to create / delete / modify large objects identified by a unique object id (OID). For example, the `lo_create(-1)` SQL function will create a new large object and return a new object id that will be used to handle the LOB. See PostgreSQL documentation for more details.

Solution

TEXT and BYTE data can be stored in PostgreSQL TEXT and BYTEA columns.

Genero BDL does not interface automatically with the PostgreSQL Large Object facility. However, the OID values can be stored in BIGINT variables, and you can use server-side LOB functions to convert large objects to BYTEA data, that can be fetched into BYTE variables. The next code example creates a table with an OID column, imports a LOB from an image file, and then fetches the LOB back into a BYTE:

```
MAIN
    DEFINE img BYTE, obj_id BIGINT
```

```
    CONNECT TO "test1+driver='dbmpgs'" USER "postgres" USING "fourjs"

    # Need superuser privileges to create the LOB....
    WHENEVER ERROR CONTINUE
    DROP TABLE t1
    WHENEVER ERROR STOP
    EXECUTE IMMEDIATE "create table t1 ( k int, image oid )"
    GRANT SELECT ON t1 TO PUBLIC
    INSERT INTO t1 VALUES ( 1, lo_import("/var/images/landscape.png") )
    SELECT image INTO obj_id FROM t1 WHERE k=1
    DISPLAY "obj_id = ", obj_id
    EXECUTE IMMEDIATE "grant select on large object "||obj_id||" to public"

    # Next block can be executed by any user:
    LOCATE img IN FILE -- a temp file will be used
    SELECT loread(lo_open(image, 262144), 1000000)
      INTO img FROM t1 WHERE k=1
    DISPLAY length(img)

    # Delete the object
    SELECT lo_unlink(obj_id) FROM t1 WHERE k=1

    DROP TABLE t1

END MAIN
```

Constraints

Constraint naming syntax

Both Informix® and PostgreSQL support primary key, unique, foreign key, default and check constraints, but the constraint naming syntax is different. PostgreSQL expects the "CONSTRAINT" keyword **before** the constraint specification and Informix® expects it **after**.

UNIQUE constraint example

Table 209: UNIQUE constraint example (Informix® vs. PostgreSQL)

Informix®	PostgreSQL

`CREATE TABLE emp (`
`  ...`
`  emp_code CHAR(10)`
`  UNIQUE CONSTRAINT pk_emp,`
`  ...`
	`CREATE TABLE emp (`
	`  ...`
	`  emp_code CHAR(10)`
	`  CONSTRAINT pk_emp UNIQUE,`
	`  ...`

Unique constraints

> **Note:** When using a unique constraint, Informix® allows only one row with a NULL value, while PostgreSQL allows several rows with NULL!

Solution

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for PostgreSQL.

Triggers

Informix® and PostgreSQL provide triggers with similar features, but the trigger creation syntax and the programming languages are totally different.

Solution

Informix® triggers must be converted to PostgreSQL triggers "by hand".

Stored procedures

Both Informix® and PostgreSQL support stored procedures, but the programming languages are totally different. With PostgreSQL you must create the stored procedure language before writing triggers or stored procedures.

Solution

Informix® stored procedures must be converted to PostgreSQL manually.

See SQL Programming for more details about executing stored procedures with PostgreSQL.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

`[`*`database`*`[@`*`dbservername`*`]:][{`*`owner`*`|"`*`owner`*`"}.]`*`identifier`*

With PostgreSQL, an object name takes the following form:

`[`*`owner`*`.]`*`identifier`*

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Data type conversion table: Informix to PostgreSQL

Table 210: Data type conversion table (Informix to PostgreSQL)

Informix® data types	PostgreSQL data types (before 8.4)	PostgreSQL data types (since 8.4)
CHAR(n)	CHAR(n)	CHAR(n)

Data manipulation
PostgreSQL related data manipulation topics.
Reserved words

SQL object names like table and column names cannot be SQL reserved words in PostgreSQL.

Solution

Table or column names which are PostgreSQL reserved words must be renamed.

Outer joins

In Informix® SQL, outer tables can be defined in the FROM clause with the **OUTER** keyword:

```
SELECT ... FROM a, OUTER(b)
 WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c))
 WHERE a.key = b.akey
  AND b.key1 = c.bkey1
   AND b.key2 = c.bkey2
```

PostgreSQL supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
```

```
 ON cust.key = order.custno
```

```
SELECT ...
 FROM cust LEFT OUTER JOIN order
  LEFT OUTER JOIN item
  ON order.key = item.ordno
 ON cust.key = order.custno
WHERE order.cdate > current date
```

See the PostgreSQL reference for a complete description of the syntax.

Solution

For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The PostgreSQL interface can convert most Informix® OUTER specifications to ANSI outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work: " `FROM OUTER(tab2), tab1`".
2. The outer join in the WHERE part must use the table name as prefix.

   Example: " `WHERE tab1.col1 = tab2.col2`".

Restrictions:

1. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: "... `FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10`".
2. Statements composed of 2 or more SELECT instructions using OUTERs are not supported.

   Example: " `SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"`

Remarks:

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias: " `OUTER( tab1 alias1)`".
2. In the outer join, *`outertab.col`* can be placed on both right or left sides of the equal sign.

   OUTER join example with table on the left: " `WHERE outertab.col1 = maintab.col2`".
3. Table names detection is not case-sensitive.

   Example: " `SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2`".
4. Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and PostgreSQL handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be set with SAVEPOINT *name* [UNIQUE].
- Transactions can be rolled back to a savepoint with ROLLBACK [WORK] TO SAVEPOINT [*name*].
- Savepoints can be released with RELEASE SAVEPOINT *name*.
- Statements executed outside of a transaction are automatically committed.

- DDL statements can be executed (and canceled) in transactions.

PostgreSQL supports transaction with savepoints:

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
- Savepoints can be placed with SAVEPOINT *name* .
- Transactions can be rolled back to a savepoint with ROLLBACK TO SAVEPOINT *name* .
- Savepoints can be released with RELEASE SAVEPOINT *name* .
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.

Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, according to the transaction model.

The main difference between Informix® and PostgreSQL resides in the fact that PostgreSQL cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
INSERT INTO tab1 ( 1, 'abc' )
    -- PK constraint violation = SQL Error, whole TX is aborted
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With PostgreSQL, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction. To workaround this problem in PostgreSQL you can use SAVEPOINT as described in Solution on page 702.

Solution

Informix® transaction handling commands are automatically converted to PostgreSQL instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with PostgreSQL.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. The SQL statements that can potentially raise an SQL error must be protected with a SAVEPOINT. If an error occurs, just rollback to the savepoint:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
CALL sql_protect()
INSERT INTO tab1 ( 1, 'abc' )
 -- PK constraint violation = SQL Error
CALL sql_unprotect()
COMMIT WORK
...
FUNCTION sql_protect()
  IF NOT dbtype == "PGS" THEN
     RETURN
  END IF
  SAVEPOINT _sql_protect_
```

```
END FUNCTION

FUNCTION sql_unprotect()
  IF NOT dbtype == "PGS" THEN
     RETURN
  END IF
  IF SQLCA.SQLCODE < 0 THEN
     ROLLBACK TO SAVEPOINT _sql_protect_
  ELSE
     RELEASE SAVEPOINT _sql_protect_
  END IF
END FUNCTION
```

Note: If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Temporary tables

Informix® temporary tables are created through the CREATE TEMP TABLE DDL instruction or through a SELECT ... INTO TEMP statement. Temporary tables are automatically dropped when the SQL session ends, but they can be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

PostgreSQL support temporary tables as Informix® does, with a little syntax difference in the SELECT INTO TEMP instruction.

Solution

Temporary tables are well supported with native PostgreSQL temp tables.

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

PostgreSQL provides the SUBSTRING() function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTRING(col1 from 2 for 2) = 'RO'
SELECT SUBSTRING('Some text' from 6 for 3) ... -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions by SUBSTRING(col from x for (y-x+1)).

Note:

- In UPDATE instructions, setting column values through subscripts will produce an error with PostgreSQL:

  `UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...`

  is converted to:

  `UPDATE tab1 SET SUBSTRING(col1 from 2 for (3-2+1)) = 'RO' WHERE ...`

- Column subscripts in ORDER BY expressions are also converted and produce an error with PostgreSQL:

  ```
  SELECT ... FROM tab1 ORDER BY col1[1,3]
  ```

  is converted to:

  ```
  SELECT ... FROM tab1 ORDER BY SUBSTRING(col1 from 1 for(3-1+1))
  ```

String delimiters

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE "tabname"."colname" = 'string'`

Informix® allows double quotes as string delimiters, but PostgreSQL doesn't. This is important since many BDL programs use that character to delimit the strings in SQL commands.

> **Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

Solution

The PostgreSQL database interface can automatically replace all double quotes by single quotes.

Escaped string delimiters can be used inside strings like following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: """
"This is a double quote: \""
```

Database object names cannot be delimited by double quotes because the database interface cannot determine the difference between a database object name and a quoted string. For example, if the program executes the SQL statement:

`WHERE "tabname"."colname" = "string"`

replacing all double quotes by single quotes would produce:

`WHERE 'tabname'.'colname' = 'string'`

This would produce an error since `'tabname'.'colname'` is not allowed by PostgreSQL.

Although double quotes are replaced automatically in SQL statements, you should use only single quotes to enforce portability.

Using column aliases in SELECT

PostgreSQL expects the ANSI notation for column aliases:

```
SELECT col1 AS col1_alias FROM ...
```

Informix® supports the ANSI notation.

Solution

The database interface cannot convert Informix® alias specification to the ANSI notation.

Review your programs and replace the Informix® notation with the ANSI form.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements. PostgreSQL supports the LIKE statement as in Informix®, plus the ~ operators that are similar but different from the Informix® MATCHES operator.

MATCHES requires * and ? wildcard characters, and LIKE uses the % and _ wildcards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The PostgreSQL LIKE operator has no operator for `[ ]` brackets character ranges.

The PostgreSQL ~ operator expects regular expressions as follows: `( col ~ 'a.*' )`

With PostgreSQL, columns defined as CHAR(N) are blank padded, and trailing blanks are significant in the LIKE expressions. As result, with a CHAR(5) value such as `'abc '` (with 2 trailing blanks), the expression `(colname LIKE 'ab_')` will not match. To workaround this behavior, you can do `(RTRIM(colname) LIKE '`*`pattern`*`')`. However, consider adding the condition `AND (colname LIKE '`*`patten`*`%')` to force the DB server to optimize the query of the column is indexed. The `CONSTRUCT` instruction uses this technique when the entered criteria does not end with a * star wildcard.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no `[ ]` bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

Querying system catalog tables

As in Informix®, PostgreSQL provides system catalog tables (actually, system views). But the table names and their structure are quite different.

Solution

No automatic conversion of Informix® system tables is provided by the database interface.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

`UPDATE table SET ( `*`col-list`*` ) = ( `*`val-list`*` )`

Or

```
UPDATE table SET table.* = codeph.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column=value [,...]
```

The LENGTH() function

Informix® provides the LENGTH() function:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

PostgreSQL has a equivalent function with the same name, but there is some difference:

Informix® does not count the trailing blanks for CHAR or VARCHAR expressions, while PostgreSQL counts the trailing blanks.

With the PostgreSQL LENGTH function, when using a CHAR column values are always blank padded, so the function returns the size of the CHAR column. When using a VARCHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

PostgreSQL raises an error if the LENGTH() parameter is NULL. Informix® returns zero instead.

Solution
The PostgreSQL database interface cannot simulate the behavior of the Informix® LENGTH() SQL function.

Review the program logic and make sure you do not pass NULL values to the LENGTH() SQL function.

You must check if the trailing blanks are significant when using the LENGTH() function.

If you want to count the number of character by ignoring the trailing blanks, you must use the RTRIM() function.

BDL programming
PostgreSQL related programming topics.
Handling SQL errors when preparing statements

The PostgreSQL connector is implemented with the PostgreSQL **libpq** API. This library does not provide a way to send SQL statements to the database server during the BDL PREPARE instruction, like the Informix® interface does. The statement is sent to the server only when opening the cursors or when executing the statement, because the database driver needs to provide the data types of the SQL parameters (only known at OPEN / EXECUTE time).

Therefore, when preparing an SQL statement with the BDL PREPARE instruction, no SQL errors can be returned if the statement has syntax errors or if a column or a table name does not exist in the database. However, an SQL error will occur after the OPEN or EXECUTE instructions.

Solution

Check that your BDL programs do not test STATUS or SQLCA.SQLCODE variable just after PREPARE instructions.

Change the program logic in order to handle the SQL errors when opening the cursors (OPEN) or when executing SQL statements (EXECUTE).

Informix® specific SQL statements in BDL

The BDL compiler supports several Informix® specific SQL statements that have no meaning when using PostgreSQL.

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and remove all static SQL statements which are Informix® specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

PostgreSQL does not support insert cursors.

Solution

Insert cursors are emulated by the PostgreSQL database interface.

Cursors WITH HOLD

Informix® closes opened cursors automatically when a transaction ends unless the WITHHOLD option is used in the DECLARE instruction. In PostgreSQL, opened cursors using SELECT statements without a FOR UPDATE clause are not closed when a transaction ends. Actually, all PostgreSQL cursors are 'WITH HOLD' cursors unless the FOR UPDATE clause issued in the SELECT statement.

Cursors declared FOR UPDATE and using the WITH HOLD option cannot be supported with PostgreSQL because FOR UPDATE cursors are automatically closed by PostgreSQL when the transaction ends.

Solution

BDL cursors that are not declared "WITH HOLD" are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since PostgreSQL automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and the WITH HOLD option results in an SQL error that does not normally appear with Informix® under the same conditions. Review the program logic in order to find another way to set locks.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to avoid several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

In both Informix® and PostgreSQL, locks are released when closing the cursor or when the transaction ends.

PostgreSQL locking granularity is at the row level.

To control the behavior of the program when locking rows, Informix® provides a specific instruction to set the wait mode:

```
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
```

The default mode is NOT WAIT. This as an Informix-specific SQL statement; PostgreSQL has no equivalent for "SET LOCK MODE TO NOT WAIT".

Solution

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

You must review the program logic if you use pessimistic locking because it is based on the NOT WAIT mode which is not supported by PostgreSQL.

UPDATE/DELETE WHERE CURRENT OF

Informix® allows positioned UPDATEs and DELETEs with the "`WHERE CURRENT OF` *`cursor`*" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

UPDATE/DELETE ... WHERE CURRENT OF is supported by PostgreSQL with server-side cursors created with a DECLARE statement.

Solution

UPDATE/DELETE ... WHERE CURRENT OF instructions are executed as is. Since SELECT FOR UPDATE statements are now executed with a server cursor by using a DECLARE PostgreSQL statement, native positioned update/delete takes place.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instructions insert rows from a text file into a database table.

PostgreSQL does not provide LOAD and UNLOAD instructions.

Solution

LOAD and UNLOAD instructions are supported.

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

PostgreSQL supports SQL Interruption in a similar way. The db client must issue an PQcancel() libPQ call to interrupt a query.

Solution

The PostgreSQL database driver supports SQL interruption and converts the SQLSTATE code 57014 to the Informix® error code -213.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

PostgreSQL supports native scrollable cursors.

Solution

The PostgreSQL database driver uses native scrollable cursors by declaring server cursors with the SCROLL clause.

SQL adaptation guide for SQLite 3.x

Installation (Runtime Configuration)
SQLite related installation topics.
Install SQLite and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. If the `dbmsqt` database driver is linked dynamically with the SQLite library, you must install the SQLite software on your computer. However, on most platforms, the driver has an embedded version of the SQLite library, and on platforms such as Linux™ as Mac OS X™, the SQLite library is usually present.
   The minimum required version is SQLite 3.6.
2. Create a new SQLite database.
   To create a new database with tables, start the sqlite3 command line tool and execute SQL statements:

```
$ sqlite3 /var/data/stores.db
sqlite> CREATE TABLE customer ( cust_id INT PRIMARY KEY, ... );
$ .exit
```

   To create an empty database, you can also issue the following command:

```
$ sqlite3 /var/data/stores.db ""
```

   or create an empty file with operating system command:

```
$ touch /var/data/stores.db
```

   And empty file can also be created from a program by using a `base.Channel` object:

```
DEFINE ch base.Channel
LET ch = base.Channel.create()
CALL ch.openFile("/var/data/stores.db","w")
CALL ch.close
```

Prepare the runtime environment - connecting to the database

1. In order to connect to SQLite, you must have a database driver "dbmsqt" in `FGLDIR/dbdrivers`. On most platforms, the SQLite driver is linked statically with the SQLite library, in other word SQLite is embedded in the ODI driver. However, on some platforms such as Linux™ and Max OS X, where the SQLite library is usually present.
2. Make sure that the SQLite environment variables are properly set. You may want to define an environment variable such as SQLITEDIR the hold the installation directory of SQLite, which can then be used to set PATH and LD_LIBRARY_PATH. See SQLite documentation for more details.
3. If the SQLite library is not embedded in the the dbmsqt* driver, the environment must be set to find the SQLite library. Verify the environment variable defining the search path for the SQLite shared library.

   Table 211: Shared library environment setting for SQLite

SQLite version	Shared library environment setting (if SQLite lib not built-in driver)
SQLite 3.6 and higher	*UNIX*™: Add $SQLITEDIR/lib to LD_LIBRARY_PATH (or its equivalent). *Windows*™: Add %SQLITEDIR%\bin to PATH.

4. Make sure that all operating system users running the application have read/write access to the database file.

5. SQLite uses UTF-8 encoding. If the locale used by the runtime system (LANG/LC_ALL) is not compatible to UTF-8 (for example, fr_FR.iso88591), Genero will do the appropriate character set conversions.
6. Set up the fglprofile entries for database connections.
   a) Define the SQLite database driver:

   ```
   dbi.database.dbname.driver = "dbmsqt"
   ```

   b) The "source" parameter defines the path to the SQLite database file. Note that the database file must reside on the local disk (SQLite does not support network file systems). SQLite also supports in-memory database creation with the :memory: db specification. See SQLite documentation (sqlite3_open) for more details.

   ```
   dbi.database.dbname.source = "/opt/myapp/stock.dbs"
   ```

   c) If the "source" parameter defines a relative path or a simple file name and the SQLite database file does not reside in that location according to the current directory of the fglrun process, define the DBPATH environment variable to find the database file. See DBPATH documentation for more details about this environment variable.

   ```
   DBPATH="/opt/myapp"
   ```

Database concepts
SQLite related database concepts topics.
Database concepts

Informix® servers can handle multiple database entities, while SQLite can manage several database files.

Solution

Map each Informix® database to a SQLite database file.

Consider creating the SQLite database file before using the connection instruction. The database file can be created as an empty file, with a OS shell command (touch) or by program by using the file utility classes.

It is possible to specify an SQLite database file name in the database specification in CONNECT TO or DATABASE instructions:

```
DATABASE "/opt/myapp/database/stock1.dbs"
```

However, it is recommended to use an indirection by using an abstract name identifier in the program, and by defining the real database file with the "source" connection parameter. The file defined by "source" is then found directly (can be a relative or absolute path), or according to DBPATH settings if not found from the current directory of fglrun (when it's not an absolute path).

In the program:

```
DATABASE stock
```

In the FGLPROFILE configuration file, define the SQLite driver and the database file:

```
dbi.database.stock.driver = "dbmsqt"
dbi.database.stock.source = "/opt/myapp/database/stock1.dbf"
```

FGLPROFILE could also define the file name only:

```
dbi.database.stock.source = "stock1.dbf"
```

And the file would be found by using DBPATH:

```
DBPATH="/opt/myapp/database"
```

When specifying `:memory:` as database file name, an empty SQLite database is created in memory. This can be useful if the persistence of the data is not required after the program has terminated:

```
DATABASE ":memory:"
```

Concurrency management

Informix® is a multiuser database engine, while SQLite is typically used for a single-user application. SQLite 3 supports multiuser access to the same database file, but it is not designed for large multiuser applications.

SQLite 3 supports two isolation levels: SERIALIZABLE (the default), and READ UNCOMMITTED. The isolation level can be changed with the PRAGMA command.

By default in the SERIALIZABLE isolation level, SQLite will raise an SQL error if a program tries to access a database resource in use by another program. To avoid the SQL error and force programs to wait for each other, programs define the behavior when the SQLite database is busy (SQLITE_BUSY), with a specific API call. No SQL command exists for this.

Solution

We recommend that you use SQLite for single-user DB applications. If several programs must access the same SQLite database, each program must perform a SET LOCK MODE TO WAIT instruction after the connection: SET LOCK MODE will be mapped to a call to the sqlite3_busy_timeout() SQLite API function to get the same behavior as Informix®, while SET ISOLATION instructions will be ignored.

Transactions handling

Informix® and SQLite have similar commands to begin, commit or rollback transaction. There are however some important differences you must be aware of.

With SQLite, DDL statements can be executed (and canceled) in transaction blocks, as with Informix®.

Informix® version 11.50 introduces savepoints with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

SQLite supports savepoints too. However, there are differences:

1. SAVEPOINT can be used instead of BEGIN TRANSACTION. In this case, RELEASE is like a COMMIT.
2. The syntax of a rollback to the savepoint is ROLLBACK [TRANSACTION] TO [SAVEPOINT] *name* .
3. The syntax of a release of the savepoint is RELEASE [SAVEPOINT] *name* .
4. Rollback must always specify the savepoint name.
5. You cannot rollback to a savepoint if cursors are opened.
6. In SQLite versions prior to 3.7, you cannot rollback are transaction if a cursor is open.

Solution

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with SQLite. The BEGIN WORK, COMMIT WORK and ROLLBACK WORK commands are translated the native commands of SQLite.

> **Note:** If you want to use savepoints, always specify the savepoint name in ROLLBACK TO SAVEPOINT and do not open cursors during transactions using savepoints. If you are using an

SQLite versions prior to 3.7, it is not possible to perform a ROLLBACK WORK if a cursor (with hold) is currently open.

See also SELECT FOR UPDATE

Database users

Informix® supports database users that must be explicitly declared to the database by granting privileges.

SQLite does not have the database users concept. However, the operating system user must have read/write access to the database file.

Solution

SQLite is mainly designed for single-user applications.

Data dictionary
SQLite related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way. As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

SQLite does not implement a native BOOLEAN type, but accepts BOOLEAN in the SQL syntax.

Solution

The SQLite database interface supports the BOOLEAN data type, and converts the BDL BOOLEAN integer values to a CHAR(1) of '1' or '0'.

CHARACTER data types

Informix® supports the following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- NVARCHAR(N[,M]) with N<=255 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/ NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/ NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

SQLite 3 provides the TEXT native data type with no strict size limitation. SQLite allows the CHAR(n), VARCHAR(n), NCHAR(n) and NVARCHAR(n) type names to be used, but actually stores the data in a TEXT native type.

SQLite treats empty strings as NOT NULL values like Informix®.

> **Note:** With the default BINARY collation, SQLite compares VARCHAR and CHAR values by taking trailing blanks into account. Informix® always ignores trailing blanks when comparing CHAR/VARCHAR values.

SQLite supports only the UTF-8 character encoding. Thus, client applications must provide UTF-8 encoded strings.

Solution

The database interface supports character string variables in SQL statements for input (BDLUSING) and output (BDL INTO).

> **Important:** With the default BINARY collation, CHAR and VARCHAR comparison in SQLite takes trailing blanks into account. As result, some queries returning rows with Informix® may not return the same result set with SQLite. When creating a table in SQLite, you can change the default collation rule to force the database engine to trim trailing blanks before comparing CHAR/VARCHAR values, by specifying COLLATION RTRIM in the column definitions. When creating a table from a Genero program, if Informix® emulation is enabled for the CHAR/VARCHAR types, the SQLite database driver adds automatically COLLATE RTRIM after the CHAR(N) or VARCHAR(N) type, to get the same comparison semantics as Informix®.

Regarding character sets, the SQLite database driver automatically converts character strings used in the programs to/from UTF-8 for SQLite.

SQLite uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics.

When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a SQLite database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in SQLite database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

See also the section about Localization.

NUMERIC data types

Informix® supports several data types to store numbers:

Table 212: Informix® numeric data types

Informix® data type	Description
SMALLINT	16 bit signed integer
INT / INTEGER	32 bit signed integer
BIGINT	64 bit signed integer
INT8	64 bit signed integer (replaced by BIGINT)
DEC / DECIMAL	Equivalent to DECIMAL(16)
DEC / DECIMAL(p)	Floating-point decimal number
DEC / DECIMAL(p,s)	Fixed-point decimal number
MONEY	Equivalent to DECIMAL(16,2)
MONEY(p)	Equivalent to DECIMAL(p,2)
MONEY(p,s)	Equivalent to DECIMAL(p,s)
REAL / SMALLFLOAT	32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)]	64-bit floating point decimal (C double)

SQLite 3 supports INTEGER (8 byte integer) and REAL (8 byte floating point) as native types to store numbers, but allows synonyms:

Table 213: SQLite numeric data types and supported synonyms

Supported synonyms	SQLite type affinity
INT, INTEGER, TINYINT, SMALLINT, MEDIUMINT, BIGINT, UNSIGNED BIG INT, INT2, INT8	INTEGER (8 bytes!)
REAL, DOUBLE, DOUBLE PRECISION, FLOAT	REAL (8 bytes!)
DECIMAL(p,s), NUMERIC	NUMERIC (based on REAL)

Important: Exact decimal types like DECIMAL(p,s) may be stored as floating point numbers (REAL), INTEGERs or TEXT, according to the type affinity selected by SQLite. When converted to floating point type, data loss and rounding rule differences are possible with SQLite.

Solution

Informix® numeric types are not translated by the database driver.

Since SQLite 3 does not have exact decimal types like DECIMAL(p,s), you must pay attention to the rounding rules and data loss when using numbers with many significant digits. Arithmetic operations like division have different results than with Informix®. It is better to fetch the original column value into a DECIMAL variable, and do arithmetic operations in the application program.

DATE and DATETIME data types

Informix® provides two data types to store date and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

SQLite 3 does not have a native type for date/time storage, but you can use data/time type names and functions based on the string representation of dates and times. The date/time values are stored in the TEXT native type. The date/time functions of SQLite are based on standard DATE (YYYY-MM-DD), TIME (hh:mm:ss) and TIMESTAMP (YYYY-MM-DD hh:mm:ss) concepts.

For maximum flexibility with other RDBMS SQL languages, SQLite allows to define table columns with your own type names. You can for example use the SMALLDATETIME, SMALLTIME, TIME(N), DATETIME(N) type names.

Solution

The following conversions are done by the ODI SQLite driver for date/time types:

- DATE type is not translated, it will be used as is by SQLite.
- DATETIME HOUR TO MINUTE is translated to SMALLTIME.
- DATETIME HOUR TO SECOND is translated to TIME.
- DATETIME HOUR TO FRACTION(n) is transalated to TIME(n).
- DATETIME YEAR TO DAY is translated to TINYDATETIME.
- DATETIME YEAR TO MINUTE is translated to SMALLDATETIME.
- DATETIME YEAR TO SECOND is translated to DATETIME.
- DATETIME YEAR TO FRACTION(n) is translated to DATETIME(n).
- DATETIME with another precision as above are translated to TIMESTAMP.

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix's INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

SQLite 3 does not provide a data type similar to Informix® INTERVAL.

Solution

It is not recommended that you use the INTERVAL data type because SQLite 3 has no equivalent native data type. This would cause problems when doing INTERVAL arithmetic on the database server side. However, INTERVAL values can be stored in CHAR(50) columns.

SERIAL data types

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

SQLite supports the **AUTOINCREMENT** attribute for columns:

- Only one column must be declared as INTEGER PRIMARY KEY AUTOINCREMENT.
- To get the last generated number, SQLite provides the sqlite_sequence table:

  ```
  SELECT seq FROM sqlite_sequence WHERE name='table_name';
  ```
- When inserting a zero in the auto-increment column, SQLite will not generate a new sequence like Informix® does.
- When inserting a NULL in the auto-increment column, SQLite generates a new sequence; Informix® denies NULLs in SERIALs.

Solution

When using SQLite, the SERIAL data type is converted to INTEGER PRIMARY KEY AUTOINCREMENT.

The SQLCA.SQLERRD[2] register is filled automatically after each INSERT with the last generated number, by fetching the value from the `sqlite_sequence` table.

SQLite (V 3.6) does not support auto-incremented BIGINTs. Therefore, BIGSERIAL or SERIAL8 cannot be converted.

Because SQLite does not behave like Informix® regarding zero and NULL value specification for auto-incremented columns, all INSERT statements must be reviewed to remove the SERIAL column from the list.

For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES ( 0 , p_value)
```

Can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

Can be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

ROWIDs

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

SQLite supports ROWID columns as 64-bit integers. Informix® ROWIDs are 16-bit integers.

With Informix®, SQLCA.SQLERRD[6] contains the ROWID of the last INSERTed or UPDATEd row. This is not supported with SQLite because SQLite ROWIDs are not INTEGERs.

Solution

If the BDL application uses Informix® ROWIDs as primary keys, the program logic should be reviewed in order to use the real primary keys.

If you cannot avoid the use of rowids, you must change the type of the variables which hold ROWID values. Instead of using INTEGER, you must use DECIMAL(20).

> **Note:** All references to SQLCA.SQLERRD[6] must be removed because this variable will not contain the ROWID of the last INSERTed or UPDATEd row when using the SQLite interface.

Foreign key support

Foreign keys are an important feature in modern database design, to enforce database integrity:

```
CREATE TABLE orders (
   ... ,
   FOREIGN KEY(ord_customer) REFERENCES customer(cust_num) )
  )
```

SQLite (3.6.19 and +) implements foreign key support, but this feature is not enabled by default. In fact, it is possible to define foreign keys on tables, but when doing database operations, the constraints are not enforced until you enable it explicitely with a PRAGMA command.

Solution

In order to turn on foreign key constraint checking, you must issue a PRAGMA command, which can for example be executed with a EXECUTE IMMEDIATE instruction:

```
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

Future releases of SQLite might change this, so that foreign key constraints enabled by default.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

SQLite 3 provides TEXT and BLOB native data types for large objects storage.

Solution

The SQLite database interface can convert BDL TEXT data to TEXT and BYTE data to BLOB.

Data type conversion table: Informix to SQLite

Table 214: Data type conversion table between Informix® and SQLite

Informix® data types	SQLite data types
CHAR(n)	CHAR(n) COLLATE RTRIM
VARCHAR(n[,m])	VARCHAR(n) COLLATE RTRIM
LVARCHAR(n)	VARCHAR(n) COLLATE RTRIM
NCHAR(n)	NCHAR(n)
NVARCHAR(n)	NVARCHAR(n)
BOOLEAN	BOOLEAN
SMALLINT	SMALLINT
INT / INTEGER	INTEGER
BIGINT	BIGINT
INT8	BIGINT
SERIAL[(start)]	INTEGER (see note 1)
BIGSERIAL[(start)]	N/A (see note 1)
INT8[(start)]	N/A (see note 1)
DOUBLE PRECISION / FLOAT[(n)]	FLOAT
REAL / SMALLFLOAT	SMALLFLOAT
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL(p)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL	DECIMAL
MONEY(p,s)	DECIMAL(p,s)
MONEY(p)	DECIMAL(p,2)
MONEY	DECIMAL(16,2)
TEXT	TEXT
BYTE	BLOB
DATE	DATE
DATETIME HOUR TO MINUTE	SMALLTIME
DATETIME HOUR TO SECOND	TIME
DATETIME HOUR TO FRACTION(n)	TIME(n)
DATETIME YEAR TO DAY	TINYDATETIME
DATETIME YEAR TO MINUTE	SMALLDATETIME
DATETIME YEAR TO SECOND	DATETIME

Informix® data types	SQLite data types
DATETIME YEAR TO FRACTION(n)	DATETIME(n)
DATETIME q1 TO q2 (different from above)	TIMESTAMP
INTERVAL q1 TO q2	CHAR(50)

Notes:

1. For more details about serial emulation, see SERIAL data types on page 715.

Data manipulation
SQLite related data manipulation topics.
Outer joins

The original syntax of OUTER joins of Informix® is different from the SQLite outer join syntax:

In Informix® SQL, outer tables are defined in the FROM clause with the **OUTER** keyword:

```
SELECT ... FROM a, OUTER(b)
  WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c))
  WHERE a.key = b.akey
  AND b.key1 = c.bkey1
  AND b.key2 = c.bkey2
```

SQLite 3 supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
 ON cust.key = order.custno

SELECT ...
FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
   ON cust.key = order.custno
WHERE order.accepted = 1
```

See the SQLite 3 SQL reference for a complete description of the syntax.

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The SQLite 3 interface can convert most Informix® OUTER specifications to SQLite 3 outer joins.

Prerequisites:

1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work: "FROM OUTER(tab2), tab1".
2. The outer join in the WHERE clause must use the table name as prefix.

   Example: "WHERE tab1.col1 = tab2.col2".

Restrictions:

1. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: "... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10".

2. Statements composed by 2 or more SELECT instructions using OUTERs are not supported.

   Example: "SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"

Remarks:

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias: "OUTER(tab1 alias1)".
2. In the outer join, <outer table>.<col> can be placed on both right or left sides of the equal sign.

   OUTER join example with table on the left: "WHERE outertab.col1 = maintab.col2 ".
3. Table names detection is not case-sensitive.

   Example: "SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2".
4. Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and SQLite have similar commands to begin, commit or rollback transaction. There are however some important differences you must be aware of.

With SQLite, DDL statements can be executed (and canceled) in transaction blocks, as with Informix®.

Informix® version 11.50 introduces savepoints with the following instructions:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

SQLite supports savepoints too. However, there are differences:

1. SAVEPOINT can be used instead of BEGIN TRANSACTION. In this case, RELEASE is like a COMMIT.
2. The syntax of a rollback to the savepoint is ROLLBACK [TRANSACTION] TO [SAVEPOINT] *name* .
3. The syntax of a release of the savepoint is RELEASE [SAVEPOINT] *name* .
4. Rollback must always specify the savepoint name.
5. You cannot rollback to a savepoint if cursors are opened.
6. In SQLite versions prior to 3.7, you cannot rollback are transaction if a cursor is open.

Solution

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with SQLite. The BEGIN WORK, COMMIT WORK and ROLLBACK WORK commands are translated the native commands of SQLite.

> **Note:** If you want to use savepoints, always specify the savepoint name in ROLLBACK TO SAVEPOINT and do not open cursors during transactions using savepoints. If you are using an SQLite versions prior to 3.7, it is not possible to perform a ROLLBACK WORK if a cursor (with hold) is currently open.

See also SELECT FOR UPDATE

Temporary tables

Informix® temporary tables are created through the CREATE TEMP TABLE DDL instruction or through a SELECT ... INTO TEMP statement. Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

> **Note:** BDL reports create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

SQLite supports temporary tables with the CREATE TEMP TABLE statement.

Solution

Informix® CREATE TEMP TABLE statements are kept as is and SELECT INTO TEMP statements are converted to SQLite native SQL CREATE TEMP TABLE AS SELECT ...

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements, while SQLite supports the LIKE statement only.

MATCHES requires * and ? wildcard characters, and LIKE uses the % and _ wildcards was equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES allows you to use brackets to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

The SQLite LIKE operator has no operator for [ ] brackets character ranges.

Solution

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

```
UPDATE table SET ( col-list ) = ( val-list )
```

Or

```
UPDATE table SET table.* = codeph.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column=value [,...]
```

BDL programming
SQLite related programming topics.
Informix-specific SQL statements in BDL

The BDL compiler supports several Informix® specific SQL statements that have no meaning when using SQLite:

- CREATE DATABASE
- DROP DATABASE
- START DATABASE (SE only)

- ROLLFORWARD DATABASE
- SET [BUFFERED] LOG
- CREATE TABLE with special options (storage, lock mode, etc.)

Solution

Review your BDL source and remove all static SQL statements which are Informix® specific.

INSERT cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

SQLite does not support insert cursors.

Solution

Insert cursors are emulated by the SQLite database interface.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to prevent several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

- The row must be fetched in order to set the lock.
- If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared "WITH HOLD", the lock is released when the cursor is closed.

SQLite does not support the FOR UPDATE close in SELECT syntax.

Solution

Review the program logic and remove SELECT ... FOR UPDATE statements, as SQLite doesn't support them.

UPDATE/DELETE WHERE CURRENT OF

Informix® allows positioned UPDATEs and DELETEs with the "`WHERE CURRENT OF cursor`" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

SELECT ... FOR UPDATE is not supported by SQLite.

Solution

Review the program logic and use primary keys to update the rows.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into a text file and the LOAD instructions insert rows from a text file into a database table.

SQLite 3.0 does not natively provide LOAD / UNLOAD instructions.

Solution

LOAD and UNLOAD instructions are supported.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

SQLite 3.x does not support native scrollable cursors.

Solution

The SQLite database driver emulates scrollable cursors with temporary files.

See Scrollable cursors on page 422 for more details about scroll cursor emulation.

Modifying many rows in a table

SQLite is very slow when doing commits, because of the technique used to ensure data integrity (see SQLite documentation for details).

When a program executes a DML statement like INSERT, it will be automatically committed by SQLite. As result, there will be as many transactions/commits as data manipulation statements.

It takes for example about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.

Solution

If a program must modify many rows in a table, execute the SQL statement within a transaction block delimited by BEGIN WORK / COMMIT WORK instructions. This will dramatically speed up the process.

See Performance with transactions on page 453.

Optimizing database file usage

By default, when deleting a large amount of data in an SQLite database it leaves behind empty space, causing the database file to be larger than stricly necessary.

This might be an issue with some mobile applications, when the disk space of the mobile device is limited.

Solution

Execute the VACUUM SQL command, to truncate the database file and reduce the disk usage.

According to the application, the VACUUM command can be executed:

- when starting the application,
- after doing a large db operation (like a synchronization with a central db),
- as a manual option that the user can trigger.

Note that SQLite also supports "PRAGMA auto_vacuum", but it appears that it's not as efficient as the VACUUM command, regarding page fragmentation.

Pay attention to the fact that VACUUM needs twice the disk space of the actual database file, because it rebuilds totally the db file.

VACUUM is not Informix SQL syntax, thus you can't write it directly in the BDL code: You must use EXECUTE IMMEDIATE:

```
EXECUTE IMMEDIATE "VACUUM"
```

SQL adaptation guide for SAP Sybase ASE 16.x

Installation (Runtime Configuration)
Sybase ASE related installation topics.
Install Sybase ASE and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install Sybase ASE software on your computer, with the Sybase client software.

   Make sure that the server is started and environment variables are properly set (On UNIX™, you will find SYBASE.* shell scripts to source in the installation directory).

2. Try to connect to the server with the isql command line tool.

   If needed, change the password of the "sa" database administrator:

```
$ isql -S server_name -U sa
1> sp_password old_password, new_password
2> go
Password correctly set.
(return status = 0)
```

   Starting with Sybase ASE 15.7, the password of the sa user is defined at installation time.

3. Define server's default character set: You must identify what server character set you want to use (typically, utf8) and re-configure the server if needed.

   With Sybase ASE, the db character set cannot be specified at the database level, it is defined at the server level, typically during the installation. It is also possible to change the srever character set with the `charset` utility and with the `sp_configure` stored procedure. You have to shutdown the server, start a first time to have the server take the new character set into account and then restart a second time for use. See Sybase documentation for more details or more recent versions of Sybase ASE.

   Make sure that you select a case-sensitive character set / sort order.

   > **Note:** Check the `$SYBROOT/locales/locales.dat` file, to make sure that your current locale (LANG/LC_ALL) is listed in the file. You may want to add the following lines for UTF-8 support, under the section of your operating system:
   >
   > ```
   >   locale = POSIX, us_english, utf8
   >   locale = en_US.utf8, us_english, utf8
   > ; Windows only:
   >   locale = .fglutf8, us_english, utf8
   > ```

   Example:

```
$ export DSQUERY=servername
$ charset -Usa -P binary.srt utf8
Please enter sa's Password:
Loading file 'binary.srt'.

Found a [sortorder] section.

This is Class-1 sort order.

Finished loading the Character Set Definition.

Finished loading file 'binary.srt'.

1 sort order loaded successfully

$ isql -Usa -P
1> sp_configure 'default sortorder id', 50, 'utf8'
2> go
```

```
3> shutdown
4> go
Server SHUTDOWN by request.
ASE is terminating this process.
.......

$ $SYBROOT/ASE_*/install/RUN_servername
... (server makes some initialization / setup and stops) ...

$ $SYBROOT/ASE_*/install/RUN_servername
...
```

4. Create a new Sybase database entity, with sufficient storage devices for data and transaction log.

   Use either the Sybase Central, the Sybase Control Center GUI tool or use isql with SQL commands.

   Connect to the server with the sa user.

   First create database devices for data and transaction log. Define a transaction that can hold the biggest transaction your application can do to avoid administrative tasks to dump the log when the server hangs. When creating the database, use the new created database devices as database segments:

   ```
   use master
   go
   disk init
        name = "devname",
        physname = "filename",
        size = devsize ...
   go
   create database dbname
      on devname
      with ...
   go
   ```

5. Leave the default transaction mode ("unchained" mode), to force explicit transaction start and end commands.

   See the `set chained` command for more details.

6. The database allows NULLs by default when creating columns.

   This is controlled by the `'allow nulls by default'` option. If this option is set to OFF, columns created without NULL or NOT NULL keywords are NOT NULL by default:

   ```
   master..sp_dboption dbname, 'allow nulls by default', true
   go
   ```

7. The database must allow Data Definition Language (DDL) statements in transaction blocks.

   To turn this on, use following commands:

   ```
   master..sp_dboption dbname, 'ddl in tran', true
   go
   checkpoint
   go
   ```

8. For development purpose, consider to set the database option to truncate the transaction log when a checkpoint occurs, otherwise you will have to dump the transaction log when it is full.

   Command to automatically truncate the transaction log on checkpoint:

   ```
   master..sp_dboption dbname, 'trunc log on chkpt', true
   go
   ```

9. Create a new login dedicated to your application: the application administrator.

Assign the new created database as default database for this user:

```
use dbname
go
sp_addlogin 'username', 'password', dbname, ... options ...
go
```

10. Create a new database user linked to the new application administrator login:

    In Sybase Central, open to the "Databases" node, select "Users" and right-click "New" ...

```
use dbname
go
sp_adduser 'username', 'group', ... options ...
go
```

    See documentation for more details about database users and privileges. You must create groups to make tables visible to all users.

11. If you plan to use SERIAL emulation based on triggers using a registration table, create the SERIALREG table.

    Create the triggers for each table using a SERIAL. See issue SERIAL data types for more details.

12. Create the application tables.

    Do not forget to convert Informix® data types to Sybase ASE data types. See topic data type Conversion Table for more details. In order to make application tables visible to all users, make sure that all users are members of the group of the owner of the application tables. For more details, see ASE documentation ("Database object names and prefixes").

Prepare the runtime environment - connecting to the database

1. In order to connect to Sybase ASE, you must have a Sybase ASE database driver "dbmase" in FGLDIR/dbdrivers.
2. If you want to connect to a remote database server, you must have the Sybase ASE Client Software installed on the computer running BDL applications.

   The Sybase Open Client Library is required.
3. Make sure that the Sybase ASE client environment variables are properly set.

   Check for example SYBASE (the path to the installation directory), SYBASE_ASE (the name of the server sub-directory), SYBASE_OCS (the name of the client sub-directory), etc. See Sybase ASE documentation for more details.
4. Verify the environment variable defining the search path for Sybase OCS database client shared libraries (libsybct[64].so, libsybcs[64].so UNIX™, LIBSYBCT[64].DLL and LIBSYBCS[64].DLL on Windows™).

   Table 215: Shared library environment setting for Sybase ASE

Sybase ASE version	Shared library environment setting
Sybase ASE 16.0 and higher	*UNIX*: Add $SYBASE_OCS/lib to LD_LIBRARY_PATH (or its equivalent). *Windows*: Add %SYBASE_OCS%\dll to PATH. Where SYBASE_OCS is the directory of the Sybase Open Client Software.

5. The name of the Sybase server must be registered in a configuration file.

   On UNIX™, the server name must be defined in the "`interfaces`" file located in $SYBASE. On Windows™, the server name must be defined in the "`sql.ini`" file located in `%SYBASE%\ini`. You

may want to define the DSQUERY environment variable to the name of the server. See Sybase documentation for more details.

When connecting from a Genero program, both database and server names can be specified with:

database@server

For more details see the description for the connection data source parameter in DATABASE and CONNECT instructions.

6. Check the database client locale settings of Sybase.

   The Sybase client locale must match the locale used by the runtime system (LC_ALL, LANG on UNIX™, ANSI code page on Windows™).

   By default, Sybase OCS uses the character set defined by the operating system. On Windows™, this is the ANSI code page, on UNIX™ it is defined by LC_CTYPE, LC_ALL or LANG environment variables. Note that Genero BDL allows to define the LANG environment variable also on Windows™. The value of the LANG environment variable must be listed in the "`locales.dat`" file under the `$SYBASE/locales` directory, otherwise you will get an error when connecting to the database.

   > **Note:** Check the `$SYBROOT/locales/locales.dat` file, to make sure that your current locale (LANG/LC_ALL) is listed in the file. You may want to add the following lines for UTF-8 support, under the section of your operating system:

   ```
     locale = POSIX, us_english, utf8
     locale = en_US.utf8, us_english, utf8
   ; Windows only:
     locale = .fglutf8, us_english, utf8
   ```

   See also Sybase OCS documentation regarding localization and character set definition.

7. Test the Sybase ASE Client Software: Make sure the server is started and try to connect to a database by using the Sybase ASE command interpreter:

   ```
   $ isql -S server -U appadmin -P password
   ```

8. Set up the fglprofile entries for database connections:

   a) Define the Sybase ASE database driver:

      ```
      dbi.database.dbname.driver = "dbmase"
      ```

   b) Define the connection timeout with the following fglprofile entry:

      ```
      dbi.database.dbname.ase.logintime = integer
      ```

      This entry defines the number of seconds to wait for a connection.

      Default is 5 seconds.

   c) Define the number of rows to be pre-fetched for result sets:

      ```
      dbi.database.dbname.ase.prefetch.rows = integer
      ```

      Default is 10 rows.

Database concepts
Sybase ASE related database concepts topics.

Database concepts

As in Informix®, a Sybase ASE engine can manage multiple database entities. When creating a database object such as a table, Sybase ASE allows you to use the same object name in different databases.

Data consistency and concurrency

Data consistency involves readers which want to access data currently modified by writers and *concurrency data access* involves several writers accessing the same data for modification. *Locking granularity* defines the amount of data concerned when a lock is set (row, page, table, ...).

Informix®:

Informix® uses a locking mechanism to manage data consistency and concurrency. When a process modifies data with UPDATE, INSERT or DELETE, an exclusive lock is set on the affected rows. The lock is held until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks** according to the **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Isolation level: SET ISOLATION TO ...
- Lock wait mode: SET LOCK MODE TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit locking: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is read committed.
- The default lock wait mode is "not wait".
- The default locking granularity is per page.

Sybase ASE:

As in Informix®, Sybase ASE uses locks to manage data consistency and concurrency. The database manager sets **exclusive locks** on the modified rows and **shared locks** when data is read, according to the **isolation level**. The locks are held until the end of the transaction. When multiple processes want to access the same data, the latest processes must wait until the first finishes its transaction or the lock timeout occurred. The **lock granularity** is at the row or table level. For more details, see Sybase ASE's Documentation.

Control:

- The lock wait mode can be controlled with: SET LOCK {WAIT seconds | NOWAIT}
- Isolation level: Can be set with: SET TRANSACTION ISOLATION LEVEL = {0|1|2|3}
- Locking granularity: Row level.
- Explicit locking: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is Read Committed (readers cannot see uncommitted data; no shared lock is set when reading data).

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by SET TRANSACTION ISOLATION LEVEL ... in Sybase ASE. The next table shows the isolation level mappings done by the Sybase ASE database driver:

Table 216: Isolation level mappings done by the Sybase ASE database driver

SET ISOLATION instruction in program	Native SQL command
SET ISOLATION TO DIRTY READ	SET TRANSACTION ISOLATION LEVEL = 0
SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]	SET TRANSACTION ISOLATION LEVEL = 1
SET ISOLATION TO CURSOR STABILITY	SET TRANSACTION ISOLATION LEVEL = 2
SET ISOLATION TO REPEATABLE READ	SET TRANSACTION ISOLATION LEVEL = 3

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

The SET LOCK MODE TO ... Informix® syntax is replaced by SET LOCK ... in Sybase ASE. If SET LOCK MODE TO WAIT is used in programs (i.e. wait forever), the driver will simulate this with a SET LOCK WAIT 5000 in Sybase ASE:

Table 217: SET LOCK MODE instruction for Sybase ASE

SET LOCK MODE instruction in program	Native SQL command
SET LOCK MODE TO NOT WAIT	SET LOCK NOWAIT
SET LOCK MODE TO WAIT n	SET LOCK WAIT n
SET LOCK MODE TO WAIT	SET LOCK WAIT 5000

See the Informix® and Sybase ASE documentation for more details about data consistency, concurrency and locking mechanisms.

Transactions handling

Informix® and Sybase ASE handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with "BEGIN WORK".
- Transactions are validated with "COMMIT WORK".
- Transactions are canceled with "ROLLBACK WORK".
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Sybase ASE:

- Sybases supports two transaction modes:
  1. The SQL standards-compatible mode, called *chained* mode, to get implicit transaction.
  2. The default mode, called *unchained* mode, where transactions have to be started/ended explicitly.
- Transactions are started with "BEGIN TRANSACTION [name]".
- Transactions are validated with "COMMIT TRANSACTION [name]".
- Transactions are canceled with "ROLLBACK TRANSACTION [name]".
- Transactions save points can be placed with "SAVEPOINT [name]".
- Sybase ASE supports named and nested transactions.
- DDL statements can be executed in transactions blocks when the 'ddl in tran' option is set to true with:

```
master..sp_dboption dbname, 'ddl in tran', true
go
```

```
checkpoint
go
```

Solution

Informix® transaction handling commands are automatically converted to Sybase ASE instructions to start, commit or rollback transactions.

Make sure that the database uses the default *unchained* mode (set chained off) and allows DDLs in transactions ('ddl in tran' option is true).

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Sybase ASE.

Database users

Until version 11.70.xC2, Informix® database users must be created at the operating system level and be members of the 'informix' group. Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as most other db servers. Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

Before a user can access an Sybase ASE database, the system administrator (DBA) must declare the application users in the database with the GRANT statement. You may also need to define groups in order to make tables visible to other users.

Solution

See Sybase ASE documentation for more details on database logins and users.

Setting privileges

Informix® and Sybase ASE user privileges management are quite similar.

Sybase ASE provides **user groups** to grant or revoke permissions to more than one user at the same time.

Data dictionary
Sybase ASE related data dictionary topics.
BOOLEAN data type

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values. Genero BDL implements the BOOLEAN data type in a different way: As in other programming languages, Genero BOOLEAN stores integer values 1 or 0 (for TRUE or FALSE). The type was designed this way to assign the result of a boolean expression to a BOOLEAN variable.

Sybase ASE provides the BIT data type to store boolean values. However, unlike Informix® types, BIT columns cannot be NULL and thus you must specify the NOT NULL constraint when creating the table.

Solution

The Sybase ASE database interface converts BOOLEAN type to BIT columns and stores 1 or 0 values in the column.

You must explicitly specify the NOT NULL constraint in the CREATE TABLE statement.

CHARACTER data types

Informix® supports following character data types:

- CHAR(N) with N<= 32767 bytes
- VARCHAR(N[,M]) with N<=255 bytes
- NCHAR(N) with N<= 32767 bytes
- LVARCHAR(N), without the 255 bytes limit (max size varies according to IDS version)

In Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is for sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order. The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable. The character set used by applications is defined by the CLIENT_LOCALE environment variable. Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N)is expressed in bytes, not characters as in some other databases)

Sybase ASE implements the following character data types:

- CHAR(N) with N <= 16384 bytes
- VARCHAR(N) with N <= 16384 bytes
- NCHAR(N) with N <= 16384 characters
- NVARCHAR(N) with N <= 16384 characters
- UNICHAR(N) with N <= 16384 characters
- UNIVARCHAR(N) with N <= 16384 characters

Like Informix®, Sybase ASE can store multibyte characters in CHAR / VARCHAR columns, according to the database character set. For example, Sybase can store UTF-8 strings in CHAR/VARCHAR columns. For multibyte character sets, you could also use the NCHAR / NVARCHAR or UNICHAR / UNIVARCHAR Sybase ASE types, the only difference with CHAR / VARCHAR is that the length is specified in characters instead of bytes. The UNICHAR / UNIVARCHAR store characters in 16bit UCS-2 charset only, but this is transparent to the database client.

Sybase supports automatic character set conversion between the client application and the server. By default, the Sybase database client character set is defined by the operating system locale where the database client runs. On Windows™, it is the ANSI code page of the login session (can be overwritten by setting the LANG environment variable), on UNIX™ it is defined by the LC_CTYPE, LC_ALL or LANG environment variable. You may need to edit the `$SYBASE/locales/locales.dat` file to map the OS locale name to a known Sybase character set.

Unlike most other database engines, Sybase ASE trims trailing blanks when inserting character strings in a VARCHAR column.

For example:

```
CREATE TABLE t1 ( k INT, vc VARCHAR(5))
INSERT INTO t1 VALUES ( 1, 'abc ' )
SELECT '['||vc||']' FROM t1 WHERE k = 1
----------------------------------------------
[abc]
```

With other database servers you would get 1 blank after `abc`:

```
[abc ]
```

Solution

If your application must support multibyte character sets like BIG5 or UTF-8, you should use CHAR / VARCHAR Sybase data types, where the length is specified in bytes like with Informix®.

Check that your database schema does not use CHAR, VARCHAR or LVARCHAR types with a length exceeding the Sybase ASE limit.

If your application creates tables with NCHAR/NVARCHAR types, the same type name will be used in Sybase. Keep in mind that the size of NCHAR/NVARCHAR in Sybase is specified in characters, while Informix® uses a number of bytes.

When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a Sybase database, the schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters)) column a in Sybase database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

Since trailing blanks are trimmed for VARCHARs, make sure that your application does not rely on this non-standard behavior.

See also the section about Localization

NUMERIC data types

Sybase ASE offers numeric data types which are quite similar to Informix® numeric data types. This table shows general conversion rules for numeric data types:

Table 218: Numeric data types (Informix® vs. Sybase ASE)

Informix®	**Sybase ASE**
SMALLINT	SMALLINT
INTEGER (synonym: INT)	INTEGER (synonym: INT)
BIGINT	BIGINT
INT8	BIGINT
DECIMAL[(p[,s)] (synonyms: DEC, NUMERIC) DECIMAL(p,s) defines a fixed point decimal where p is the total number of significant digits and s the number of digits that fall on the right of the decimal point. DECIMAL(p) defines a floating point decimal where p is the total number of significant digits. The precision p can be from 1 to 32. DECIMAL is treated as DECIMAL(16).	DECIMAL[(p[,s)] (synonyms: DEC, NUMERIC) DECIMAL[(p[,s])] defines a fixed point decimal where p is the total number of significant digits and s the number of digits that fall on the right of the decimal point. The precision p can be from 1 to 38. The default precision is 18 and the default scale is 0: • DECIMAL in Sybase ASE = DECIMAL(18,0) in Informix® • DECIMAL(p) in Sybase ASE = DECIMAL(p,0) in Informix®
MONEY[(p[,s])	Sybase ASE provides the MONEY and SMALLMONEY data types, but the currency symbol handling is quite different. Therefore, Informix® MONEY columns should be implemented as DECIMAL columns in Sybase ASE.
SMALLFLOAT (synonyms: REAL)	REAL
FLOAT[(n)] (synonyms: DOUBLE PRECISION) The precision (n) is ignored.	DOUBLE PRECISION

Sybase ASE does not support implicit character string to numeric conversions. For example, if you compare an integer column to '123' in a WHERE clause, Sybase will raise a conversion error. The problem exists also when using CHAR or VARCHAR SQL parameters.

Solution

In BDL programs

When creating tables from BDL programs, the database interface automatically converts Informix® data types to corresponding Sybase ASE data types.

There is no Sybase ASE equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use Sybase ASE compatible types. To workaround the Sybase ASE limitation, the Sybase ASE database drivers convert DECIMAL(p) types to a DECIMAL(2*p, p), to store all possible numbers an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since Sybase ASE maximum DECIMAL precision is 38(2*19). If the original precision is bigger as 19, a CREATE TABLE statement executed from a Genero program will fail with an Sybase ASE error 2756.

Database creation scripts

- SMALLINT and INTEGER columns do not have to use another data type in Sybase ASE.
- For DECIMALs, check the precision limit. Always use a precision and a scale.
- Convert MONEY columns to DECIMAL(p,s) columns. Always use a precision and a scale.
- Convert SMALLFLOAT columns to REAL columns.
- Since FLOAT precision is ignored in Informix®, convert this data type to FLOAT(15).

Since Sybase ASE does not support implicit character string to numeric conversions, you must check that your programs do not use string literals or CHAR/VARCHAR SQL parameters in integer expressions, as in this example:

```
DEFINE pv CHAR(1)
CREATE TABLE mytable ( v1 INT, v2 INT )
LET pv = '1'
SELECT * FROM mytable WHERE v1 = '1' AND v2 = pv
```

DATE and DATETIME data types

Informix® provides two data types to store dates and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction(1-5) storage.

Sybase ASE provides these data type to store dates:

- DATE = for year, month, day storage.
- TIME = for hour, minutes, seconds, fraction(3) storage.
- SMALLDATETIME = for hour, minutes, seconds, fraction(3) storage.
- DATETIME = for hour, minutes, seconds, fraction(3) storage.
- BIGTIME = for hour, minutes, seconds, fraction(6) storage.
- BIGDATETIME = for year, month, day, hour, minutes, seconds, fraction(6) storage.

String representing date time information

Informix® is able to convert quoted strings to DATE / DATETIME data if the string contents matches environment parameters (i.e. DBDATE, GL_DATETIME). As in Informix®, Sybase ASE can convert quoted strings representing datetime data in the ANSI format. The CONVERT() SQL function allows you to convert strings to dates.

Date time arithmetic

- Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is a number of days when only DATEs are used and an INTERVAL value if a DATETIME is used in the expression.
- Informix® automatically converts an integer to a date when the integer is used to set a value of a date column. Sybase ASE does not support this automatic conversion.
- Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in Sybase ASE.
- With Sybase ASE you must use built-in functions to do date/time computing (for example, see dateadd() function).
- Informix® converts automatically an integer to a date when the integer is used to set a value of a date column. Sybase ASE does not support this automatic conversion.

Solution

Sybase ASE has the same DATE data type as Informix® (year, month, day). So you can use Sybase ASE DATE data type for Informix® DATE columns.

Sybase ASE BIGTIME data type can be used to store Informix® DATETIME HOUR TO SECOND and DATETIME HOUR TO FRACTION(5) values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION(5) can be stored in Sybase ASE BIGDATETIME columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the ASE TIMESTAMP value will be "1900-01-01 11:45:00.0".

See also Date and time in SQL statements on page 432 for good SQL programming practices.

INTERVAL data type

Informix's INTERVAL data type stores a value that represents a span of time. INTERVAL types are divided into two classes: year-month intervals and day-time intervals.

Sybase ASE does not provide a data type corresponding to the Informix® INTERVAL data type.

Solution

The INTERVAL data type is not well supported because the database server has no equivalent native data type. However, you can store into and retrieve from CHAR columns BDL INTERVAL values.

SERIAL data type

Informix® supports the SERIAL, SERIAL8 and BIGSERIAL data types to produce automatic integer sequences. SERIAL is based on INTEGER (32 bit), while SERIAL8 and BIGSERIAL can store 64 bit integers:

- The table column must be of type SERIAL, SERIAL8 or BIGSERIAL.
- To generate a new serial, no value or a zero value is specified in the INSERT statement:

```
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

- After INSERT, the new SERIAL value is provided in SQLCA.SQLERRD[2], while the new SERIAL8 and BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERTs that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
```

```
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

Sybase ASE IDENTITY columns:

- When creating a table, the IDENTITY keyword must be specified after the column data type:

  ```
  CREATE TABLE tab1 ( k integer identity, c char(10) )
  ```

- You cannot specify a start value
- A new number is automatically created when inserting a new row:

  ```
  INSERT INTO tab1 ( c ) VALUES ( 'aaa' )
  ```

- To get the last generated number, Sybase ASE provides a global variable:

  ```
  SELECT @@IDENTITY
  ```

- When IDENTITY_INSERT is ON, you can set a specific value into a IDENTITY column, but zero does not generate a new serial:

  ```
  SET IDENTITY_INSERT tab1 ON
  INSERT INTO tab1 ( k, c ) VALUES ( 100, 'aaa' )
  ```

Informix® SERIALs and MS Sybase ASE IDENTITY columns are quite similar; the main difference is that MS Sybase ASE does not generate a new serial when you specify a zero value for the identity column.

Solution

With Sybase ASE, the SERIAL emulation can use IDENTITY columns (1) or insert triggers based on the SERIALREG table (2). The first solution is faster, but does not allow explicit serial value specification in insert statements; the second solution is slower but allows explicit serial value specification. You can initially use the second solution to have unmodified BDL programs working on Sybase ASE, but you should update your code to use native IDENTITY columns for performance.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial.emulation = {"native"|"regtable"}`

- native: uses IDENTITY columns.
- regtable: uses insert triggers with the SERIALREG table.

The default emulation technique is "`native`".

This entry must be used in conjonction with:

`dbi.database.`*`dbname`*`.ifxemul.datatype.serial = {true|false}`

If the `datatype.serial` entry is set to false, the emulation method is ignored.

Using the `native` serial emulation

In database creation scripts, all SERIAL data types must be converted by hand to INTEGER IDENTITY data types, while BIGSERIAL must be converted to BIGINT IDENTITY.

Start values SERIAL(n) / BIGSERIAL(n) cannot be converted, there is no INTEGER IDENTITY(n) in Sybase ASE.

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER IDENTITY[(n,1)]".

In BDL, the new generated SERIAL value is available from the SQLCA.SQLERRD[2] variable. This is supported by the database interface which performs a "SELECT @@IDENTITY". However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must use @@IDENTITY.

When you insert a row with zero as serial value, the serial column gets the value zero. You must review all INSERT statements using zero for the serial column. For example, the following statement:

```
INSERT INTO tab (col1, col2)VALUES (0, p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without braces, serial column is removed
```

Using the `regtable` serial emulation

First, you must prepare the database and create the SERIALREG table as follows:

```
CREATE TABLE serialreg (
    tablename VARCHAR(50) NOT NULL,
    lastserial BIGINT NOT NULL,
    PRIMARY KEY ( tablename )
)
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL column types must be changed to BIGINT, and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers.

Sybase ASE does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.

Note:

- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER.
- Sybase ASE triggers are not automatically dropped when the corresponding table is dropped. Database administrators must be aware of this behavior when managing schemas.
- INSERT statements using NULL for the SERIAL column will produce a new serial value:

  ```
  INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
  ```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```
INSERT INTO tab (col2) VALUES('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value.

- The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.

ROWIDs

When creating a table, Informix® automatically adds a "ROWID" integer column (applies to non-fragmented tables only). The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

Sybase ASE tables have no ROWIDs.

Solution

If the BDL application uses ROWIDs, the program logic should be reviewed in order to use the real primary keys (usually, serials which can be supported).

All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last INSERTed or UPDATEd row when using the Sybase ASE interface.

Case sensitivity

In Informix®, database object names like table and column names are not case sensitive:

```
CREATE TABLE Customer ( Custno INTEGER, ... )
SELECT CustNo FROM cuSTomer ...
```

In Sybase ASE, database object names **and character data** are case-insensitive by default:

```
CREATE TABLE Customer ( Custno INTEGER, CustName CHAR(20) )
INSERT INTO CUSTOMER VALUES ( 1, 'TECHNOSOFT' )
SELECT CustNo FROM cuSTomer WHERE custname = 'techNOSoft'
```

Solution

When you create a Sybase ASE database with `dbinit`, you can use the -c option to make the database case-sensitive.

Large OBject (LOB) types

IBM® Informix® and Genero support the TEXT and BYTE types to store large objects: TEXT is used to store large text data, while BYTE is used to store large binary data like images or sound.

Sybase ASE provides the TEXT and IMAGE data types for large objects storage.

Important: Sybase ASE 16.0 does not support TEXT/IMAGE expressions in WHERE clauses.

The ASE driver is implemented with the Sybase Open Client Library C API. In Sybase version 16.0, this API has a limited support for LOBs, especially when it comes to update LOB data in the database: You cannot directly INSERT large LOB data, you must first INSERT nulls and then UPDATE the row with the real data. Additionally, UPDATE can only take one LOB parameter at a time. Fetching LOB data is supported, with the following limitation: LOB columns must appear at the end of the SELECT list.

Solution

TEXT and BYTE character data types are supported by the Sybase ASE database interface, with some limitation.

When INSERTing TEXT/BYTE in a table, you must first insert with nulls, the update the new row, and only with one TEXT/BYTE parameter at a time:

```
DEFINE ptext TEXT, pbyte BYTE
...
LOCATE ptext IN ...
LOCATE pbyte IN ...
CREATE TABLE tab (k INT, t TEXT, b BYTE)
-- First INSERT a new row with NULLs
INSERT INTO tab VALUES (123,null,null)
-- Then UPDATE first TEXT column
UPDATE tab SET t = ptext WHERE k = 123
-- Then UPDATE second BYTE column
UPDATE tab SET b = pbyte WHERE k = 123
```

Fetching TEXT and BYTE columns is possible as long as the columns appear at the end of the SELECT list. For example, if you have a statement such as (where pdata is a TEXT or BYTE column):

```
SELECT pid, pdata, ptimestamp FROM pic WHERE ...
```

Put the BYTE column at the end of the SELECT list:

```
SELECT pid, ptimestamp, pdata FROM pic WHERE ...
```

The ALTER TABLE instruction

Informix® and MS Sybase ASE use different implementations of the ALTER TABLE instruction. For example, Informix® allows you to use multiple ADD clauses separated by comma. This is not supported by Sybase ASE:

Informix®:

```
ALTER TABLE customer ADD(col1 INTEGER), ADD(col2 CHAR(20))
```

Sybase ASE:

```
ALTER TABLE customer ADD col1 INTEGER, col2 CHAR(20)
```

Solution

No automatic conversion is done by the database interface. There is no real standard for this instruction (that is, no common syntax for all database servers). Read the SQL documentation and review the SQL scripts or the BDL programs in order to use the database server specific syntax for ALTER TABLE.

Constraints

Constraint naming syntax

Both Informix® and Sybase ASE support primary key, unique, foreign key, default and check constraints. But Sybase ASE does not support constraint naming syntax:

```
CREATE TABLE emp (
   emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
   ... )
```

Solution: Constraint naming syntax

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for Sybase ASE.

Triggers

Informix® and Sybase ASE provide triggers with similar features, but the programming languages are totally different.

Sybase ASE does not support triggers on temporary tables.

Solution

Informix® triggers must be converted to Sybase ASE triggers "by hand".

Stored procedures

Both Informix® and Sybase ASE support stored procedures, but the programming languages are totally different.

Solution

Informix® stored procedures must be converted to Sybase ASE"by hand".

See SQL Programming for more details about executing stored procedures with Sybase ASE.

Name resolution of SQL objects

Informix® uses the following form to identify an SQL object:

```
[database[@dbservername]:][{owner|"owner"}.]identifier
```

With Sybase ASE, an object name takes the following form:

```
[{database|[database]}.[{owner|[owner]}.]]{identifier|[identifier]}
```

Informix® database object names are **not case sensitive** in non-ANSI databases.

Sybase ASE database objects names are **case sensitive** by default.

Solution

As a general rule, to write portable SQL, you should only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Always create and use tables and columns names in lower case.

Data type conversion table: Informix to Sybase ASE

Table 219: Data type conversion table (Informix to Sybase ASE)

Informix® data types	Sybase ASE data types
CHAR(n)	CHAR(n) (limit = page size, ex:16384 bytes)
VARCHAR(n[,m])	VARCHAR(n) (limit = page size, ex:16384 bytes)
LVARCHAR(n)	VARCHAR(n) (limit = page size, ex:16384 bytes)
NCHAR(n)	NCHAR(n) (length in characters)
NVARCHAR(n[,m])	NVARCHAR(n) (length in characters)
BOOLEAN	BIT (must be NOT NULL!)
SMALLINT	SMALLINT

Informix® data types	**Sybase ASE data types**
INT / INTEGER	INTEGER
BIGINT	BIGINT
INT8	BIGINT
SERIAL without start value!	INTEGER (see note 1)
BIGSERIAL without start value!	BIGINT (see note 1)
SERIAL8 without start value!	BIGINT (see note 1)
DOUBLE PRECISION / FLOAT[(n)]	DOUBLE PRECISION
REAL / SMALLFLOAT	REAL
NUMERIC / DEC / DECIMAL(p,s)	DECIMAL(p,s)
NUMERIC / DEC / DECIMAL(p) with p<=19	DECIMAL(2*p,p)
NUMERIC / DEC / DECIMAL(p) with p>19	N/A
NUMERIC / DEC / DECIMAL	DECIMAL(32,16)
MONEY(p,s)	DECIMAL(p,s)
MONEY(p)	DECIMAL(p,2)
MONEY	DECIMAL(16,2)
DATE	DATE(yyyy-mm-dd)
DATETIME HOUR TO FRACTION(n)	BIGTIME(hh:mm:ss.ffffff)
DATETIME HOUR TO SECOND	BIGTIME(hh:mm:ss.ffffff)
Other sort of DATETIME type	BIGDATETIME(yyyy-mm-dd hh:mm:ss.ffffff)
INTERVAL q1 TO q2	CHAR(50)
TEXT	TEXT
BYTE	IMAGE

Notes:

1. For more details about serial emulation, see SERIAL data type on page 733.

Data manipulation
Sybase ASE related data manipulation topics.
Reserved words

Even if Sybase ASE allows SQL reserved keywords as SQL object names if enclosed in square braces (create table [table] (col1 int)), you should take care of your existing database schema and check that you do not use Sybase ASE SQL words.

Solution

Database objects having a name which is a Sybase ASE SQL reserved word must be renamed.

All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™ 'grep' or 'awk' tools. Most modifications can be automatically done with UNIX™ tools like 'sed' or 'awk'.

Outer joins

The original OUTER join syntax of Informix® is different from the Sybase ASE outer join syntax:

In Informix® SQL, outer tables can be defined in the **FROM** clause with the **OUTER** keyword:

```
SELECT ... FROM cust, OUTER(order)
 WHERE cust.key = order.custno

SELECT ... FROM cust, OUTER(order,OUTER(item))
 WHERE cust.key = order.custno
    AND order.key = item.ordno
    AND order.accepted = 1
```

Sybase ASE Version 7 supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
                     ON cust.key = order.custno

SELECT ...
  FROM cust LEFT OUTER JOIN order
                 LEFT OUTER JOIN item
                 ON order.key = item.ordno
             ON cust.key = order.custno
 WHERE order.accepted = 1
```

The old way to define outer joins in Sybase ASE looks like the following:

```
SELECT ... FROM a, b WHERE a.key *= b.key
```

See the Sybase ASE reference manual for a complete description of the syntax.

Solution

For better SQL portability, you should use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The Sybase ASE interface can convert simple Informix® OUTER specifications to Sybase ASE ANSI outer joins.

Prerequisites:

1. The outer join in the WHERE part must use the table name as prefix.

   Example: `"WHERE tab1.col1 = tab2.col2 "`
2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   Example: `"... FROM tab1, OUTER(tab2) WHERE tab1.col1 = tab2.col2 AND tab2.colx > 10"`
3. Statements composed of 2 or more SELECT instructions using OUTERs are not supported.

   Example: `"SELECT ... UNION SELECT" or "SELECT ... WHERE col IN (SELECT...)"`

   Note:

   1. Table aliases are detected in OUTER expressions.

      OUTER example with table alias: `"OUTER( tab1 alias1)"`
   2. In the outer join, <outer table>.<col> can be placed on both right or left sides of the equal sign.

      OUTER join example with table on the left: `"WHERE outertab.col1 = maintab.col2 "`
   3. Table names detection is not case-sensitive.

      Example: `"SELECT ... FROM tab1, TAB2 WHERE tab1.col1 = tab2.col2"`

4. Temporary tables are supported in OUTER specifications.

Transactions handling

Informix® and Sybase ASE handle transactions in a similar manner.

Informix® native mode (non ANSI):

- Transactions are started with "BEGIN WORK".
- Transactions are validated with "COMMIT WORK".
- Transactions are canceled with "ROLLBACK WORK".
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

Sybase ASE:

- Sybases supports two transaction modes:
  1. The SQL standards-compatible mode, called *chained* mode, to get implicit transaction.
  2. The default mode, called *unchained* mode, where transactions have to be started/ended explicitly.
- Transactions are started with "BEGIN TRANSACTION [name]".
- Transactions are validated with "COMMIT TRANSACTION [name]".
- Transactions are canceled with "ROLLBACK TRANSACTION [name]".
- Transactions save points can be placed with "SAVEPOINT [name]".
- Sybase ASE supports named and nested transactions.
- DDL statements can be executed in transactions blocks when the 'ddl in tran' option is set to true with:

```
master..sp_dboption dbname, 'ddl in tran', true
go
checkpoint
go
```

Solution

Informix® transaction handling commands are automatically converted to Sybase ASE instructions to start, commit or rollback transactions.

Make sure that the database uses the default *unchained* mode (set chained off) and allows DDLs in transactions ('ddl in tran' option is true).

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Sybase ASE.

Temporary tables

Informix® temporary tables are created through the CREATE TEMP TABLE DDL instruction or through a SELECT ... INTO TEMP statement. Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

The CREATE TEMP TABLE and SELECT INTO TEMP statements are not supported in Sybase ASE.

Sybase ASE supports temporary tables by using the # pound sign before the table name:

```
CREATE TABL #temp1 ( kcol INTEGER, .... )
SELECT * INTO #temp2 FROM customers WHERE ...
```

Solution

In BDL, Informix® temporary tables instructions are converted to generate native Sybase ASE temporary tables.

SELECT INTO TEMP statements cannot be converted, because Sybase ASE does not provide a way to create a temporary table from a result set, such as CREATE TABLE xx AS (SELECT ...).

Substrings in SQL

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE  col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE  col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET  col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY  col1[1,3]
```

Sybase ASE provides the SUBSTRING() function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE  SUBSTRING(col1,2,2)  = 'RO'
SELECT SUBSTRING('Some text',6,3 ) FROM DUAL -- Gives 'tex'
```

Solution

You must replace all Informix® col[x,y] expressions by SUBSTRING(col from x for (y-x+1)).

Note:

- In UPDATE instructions, setting column values through subscripts will produce an error with PostgreSQL:

  `UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...`

  is converted to:

  `UPDATE tab1 SET SUBSTRING(col1 from 2 for (3-2+1)) = 'RO' WHERE ...`
- Column subscripts in ORDER BY expressions are also converted and produce an error with PostgreSQL:

  `SELECT ... FROM tab1 ORDER BY col1[1,3]`

  is converted to:

  `SELECT ... FROM tab1 ORDER BY SUBSTRING(col1 from 1 for(3-1+1))`

String delimiters

The ANSI string delimiter character is the single quote ('string'). Double quotes are used to delimit database object names ("object-name").

Example: `WHERE"tabname"."colname" = 'a string value'`

As Informix®, Sql Server Anywhere allows to use double quotes as string delimiters, if the QUOTED_IDENTIFIER session option is OFF (the default):

`SET QUOTED_IDENTIFIER OFF`

Remark: This problem concerns only double quotes within SQL statements. Double quotes used in BDL string expressions are not subject of SQL compatibility problems.

Solution

When the `dbi.database.`*`dbname`*`.ifxemul.dblquotes` FGLPROFILE option is set, the Sybase ASE database interface converts all double quotes to single quotes in SQL statements. The Sybase ASE database driver does not set the `QUOTED_IDENTIFIER` option implicitly.

Getting one row with SELECT

With Informix®, you must use the system table with a condition on the table id:

`SELECT user FROM systables WHERE tabid=1`

With Sybase ASE, you can omit the FROM clause to generate one row only:

```
SELECT user
```

Solution

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

MATCHES and LIKE in SQL conditions

Informix® supports MATCHES and LIKE in SQL statements, while Sybase ASE supports the LIKE statement only.

The MATCHES operator of Informix® uses the star (*), question mark (?) and square braces ([ ]) wildcard characters. The LIKE operator of SQL SERVER offers the percent (%), underscore (_) and square braces ([ ]) wildcard characters:

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x[a-z]' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x[a-z]' )
```

Solution
The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

However, for maximum portability, consider replacing the MATCHES expressions to LIKE expressions in all SQL statements of your programs.

Avoid using CHAR(N) types for variable length character data (such as name, address).

See also: MATCHES and LIKE operators on page 438.

Querying system catalog tables

As in Informix®, Sybase ASE provides system catalog tables (sysobjects, syscolumns, etc.) in each database, but the table names and their structure are quite different.

Solution

No automatic conversion of Informix® system tables is provided by the database interface.

Syntax of UPDATE statements

Informix® allows a specific syntax for UPDATE statements:

```
UPDATE table SET ( col-list ) = ( val-list )
```

Or

```
UPDATE table SET table.* = codeph.*
```

```
UPDATE table SET * = myrecord.*
```

Solution

Static UPDATE statements using this syntax are converted **by the compiler** to the standard form:

```
UPDATE table SET column=value [,...]
```

BDL programming
Sybase ASE related programming topics.
Informix-specific SQL statements in BDL

The BDL compiler supports several Informix® specific SQL statements that have no meaning when using Sybase ASE.

Examples:

- CREATE DATABASE dbname IN dbspace WITH BUFFERED LOG
- START DATABASE (SE only)
- ROLLFORWARD DATABASE
- CREATE TABLE ... IN dbspace WITH LOCK MODE ROW

Solution

Review your BDL source and remove all static SQL statements that are Informix-specific.

Insert cursors

Informix® supports insert cursors. An "insert cursor" is a special BDL cursor declared with an INSERT statement instead of a SELECT statement. When this kind of cursor is open, you can use the PUT instruction to add rows and the FLUSH instruction to insert the records into the database.

For Informix® database with transactions, OPEN, PUT and FLUSH instructions must be executed within a transaction.

Sybase ASE does not support insert cursors.

Solution

Insert cursors are emulated by the Sybase ASE database interface.

Cursors WITH HOLD

Informix® automatically closes opened cursors when a transaction ends unless the WITH HOLD option is used in the DECLARE instruction.

Sybase ASE does not close cursors when a transaction ends, as long as the global parameter close_on_endtrans is off.

Solution

BDL cursors that are not declared "WITH HOLD" are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed by the BDL program.

SELECT FOR UPDATE

A lot of BDL programs use pessimistic locking in order to avoid several users editing the same rows at the same time.

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

- A transaction must be started before opening cursors declared for update.
- The row must be fetched in order to set the lock.
- The lock is released when the transaction ends (if the cursor is not declared "WITH HOLD") or when the cursor is closed.

Sybase ASE ignores the FOR UPDATE clause when not used in a native Sybase SQL DECLARE command. In order to lock rows when doing a SELECT, with Sybase you must add the **holdlock** hint or the **at isolation repeatable read** clause. Sybase supports SELECT locking outside transactions (i.e. WITH HOLD cursors).

- Locks are acquired when opening the cursor.
- When the cursor (WITH HOLD) is opened outside a transaction, locks are released when the cursor is closed.
- When the cursor is opened inside a transaction, locks are released when the transaction ends.

Sybase ASE's locking granularity is at the row level, page level or table level (the level is automatically selected by the engine for optimization).

To control the behavior of the program when locking rows, Informix® provides a specific instruction to set the wait mode:

```
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds}
```

The default mode is WAIT. SET LOCK MODE is as an Informix® specific SQL statement which is translated by the driver.

Solution

SELECT FOR UPDATE statements are supported: The Sybase ASE driver adds the "**at isolation repeatable read**" keywords to the end of any SELECT FOR UPDATE statement.

Sybase ASE requires a PRIMARY KEY or UNIQUE INDEX on the table using in the SELECT .. FOR UPDATE statement.

Sybase ASE locks the rows when you open the cursor. You will have to test SQLCA.SQLCODE after doing an OPEN.

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

The SELECT FOR UPDATE statement cannot contain an ORDER BY clause if you want to perform positioned updates/deletes with WHERE CURRENT OF.

The LOAD and UNLOAD instructions

Informix® provides two SQL instructions to export / import data from / into a database table: The UNLOAD instruction copies rows from a database table into an text file and the LOAD instruction inserts rows from an text file into a database table.

Sybase ASE has LOAD and UNLOAD instructions, but those commands are related to database backup and recovery. Do not confuse with Informix® commands.

Solution

LOAD and UNLOAD instructions are supported.

The LOAD instruction does not work with tables using emulated SERIAL columns because the generated INSERT statement holds the "SERIAL" column which is actually a IDENTITY column in Sybase ASE. See the limitations of INSERT statements when using SERIALs.

In Sybase ASE, Informix® DATETIME data is stored in BIGDATETIME columns, but DATETIME columns are similar to Informix® DATETIME YEAR TO FRACTION(5) columns. Therefore, when using LOAD and UNLOAD, those columns are converted to text data with the format "YYYY-MM-DD hh:mm:ss.fffff".

SQL Interruption

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

Solution

The Sybase ASE database driver supports SQL interruption and raises error code -213 if the statement is interrupted.

Scrollable Cursors

The Genero programming language supports scrollable cursors.

Sybase ASE supports native scrollable cursors.

Solution

The Sybase ASE database driver uses the native Sybase ASE Open Client Library scrollable cursors.

User interface

These topics cover programming the user interface (UI) with the Genero Business Development Language.

- User interface basics on page 747
- Form definitions on page 769
- Dialog instructions on page 1034
- User interface programming on page 1249

User interface basics

This section introduces to the foundation of the Genero user interface.

- The user interface on page 27
- Genero user interface modes on page 752
- The dynamic user interface on page 747
- Establish a GUI front-end connection on page 755
- The abstract user interface tree on page 749
- Special user interface features on page 759
- Configuring a text terminal on page 762

The dynamic user interface

The dynamic user interface is the base concept of the Genero user interaction components.

The *dynamic user interface* (DUI) concept implements a flexible graphical user interface programming toolkit, based on the usage of XML standards to define an abstract representation of the application forms, that can be displayed by different sort of display devices called front ends, which execute on the user workstation or on the same platform as the runtime system.

By using the same program source code, the abstract definition of the user interface that can be manipulated at runtime as a tree of interface objects. This tree is called the abstract user interface tree.

The runtime system is in charge of the abstract user interface tree and the front end is in charge of rendering this abstract tree visible on the screen. The front end gets a copy of that tree which is automatically synchronized by the runtime system by using the front end protocol.

In development, application screens are defined by form specification files. These files are compiled by the fglform form compiler to produce the runtime form files that can be deployed in production environments.

The following schema describes the dynamic user interface concept, showing how the abstract user Interface tree is shared by the runtime system and the front end.

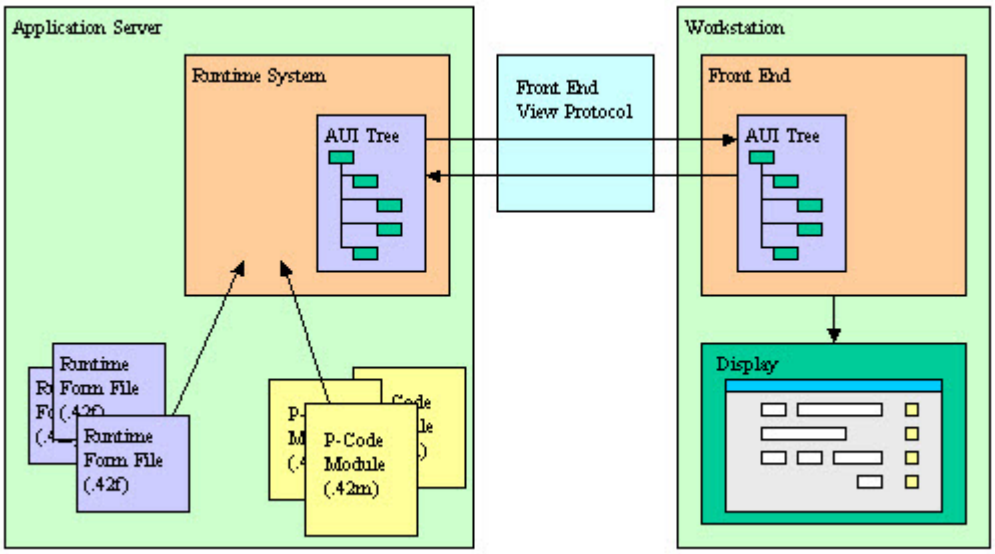

Figure 35: AUI tree shared between the runtime system and front end

The abstract user interface tree (AUI tree) on the front-end is synchronized with the runtime system AUI tree when a user interaction instruction takes the control. This means that the user will not see any display as long as the program is doing batch processing, until an interactive statement is reached.

For example, the following program shows nothing:

```
MAIN
  DEFINE cnt INTEGER
  OPEN WINDOW w WITH FORM "myform"
  FOR cnt=1 TO 10
    DISPLAY BY NAME cnt
    SLEEP 1
  END FOR
END MAIN
```

If you want to show something on the screen while the program is running in a batch procedure, you must force synchronization with the front-end, by calling the `refresh()` method of the `ui.Interface` built-in class:

```
MAIN
  DEFINE cnt INTEGER
  OPEN WINDOW w WITH FORM "myform"
  FOR cnt=1 TO 10
    DISPLAY BY NAME cnt
    CALL ui.Interface.refresh()   -- Sync the front-end!
    SLEEP 1
  END FOR
END MAIN
```

Note that the `refresh()` method must only be called when really needed: By default, the AUI tree will be automatically synchronized when the control goes back to the runtime system dialog instruction.

Keep in mind that when the AUI trees are synchronized, only the changes are sent to the front-end. If a modification has been made that does not result in a change in the values of the attributes of a node of the tree (for example, you change the contents of an image file but keep the same name), that modification will not be sent to the front-end.

Note that when running on a mobile device, both front-end and runtime system execute on the same platform. Still the AUI tree protocol takes place, and both component perform the tasks they are dedicated to.

The abstract user interface tree

The abstract user interface tree is the XML representation of the application forms displayed to the end user.

The *abstract user interface tree* (AUI tree) is a DOM tree describing the objects of the user interface elements of a program at a given time.

A copy of the AUI tree is held by both the front end and the runtime system.

AUI tree synchronization is automatically done by the runtime system using the front end protocol.

The programs can manipulate the AUI tree element by using XML utility classes or high-level built-in classes such as `ui.Dialog` and `ui.Form`.

What does the abstract user interface tree contain?

The abstract user interface defines a tree of objects organized by parent/child relationship. The different kinds of user interface objects are defined by attributes. The AUI tree can be serialized as text according to the XML standard notation.

The following example shows a part of an AUI tree defining a toolbar serialized with the XML notation:

```
<ToolBar>
  <ToolBarItem name="f5" text="List" image="list" />
  <ToolBarSeparator/>
  <ToolBarItem name="Query" text="Query" image="search" />
  <ToolBarItem name="Add" text="Append" image="add" />
  ...
</ToolBar>
```

Manipulating the abstract user interface tree

Modifying the AUI tree with user interface specific built-in classes

The objects of the abstract user interface tree can be queried and modified at runtime with specific built-in classes like `ui.Form`, provided to manipulate form elements.

The next code example gets the current window object, then gets the current form in that window, and hides a group-box form element identified by the name "`gb1`":

```
DEFINE w ui.Window
DEFINE f ui.Form
LET w = ui.Window.getCurrent()
LET f = w.getForm()
CALL f.setElementHidden("gb1",1)
```

Using the user interface specific built-in classes is the recommended way to modify the AUI tree in your programs.

Using low-level APIs to modify the AUI tree

In very special cases, you can also directly access the nodes of the AUI tree by using DOM built-in classes like `om.DomDocument` and `om.DomNode`.

> **Important:** As we continue to add new features to the product we encounter situations that may force us to modify the AUI Tree in order to add new elements types and attributes. If you are using the low level API's to directly modify the tree, your code may be slightly impacted when we release

a change in the AUI Tree structure. In order to minimize the impact of any such AUI tree definition changes, we would like to suggest the following course of action with regards to use of the DOM/SAX API's:

1. Place all custom calls to the DOM/SAX API within centralized Library functions that are accessible to all modules, as opposed to scattering function calls throughout your code base.
2. Do not create nodes or change attributes that are not explicitly documented as modifiable. For example, `TopMenu` or `ToolBar` nodes can be created and configured dynamically, but you should not add `FormField` nodes to existing forms, or modify yourself the `active` attribute of fields or actions.

To get the user interface nodes at runtime, the language provides different kinds of API functions or methods, according to the context. For example, to get the root of the AUI tree, call the `ui.Interface.getRootNode()` method. You can also get the current form node with `ui.Form.getNode()` or search for an element by name with the `ui.Form.findNode()` method.

XML node types and attribute names

By tradition the language uses uppercase keywords, such as `LABEL` in form files, and the examples in this documentation reflect that convention. The language itself is not case-sensitive. However, XML is case-sensitive, and by convention node types use uppercase/lowercase combinations to indicate word boundaries. Therefore, the nodes and attributes of an abstract user interface tree are handled as follows:

- Node types - the first letter of the node type is always capitalized. Subsequent letters are lowercase, unless the type consists of multiple words joined together. In that case, the first letter of each of the multiple words is capitalized (the camel-case convention). Examples: `Label`, `FormField`, `DateEdit`, `Edit`.
- Attribute names - the first letter of the name is always lowercase; subsequent letters are also lowercase, unless the name consists of multiple words joined together. In that case, the first letter of each subsequent word is capitalized (the Lower camel-case convention). Examples: `text`, `colName`, `width`, `tabIndex`
- Attribute values - the values are enclosed in quotes, and the runtime system does not convert them.

If you reference AUI tree XML nodes or attributes in your code, you must always respect the naming conventions.

Actions in the abstract user interface tree

The abstract user interface identifies all possible actions that can be received by the current interactive instruction with a list of `Action` nodes. The list of possible actions are held by a `Dialog` node. An `Action` node is identified by the '`name`' attribute and defines common properties such as the accelerator key, default image, and default text.

Interactive elements are bound to `Action` nodes by the '`name`' attribute. For example, a toolbar button (a.k.a toolbar item) with the name 'cancel' is bound to the `Action` node having the name 'cancel', which in turn defines the accelerator key, the default text, and the default image for the button.

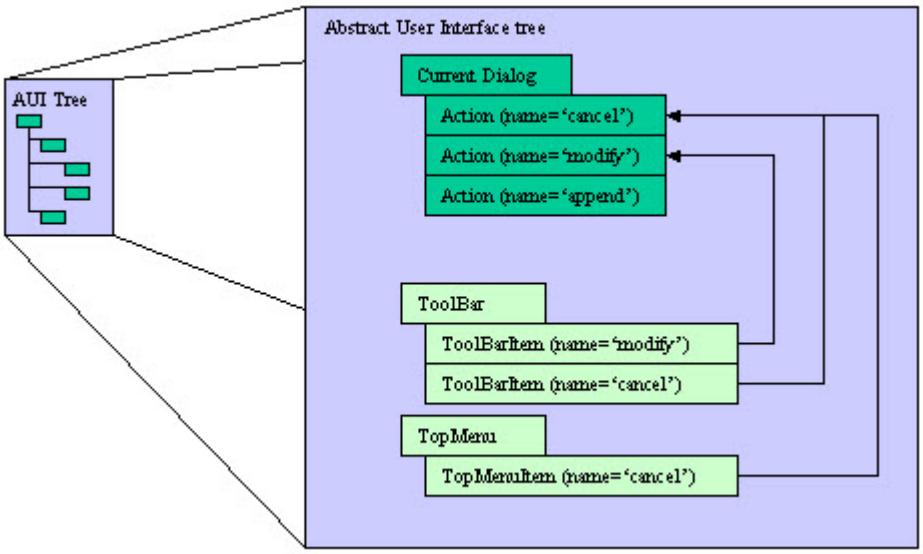

Figure 36: AUI Tree binding

When an interactive element is used (such as a form field input, toolbar button click, or menu option selection), an `ActionEvent` node is sent to the runtime system. The name of the `ActionEvent` node identifies what `Action` occurred and the '`idRef`' attribute indicates the source element of the action.

Inspecting the AUI tree of a front end

The abstract user interface tree build on a front end side can be inspected

When executing a program displaying on a front end, it is possible to inspect the content of the abstract user interface built on the front end side. The way to show the AUI tree depends on the type of front end.

Genero Desktop Client

The GDC must have been started in debug mode (`-aD` option).

In the current window of the running program, do a control-right-click with the mouse: This will open the AUI tree debug window.

You can then browse the AUI tree created on the GDC side.

Genero Web Client - JavaScript

The GAS / GWC-JS must have been started with debug option. In the `as.xcf` configuration file, add the following line:

```
<CONFIGURATION ...>
  <APPLICATION_SERVER>
     ...
     <RESOURCE Id="res.uaproxy.param" Source="INTERNAL">--development</
RESOURCE>
     ...
```

Start your application in a web browser: a debug icon should appear on the right of the window. Click the icon to display the AUI debug tree.

You can then browse the AUI tree created on the GMA side.

Genero Mobile for Android

The GMA must execute with debug mode enabled in the settings panel.

Open a web browser an enter the following URL:

```
http://device-ip-address:6480
```

You can then browse the AUI tree created on the GMA side.

Genero Mobile for iOS

The GMI must have been started in debug mode: the debug option needs to be enabled in GMI app settings on the device.

Open a web browser an enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

You can then browse the AUI tree created on the GMI side.

Genero user interface modes

User interface modes allow to adapt the application form rendering to different sort of displays.

There supported user interface modes are:

- Text mode rendering on page 752
- Graphical mode rendering on page 753
- Traditional GUI mode on page 753

Text mode rendering

The text user interface (TUI) has been designed for character-based terminals. This mode can be used to run your application on a text terminal hardware or in a terminal emulator.

In order to run a Genero program on text mode, set the FGLGUI environment variable to 0 (zero).

In TUI mode, the application windows/forms will display within the current console/terminal window as shown.

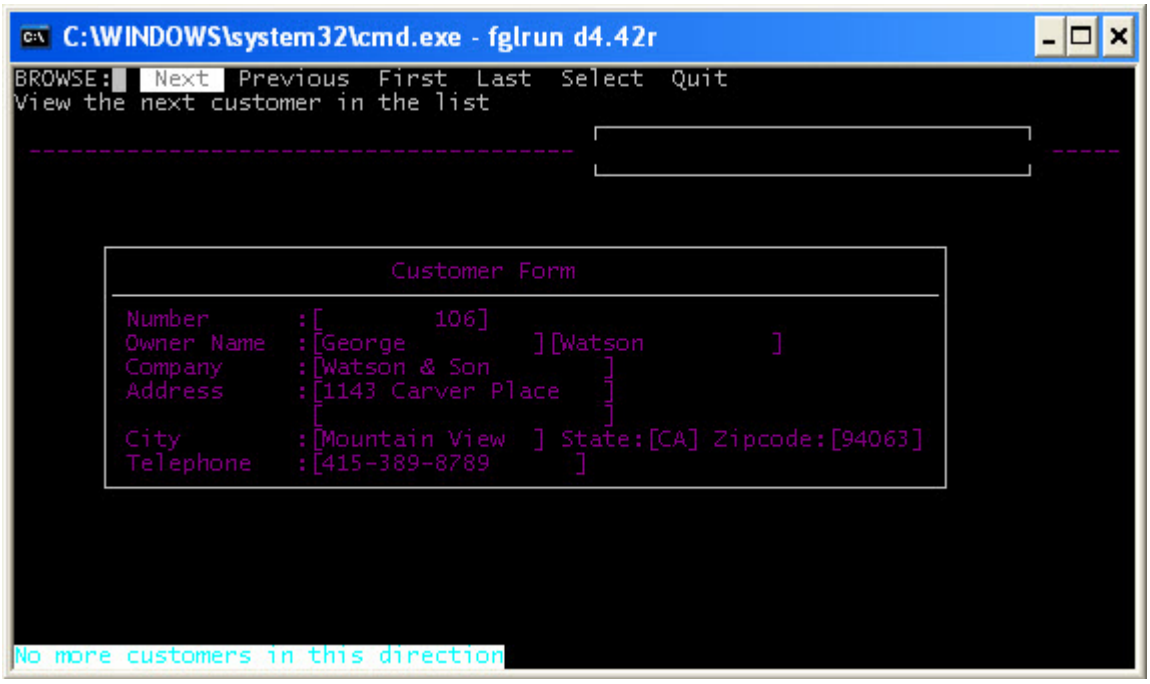

Figure 37: Text mode rendering

On UNIX™ platforms, you need to configure you terminal capabilities with environment variables with TERM, TERMINFO or TERMCAP environment variables.

Graphical mode rendering

Genero supports the graphical user interface (GUI) to provide a real graphical look and feel, for desktop workstation, web browsers and mobile front-end platforms.

When set to 1, the FGLGUI environment variable defines the graphical mode usage. This is the default. In graphical mode, the application forms are displayed on the front-end workstation identified with the FGLSERVER environment variable. Application forms will be rendered with real graphical widgets providing a nice look-and-feel as shown.

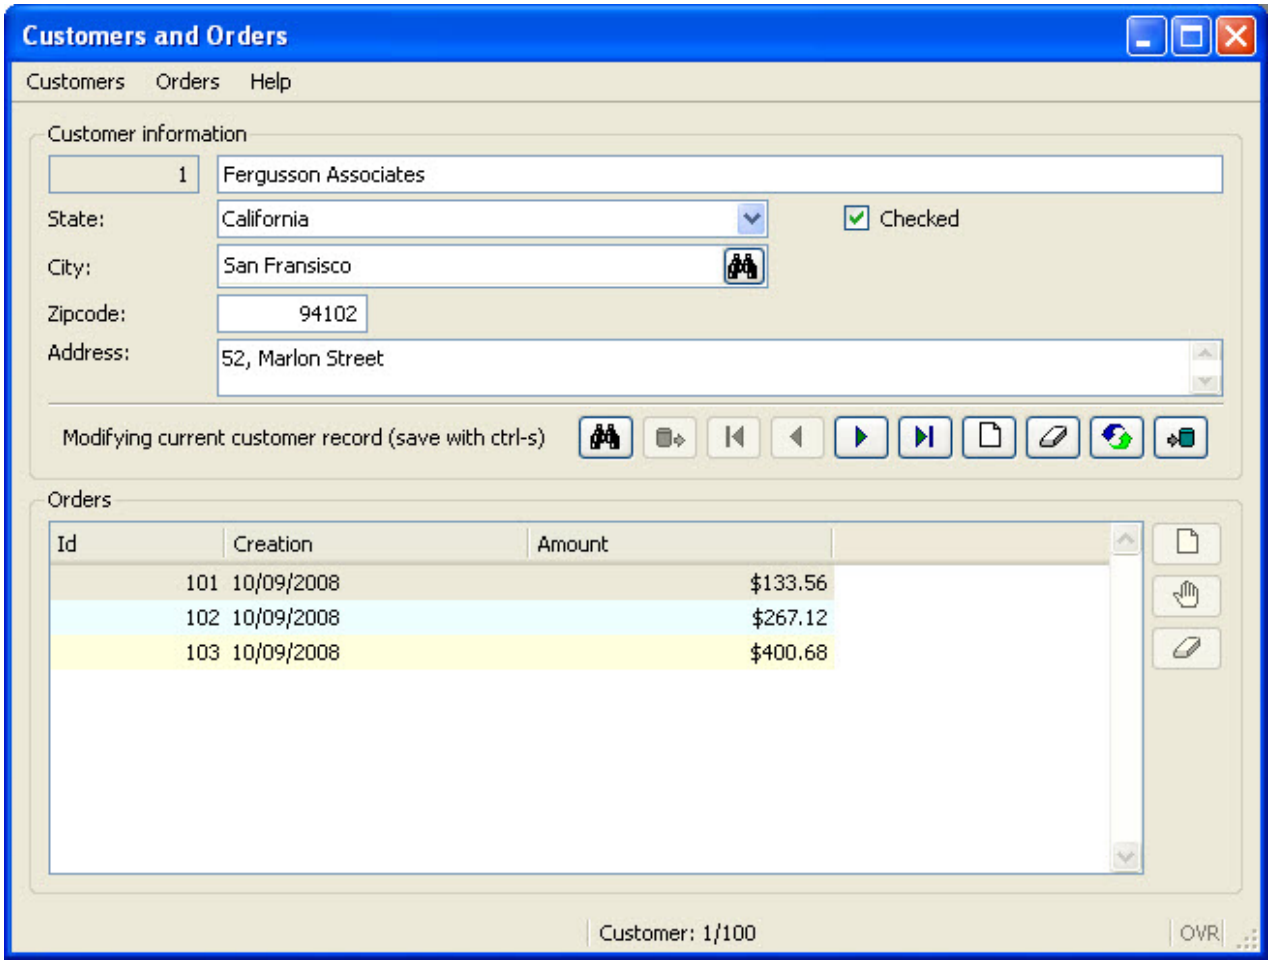

Figure 38: Graphical mode rendering

To simplify migration from text mode to graphical mode with legacy applications, you can use the traditional GUI mode option to render application windows in a single front end GUI window.

Traditional GUI mode

What is the Traditional GUI mode designed for?

With the graphical mode, you immediately get the benefit of standard GUI widgets and windows. Forms are rendered as real movable and re-sizeable windows, form labels and fields become widgets using variable fonts, toolbars and pull-down menus are displayed, and error messages are displayed in the status bar. However, that can be annoying if you have to migrate from a project that was developed for dumb terminals (i.e. TUI mode).

You can use the *traditional GUI mode* to ease migration from TUI based applications to GUI mode.

With the traditional mode, application windows bound to forms using a SCREEN section will be displayed as simple boxes in a main front end window. Other windows bound to forms defined with the LAYOUT section will be displayed as new GUI windows.

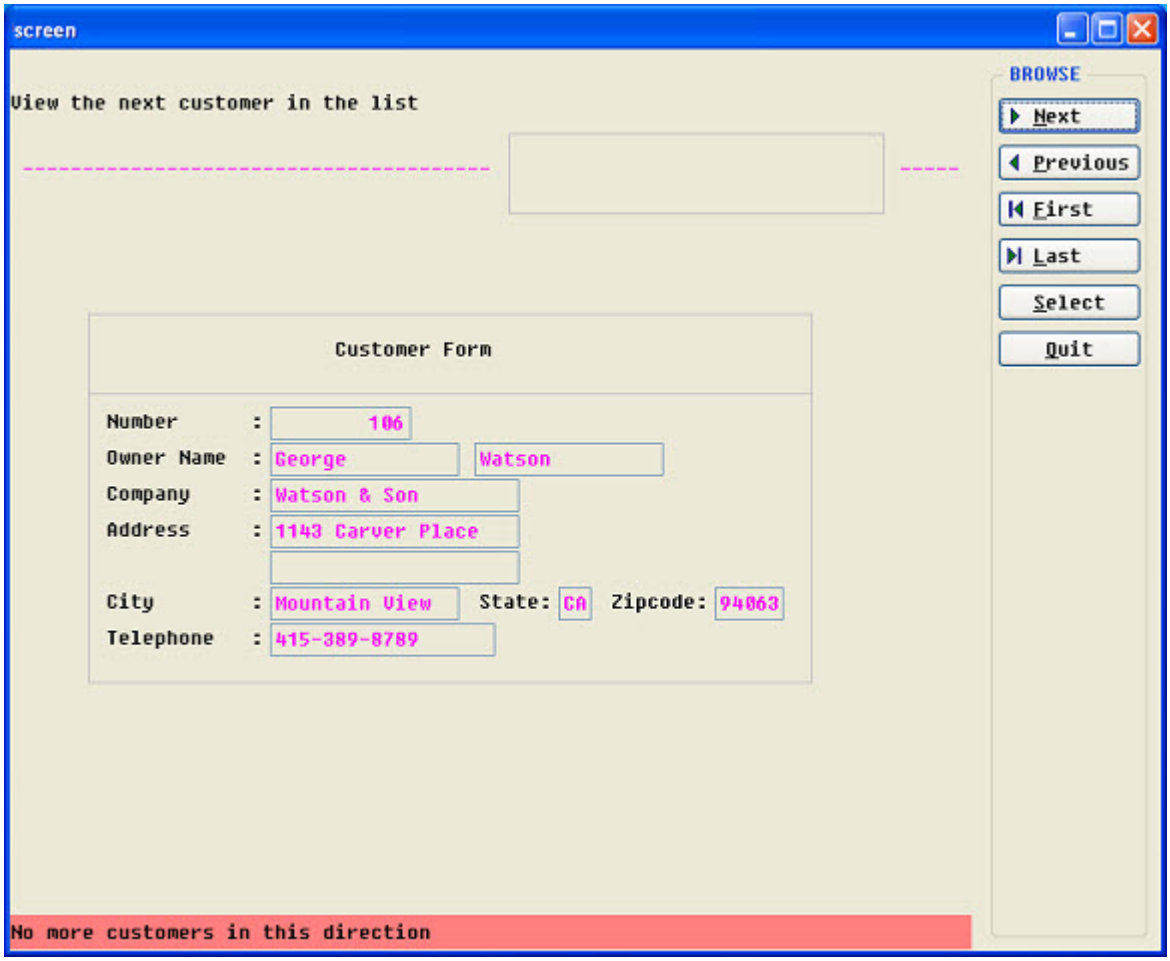

Figure 39: Traditional GUI mode rendering

Enabling the traditional GUI mode

The traditional GUI mode can be enabled with the following FGLPROFILE entry:

```
gui.uiMode = "traditional"
```

By default, the traditional GUI mode is off.

Window rendering rules

If the traditional GUI mode is enabled, the `OPEN WINDOW` statement works differently depending on the layout type of bound forms.

On the front end side, there is one unique main graphical window (a top-level widget called "*compatibility window container*") created to host all the windows created by a program. Traditional forms are form files which have a SCREEN section instead of the LAYOUT section. When migrating from an TUI mode project, all forms initially contain a SCREEN section; hence all windows opened in traditional mode will appear in the compatibility window container.

To rebuild a form file with graphical items such as group boxes, buttons and tables, use a `LAYOUT` section. If the rebuilt form file is loaded via `OPEN WINDOW ... WITH FORM form-file` then, even in traditional mode, the newly created window will appear as a new top-level widget on the front end side. This opens a smooth migration path using the traditional mode; as a first step, it is possible to migrate and enhance some application forms like typical search lists, while keeping the rest of the application forms running in the traditional rendering.

Note, however, that following instructions do not work in traditional GUI mode:

1. `OPEN WINDOW` *`window_id`* `AT` *`line, column`* `WITH` *`height`* `ROWS,` *`width`* `COLUMNS`
2. `OPEN FORM` *`form_id`* `FROM "`*`form_file`*`"`

   (where *form_file* is defined with a `LAYOUT` section)
3. `DISPLAY FORM` *`form_id`*

A runtime error results, because you cannot display a form with dynamic geometry in a fixed geometry container. Only forms with a `SCREEN` section can be displayed at a later stage in a window that was initially opened inside the compatibility window container.

Function key shifting

When the traditional mode is enabled, you can map Shift-Fx and Ctrl-Fx key strokes to F(x+offset) actions. The offset is defined with the `gui.key.add_function` entry:

```
gui.key.add_function = 12
```

This entry defines the number of function keys of the keyboard (default is 12). When defined as 12, a Shift-F1 will be received as an F13 (12+1) action event by the program, and a Control-F1 will be F25 (12*2+1).

Establish a GUI front-end connection

This section explains runtime to front-end connection in it's simplest form.

Connecting with a front-end

In graphical mode, according to the front-end technology that is used (i.e. desktop client, mobile client, web server client), there are different solutions to establish the connection between the runtime system and the front-end.

This topic describes the development context case, where programs are executed directly with `fglrun`. In a production environment, programs will typically be started with another technology, since the execution of programs will be triggered by the end user interacting with the front-end. Read front-end specific documentation for more details.

From the point of view of the runtime system, the front-end acts as a graphical server and thus the programs must connect to that GUI server in order to display forms and get user input.

The runtime system will try to connect to the front-end only when the first interactive instruction like `MENU` or `INPUT` is reached.

For the runtime system, the front end is identified by the FGLSERVER environment variable. This variable defines the host name of the machine where the front end resides, and the number of the front end instance to be used.

The syntax for FGLSERVER is:

```
{hostname|ip-address}[:servernum]
```

For example:

```
$ FGLSERVER=fox:1
$ fglrun myprog
```

The *servernum* parameter is a whole number that defines the instance of the front-end. It is actually defining a TCP port number the front-end is listening to, starting from 6400. For example, if *servernum* equals 2, the TCP port number used is 6402 (6400+2).

This is the standard/basic connection technique, but you can set up different types of configurations. For example, you can have the front end connect to an application server via ssh, to pass through firewalls over the internet. Refer to the front end documentation for more details.

There can an exception to the standard FGLSERVER specification, if the front-end is denied to listen to a port. If you need to revert the connection principle in this particular case, use the `--gui-listen` option of fglrun. With this option, the runtime system will listen to the specified port, so the front-end can bind to the program and start to use the GUI protocol. The procedure to work in such configuration is the following:

1. Start the program with:

```
fglrun --gui-listen tcp-port prog-name
```

2. Connection from the front-end, for example, with an URL with the following format:

```
fgl://host-name:tcp-port
```

The front end protocol

The *front end protocol* (FEP) is an internal protocol used by the runtime system to synchronize the abstract user interface (AUI) representation on the front end side. This protocol defines a simple set of operations to modify the AUI tree. This protocol is based on a command processing principle (send command, receive answer) and can be serialized to be transported over any network protocol, like HTTP for example.

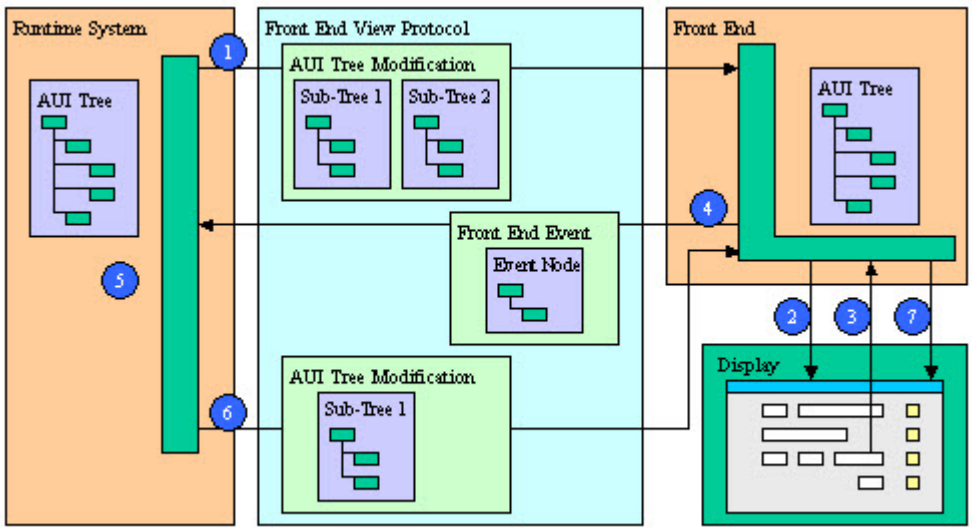

Figure 40: Typical communication between the Runtime System and the Front End

1. Initialization phase: The runtime system sends the initial AUI tree.
2. The front end builds the graphical user interface according to the AUI tree.
3. The front end waits for a user interaction (mouse click, keyboard typing).
4. When the user performs some interaction, the front end sends front end events corresponding to the modifications made by the user.
5. Front end events are analyzed and validated by the runtime system.
6. The runtime system sends back the result of the front end requests, by the way of AUI tree modifications commands.

7. When receiving these commands, the front end modifies its version of the AUI tree and updates the graphical user interface. It then waits for new user interactions (step 3).

Front-end identification

To start a program from the front-end platform, the front-end can open a terminal session on the application server. This is done for example by using a *ssh*, *rlogin*, or *telnet* terminal session. When the terminal session is open, the front end sends a couple of shell commands to set environment variables like FGLSERVER before starting the program to display the application forms on the front end where the terminal session was initiated.

In this configuration, front end identification takes place. The front end identification prevents the display of application forms on a front end that did not start the program on the server. If the front-end was not identified, it would result in an important security problem, as anyone could run a fake program that would display on any front-end and ask for a password.

> **Important: Front end identification is achieved automatically by an initial protocol handshake. However, there can be a security hole if regular operating system users on the application server can overwrite the program or the shell script started by the front end terminal session. Malicious programs can try to display the application on another workstation to read confidential data. As long as basic application users do not have read and write privileges on the program files, there is no risk. To make sure that program files on the server side are protected from basic users, create a special user on the server to manage the application program files, and give other users only read access to those files. As long as basic users cannot modify programs on the server side, there is no security issue.**

Configure the GUI connection timeout

When initiating the connection to the front end, if the front end software is stopped, the host machine is down, or a firewall drops connections for the TCP port used for the GUI connection, the program will stop with an error after a given timeout.

This timeout can be specified with the following FGLPROFILE entry:

```
gui.connection.timeout = seconds
```

The default timeout is 30 seconds.

Wait for front end ping timeout

You can configure the wait-for-ping timeout with the following FGLPROFILE entry:

```
gui.protocol.pingTimeout = 800
```

> **Important:** This feature is not supported when running or mobile devices, or when displaying applications on mobile devices.

It can happen that the user leaves the program for a while without using it. The network policy (firewall) might force a close of the TCP connection after a given period of inactivity. To avoid such connection shutdown when there is no GUI exchange, the front end sends a 'ping' event every N minutes (this is usually configurable in the front-ends) to keep the TCP connection alive. The front end ping is a normal situation and part of the GUI client/server protocol.

> **Important:** With this "keep alive" technique, a front-end connection remains always open, even if the user leaves the workstation for several hours. If your network connection has a cost, you should consider to configure the front-end to turn off the ping event or stop it after a given number of pings. Check the front-end configuration documentation for more details.

If the front end program is not stopped properly (when killed by a system reboot, for example), the TCP connection is lost and the runtime system does not receive any more 'ping' events. In this case, the runtime system waits for a specified time before it stops with fatal error **-8063**.

By default, the runtime system waits for 600 seconds (10 minutes).

> **Important:** If you set the wait-for-ping timeout to a value lower than the ping delay of the front-end, the program will stop with a fatal error after that timeout, even if the TCP connection is still alive. For example, with a front end having a ping delay of 5 minutes, the minimum value for this parameter should be about 330 seconds (5 minutes + 30 seconds to make sure the client ping arrives).

GUI protocol compression

GUI protocol compression might be used to reduce the amount of data exchanged between the front-end and the runtime system. Compression is typically useful on slow networks. The compression algorithm is provided by the standard ZLIB library of the system.

When using the Genero Web Client (GWC/GAS), compression is not useful and is automatically disabled.

Compression makes sense on slow networks (for example, with a phone-line dialup modem, or broadband modem based networks); On fast networks, compression is not required and will in fact use unnecessary processor time.

Compression is disabled by default, and can be enabled with this FGLPROFILE entry:

```
gui.protocol.format = "zlib"
```

If this parameter is defined, but the ZLIB library is not installed on your system or if the ZLIB version is not compatible with the version needed by the runtime system, compression cannot be supported, and the program will stop with error -6317. The ZLIB version must be 1.2.5 (or compatible with version 1.2.5). On Microsoft™ Windows™ platforms, the name of the library must be ZLIB1.DLL; Precompiled binary packages can easily be found on the internet. On UNIX™ platforms, the name of the shared library must be libz.so (normally located in /usr/lib). Note that on Linux™ distributions, you typically have to install the zlib (or zlib1g) package and create a symbolic link for libz.so. The libz.so file is part of zlib-devel package, though.

Front-end errors

When the front end receives an invalid order, it stops the application. The runtime system then stops and displays error -6313 with an additional message, for example:

```
Program stopped at 'myprog.4gl', line number 675.
 FORMS statement error number -6313.
 The User Interface has been destroyed: Unexpected interface version sent
 by the runtime system.
```

Debugging the front-end protocol

When setting the FGLGUIDEBUG environment variable to 1, information about GUI communication will be printed to stderr by the runtime system, and the GUI protocol exchange will be indented for a better readability in the front-end log window.

UNIX™ (shell) example:

```
$ FGLGUIDEBUG=1
$ export FGLGUIDEBUG
$ fglrun myprog 2>guidbg.txt
```

Note that in TUI mode, displayed screens can be dumped by setting the DBSCREENDUMP or DBSCREENOUT environment variables. This can be used to take a snapshot of the current TUI screen, for debugging or testing purpose.

Front-end protocol logging

GUI protocol exchanges can be logged to a file with the `--start-guilog=`*`filename`* option of fglrun, and replayed with the `--run-guilog=`*`filename`* option.

This feature can be used to log .

The options take the log file as parameter:

UNIX™ (shell) example:

```
$ fglrun --start-guilog=mylog.txt myprogram
```

When the program is started, all user interaction and AUI tree updates will be logged to the file specified by the `--start-guilog` option.

The log file can then be replayed with the `--run-guilog` option, to mimic the user interaction, and reproduce potential issues:

```
$ fglrun --run-guilog=mylog.txt
```

Special user interface features

This section describes special features regarding the user interface domain.

The special GUI supported features are:

- Setting key labels on page 759
- Automatic front end startup on page 761
- Text mode screen dump on page 762

Setting key labels

Labels can be defined to decorate buttons controlled by `ON KEY`/`COMMAND KEY` action handlers.

Syntax

Key label configuration can take place at different levels.

- FGLPROFILE definitions

```
key.key-name.text = "label"
```

- Program-level key labels

```
CALL fgl_setkeylabel( "key-name", "label" )
```

- Form level key labels (in KEYS section)

```
KEYS key-name = [%]"label"
[...]
[END]
```

- Dialog level key labels

```
CALL fgl_dialog_setkeylabel( "key-name", "label" )
```

- Form field level key labels (in field definition)

```
KEY key-name = [%]"label"
```

1. *key-name* is the name of the key.
2. *label* is the text to be displayed in the default action view (button).

Usage

When using the graphical mode, `ON KEY` and `COMMAND KEY` action handlers in dialogs can be shown as form buttons when a label text is defined for the key. By defining a label for a key, the runtime system will automatically show a default button for the key action.

> **Important:** Key label configuration is provided for backward compatibility. Consider using action configuration in new programs.

In the next example, the function key `F10` is used to show a detail window in this interactive dialog:

```
INPUT BY NAME myrecord.*
  ON KEY (F10)
    CALL ShowDetail()
END INPUT
```

By default, if you do not specify a label, no default action button is displayed for a function key or control key.

If the text provided for the key label is empty or null, the default action button will not be displayed.

Table 220: Key names recognized by the runtime system

Key Name	Description
`f1` to `f255`	Function keys.
`control-a` to `control-z`	Control keys.
`accept`	Predefined dialog validation action.
`interrupt`	Predefined dialog cancellation action. The action name is *cancel*, not *interrupt*.
`insert`	Predefined `INPUT ARRAY` dialog row insertion action.
`append`	Predefined `INPUT ARRAY` dialog row addition action.
`delete`	Predefined `INPUT ARRAY` dialog row deletion action.
`help`	Predefined help action.

Key labels can be defined at different levels. The order of precedence for key label definition is the following:

1. The label defined with the KEY attribute of the form field.
2. The label defined for the current dialog, using the FGL_DIALOG_SETKEYLABEL function.
3. The label defined in the KEYS section of the form specification file.
4. The label defined as default for a program, using the FGL_SETKEYLABEL function.
5. The label defined in the FGLPROFILE configuration file (`key.`*`key-name`*`.text` entries).

In Genero, you typically define action labels with action attributes. However, if key labels are defined, they will overwrite the text defined in action attributes for the corresponding key action. In BDS 3.xx versions, default key labels are defined in FGLDIR/etc/fglprofile. These defaults have been commented out in Genero to have action attribute text applied (In Genero, by default, fgl_getkeylabel() returns NULL for all keys). If you want to get the same default key labels as in BDS 3.xx, uncomment the key.* lines in FGLDIR/etc/fglprofile.

You can query the label defined at the program level with the FGL_GETKEYLABEL function and, for the current interactive instruction, with the FGL_DIALOG_GETKEYLABEL function.

Automatic front end startup

This section describes how to start a graphical front-end automatically when the runtime system and the front-end reside on the same computer.

When a program starts in graphical mode, the runtime system tries to open a connection to the graphical front end according to the FGLSERVER environment variable. This requires having the front end already started and listening to the TCP port defined according to FGLSERVER.

In some configurations, such as *X11 workstations* or *METAFRAME/Citrix Winframe* or *Microsoft™ Windows™ Terminal Server*, each user may want to start his own front end to have a dedicated process. This can be done by starting the front end automatically when the program executes, according to the DISPLAY (X11) or SESSIONNAME/CLIENTNAME (WTSE) environment variables.

Automatic front end startup settings are defined with `gui.server.autostart.*` entries in FGLPROFILE. In these FGLPROFILE entries, the term "GUI server" refers to the graphical front end.

In a first time, the runtime system tries to establish the connection without starting the front end (in a normal usage, it is already started). The front end is identified by the FGLSERVER environment variable. If FGLSERVER is not defined, it defaults to `localhost:0`, except if `gui.server.autostart.wsmap` entries are defined in FGLPROFILE. When `wsmap` entries are defined, workstation id to GUI server id mapping takes place and FGLSERVER defaults to `localhost:n`, where n is the GUI server number found from `wsmap` entries.

If this first connection fails and the `gui.server.autostart.cmd` entry is defined, the runtime system executes the command to start the GUI server, then waits for n seconds as defined by `gui.server.autostart.wait` entry, and after this delay tries to connect to the front end. If the connection fails, it tries again for a number of attempts defined by the `gui.server.autostart.repeat` entry. Finally, it the last try failed, the runtime system stops with a GUI connection error -6300.

If the `gui.server.autostart.cmd` entry is not defined, neither workstation id to GUI id mapping, nor automatic front-end startup is done.

Here is a detailed description of each `gui.server.autostart` FGLPROFILE entry:

The `cmd` entry is used to define the command to be executed to start the front-end:

```
gui.server.autostart.cmd = "/opt/app/gdc-2.30/bin/gdc -p %d -q -M"
```

Here, `%d` will be replaced by the TCP port the front-end must listen to.

By default the runtime system waits for two seconds before it tries to connect to the front-end. You can change this delay with the **wait** entry:

```
gui.server.autostart.wait = 5   -- wait five seconds
```

The runtime system tries to connect to the front-end ten times. You can change this with the `repeat` entry:

```
gui.server.autostart.repeat = 3 -- repeat three times
```

The following FGLPROFILE entries can be used to define workstation id to front-end id mapping:

```
gui.server.autostart.wsmap.max = 3
gui.server.autostart.wsmap.0.names = "fox:1.0,fox.sxb.4js.com:1.0"
gui.server.autostart.wsmap.1.names = "wolf:1.0,wolf.sxb.4js.com:1.0"
gui.server.autostart.wsmap.2.names = "wolf:2.0,wolf.sxb.4js.com:2.0"
```

The first `wsmap.max` entry defines the maximum number of front-end identifiers to look for. The `wsmap.N.names` entries define a mapping for each GUI server, where **N** is the front-end identifier. The value of those entries defines a comma-separated list of workstation names to match. If no wsmap entries are defined, the GUI server number will default to zero.

For `gui.server.autostart.wsmap` entries, the first GUI server number starts at zero.

On X11 configurations, a workstation is identified by the DISPLAY environment variable. In this example, `fox:1.0` identifies a workstation that will make the runtime start a front end with the number 1.

On Windows™ Terminal Server, the CLIENTNAME environment variable identifies the workstation. If no corresponding front end id can be found in the `wsmap` entries, the front end number defaults to the id of the session defined by the SESSIONNAME environment variable, plus one. The value of this variable has the form *`protocol#id`*; for example, `RDP-Tcp#4` would automatically define a front end id of 5 (4+1).

If the front end processes are started on the same machine as the runtime system, you do not need to set the FGLSERVER environment variable. This will then default to `localhost:`*`id`*, where *id* will be detected according to the `wsmap` workstation mapping entries.

If the front end is executed on a middle-tier machine that is different from the application server, MIDHOST for example, you can set FGLSERVER to MIDHOST without a GUI server id. The workstation mapping will automatically find the id according to `wsmap` settings.

Some front ends such as the Genero Desktop Client (GDC), raise the control panel to the top of the window stack when you try to restart it. In this case the program window might be hidden by the GDC control panel. To avoid this problem, you can use the -M option to start the GDC in minimized mode.

Text mode screen dump

For compatibility with IBM® Informix® 4GL, Genero supports the DBSCREENDUMP and DBSCREENOUT environment variables for debugging purpose, to let you do a screen shot when running in TUI mode and write the result into a file.

To enable TUI screen shot, set either DBSCREENDUMP or DBSCREENOUT to the name of the output file, then run your Genero program with FGLGUI=0 set and press the Ctrl-P key to dump the current screen. Each time you press Ctrl-P the output file will be overwritten.

The DBSCREENDUMP variable writes the screen with escape sequences of TTY attributes, while DBSCREENOUT writes only the characters displayed on the screen, which makes the output more readable.

If both variables are set, the runtime will generate both output files. You should however use different file names, otherwise the output is undefined.

Configuring a text terminal

This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

Terminal type and terminal capabilities definition is not a Genero-specific configuration: TERM, TERMCAP and TERMINFO are also used by other UNIX™ applications and commands.

On UNIX™ platforms, the TERM environment variable must be set to define the terminal type/name. For example, if you execute the application in an xterm X11 window, set TERM=xterm.

On Windows™ platforms, you can run applications in text mode inside a CMD console window. You must not set the TERM environment variable in this case.

Genero supports both *termcap* and *terminfo* implementations of text terminal capabilities. The INFORMIXTERM environment variable defines the type of library used to interact with the terminal. When INFORMIXTERM is set to `termcap` (the default), the runtime system reads terminal capabilities from the file defined by the TERMCAP environment variable. When INFORMIXTERM is set to `terminfo`, the runtime system uses the ncurses library of the operating system to interact with the terminal. We strongly recommend you to use the terminfo solution.

TERMINFO terminal capabilities

When the INFORMIXTERM environment variable is set to `terminfo`, the runtime system will use the ncurses or curses library of the UNIX™ system to display and interact with the terminal device, according to the TERM environment variable.

Make sure that the `libncurses.so` or the `libcurses.so` library is installed on your UNIX™ operating system.

The TERMINFO environment variable can be used to define a different terminal capabilities database as the default. If your UNIX™ system is properly configured, you should not have to set the TERMINFO environment variable.

TERMCAP terminal capabilities

When the INFORMIXTERM environment variable is set to `termcap` or when this variable is undefined, the runtime system will use the termcap terminal capabilities database.

The termcap solution is provided for backward compatibility. You should use terminfo instead, by setting the INFORMIXTERM variable to `terminfo`.

The default termcap database is in the `/etc/termcap` file. If this file is not found, the runtime system will use its default file `$FGLDIR/etc/termcap`. Use the TERMCAP environment variable to specify a different termcap file as the defaults. If you plan to modify the default termcap file, we strongly recommend that you make a copy of the original file and point to the new file with the TERMCAP variable.

In this section we will briefly describe the syntax of the termcap file. For a complete definition please refer to your operating system documentation (see man pages describing the termcap file syntax).

Termcap syntax

All termcap entries contain a list of terminal names, followed by a list of terminal capabilities, in the following format:

- Each capability, including the last one in the entry, is followed by a colon (:).
- ESCAPE is specified as a backslash (\ ) followed by the letter E. CTRL is specified as a caret (^). Do not use the ESCAPE or CTRL keys to indicate escape sequences or control characters in a termcap entry.
- Entries must be defined on a single logical line; a backslash (\ ) appears at the end of each line that wraps to the next line.
- Comment lines begin with a sharp sign (#).

Example: xterm terminal definition:

```
xterm|xterm terminal emulator:\
:km:mi:ms:xn:pt:\
:co#80:li#24:\
:is=\E[r\E[m\E[2J\E[H\E[?7h\E[?1;3;4;6l:\
...
```

Terminal Names

Termcap entries begin with one or more names for the terminal, each separated by a vertical (|) bar. Any one of these names can be used for access to the termcap entry.

Boolean capabilities

Boolean capabilities are two-character codes indicating whether a terminal has a specific feature. If the boolean capability exists in the termcap entry, the terminal has that particular feature.

For example:

```
:bs:am:
# bs backspace with CTRL-H
# am automatic margins
```

Numeric Capabilities

Numeric capabilities are two-character codes followed by a sharp symbol (#) and a value.

For example:

```
:co#80:li#24:
# co number of columns in a line
# li number of lines on the screen
```

The runtime system assumes that the value is zero for any numeric capabilities that are not listed.

String Capabilities

String capabilities specify a sequence that can be used to perform a terminal operation.

A string capability is a two-character code, followed by an equal sign (=) and a string ending at the next delimiter (:).

Most termcap entries include string capabilities for clearing the screen, arrow keys, cursor movement, underscore, function keys, etc.

For example, this shows some string capabilities for a Wyse 50 terminal:

```
:ce=\Et:cl=\E*:\
:nd=^L:up=^K:\
:so=\EG4:se=\EG0:
# ce=\Et clear to end of line
# cl=\E* clear the screen
# nd=^L non-destructive cursor right
# up=^K up one line
# so=\EG4 start stand-out
# se=\EG0 end stand-out
```

Genero-specific termcap definitions

Extending Function Key Definitions

In TUI mode, the runtime system recognizes function keys F1 through F36. These keys correspond to the termcap capabilities k0 through k9, followed by kA through kZ.

The termcap entry for these capabilities is the sequence of ASCII characters your terminal sends when you press the function keys (or any other keys you choose to use as function keys).

This example shows some function key definitions for the xterm terminal:

```
k0=\E[11~:k1=\E[12~:k2=\E[13~:k3=\E[14~:\
...
k9=\E[21~:kA=\E[23~:kB=\E[24~:\
```

Defining dialog action keys

Dialog action keys for insert, delete and list navigation can be defined with the following capabilities:

- **ki** : Insert line (default is CTRL-J)
- **kj** : Delete line (default is CTRL-K)
- **kf** : Next page (default is CTRL-M)
- **kg** : Previous page (default is CTRL-N)

  Note: You can also use the OPTIONS statement to name other function keys or CTRL keys for these operations.

Specifying Characters for Window Borders

The runtime system uses the graphics characters in the termcap file when you specify a window border in an `OPEN WINDOW` statement.

The runtime system uses characters defined in the termcap file to draw the border of a window. If no characters are defined in this file, the runtime system uses the hyphen (-) for horizontal lines, the vertical bar (|) for vertical lines, and the plus sign (+) for corners.

Steps to define the graphical characters for window borders for your terminal type:

1. Determine the escape sequences for turning the terminal graphics mode ON and OFF (Refer to the manual of your terminal). For example, on Wyse 50 terminals, the escape sequence for entering graphics mode is ESC H^B, and the escape sequence for leaving graphics mode is ESC H^C.
2. Identify the ASCII equivalents for the six graphics characters that Genero requires to draw the window borders. The ASCII equivalent of a graphics character is the key you would press in graphics mode to obtain the indicated character. The six graphical characters needed by Genero are:
   a. The upper left corner
   b. The lower left corner
   c. The upper right corner
   d. The lower right corner
   e. The horizontal line
   f. The vertical line
3. Edit the termcap entry for your terminal, and define the following string capabilities:
   - **gs** : The escape sequence for entering graphics mode. In the termcap file, ESCAPE is represented as a backslash (\ ) followed by the letter E; CTRL is represented as a caret (^). For example, the Wyse 50 escape sequence ESC-H CTRL-B is represented as \EH^B.
   - **ge** : The escape sequence for leaving graphics mode. For example, the Wyse 50 escape sequence ESC-H CTRL-C is represented as \EH^C.
   - **gb** : The concatenated, ordered list of ASCII equivalents for the six graphics characters used to draw the border. Using the order as listed in (2).

     For example, if you are using a Wyse 50 terminal, you would add the following, in a linear sequence:

     ```
     :gs=\EH^B:ge=\EH^C:gb=2135z6:\
     ```

For terminals without graphics capabilities, you must enter a blank value for the **gs** and **ge** capabilities. For **gb**, enter the characters you want Genero to use for the window border. The following example shows possible values for **gs**, **ge**, and **gb** in an entry for a terminal without graphics capabilities:

```
:gs=:ge=:gb=.|.|_|:
```

With these settings, window borders would be drawn using underscores (_) for horizontal lines, vertical bars (|) for vertical lines, periods (.) for the top corners, and vertical bars (|) for the lower corners.

Adding Color and Intensity

In TUI mode, a Genero program can be written either for a monochrome or a color terminal, and then you can run the program on either type of terminal. If you set up the termcap files as described, the color attributes and the intensity attributes are related.

Table 221: Relationship between color attributes and intensity attributes

Number	Color	Intensity	Note
0	WHITE	NORMAL	
1	YELLOW	BOLD	

Number	Color	Intensity	Note
2	MAGENTA	BOLD	
3	RED	BOLD (*)	If the keyword BOLD is indicated as the attribute, the field will be RED on a color terminal
4	CYAN	DIM	
5	GREEN	DIM	
6	BLUE	DIM (*)	If the keyword DIM is indicated as the attribute, the field will be BLUE on a color terminal
7	BLACK	INVISIBLE	

The background for colors is BLACK in all cases. In either color or monochrome mode, you can add the REVERSE, BLINK, or UNDERLINE attributes if your terminal supports them.

The ZA String Capability

Genero uses a parameterized string capability named **ZA** in the termcap file to determine color assignments. Unlike other termcap string capabilities that you set to a literal sequence of ASCII characters, ZA is a function string that depends on the following four parameters:

Table 222: ZA function parameters

Parameter	Name	Description
1	p1	Color number between 0 and 7 (see Table 221: Relationship between color attributes and intensity attributes on page 765).
2	p2	0 = Normal; 1 = Reverse.
3	p3	0 = No-Blink; 1 = Blink.
4	p3	0 = No-underscore; 1 = Underscore.

ZA uses the values of these four parameters and a stack machine to determine which characters to send to the terminal. The ZA function is called, and these parameters are evaluated, when a color or intensity attribute is encountered in a Genero program. Use the information in your terminal manual to set the ZA parameters to the correct values for your terminal.

The ZA string uses stack operations to push values onto the stack or to pop values off the stack. Typically, the instructions in the ZA string push a parameter onto the stack, compare it to one or more constants, and then send an appropriate sequence of characters to the terminal. More complex operations are often necessary; by storing the display attributes in static stack machine registers (named a through z), you can have terminal-specific optimizations.

The different stack operators that you can use to write the descriptions are summarized here. For a complete discussion of stack operators, see your operating system documentation.

Operators That Send Characters to the Terminal

- **%d** pops a numeric value from the stack and sends a maximum of three digits to the terminal. For example, if the value 145 is at the top of the stack, %d pops the value off the stack and sends the ASCII

representations of 1, 4, and 5 to the terminal. If the value 2005 is at the top of the stack, %d pops the value off the stack and sends the ASCII representation of 5 to the terminal.

- **%2d** pops a numeric value from the stack and sends a maximum of two digits to the terminal, padding to two places. For example, if the value 145 is at the top of the stack, %2d pops the value off the stack and sends the ASCII representations of 4 and 5 to the terminal. If the value 5 is at the top of the stack, %2d pops the value off the stack and sends the ASCII representations of 0 and 5 to the terminal.
- **%3d** pops a numeric value from the stack and sends a maximum of three digits to the terminal, padding to three places. For example, if the value 7 is at the top of the stack, %3d pops the value off the stack and sends the ASCII representations of 0, 0, and 7 to the terminal.
- **%c** pops a single character from the stack and sends it to the terminal.

Operators That Manipulate the Stack

- **%p[1-9]** pushes the value of the specified parameter on the stack. The notation for parameters is p1, p2, ... p9. For example, if the value of p1 is 3, %p1 pushes 3 on the stack.
- **%P[a-z]** pops a value from the stack and stores it in the specified variable. The notation for variables is Pa, Pb, ... Pz. For example, if the value 45 is on the top of the stack, %Pb pops 45 from the stack and stores it in the variable Pb.
- **%g[a-z]** gets the value stored in the corresponding variable (P[a-z]) and pushes it on the stack. For example, if the value 45 is stored in the variable Pb, %gb gets 45 from Pb and pushes it on the stack.
- **%'c'** pushes a single character on the stack. For example, %'k' pushes k on the stack.
- **%{n}** pushes an integer constant on the stack. The integer can be any length and can be either positive or negative. For example, %{0} pushes the value 0 on the stack.
- **%S[a-z]** pops a value from the stack and stores it in the specified static variable. (Static storage is nonvolatile since the stored value remains from one attribute evaluation to the next.) The notation for static variables is Sa, Sb, ... Sz. For example, if the value 45 is on the top of the stack, %Sb pops 45 from the stack and stores it in the static variable Sb. This value is accessible for the duration of the Genero program.
- **%G[a-z]** gets the value stored in the corresponding static variable (S[a-z]) and pushes it on the stack. For example, if the value 45 is stored in the variable Sb, %Gb gets 45 from Sb and pushes it on the stack.

Arithmetic Operators

Each arithmetic operator pops the top two values from the stack, performs an operation, and pushes the result on the stack.

- **%+** Addition.

  For example, %{2}%{3}%+ is equivalent to 2+3.
- **%-** Subtraction.

  For example, %{7}%{3}%- is equivalent to 7-3.
- **%*** Multiplication.

  For example, %{6}%{3}%* is equivalent to 6*3.
- **%/** Integer division.

  For example, %{7}%{3}%/ is equivalent to 7/3 and produces a result of 2.
- **%m** Modulus (or remainder).

  For example, %{7}%{3}%m is equivalent to (7 mod 3) and produces a result of 1.

Bit Operators

The following bit operators pop the top two values from the stack, perform an operation, and push the result on the stack:

- **%&** Bit-and.

For example, %{12}%{21}%& is equivalent to (12 and 21) and produces a result of 4.

- **%|** Bit-or.

  For example, %{12}%{21}%| is equivalent to (12 or 21) and produces a result of 29.
- **%^** Exclusive-or.

  For example, %{12}%{21}%^ is equivalent to (12 exclusive-or 21) and produces a result of 25.

The following unary operator pops the top value from the stack, performs an operation, and pushes the result on the stack:

- **%~** Bitwise complement.

  For example, %{25}%~ results in a value of -26.

Logical Operators

The following logical operators pop the top two values from the stack, perform an operation, and push the logical result (0 for false or 1 for true) on the stack:

- **%=** Equal to.

  For example, if the parameter p1 has the value 3, the expression %p1%{2}%= is equivalent to 3=2 and produces a result of 0 (false).
- **%>** Greater than.

  For example, if the parameter p1 has the value 3, the expression %p1%{0}%> is equivalent to 3>0 and produces a result of 1 (true).
- **%<** Less than.

  For example, if the parameter p1 has the value 3, the expression %p1%{4}%< is equivalent to 3<4 and produces a result of 1 (true).

The following unary operator pops the top value from the stack, performs an operation, and pushes the logical result (0 or 1) on the stack.

- **%!** Logical negation.

  This operator produces a value of zero for all nonzero numbers and a value of 1 for zero. For example, %{2}%! results in a value of 0, and %{0}%! results in a value of 1.

Conditional Statements

The conditional statement has the following format:

```
%? expr %t thenpart %e elsepart %;
```

The *%e elsepart* is optional. You can nest conditional statements in the *thenpart* or the *elsepart* .

When Genero evaluates a conditional statement, it pops the top value from the stack and evaluates it as either true or false. If the value is true, the runtime performs the operations after the %t; otherwise it performs the operations after the %e (if any).

For example, the expression:

```
%?%p1%{3}%=%t;31%;
```

is equivalent to:

```
if p1 = 3 then print ";31"
```

Assuming that p1 in the example has the value 3, Genero would perform the following steps:

- **%?** does not perform an operation but is included to make the conditional statement easier to read.
- **%p1** pushes the value of p1 on the stack.
- **%{3}** pushes the value 3 on the stack.
- **%=** pops the value of p1 and the value 3 from the stack, evaluates the boolean expression p1=3, and pushes the resulting value 1 (true) on the stack.
- **%t** pops the value from the stack, evaluates 1 as true, and executes the operations after %t. (Since ";31" is not a stack machine operation, Genero prints ";31" to the terminal.)
- **%;** terminates the conditional statement.

ZA example

The ZA sequence for the ID Systems Corporation ID231 (color terminal) is:

```
ZA =
\E[0;                  # Print lead-in
%?%p1%{0}%=%t%{7}      # Encode color number (translate color number
                       # to number for the ID231 term)
%e%p1%{1}%=%t%{3}      #
%e%p1%{2}%=%t%{5}      #
%e%p1%{3}%=%t%{1}      #
%e%p1%{4}%=%t%{6}      #
%e%p1%{5}%=%t%{2}      #
%e%p1%{6}%=%t%{4}      #
%e%p1%{7}%=%t%{0}%;    #
%?%p2%t30;%{40}%+%2d # if p2 is set, print '30' and '40' + color number
 (reverse)
%e40;%{30}%+%2d%;      #  else print '40' and '30' + color number (normal)
%?%p3%t;5%;            # if p3 is set, print 5 (blink)
%?%p4%t;4%;            # if p4 is set, print 4 (underline)
m                      # print 'm' to end character sequence
```

Form definitions

This section describes how to define application forms and program resources related to the presentation layer.

- Windows and forms on page 769
- Using images on page 782
- Accessibility guidelines on page 791
- Message files on page 794

- DISPLAY AT on page 781

Understanding windows and forms

Programs manipulate windows and forms, to define display and input areas controlled by interactive instructions such as the `INPUT` dialog. When a dialog is started, it uses the form associated with the current window. Forms are defined in .42f compiled form files and are loaded and displayed in windows.

Window objects

The windows are created from programs; they define a display context for sub-elements like forms, menus, message and error lines. A window can contain only one form at a time, but you can display different forms successively in the same window.

When using a the text mode (FGLGUI=0), windows are displayed in the character terminal as fixed-size boxes, at a given line/column position, width and height. When using a graphical desktop front end (FGLGUI=1), windows are displayed as independent re-sizeable windows by default. Note that a GUI application can run in traditional mode (`gui.uiMode="traditional"` FGLPROFILE setting), displaying windows as simple static areas inside a real graphical parent window. When using a mobile device front-end, only one window is visible at the time, because of device platform GUI standards and the limited screen sizes (smartphones). Split views is the exception, and allows to display two windows side by side for a typical list-detail display on tablets.

A program creates a new window with the `OPEN WINDOW` instruction, which also defines the window identifier. A window is destroyed with the `CLOSE WINDOW` instruction:

```
OPEN WINDOW mywindow WITH FORM "myform"
...
CLOSE WINDOW mywindow
```

If there is a current window, it is possible to display several forms successively in that same window. The previous form is removed automatically by the runtime system when displaying a new form to the window:

```
OPEN WINDOW mywindow WITH FORM "form1"
INPUT BY NAME ... -- uses form1 elements
...
OPEN FORM f1 FROM "form2"
DISPLAY FORM f1  -- removes "form1" from the window
INPUT BY NAME ... -- uses form2 elements
...
```

When a program starts, the runtime system creates a default window named `SCREEN`. This default window can be used as a regular window: it can hold a menu and a form. If needed, it can be closed with `CLOSE WINDOW SCREEN`. You typically display the main form of your program in the `SCREEN` window, by using `OPEN FORM` + `DISPLAY FORM`:

```
MAIN
```

```
    -- The SCREEN window exists by default
    ...
    OPEN FORM f_main FROM "customers"
    DISPLAY FORM f_main -- displays in SCREEN
    ...
END MAIN
```

Several windows can be created, but there can be only one current window when using modal dialogs (only one dialog is active at the time, thus only the current window can be active). By using parallel dialogs, several windows can be active concurrently. Parallel dialogs were introduced to implement split views, for mobile devices.

There is always a current window. The last created window becomes the current window. When the last created window is closed, the previous window in the window stack becomes the current window. Use the `CURRENT WINDOW` instruction to make a specific window current before executing the corresponding dialog that is controling the window content:

```
OPEN WINDOW w_customers ...
OPEN WINDOW w_orders ...
...
CURRRENT WINDOW IS w_customers
...
CLOSE WINDOW w_customers
CURRRENT WINDOW IS w_orders
...
```

By default, a window has no particular type and displays as a modal window on the front-end, to be controlled by a modal dialog instruction. In some situations, you must specify the type of the window to get a specific rendering and behavior. This is achieved by defining the `TYPE` attribute in the `ATTRIBUTES` clause of the `OPEN WINDOW` instruction:

```
OPEN WINDOW w_cust WITH FORM "f_cust" ATTRIBUTES(TYPE=LEFT)
...
OPEN WINDOW w_pref WITH FORM "f_pref" ATTRIBUTES(TYPE=POPUP)
...
```

Specify decoration options with a presentation style for the window, identified the `STYLE` attribute of the `ATTRIBUTES` section of `OPEN WINDOW`. Window styles can also be specified at form level, with the `WINDOWSTYLE` form attribute in the `LAYOUT` of the form definition:

```
OPEN WINDOW w_cust WITH FORM "f_cust" ATTRIBUTES(STYLE="dialog2")
```

The `ui.Window` built-in class can be used to manipulate windows as objects. The common practice is to get the current form of the window and use it as `ui.Form` object to manipulate its content.

The windows can be displayed in an WCI container application, by using the `ui.Interface` methods to define parent / child relationship.

Form objects

Forms define the layout and presentation of areas used by the dialogs (`INPUT`), to display or input data. Forms are loaded by programs from external files with the .42f extension, the compiled version of .per form specification files.

Forms can be stamped with the `VERSION` attribute. The form version attribute is used to indicate that the form content has changed. The front end is then able to distinguish different form versions and avoid saved settings being applied for new form versions.

Forms can be loaded with the `OPEN FORM` instruction followed by a `DISPLAY FORM`, to display the form into the current window, or forms can be used directly as window creation argument with the `OPEN WINDOW ... WITH FORM` instruction:

```
OPEN FORM f_cust FROM "f_cust"
DISPLAY FORM f_cust -- into current window
...
OPEN WINDOW w_cust WITH FORM "f_cust"
```

The form that is used by interactive instructions like `INPUT` is defined by the current window containing the form. Switching between existing windows (and thus, between forms associated to the windows) is done with the `CURRENT WINDOW` instruction.

Several forms can be successively displayed in the same (current) window. The last displayed form will be used by the next dialog, while the form displayed before will be automatically removed from the window:

```
OPEN WINDOW w_common WITH 20 ROW, 60 COLUMNS
...
OPEN FORM f1 FROM "f_cust"
DISPLAY FORM f1 -- f_cust is shown
INPUT BY NAME rec_cust.* ...
...
OPEN FORM f2 FROM "f_ord"
DISPLAY FORM f2 -- f_ord is shown (f_cust is removed)
INPUT BY NAME rec_ord.* ...
```

The `ui.Form` built-in class is provided to handle form elements. You can, for example, hide some parts of a form with the `setElementHidden()` method. Get a `ui.Form` object with the `ui.Window.getForm()` method.

OPEN WINDOW
Creates and displays a new window.

Syntax

```
OPEN WINDOW identifier
   [ AT line, column ]
   WITH { FORM form-file
        | height ROWS, width COLUMNS
        }
   [ ATTRIBUTES ( window-attributes ) ]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
| BORDER
| TEXT = "string"
| TYPE = { RIGHT | LEFT | POPUP | NAVIGATOR }
| STYLE = "string"
| PROMPT LINE = integer
| MENU LINE = integer
| MESSAGE LINE = integer
| ERROR LINE = integer
| COMMENT LINE = { OFF | integer }
}
```

1. *identifier* is the name of the window. It is always converted to lowercase by the compiler.

2. *line* is the integer defining the top position of the window. The first line in the screen is 1, while the relative line number inside the window is zero.
3. *column* is the integer defining the position of the left margin. The first column in the screen is 1, while the relative column number inside the window is zero.
4. *form-file* defines the .42f compiled form specification file to be used, without the file extension.
5. *height* defines the number of lines of the window in character units; includes the borders in character mode.
6. *width* defines the number of lines of the window in character units; includes the borders in character mode.

Usage

An `OPEN WINDOW` statement can have the following effects:

- Declares a name (the *identifier*) for the window.
- Indicates which form has to be used in that window.
- Specifies the display attributes of the window.
- When using character mode, specifies the position and dimensions of the window, in character units.

For graphical applications, use this instruction without the `AT` clause, and with the `WITH FORM`clause.

The window identifier must follow the rules for identifiers and be unique among all windows defined in the program. Its scope is the entire program. You can use this identifier to reference the same Window in other modules with other statements (for example, `CURRENT WINDOW` and `CLOSE WINDOW`).

The compiler converts the window identifier to lowercase for internal storage. When using functions or methods receiving the window identifier as a string parameter, the window name is case-sensitive. We recommend that you always specify the window identifier in lowercase letters.

The runtime system maintains a stack of all open windows. If you execute `OPEN WINDOW` to open a new window, it is added to the window stack and becomes the current window. Other statements that can modify the window stack are `CURRENT WINDOW` and `CLOSE WINDOW`.

Example

```
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  MENU "Test"
    COMMAND KEY(INTERRUPT) "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

Window position and size

Window objects can be created with a position and size for the TUI mode.

When using the full GUI mode (without the traditional mode), the `AT` *`line, column`* clause is optional and if used, the `WITH` *`lines`* `ROWS,` *`characters`* `COLUMNS` clause is ignored, because the size of the window is automatically calculated according to its contents.

When using the TUI mode, the `AT` *`line, column`* clause defines the position of the top-left corner of the window on the terminal screen and `WITH` *`lines`* `ROWS,`*`characters`* `COLUMNS` clause specifies explicit vertical and horizontal dimensions for the window. The expression at the left of the `ROWS` keyword specifies the height of the window, in character unit lines. This must be an integer between 1 and max, where max is the maximum number of lines that the screen can display. The integer expression after the comma at the left of the `COLUMNS` keyword specifies the width of the window, in character unit columns. This must return a whole number between 1 and length, where length is the number of characters that your monitor can display on one line. In addition to the lines needed for a form, allow room for the `COMMENT` line, the `MENU` line, the `MENU` comment line and the `ERROR` line. The runtime system issues a runtime error if the window

does not include sufficient lines to display both the form and these additional reserved lines. The minimum number of lines required to display a form in a window is the number of lines in the form, plus an additional line below the form for prompts, messages, and comments.

OPEN WINDOW attributes
List if attributes for the OPEN WINDOW instruction.

Table 223: Window-attributes supported by the OPEN WINDOW statement

Attribute	Description
`TEXT = string`	Defines the default title of the window. When a form is displayed, the form title (`LAYOUT(TEXT="mytitle")`) will be used as window title. **Tip:** We recommend that you define the window title in the form file.
`STYLE = string`	Defines the default style of the window. If the form defines a window style, (`LAYOUT(WINDOWSTYLE="mystyle")`), it overwrites the default window style. **Tip:** We recommend that you define the window style in the form file.
`TYPE = [LEFT|RIGHT|POPUP|NAVIGATOR]`	Defines the window type. According to the type specified, the window will appear differently, following front-end platform GUI standards. For example, on iOS devices, a window created with `TYPE=POPUP` will show up from the bottom of the screen. See Window types on page 777.
`BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, YELLOW`	Default TTY color of the data displayed in the window.
`BOLD, DIM, INVISIBLE, NORMAL`	Default TTY font attribute of the data displayed in the window.
`REVERSE, BLINK, UNDERLINE`	Default TTY video attribute of the data displayed in the window.
`PROMPT LINE integer`	In character mode, indicates the position of the prompt line for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.
`FORM LINE integer`	In character mode, indicates the position of the form line for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.
`MENU LINE integer`	In character mode, indicates the position of the ring menu line for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.

Attribute	Description
`MESSAGE LINE integer`	In character mode, indicates the position of the message line for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.
`ERROR LINE integer`	In character mode, indicates the position of the error line for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.
`COMMENT LINE {OFF|integer}`	In character mode, indicates the position of the comment line or no comment line at all, for this window. The position can be specified with `FIRST` and `LAST` predefined line positions.
`BORDER`	Indicates if the window must be created with a border in character mode. A border frame is drawn outside the specified window. This means, that the window needs 2 additional lines and columns on the screen.

The following list describes the default line positions in character mode:

- First line: Prompt line (output from `PROMPT` statement) and Menu line (command value from `MENU` statement).
- Second line: Message line (output from `MESSAGE` statement; also the descriptions of `MENU` options).
- Third line: Form line (output from `DISPLAY FORM` statement).
- Last line: Error line (output from `ERROR` statement). Also comment line in any window except `SCREEN`.

The WITH FORM clause
Creating a window object with a form.

As an alternative to specifying explicit dimensions for a window, the `WITH FORM` clause can specify the name of a compiled form file, without the `.42f` file extension. A window object is automatically opened and sized to the screen layout of the form. When using the TUI mode, the width of the window is from the left-most character on the screen form (including leading blank spaces) to the right-most character on the screen form (truncating trailing blank spaces). The length of the window is calculated as (form line) + (form length).

```
OPEN WINDOW w1 WITH FORM "custlist"
```

It is recommended that you use the `WITH FORM` clause, especially in the default GUI mode, because the window is created in accordance with the form. If you use this clause, you do not need the `OPEN FORM`, `DISPLAY FORM`, or `CLOSE FORM` statement to open and close the form. The `CLOSE WINDOW` statement closes the window and the form.

Window styles
Use the `STYLE` attribute to set a style for a window.

By default, windows are displayed as normal application windows, but you can use the *window style* to show a window at the top of all other windows, as a "modal window".

The window style defines the type of the window (normal, modal) and its decoration, via a presentation style. The presentation style specifies a set of attributes in an external file (.4st).

There are different ways to define the style of a window: The `STYLE` attribute can be used in the `OPEN WINDOW` instruction to define the default style for a window, but it is better to specify the window style in the

form file, with the WINDOWSTYLE attribute of the LAYOUT section. This avoids decoration-specific code in the programs.

Table 224: Standard window styles defined in the default presentation style file

Style name in 4st file	Description
Window	Defines presentation attributes for common application windows. When using MDI containers, normal windows are displayed as MDI children.
Window.main, Window.main2	Defines presentation attributes for starter applications, where the main window shows a startmenu if one is defined by the application.
Window.dialog, Window.dialog2, Window.dialog3, Window.dialog4	Defines presentation attributes for typical OK/Cancel modal windows. On iOS mobile devices, opening a new window with the predefined style 'dialog' causes the window to slide up from the bottom: `OPEN WINDOW w_opt WITH FORM "f_opt" ATTRIBUTES(STYLE="dialog")`
Window.naked	Defines presentation attributes for windows that should not show the default view for ring menus and action buttons (OK/Cancel).
Window.viewer	Defines presentation attributes for viewers as the report pager (fglreport.per).

It is recommended that you not change the default settings of windows styles in the FGLDIR/lib/default.4st file. If you create your own style file, copy the default styles into your own file in a different directory.

It is not possible to change the presentation style attributes of windows dynamically in the AUI tree. The style is applied when the window and form are loaded.

If you open and display a second form in an existing window, the window style of the second form is not applied.

Window titles
Use the TEXT attribute to define a title for a window.

The TEXT attribute in the ATTRIBUTE clause of OPEN WINDOW defines the default title of the window. If the window is opened with a form (WITH FORM clause) that defines a TEXT attribute in the LAYOUT section, the default is ignored. Subsequent OPEN FORM / DISPLAY FORM instructions may change the window title if the new form defines a different title in the LAYOUT section.

It is recommended that you specify the window title in the form file, instead of using the TEXT attribute of the OPEN WINDOW instruction.

If you want to set a window title dynamically, you can use the setText() method of the ui.Window built-in class.

Window icons
Use a IMAGE attribute to define the icon for a window.

If the window is opened with OPEN WINDOW WITH FORM, by using a form file that defines an IMAGE attribute in the LAYOUT section, the window will use this image as icon. Subsequent OPEN FORM /

`DISPLAY FORM` instructions may change the window icon if the new form defines a different image in the `LAYOUT` section.

If you want to set a window icon dynamically, you can use the `setImage()` method of the `ui.Window` built-in class.

Window types
Use the `TYPE` attribute to define the type of a window.

> **Important:** This feature is only for mobile platforms.

The type of a window can be specified with the `TYPE` attribute in the `OPEN WINDOW` instruction:

```
OPEN WINDOW w_main WITH FORM "navi"
     ATTRIBUTES( TYPE = NAVIGATOR )
```

This attribute was introduced to implement split-views on mobile front-ends.

Possible values for the `TYPE` attribute are described in the following table:

Table 225: Supported window types

Name	Description
`LEFT`	Defines the window as the left pane when implementing split views. The window will be the parent window of a window cascade displayed on the left-hand side.
`NAVIGATOR`	Defines the window as the action pane (i.e. iOS Tab bar) when implementing split views. This type of window will be used as top-level navigator window, showing the options to switch between different windows controlled by parallel dialogs.
`POPUP`	Defines the window as popup (modal) window, to open on the top of other windows.
`RIGHT`	Defines the window as the right pane when implementing split views. The window will be the parent window of a window cascade displayed on the right-hand side.

CLOSE WINDOW
Closes and destroys a window.

Syntax

```
CLOSE WINDOW { identifier | SCREEN }
```

1. *identifier* is the name of the window.

Usage

If the `OPEN WINDOW` statement includes the `WITH FORM` clause, it closes both the form and the window.

Closing a window has no effect on variables that were set while the window was open.

Closing the current window makes the next window on the stack the new current window. If you close any other window, the runtime system deletes it from the stack, leaving the current window unchanged.

If the window is currently being used for input, `CLOSE WINDOW` generates a runtime error.

You can close the default screen window with the `CLOSE WINDOW SCREEN` instruction.

Example

```
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  MENU "Test"
    COMMAND KEY(INTERRUPT) "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

CURRENT WINDOW
Makes a specified window the current window.

Syntax

```
CURRENT WINDOW IS { identifier | SCREEN }
```

1. *identifier* is the name of the window.

Usage

Programs with multiple windows might need to switch to a different open window so that input and output occur in the appropriate window. To make a window the current window, use the `CURRENT WINDOW` statement.

When a program starts, the screen is the current window. Its name is SCREEN. To make this the current window, specify the keyword `SCREEN` instead of a window identifier.

If the window contains a form, that form becomes the current form when a `CURRENT WINDOW` statement specifies the name of that window. All interactive instruction such as `CONSTRUCT`, `INPUT` use only the current window for input and output. If the user displays another form (for example, through an `ON KEY` clause) in one of these statements, the window containing the new form becomes the current window. When an interactive instruction resumes, its original window becomes the current window.

The `CURRENT WINDOW` instruction is typically used in TUI based applications, when distinct areas of the screen are reserved for different usage. In a GUI application, windows are rather opened and closed sequentially or on a stack of windows.

Example

```
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  ...
  OPEN WINDOW w2 WITH FORM "custlist"
  ...
  CURRENT WINDOW IS w1
  ...
  CURRENT WINDOW IS w2
  ...
  CLOSE WINDOW w1
  CLOSE WINDOW w2
END MAIN
```

CLEAR WINDOW

Clears the contents of a window.

Syntax

```
CLEAR WINDOW { identifier | SCREEN }
```

1. *identifier* is the name of the window.

Usage

The `CLEAR WINDOW` instruction clears the content of the specified window that was declared in an `OPEN WINDOW`. If the window was created with borders, these are left untouched (only the content of the window is cleared).

If you specify `CLEAR WINDOW SCREEN`, the root screen will be cleared, except areas occupied by an existing window. `CLEAR WINDOW SCREEN` will not change the current window setting.

The `CLEAR WINDOW` instruction is typically used in TUI based applications, as it clears the whole content of the window, including static labels and messages.

OPEN FORM

Declares a compiled form in the program.

Syntax

```
OPEN FORM identifier FROM filename
```

1. *identifier* is an identifier that defines the name of the form object.
2. *filename* is a string expression defining the name of the compiled form file, without .42f extension.

Usage

In order to use a .42f compiled version of a form specification file, the programs must declare the form with the `OPEN FORM` instruction and then display the form in the current window by using the `DISPLAY FORM` instruction.

`OPEN FORM` / `DISPLAY FORM` are typically used at the beginning of programs to display the main form in the default `SCREEN` window:

```
OPEN FORM custform FROM "customer"
DISPLAY FORM custform
```

The form identifier does not need to match the name of the form specification files, but it must be unique among form names in the program. Its scope of reference is the entire program.

The quoted string that follows the `FROM` keyword must specify the name of the file that contains the compiled screen form. This filename can include a pathname, but this is not recommended.

Form files are found by using the directory paths defined in the DBPATH or FGLRESOURCEPATH environment variable. It is not recommended that you provide a path for *filename*; Instead, use simple file names in programs and put the compiled forms in a directory defines in DBPATH / FGLRESOURCEPATH environment variable.

If you execute an `OPEN FORM` with the name of an open form, the runtime system first closes the existing form before opening the new form.

The scope of reference of form identifier is the entire program.

When the window is dedicated to the form, use the `OPEN WINDOW WITH FORM` instruction to create the window and the form object in one statement.

In TUI mode, the form is displayed in the current window at the position defined by the FORM LINE attribute that can be specified in the ATTRIBUTE clause of OPEN WINDOW or as default with the OPTIONS instruction.

After the form is loaded, you can activate the form by executing a CONSTRUCT, DISPLAY ARRAY, INPUT, INPUT ARRAY, or DIALOG statement. When the runtime system executes the OPEN FORM instruction, it allocates resources and loads the form into memory. To release the allocated resources when the form is no longer needed, the program must execute the CLOSE FORM instruction. This is a memory-management feature to recover memory from forms that the program no longer displays on the screen. If the form was loaded with a window by using the WITH FORM clause, it is automatically closed when the window is closed with a CLOSE WINDOW instruction.

Example

```
MAIN
  OPEN FORM f1 FROM "customer"
  DISPLAY FORM f1
  CALL input_customer()
  CLOSE FORM f1
  OPEN FORM f2 FROM "custlist"
  DISPLAY FORM f2
  CALL input_custlist()
  CLOSE FORM f2
END MAIN
```

DISPLAY FORM
Displays and associates a form with the current window.

Syntax

```
DISPLAY FORM identifier
[ ATTRIBUTES ( display-attributes ) ]
```

1. *identifier* is the name of the form.
2. *window-attributes* defines the display attributes of the form.

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

Usage

The DISPLAY FORM instruction creates a form element in the current window, from a form resource loaded by the OPEN FORM instruction.

> **Important:** The INVISIBLE display attribute is ignored.

The runtime system applies display attributes that you specify in the ATTRIBUTES clause to any fields that have not been assigned attributes by the ATTRIBUTES section of the form specification file, or by the database schema files, or by the OPTIONS runtime configuration statement. If the form is displayed in a window, color attributes from the DISPLAY FORM statement supersede any from the OPEN WINDOW statement. If subsequent CONSTRUCT, DISPLAY, or DISPLAY ARRAY statements that include an

ATTRIBUTES clause reference the form, however, their attributes take precedence over those specified in the DISPLAY FORM instruction.

CLOSE FORM
Closes the resources allocated by OPEN FORM.

Syntax

```
CLOSE FORM identifier
```

1. *identifier* is the name of the form.

Usage

The CLOSE FORM instruction releases the memory allocated to the form.

A form associated with a window by the OPEN WINDOW WITH FORM instruction is automatically closed when the program closes the window with a CLOSE WINDOW instruction.

CLEAR SCREEN
Clears the complete application screen.

Syntax

```
CLEAR SCREEN
```

Usage

The CLEAR SCREEN instruction is typically used in TUI mode to clear the complete screen and make the root screen window the current window on the stack.

The whole screen will be cleared, including prompt, error and message lines (the menu line is not cleared).

DISPLAY AT
Displays text at a given line/column position in the current window.

Syntax

```
DISPLAY text AT line, column [ ATTRIBUTES ( display-attributes ) ]
```

1. *text* is any expression to be evaluated and displayed at the given position in the current window.
2. *line* is an integer expression defining the line position in the current window.
3. *column* is an integer expression defining the column position on the screen.
4. *display-attributes* defines the display attributes for the *text*.

Usage

The DISPLAY AT instruction evaluates a string expression and displays the result at a given line and column in the current window. This instruction is typically used in text-based applications to display static text on the screen such as messages or decoration lines with - (dash) or _(underscore) characters.

The DISPLAY AT instruction should only be used in TUI mode. To display data at a given place in a graphical form, use form fields and the DISPLAY BY NAME or DISPLAY TO instructions, or use interative instructions with the UNBUFFERED mode to automatically display program variable data to form fields.

When using DISPLAY AT in GUI mode, the text will only be displayed if the current window contains no form, or contains a form defined with the SCREEN layout.

Table 226: Display-attributes supported by the DISPLAY AT statement

Attribute	Description
`BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, YELLOW`	The TTY color of the displayed text.
`BOLD, DIM, INVISIBLE, NORMAL`	The TTY font attribute of the displayed text.
`REVERSE, BLINK, UNDERLINE`	The TTY video attribute of the displayed text.

Using images

Describes how to use pictures in the forms of your application.

- Image handling basics on page 782
- Controlling the image layout on page 783
- Providing the image resource on page 784
- Static images on page 787
- Runtime images on page 787

Image handling basics

This is an introduction to image handling in Genero.

Purpose of images in applications

Graphical applications typically use images for different purpose:

- Application icon for the operating system taskbar / window manager.
- Icons in popup messages, menu options, form buttons, toolbars, list elements, treeview nodes.
- Decoration pictures in forms like background images, company logo, etc.
- Application photos, to get a visual identification for objects or people.

Images can be static (like toolbar icons, logos), or can change during the program execution (images related to application data).

In `.per` form definition files, specify static or dynamic image form items, with the IMAGE item type on page 888.

Sources for image data

An image can come from different sources:

- An image file located on the system where the program executes (available on the platform, or from your own application).
- An URL (or URI) resource: the image file is located on a web server an can be downloaded from the internet.
- Image data stored in a database within Binary Large Object (BLOB) typed columns.
- Pictures coming from a mobile device photo gallery, or camera.

In all cases, the image data must be available locally on the front-end platform to be displayed. Since the program can run on a different platform as the front-end, Genero provides several solutions to transmit the image data to the front-end, when the image is not available as a local file. For more details, see Providing the image resource on page 784.

Image triggering actions

If needed, it is possible to associate an action to an image by defining the ACTION attribute. The associated action handler will then be executed in the program code, for example to react on mouse clicks on the image for desktop front-ends:

```
IMAGE i1: logo,
   IMAGE = "genero_logo",
   ACTION = show_about_box;
```

For more details about action handling, see Dialog actions on page 1276.

Controlling the image layout

Explains how image form items can be sized, according to the type of front-end layout system.

Image sizing basics

How an IMAGE item renders on the front-end screen depends on these factors:

- The type of layout used (grid-based or stack-based layout).
- The size of the form item tag in the LAYOUT section, or the WIDTH and HEIGHT attributes defined for the IMAGE item.
- The combination of image item attributes (SIZEPOLICY, AUTOSCALE, STRETCH). These attributes may have a limited effect based on the front-end platform.
- The image resource (actual picture file) size when displayed (especially when SIZEPOLICY=DYNAMIC/INITIAL).
- The scaleIcon presentation style attribute, for elements using icons such as BUTTON or TOOLBAR items.

Image size in grid-based layout

The AUTOSCALE attribute indicates if the picture must be scaled to the available space in the image item. The space is defined by the SIZEPOLICY attribute, the STRETCH attribute, and the form item size (the form item tag in the layout or the WIDTH and HEIGHT attributes).

The STRETCH attribute defines how the image item adapts to the parent container when it is re-sized. The default is NONE.

The SIZEPOLICY attribute defines how the image widget gets its size, according to the context:

- When SIZEPOLICY is INITIAL (the default) and AUTOSCALE is not used, the size of the widget is defined by the first picture displayed in the form element. The size will not change if other pictures with different sizes display in the widget.
- When SIZEPOLICY is DYNAMIC, the size of the widget is automatically adapted to the size of the pictures displayed in the image form item. The AUTOSCALE attribute makes no sense and will have no effect.
- If SIZEPOLICY attribute is set to FIXED, the size of the widget is defined by the form specification file, either by the size of the *item-tag* in the layout, or by the WIDTH and HEIGHT attributes. With a fixed image widget size, if AUTOSCALE is not used, scrollbars may appear if the picture is greater than the widget.

By default, the size of the image widget defaults to the relative width and height defined by the *item-tag* in the form layout section. The size of an image widget can also be specified in the WIDTH and HEIGHT attributes, but these attributes will only have an effect when SIZEPOLICY=FIXED.

> **Note:** On some platforms, the image widgets automatically add a border to the source picture. For these platforms, if the image form item is the same size as the image, you may need to increase the size of the image form item to avoid automatic scrollbars. For example, if your image source has a size of 500x500 pixels and the widget displays a border with as size of 1 pixel, you will have to set WIDTH and HEIGHT to 502 pixels. If you do not, scrollbars will appear or the image will shrink

if AUTOSCALE is used. Alternatively, you can avoid the image border with the `border`presentation style attribute.

Image size in stack-based layout

With a stacked layout, where form items display vertically on each other, by default the image is auto-scaled with the correct aspect/ratio into the available form space.

The image size can be controlled by the HEIGHT attribute.

If the HEIGHT attribute is set, it is expressed in CHARACTERS as for grid-based layout, and the width is determined by the correct aspect/ratio.

Providing the image resource

There are several things you need to know about providing an image resource in a Genero program.

Supported image formats

Genero supports several image data formats, typically PNG, JPEG and SVG. Check the front-end platform documentation for supported image formats. True Type Font (TTF) files are also supported, the TTF format is used when image-to-font-glyph mapping is enabled by specifying a mapping file in the FGLIMAGEPATH environment variable.

Image resolution

Consider using the appropriate image resolution for the target front-end platform. For example, mobile devices have a much higher pixel density (a higher resolution) than desktop monitors. An image which looks nice on a desktop can appear small or as an upscaled image on a mobile device.

Static and dynamic image resources

The image resource specification is different for static and dynamic images:

- For static images (such as button icons), set the image resource in the image attribute (IMAGE, IMAGELEAF, and so on). See Static images on page 787.
- For dynamic images (such as image fields displaying photos from a database), the image resource is specified with the field/variable value, to be rendered in a form field. The form field is typically defined as an IMAGE item, or an IMAGECOLUMN in a table view. For more details, see Runtime images on page 787.

Image resource lookup

The image data can be provided in different ways, according to the image resource specification:

1. As a Uniform Resource Locator (URL).
2. As a simple image name (typical for icons).
3. As a simple file name, typically with a `.png` or `.jpg` extension, or a relative or absolute file path .

Using an URL image resource

If the image specification starts with a URL prefix, the front-end will try to download the image from the location specified by the URL.

The network access to the web server must exist and network bandwidth must be sufficient to rapidly download the images.

Table 227: Supported image resource locations (URLs)

Image resource location (URL)	Description
`http://location-specification`	HTTP server
`https://location-specification`	HTTPS server (HTTP over SSL)

Using a simple image name (centralized icons)

If the image specification is a simple name (without a file extension), and the FGLIMAGEPATH environment variable defines an icon mapping file for the runtime system, the image name is converted to a font file and font glyph according to the mapping file entries, and the image form item displays that glyph/icon. The mapping file and the font definition file are centralized on the application server.

A line in the image-to-font-glyph mapping file must have the following format:

```
image-name=font-file:hexa-ordinal[:color-spec]
```

For example, if the image mapping file defines the following lines:

```
smiley=FontAwesome.ttf:f118
red_smiley=FontAwesome.ttf:f118:#8B0000
```

An image resource (`IMAGE` attribute, `IMAGECOLUMN` value, and so on) with the name "`smiley`" will be mapped to the glyph with ordinal position `0xf118` in the `FontAwesome.ttf` font file, and the image resources using "`red_smiley`" will use the same glyph, but will get a red color.

> **Important:** The directory to the font file must be specified in FGLIMAGEPATH, except if the font file is located in the same directory as the mapping file.

A default color can be defined for all TTF icons of a window, by using the `defaultTTFColor` style attribute:

```
<StyleList>
  <Style name="Window.important">
     <StyleAttribute name="defaultTTFColor" value="red" />
  </Style>
  ...
```

A default mapping file named "`image2font.txt`" and the "`FontAwesome.ttf`" font file are provided in `FGLDIR/lib`. If FGLIMAGEPATH is not defined, the runtime system will use these files to make the image to font glyph mapping.

> **Important:** When providing your own customized font file, it must be a valid TTF file. For example, changing the file name is not sufficient to turn it into another different font: In order to produce a valid TTF file, use font management tools such as FontForge (http://fontforge.github.io/en-US/) or Fontello (http://fontello.com). Further, to target Microsoft Internet Explorer (version 11), you will need to patch the generated TTF file to remove embedding limitations from TrueType fonts, by setting the `fsType` field in the OS/2 table to zero. This modification can be done with freeware tools like ttembed

It is possible to mix several plain image file directories with several image-to-font glyph mapping files in FGLIMAGEPATH. The list of mapping files and directories defines the order of precedence, for example:

```
$ export FGLIMAGEPATH="/var/myapp/myimages:/var/myapp/myicons.txt:/var/
myapp/fontfiles:$FGLDIR/lib/image2font.txt:$FGLDIR/lib"
-- /var/myapp/myimages:           Directory where plain image files can be
 found
-- /var/myapp/myicons.txt:        custom image-to-font-glyph mapping file
 (icons)
```

```
-- /var/myapp/fontfiles:          Font files used by the myicons.txt mapping
 file
-- $FGLDIR/lib/image2font.txt:    Genero default icon mapping files
 (using FontAwesome.ttf)
```

Consider defining your own image mapping file and make FGLIMAGEPATH point to your own files.

> **Note:** When executing the application on a mobile device, you must define the FGLIMAGEPATH environment variable with the `mobile.environment.FGLIMAGEPATH` entry in FGLPROFILE. Use $FGLAPPDIR and $FGLDIR placeholders to include the current *`appdir`* (i.e. program file directory) and the FGL runtime system directory, respectively.

See FGLIMAGEPATH on page 182 for more details about this environment variable.

Using file names or paths

If the image specification is a simple file path (without an URL prefix, and typically with an image file extension), the front-end gets the image file from the runtime system. The image file is searched on the platform where the program executes. The runtime system uses FGLIMAGEPATH on page 182 environment variable when searching for the images. If FGLIMAGEPATH is not set, the current working directory is searched for the image files.

The front-end provides the name of the image file, and a list of supported file extensions. The runtime system searches for image files in different locations as described here: The search depends on the name of the image file, the list of directories defined in FGLIMAGEPATH, and the expected file extensions provided by the front-end.

For example:

- Name of the image file: "`mycalendar`"
- FGLIMAGEPATH="`/var/myapp/myicons/common:business`"
- Extensions provided by front-end: "`.jpg, .png`"

The search for the image file would be as follows:

1. `/var/myapp/myicons/common/mycalendar`
2. `/var/myapp/myicons/common/mycalendar.jpg`
3. `/var/myapp/myicons/common/mycalendar.png`
4. `business/mycalendar`
5. `business/mycalendar.jpg`
6. `business/mycalendar.png`

This search procedure using a proposal of file extensions was implemented to allow different type of front-ends to pass the type of image compression format required, so you can define the image name in your forms without any extension. However, it is much more efficient to specify the image file with a portable extension.

When FGLIMAGEPATH is defined, the current working directory is not searched. If you want to look for image files in the current working directory and in other directories, add "." to the FGLIMAGEPATH path list.

> **Note:** When specifying a file name as an image resource, consider using the extension (`.png`, `.jpg`), to avoid unnecessary file searching, trying different combinations with all supported formats (FGLIMAGEPATH). The file extension will also be used by the front-end to easily identify the compression format (for example, to define the Content-Type in an HTML entity).

Application images in Web Components

Web Components can display static images (part of the Web Component assets), and application images provided at runtime (for example, a photo gallery web component). In order to provide application images

to a Web Component, the program must use the `ui.Interface.filenameToURI()` method to convert the local file name to a URI that can be accessed by the front-end.

For more details, see Using image resources with the gICAPI web component on page 1430.

Static images
Describes how to decorate forms with icons.

Static image usage context

Static images are application pictures that do not change during program executing, like icons in toolbar buttons and window icons.

Static images can be defined in different contexts withing form definition, or configuration files:

- Global application icon for platform window managers (taskbars), by using the ui.Interface.setImage on page 1766 method. For mobile devices, the application icon should be provided in the installation package (.apk for Android™, .ipa for iOS).
- Window specific icons, with the `IMAGE` attribute in the `LAYOUT` definition of a form (recommended) or at runtime, with the ui.Window.setImage on page 1773 method (if it must be changed during program execution).
- As default icon for action action views, with the `IMAGE` action configuration attribute (in action defaults for example).
- As specific action view icons, directly in the form item definition with the `IMAGE` attribute (for toolbars, menu items, buttons, buttonedits, etc).
- Image form items (logos), defined by the `IMAGE item-tag : item-name` syntax, using the `IMAGE` attribute.
- Default treeview node icons, with the `IMAGEEXPANDED`, `IMAGECOLLAPSED`, `IMAGELEAF` attributes of a `TREE` container.

Static image examples

The following code example, defines an `ITEM` toolbar element using a icon, that is specified with the `IMAGE` attribute:

```
TOOLBAR
   ITEM print ( TEXT="Print", IMAGE="printer" )
```

Next example defines a `BUTTONEDIT` form field with an icon named "listchoice":

```
ATTRIBUTES
BUTTONEDIT f05 = customer.cust_city,
    ACTION=get_city,
    IMAGE="listchoice",
    ... ;
```

Runtime images
Explains how to display pictures at runtime.

Dynamic image usage context

Application images like photos or variable icons (in list views) are only known at runtime, and will be displayed during program execution. Such images are typically centralized on a server, as BLOBs in a database, or on the file system, as regular files.

For simple files (not URLs), images to be displayed are automatically handled by Genero: the program just needs to specify the name of the file to be displayed.

This section describes programming patterns to handle application images. For a complete description of the mechanisms to provide images to front-ends, see Providing the image resource on page 784.

IMAGE form fields

To display a picture dynamically in a form area, you must define a form field with the `IMAGE` item type:

```
LAYOUT
GRID
{
[img1                  ]
[                      ]
[                      ]
}
END
END
ATTRIBUTES
IMAGE img1 = FORMONLY.image_field, AUTOSCALE, ...
```

The program can then display an image dynamically by assigning the image resource to the form field, for example, with a `DISPLAY TO` instruction:

```
DEFINE image_field STRING
LET image_field = "local_image_file.png"
DISPLAY BY NAME image_field
```

It is also possible to use the program variable containing the image resource in a dialog using the `UNBUFFERED` option:

```
DEFINE rec RECORD
               pk INT,
               name VARCHAR(30),
               image_field VARCHAR(50)
           END RECORD
INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
   ON ACTION set_picture
      LET rec.image_field = "local_image_file.png"
...
```

IMAGECOLUMN attribute of TABLE/TREE

The `IMAGECOLUMN` attribute can be used to define a `PHANTOM` field that will hold the image resource for a `TABLE` or `TREE` column:

```
...
ATTRIBUTES
PHANTOM FORMONLY.item_icon;
EDIT FORMONLY.item_desc, IMAGECOLUMN=item_icon;
...
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.item_icon, FORMONLY.item_desc, ...);
...
```

In the program code, the image resource will be specified in the array member attached to the icon field. Each row can define a different image for the cell:

```
LET arr[1].item_icon = "honda_logo.png"
LET arr[1].item_desc = "Honda CB600 Hornet (red)"
LET arr[2].item_icon = "honda_logo.png"
```

```
LET arr[2].item_desc = "Honda CB1000r (black)"
LET arr[3].item_icon = "ducati_logo.png"
LET arr[3].item_desc = "Ducati Diavel Carbon"
DISPLAY ARRAY arr TO sr.*
   ...
```

Displaying images contained in BYTE variables

Application images managed by a program can be held in a `BYTE` variable. You need to use this data type to interface with databases storing images in Binary Large OBject (BLOB) columns.

When using an `IMAGE` field, if the BYTE variable holding the image data is located in a file (`LOCATE IN FILE`), the runtime system can automatically send the content of the `BYTE` file to the front-end when doing a `DISPLAY BY NAME`, `DISPLAY TO field`, or if the `BYTE` variable is controlled by a dialog using the `UNBUFFERED` option.

```
DEFINE pb BYTE
LOCATE pb IN FILE -- temp file used
...
OPEN FORM f1 FROM "myform"
DISPLAY FORM f1
...
SELECT image_col INTO pb FROM mytable WHERE pk = ...
DISPLAY pb TO image_field
...
```

Further, if the image data is modified, without changing the name of the file (i.e., without a new LOCATE IN FILE instruction), the runtime system detects the file modification time, and if needed, re-sends the image data to the front-end. For example, consider the following program flow:

```
DEFINE pb BYTE
LOCATE pb IN FILE -- temp file used
...
-- A first SELECT fetches image data from row 345 into the BYTE
SELECT image_col INTO pb FROM mytable WHERE pk = 345
-- And displays the BYTE image to a field
DISPLAY pb TO image_field
-- A second SELECT fetches new image data from row 672 into the BYTE
SELECT image_col INTO pb FROM mytable WHERE pk = 672
-- And displays the BYTE image to a field
DISPLAY pb TO image_field
-- The BYTE file name has not changed, only the image data has changed
...
```

Images on mobile devices

When executing the application on a mobile device, it is possible to use a front call to choose or take a photo. Those front calls return an opaque file identifier referencing an image in the device photo gallery (or database).

On all mobile platforms, you can directly display the returned opaque file path to an `IMAGE` form field:

```
DEFINE path STRING
-- Here we use "choosePhoto" front call, could be "takePhoto"
CALL ui.Interface.frontCall("mobile", "choosePhoto", [], [path])
DISPLAY path TO ff_image
```

Consider the path returned by such a front call as an opaque local file identifier, and do not use it as a persistent file name for the picture. For example, if you store such a path name in a database, and if the mobile photo gallery storage technology changes, the stored file names will no longer be valid.

If you need to keep the image data in the application (to store it in a local file or in the database), grab the image data into the runtime system context with a `fgl_getfile()` call. The mobile picture *path* can be used in a `fgl_getfile()` call to the photo from the mobile device into the file storage context where the runtime system executes. When the runtime system executes on the mobile device, the `fgl_getfile()` call will copy the picture to the application sandbox. If the program executes on an application server, the call will transfer the picture to the application server file system. It is possible to load the picture data into a BYTE variable, by transferring the image data directly into the file used by the BYTE variable locates in `byte_file`, by doing a `fgl_getfile(`*`mobile_path, byte_file`*`)`. It is also possible to keep the transferred files on the file system where the VM executes, if you do not want to use BYTE variables to store images in your database.

```
CONSTANT vm_fn = "mypic.tmp"
DEFINE md_fn STRING, image BYTE
CALL ui.Interface.frontCall(
        "mobile",
        "choosePhoto",  -- could be "takePhoto"
        [], [md_fn])
CALL fgl_getfile(md_fn,vm_fn)
LOCATE image IN FILE vm_fn
DISPLAY image TO ff_image
UPDATE mytab SET pic = image WHERE ...
```

> **Note:** When using `fgl_getfile()` in conjunction with BYTE variables located in files, pay attention to the fact that `INITIALIZE` *`byte_var`* `TO NULL` will set the internal null indicator of the BYTE variable, and a subsequent `fgl_getfile(`*`mobile_path, byte_file`*`)` will only modify the file without touching the null flag. The recommended pattern is to re-locate the BYTE variable after the `fgl_getfile()` call:
>
> ```
> CALL fgl_getfile(mobile_path, byte_file)
> LOCATE byte_var IN FILE byte_file
> ```

Videos on mobile devices

Let the user take videos or choose videos from the gallery with the takeVideo on page 1939 and chooseVideo on page 1927 front calls.

Similar to photo front calls, the video front calls return an opaque path to the video file, which can then be used in the `fgl_getfile()` function to transfer the video file from the device context to the runtime system context in a BYTE variable for persistent storage.

> **Note:** The opaque path can, however, be used to show the video with the `"launchURL"` front call.

For example:

```
IMPORT os

CONSTANT VM_MOVIES = "./movies"

MAIN
  DEFINE r INTEGER,
         mb_path STRING,
         vm_path STRING

  LET r = os.Path.delete(VM_MOVIES)
  LET r = os.Path.mkDir(VM_MOVIES)

  MENU
    COMMAND "take_video"
      CALL ui.Interface.Frontcall("mobile", "takeVideo", [], [mb_path])
      IF mb_path IS NOT NULL THEN
```

```
         LET vm_path = SFMT("%1/%2", VM_MOVIES, os.Path.baseName(mb_path) )
         CALL fgl_getfile(mb_path, vm_path)
      END IF
    COMMAND "choose_video"
      CALL ui.Interface.Frontcall("mobile", "chooseVideo", [], [mb_path])
      IF mb_path IS NOT NULL THEN
         LET vm_path = SFMT("%1/%2", VM_MOVIES, os.Path.baseName(mb_path) )
         CALL fgl_getfile(mb_path, vm_path)
      END IF
    COMMAND "show_video"
      IF mb_path IS NOT NULL THEN
         CALL ui.Interface.Frontcall("standard", "launchURL", [mb_path], [])
      END IF
    COMMAND "quit"
      EXIT MENU
  END MENU

END MAIN
```

Accessibility guidelines

This section describes the best practices to make a your application accessible to disabled people.

- Keyboard access on page 791
- Form description for screen readers on page 792
- Usability and ergonomics on page 793

Keyboard access

Defining keyboard accelerators for every action

Since a mouse or other pointing devices may not be used by people with reduced vision, an accessible application must be usable with the keyboard alone. Therefore, all the possible actions that could be triggered by a user must have a keyboard shortcut.

We strongly suggest that you define consistent keyboard shortcuts for all actions through the use of action defaults. Developers can avoid overriding the system default shortcuts by checking the target platform guidelines, especially for system shortcuts that trigger accessible actions (for example, Ctrl-Shift-Enter, which triggers spoken information about the currently selected item). Overriding system shortcuts is generally a bad practice, even for non-accessible applications, although overriding may be unavoidable due to compatibility issues.

Keyboard focus and action views

Generally, keyboard navigation in an application may be easier if you keep the `MENU` actions in the menu frame; the actions can have the keyboard focus and the user can navigate through them using the up and down arrows.

You can also use a `TOPMENU`, because you can pull it down with the keyboard (for example, the Alt key on Windows™) and then navigate using arrow keys, but it may be less accessible than the menu panel. You must also be sure that every item of the menu can be activated by a keyboard shortcut. You may use the & (ampersand) in menu items to specify character which letter should be used, to let the front-end automatically create a shortcut to trigger the action with that letter.

Avoid using toolbars only in an accessible application, because toolbars by default are not accessible using the keyboard. Toolbars cannot have the keyboard focus, and there is no way to navigate through all toolbar items or to activate one of them using the keyboard. If you do use toolbars, provide keyboard shortcuts and duplicate them in a topmenu.

Form description for screen readers

Understanding screen readers

Screen readers are special system applications that transform the application's graphical user interface into speech. The behavior may change between screen reader implementations, but, basically, each widget is named and described by speech. On some workstation operating systems, special keyboard shortcuts are available to trigger the complete enumeration of all the components of a window, or to describe only the component having the current focus.

Providing form item descriptions to screen readers

Screen readers use special bindings to get the information that they need (name, full description, hierarchy, triggered actions, and so on) about each graphical component of the entire graphical user interface. It is up to the programmer to provide these bindings to the screen reader, but most of the work is already done by the front-end.

Programmers can provide two things for each widget to provide speech information to screen readers:

- an accessible **name**, using the `TEXT` form attribute if available, otherwise with the `COMMENT` form attribute.
- an accessible **description**, with the `COMMENT` form attribute.

This can be tedious, but it absolutely must be done carefully, keeping in mind that the text will be spoken. As such, *customer's name* is preferable to *cust_name_str*.

Spaces and punctuation are allowed.

Most of the form items are supported: All kind of form field, static labels, static images, and action-based items (such as buttons); some containers (`GROUP` and `FOLDER`) should work out of the box as soon as their `TEXT` attributes are set.

Examples

In an action defaults file (mydefaults.4ad)

```
<ActionDefaultList>
  <ActionDefault name="new" text="New..." image="new.svg"
     comment="Create a new database"
   acceleratorName="control-n" />
  <ActionDefault name="open" text="Open..." image="open.svg"
     comment="Open an existing database"
   acceleratorName="control-o" />
  <ActionDefault name="save" text="Save" image="save.svg"
     comment="Save the current database"
   acceleratorName="control-s" />
  ...
```

In field definitions on a form specification file (myform.per)

```
ATTRIBUTES
  EDIT login_name = formonly.login_name, NOT NULL,
    COMMENT="Login name of the current user";
  EDIT password = formonly.password, NOT NULL, INVISIBLE,
 VERIFY,
    COMMENT="Password of the current user";
  EDIT first_name = formonly.first_name, NOT NULL,
    COMMENT="First name of the current user";
  EDIT last_name = formonly.last_name, NOT NULL,
    COMMENT="Last name of the current user";
  DATEEDIT birthdate = formonly.birthdate, FORMAT="mm/dd/yyyy",
    COMMENT="Date of birth of the current user";
```

```
  EDIT email = formonly.email,
    COMMENT="E-mail of the current user";
END -- ATTRIBUTES
```

In this form specification file, the `COMMENT` attribute is used for both the accessible name and the accessible description.

Usability and ergonomics

Design simple application forms

Keep your forms as simple as possible. Because everything will be described by the screen reader software, it is preferable to have a lot of small and concise forms with a few fields. With forms containing a lot of labels and fields, the screen reader will take a long time to enumerate every name and description. The end user must be able to make a picture of the form in their mind, according to the form description.

Make form content bigger

Consider using a special .4st presentation styles file defining big fonts, big icons, and high contrast color themes; This will make your application a lot more efficient for users who are partially sited. Forms will take more space on the screen, assuming that the forms have a limited number of fields to have sufficient room for large widgets.

Use large icons (such as 64x64 pixel icons), for people with impaired vision. Do not forget that most of the default sizes (font, icons, gui components, and so on) were set when the default resolution was 640*640 pixels in 16 colors. Now, even if the user has very good eyes, with the screen resolution available today, old-style icons look small.

Use a high contrast color theme. Although support of the system high contrast theme is only partial, nothing prevents you from setting up the correct theme using a specific presentation style attributes.

Example

Presentation styles file defining larger, bolder fonts and large icons:

```
<StyleList>

  <Style name="*" >
    <StyleAttribute name="fontSize" value="10" />
  </Style>

  <Style name="Action" >
    <StyleAttribute name="scaleIcon" value="28px"/>
    <StyleAttribute name="fontSize" value="12" />
  </Style>

  <Style name="Window" >
    <StyleAttribute name="actionPanelPosition" value="bottom"/>
    <StyleAttribute name="actionPanelButtonSpace" value="huge"/>
    <StyleAttribute name="actionPanelHAlign" value="center"/>
    <StyleAttribute name="ringMenuPosition" value="bottom"/>
    <StyleAttribute name="ringMenuButtonSpace" value="huge"/>
    <StyleAttribute name="ringMenuHAlign" value="center"/>
  </Style>

  <Style name="ToolBar" >
    <StyleAttribute name="scaleIcon" value="32px"/>
  </Style>

  <Style name="Edit:focus" >
    <StyleAttribute name="fontWeight" value="bold" />
```

```
    <StyleAttribute name="backgroundColor" value="darkBlue" />
    <StyleAttribute name="textColor" value="white" />
  </Style>

</StyleList>
```

Message files

Message files centralize strings and larger texts identified by a number, that can be used in programs.

- Understanding message files on page 794
- Syntax of message files (.msg) on page 794
- Using message files on page 795
  - Compiling message files on page 795
  - Using message files at runtime on page 795
- Examples on page 796
  - Example 1: Help message file used in a MENU on page 796

Understanding message files

Message files define text messages with a unique integer identifier.

Several message files can be created and loaded by the same program.

Message files are typically used to implement application help system, and are especially designed for the the TUI mode.

In order to use a message file, do the following:

1. Create the .msg source message file with a text editor.
2. Compile the source message file with fglmkmsg to create the .iem binary format.
3. Copy the binary file to a distribution directory.
4. In programs, specify the message file with the `OPTIONS HELP FILE` instruction.
5. Use a specific message with the `HELP` clause of dialogs, or load a given message with the `SHOWHELP( )` function.

Message files provide a simple way to implement a help system in your application.

For other application messages and texts, consider using localized strings instead of message files.

Syntax of message files (.msg)

A message file contains a set of messages identified by an integer number.

```
filename.msg
```

1. *filename* is the name of the message source file.

Syntax of a message file

```
{
  message-definition
| include-directive
}[...]
```

where *message-definition* is:

```
.message-number
message-line | new-page
```

```
[...]
```

where *include-directive* is:

```
.include filename
```

And where *new-page* is:

```
^L (Control-L, ASCII 12)
```

1. *message-number* is an integer in the range -2147483648 to 2147483647.
2. You can split the message into pages by adding the ^L (Control-L / ASCII 12) in a line.
3. Note that multi-line messages will include the newline (ASCII 10) characters.

Using message files
To use message files, you must understand how they work and how to structure the code.
Compiling message files

In order to use message files in a program, the message source files (with .msg extension) must be compiled with the fglmkmsg utility to produce compiled message files (with .iem extension).

The following command line compiles the message source file mess01.msg:

```
fglmkmsg mess01.msg
```

This creates the compiled message file mess01.iem.

For backward compatibility, you can specify the output file as second argument:

```
fglmkmsg mess01.msg mess01.iem
```

The .iem compiled version of the message file must be distributed on the machine where the programs are executed.

Using message files at runtime

In order to use compiled message files (`.iem`) in programs, specify the current message file with the `OPTIONS HELP FILE` command:

```
OPTIONS HELP FILE "mymessages.iem"
```

The message file will first be searched with the string passed to the `OPTIONS HELP FILE` command (i.e. the current directory if the file is specified without a path), and if not found, the DBPATH / FGLRESOURCEPATH environment variable with be used.

After the message file is defined, you can start the help viewer by calling the `SHOWHELP()` function:

```
CALL showhelp(1242)
```

Use the `HELP` clause in a dialog instruction such as `INPUT` to define particular message number for that the dialog:

```
INPUT BY NAME ... HELP 455
```

The help viewer will automatically display the message text corresponding to the number when the user pressed the help key. By default, the help key is Ctrl-W in TUI mode and F1 in GUI mode.

Note that you can implement your own help viewer by overloading the `SHOWHELP()` function defined in `FGLDIR/src/fglhelp.4gl`. This allows you to customize the help system for your application.

Examples

Example 1: Help message file used in a MENU

The message source file help.msg:

```
.101
This is help about option 1
.102
This is help about help
.103
This is help about My Menu
```

Compiling the message file:

```
$ fglmkmsg help.msg
```

Program using the .iem compiled message file.

```
MAIN
    OPTIONS
        HELP FILE "help.iem"
    MENU "Sample"
        COMMAND "Option 1" HELP 101
            DISPLAY "Option 1 chosen"
        COMMAND "Help"
            CALL showhelp(103)
    END MENU
END MAIN
```

Action defaults files

Action defaults files allow to centralize action configuration parameters such as text, icon, accelerators and behavior options in XML format.

- Understanding action defaults files on page 796
- Syntax of action defaults file (.4ad) on page 796
- Action default attributes reference (.4ad) on page 797
- Examples on page 799
  - Example 1: Loading a global action defaults file on page 799

Understanding action defaults files

Action defaults files define the defaults for action attributes in an XML file. These defaults can be overwritten with form item attributes, or with dialog action handler attributes, when using default action views.

This section describes only the `.4ad` action defaults file reference, for more details see Configuring actions on page 1318.

Syntax of action defaults file (.4ad)

Action defaults are defined in the .4ad file with this syntax:

```
<ActionDefaultList>
  <ActionDefault name="action-name" [ attribute=value [...] ] />
  [...]
</ActionDefaultList>
```

1. *action-name* identifies the action.
2. *attribute* is the name of an attribute.

3. *value* defines the value to be assigned to *attribute*.

Action default attributes reference (.4ad)

Table 228: Action default attributes

Attribute	Description
`name = "action-name"`	This attribute identifies the action.
`text = "action-label"`	The default label to be displayed in action views (typically, the text of buttons). See also: TEXT attribute on page 987
`comment = "action-comment"`	The default help text for this action (typically, displayed as bubble help). See also: COMMENT attribute on page 959
`image = "action-icon"`	The default image file to be displayed in the action view. See also: IMAGE attribute on page 967
`acceleratorName = "key-name"`	The default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1343. See also: ACCELERATOR attribute on page 953
`acceleratorName2 = "key-name"`	The second default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1343. See also: ACCELERATOR2 attribute on page 953
`acceleratorName3 = "key-name"`	The third default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1343. See also: ACCELERATOR3 attribute on page 954
`acceleratorName4 = "key-name"`	The fourth default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1343. See also: ACCELERATOR4 attribute on page 954
`defaultView = {"yes"|"no"|"auto"}`	Defines whether the front-end must show the default action view (buttons in control frame). Values can be: • `"no"` the default action view is never visible. • `"yes"` the default action view is always visible, if the action is visible (`ui.Dialog.setActionHidden`).

Attribute	Description
	• `"auto"` the default action view is visible if no other action view is explicitly defined and the action is visible (`ui.Dialog.setActionHidden`). The default is `"auto"`. See also: DEFAULTVIEW attribute on page 961
`contextMenu = {"yes"|"no"|"auto"}`	Defines whether the front-end must render the action in the default context menu. Values can be: • `"no"` the context menu option is never visible. • `"yes"` the context menu option is always visible, if the action is visible (`ui.Dialog.setActionHidden`). • `"auto"` the context menu option is visible if no other action view is explicitly defined and the action is visible (`ui.Dialog.setActionHidden`). The default is `"yes"`. See also: CONTEXTMENU attribute on page 958
`validate = "no"`	Defines the behavior of data validation when the action is invoked. Values can be: • `"no"` no data validation is done (field text only available in input buffer). By default, data validation is driven by the dialog mode (`UNBUFFERED` or default mode). For more details, see Data validation at action invocation on page 1331. See also: VALIDATE attribute on page 991

Using action defaults files

To use action default files, you must understand how they work and how to structure the code.

Using action defaults files at runtime

Global action defaults are defined in an XML file with the `4ad` extension. By default, the runtime system searches for a file named `default.4ad` in the current directory. If the file does not exist, it searches in the directories defined by the FGLRESOURCEPATH (or DBPATH) environment variable. If no file was found using the environment variable(s), standard action default settings are loaded from the `FGLDIR/lib/default.4ad` file.

Action defaults files usage is related to action configuration concepts. For more details, see Configuring actions on page 1318.

Examples
Example 1: Loading a global action defaults file

Some Action Defaults in XML format (exit action has Localized Strings):

```
<ActionDefaultList>
   <ActionDefault name="print" text="Print" image="printer"
       comment="Print report" />
   <ActionDefault name="modify" text="Update"
       comment="Update the record" />
   <ActionDefault name="exit" text="Quit" image="byebye"
       comment="Exit the program" validate="no" >
       <LStr text="common.exit.text" />
   </ActionDefault>
</ActionDefaultList>
```

The program loading the action defaults file:

```
MAIN
  CALL ui.Interface.loadActionDefaults("mydefaults")
  OPEN FORM f FROM "myform"
  DISPLAY FORM f
  ...
END MAIN
```

Presentation styles

Use presentation styles to specify decoration attributes for window and form elements.

- Understanding presentation styles on page 799
- Syntax of presentation styles file on page 801
- Using presentation styles on page 801
- Predefined attribute values on page 807
- Style attributes reference on page 818
- Examples on page 849

Understanding presentation styles

Presentation styles centralize the attributes related to the decoration of the graphical user interface elements.

The decoration attributes are defined in a separate file, which can be easily modified to customize the application.

Presentation styles are only supported for the GUI front-ends. If you design an application for the TUI mode, you can use TTY attributes.

Styles are applied implicitly by using global styles, or explicitly by naming a specific style in the `style` attribute of the element.

Common presentation attributes define font properties, foreground colors and background colors. Some presentation attributes are specific to a given class of widgets (like the first day of the week in a `DATEEDIT`).

Presentation styles are defined in a resource file having an extension of `.4st`. The `.4st` file must be distributed with the other runtime files.

Presentation styles are inspired from the *cascading style sheets* (CSS) used in HTML, with the following deviations:

1. The elements using style definitions are AUI tree elements; CSS styles apply to HTML elements.
2. To specify a style for an AUI tree element, you must use the "style" attribute; HTML/CSS use the "class" attribute.

3. Inline-style definition is not supported in the AUI tree.
4. Some pseudo selectors, such as "query, are specific to Genero.

Figure 41: Form without presentation styles (GDC) on page 800 shows a desktop application without presentation styles:

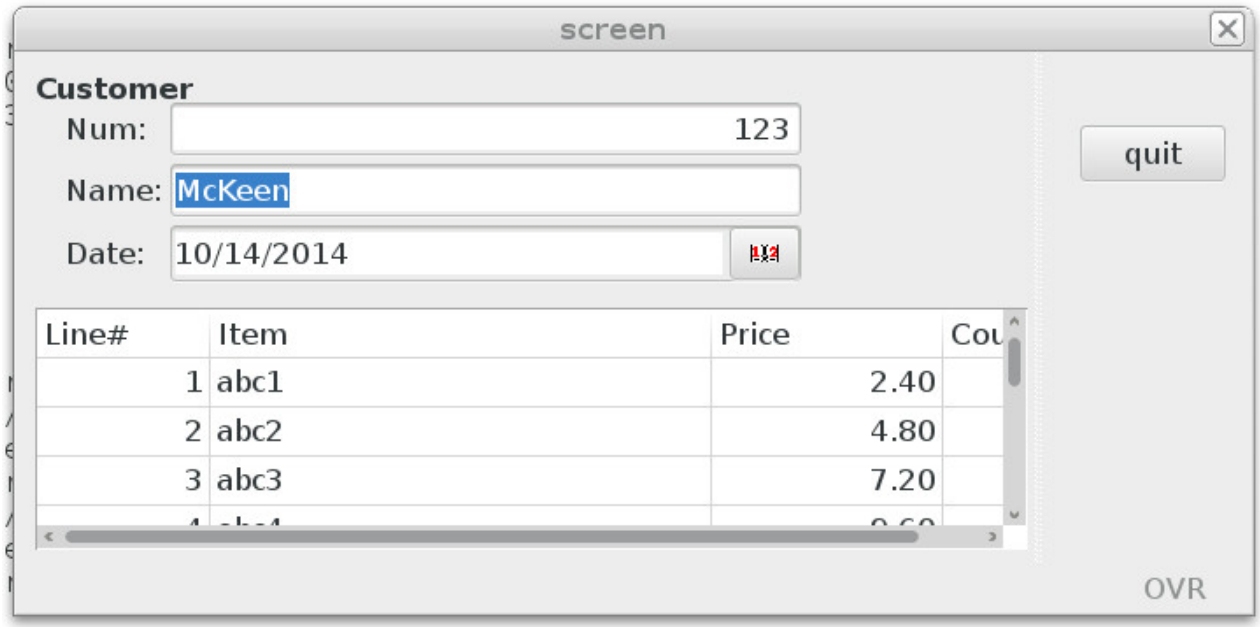

Figure 41: Form without presentation styles (GDC)

Figure 42: Form using presentation styles (GDC) on page 800 shows a desktop application without presentation styles:

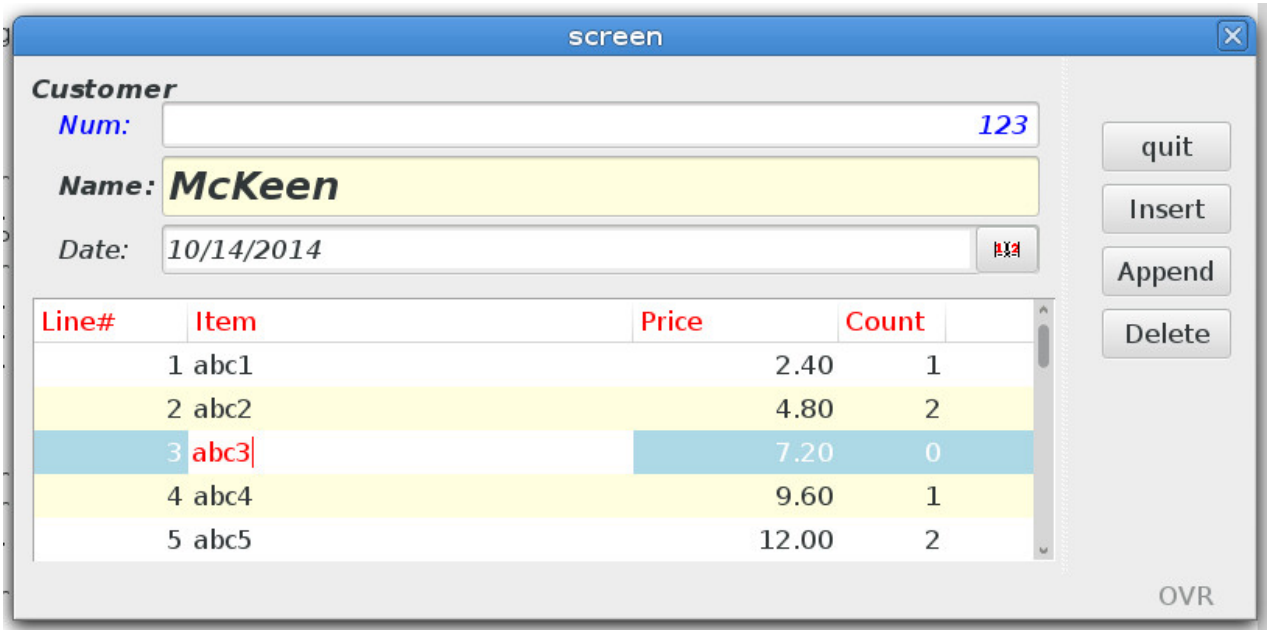

Figure 42: Form using presentation styles (GDC)

Syntax of presentation styles file

A presentation styles file (4st) is an XML file comprised of `StyleList`, `Style`, and `StyleAttribute` elements.

Syntax (.4st)

```
<StyleList>
  <Style name="style-identifier" >
    <StyleAttribute name="attribute-name" value="attribute-value" />
      [...]
  </Style>
  [...]
</StyleList>
```

where *style-identifier* is:

```
{ [ element-type ] [ .style-name ] [ :pseudo-selector ]
| *
}
```

1. *element-type* is a type of AUI tree element, such as `Edit`, `Window`.
2. *style-name* is an explicit style name, that can be referenced in `STYLE` attributes of form items.
3. *pseudo-selector* indicates in what context the style should apply.
4. *attribute-name* defines the name of the style attribute.
5. *attribute-value* defines the value to be assigned to *attribute-name*.

Syntax of attribute values

Presentation style attribute values are always specified as strings, for example:

```
<StyleAttribute name="fontFamily" value="Serif" />
```

Numeric values must be specified in quotes:

```
<StyleAttribute name="completionTimeout" value="60" />
```

Boolean values must be specified with the values `"yes"` or `"no"`:

```
<StyleAttribute name="forceDefaultSettings" value="yes" />
```

> **Note:** Some front-ends may also support the boolean values `0/1` and `true/false`. However, it is recommended to use `yes/no` values only.

Using presentation styles

Use presentation styles to centralize the decoration of your user interface.

- Understanding presentation styles on page 799
- Defining a style on page 802
- Pseudo selectors on page 802
- Using a style on page 804
- Order of precedence on page 804
- Combining styles on page 805
- Style attribute inheritance on page 805
- Presentation styles in the AUI tree on page 805
- Loading presentation styles on page 805
- Combining TTY and style attributes on page 806

- Element types on page 807

Defining a style
Styles can be defined to be global (for all elements), for an element in general, or for specific types of an element.

The style is identified by the `name` attribute, that can be a combination of element type, style name and pseudo selector, or the star character. See Syntax of presentation styles file on page 801 for a complete description of the presentation style definition syntax.

In the definition of a style, the `name` attribute is used as a selector to apply style attributes to graphical elements.

You can define a style as global or specific to a class of graphical object:

- A style identified by a star (`*`) is a global style that is automatically applied to all elements:

```
<Style name="*" >
```

- A style identified by an *element-type* is a global style that is automatically applied to all objects of this type:

```
<Style name="ComboBox" >
```

- A style identified by a *style-name* is a specific style that can be applied to any element types using that style name in a `STYLE` attribute:

```
<Style name=".important" >
```

- A style identified by an *element-type* followed by a dot and a *style-name* is a specific style that will only be applied to elements of the given type and using the style name in a `STYLE` attribute:

```
<Style name="Window.main" >
```

- A style identified by an *element-type* followed by a colon and a *pseudo-selector* is a style that will only be applied to elements of the given type, if the condition defined by the pseudo-selector is satisfied:

```
<Style name="Edit:focus" >
```

- A style identified by an *element-type* followed by a dot and a *style-name*, and a colon with a pseudo-selector, is a specific style that will only be applied to elements of the given type, using the style name in a `STYLE` attribute, if the condition defined by the pseudo-selector is satisfied:

```
<Style name="Edit.important:focus" >
```

- It is possible to combine pseudo-selectors:

```
<Style name="Edit:query:focus" >
```

Pseudo selectors
Pseudo selectors can be used to apply only when some conditions are fulfilled.

Pseudo selectors are preceded with a colon and can be combined:

```
<Style name="Table:even:input" >
<Style name="Edit:focus" >
<Style name="Edit.important:focus" >
```

When combining several pseudo selectors, the style will be applied if all pseudo selector conditions are fulfilled.

Note: Depending on the type of the front-end, some pseudo selectors are meaningless, or unsupported. See the table below to check which pseudo selectors are supported on your front-end platform.

Pseudo selectors have different priorities; the style with the most important pseudo selector will be used when several styles match.

Table 229: Pseudo selectors for presentation styles

Priority	Pseudo selectors	Condition	GDC	HTML5	GMA	GMI
1	`focus`	The widget has the focus	Yes	Yes	Yes	Yes
2	`query`	The widget is in construct mode	Yes	Yes	Yes	Yes
3	`display`	The widget is in a display array	Yes	Yes	Yes	Yes
4	`input`	The widget is in an input array, input or construct	Yes	Yes	Yes	Yes
5	`even`	This widget is on an even row if an list (Table or Tree)	Yes	Yes	No	No
6	`odd`	This widget is on an odd row if an list (Table or Tree)	Yes	Yes	No	No
7	`inactive`	The widget is inactive	Yes	Yes	Yes	Yes
8	`active`	The widget is active	Yes	Yes	Yes	Yes
9	`message`	Applies only to text displayed with the `MESSAGE` instruction	Yes	Yes	Yes	Yes
10	`error`	Applies only to text displayed with the `ERROR` instruction	Yes	Yes	Yes	Yes
11	`summaryLine`	Applies only to text displayed in `AGGREGATE` fields of tables	Yes	Yes	No	No

Pseudo selectors also define the priority of your styles. A more generic style will be used when the pseudo-selector has a higher priority.

For instance: you want all important edits to have red text, but you want the current field to be displayed in blue:

```
<Style name="Edit.important" >
<Style name=":focus" >
```

The style "`:focus`" is more generic than "`Edit.important`"; therefore, it will be used for the focused item, as the pseudo selector is more precise.

Using a style

To apply a specific style, set the *style-name* in the `style` attribute of the node representing the graphical element in the abstract user interface tree.

There are different ways to set the `style` attribute of a element:

- As a form element attribute, with a `STYLE` attribute in the form specification file.
- In the `ATTRIBUTES` clause of instructions such as `OPEN WINDOW`, `MESSAGE`, `ERROR`.
- Dynamically by a program, using the ui.Form.setElementStyle() method.

For example, to define a style in a form file for a input field:

```
EDIT f001 = customer.fname, STYLE = "info";
```

> **Note:** The string used to define the `STYLE` attribute must be a *style-name* only, it must not contain the *element-type* that is typically used to define the style in a `.4st` file (as `CheckBox.important` for example)

Order of precedence

Style definitions are applied according to the order of precedence.

If different styles can be applied to an element, the following priority is used to determine the style definition to be applied:

1. *element-type*.*style-name*:*pseudo-selector*
2. .*style-name*:*pseudo-selector*
3. *element-type*.*style-name*
4. *element-type*:*pseudo-selector*
5. :*pseudo-selector*
6. .*style-name*
7. *element-type*
8. *

> **Note:** The precedence rules to apply styles may vary according to the front-end type. As a general rule, Genero presentation styles precedence rules are similar HTML/CSS precedence rules.

For example, consider an `Edit` element with the style attribute set to '`mandatory`':

```
EDIT f1 = FORMONLY.cust_name, STYLE="mandatory"
```

With the following style definitions (`mystyles.4st`):

```
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <Style name="Edit.mandatory:focus">
     <StyleAttribute name="backgroundColor" value="yellow" />
  </Style>
  <Style name=".mandatory:focus">
     <StyleAttribute name="backgroundColor" value="blue" />
  </Style>
  <Style name="Edit.mandatory">
     <StyleAttribute name="backgroundColor" value="green" />
  </Style>
  <Style name="Edit:focus">
     <StyleAttribute name="backgroundColor" value="red" />
  </Style>
  <Style name=":focus">
     <StyleAttribute name="backgroundColor" value="cyan" />
  </Style>
  <Style name=".mandatory">
     <StyleAttribute name="backgroundColor" value="magenta" />
```

```
  </Style>
  <Style name="*">
     <StyleAttribute name="backgroundColor" value="orange" />
  </Style>
</StyleList>
```

The style definitions are scanned in the following order:

1. `Edit.mandatory:focus`
2. `.mandatory:focus`
3. `Edit.mandatory`
4. `Edit:focus`
5. `:focus`
6. `.mandatory`
7. `Edit`
8. `*`

If the Edit field `f1` has the focus, with the `mystyles.4st` definition file, the field background color will be yellow. If the Edit field `f1` does not have the focus, the field background color will be green.

Combining styles
You can combine several styles, by using the space character as a separator in the `STYLE` attribute.

In the following example, the `STYLE` attribute defines three different style names:

```
EDIT f001 = customer.fname, STYLE = "info highlight mandatory";
```

When several styles are combined, the same presentation attribute might be defined by different styles. In this case, the first style listed that defines the attribute takes precedence over the other styles.

For example, if the `textColor` presentation attribute is defined as follows by the `info`, `highlight` and `mandatory` styles:

- `info` style does not define `textColor`.
- `highlight` style defines `textColor` as `blue`.
- `mandatory` style defines `textColor` as `red`.

The widgets having a style set to `"info highlight mandatory"` will get a blue text color, because `highlight` is listed before `mandatory`.

Style attribute inheritance
A style attribute may be inherited by the descendants of a given node in the abstract user interface tree.

For example, when using a style defining a `fontFamily` in a window container, you would expect that all the children in that group box get the same font.

However, some style attributes should are not inherited, when specific to a given type of form element. Style inheritance is implicitly defined by the attribute.

Presentation styles in the AUI tree
Presentation styles are loaded in the abstract user interface tree, under the `UserInterface` node, in a `StyleList` node following the presentation style syntax.

The `StyleList` node holds a list of `Style` nodes that define a set of attribute values. Attribute values are defined in `StyleAttribute` nodes, with a `name` and a `value` attribute.

Loading presentation styles
Presentation styles are defined in an XML file with a `4st` extension. In order to load the presentation styles, the engine needs to locate the appropriate style file.

By default, the runtime system searches for a file named `default.4st` in the current directory. If this file does not exist, it searches in the directories defined by the `FGLRESOURCEPATH` / `DBPATH` environment

variables. If the file was not found using the FGLRESOURCEPATH / DBPATH environment variables, default presentation styles are loaded from the FGLDIR/lib/default.4st file.

Overwrite the default search by loading a specific presentation style file with the ui.Interface.loadStyles() method:

```
MAIN
  CALL ui.Interface.loadStyles("mystyles")
  ...
END MAIN
```

This method accepts an absolute path with the 4st extension, or a simple file name without the 4st extension. If you give a simple file name, for example "mystyles", the runtime system searches for the mystyles.4st file in the current directory. If the file does not exist, it searches in the directories defined by the FGLRESOURCEPATH environment variable. If FGLRESOURCEPATH is not defined, it searches in the directories defined by the DBPATH environment variable.

The presentation styles must be defined in a unique 4st file. When loading a styles file with the ui.Interface.loadStyles() method, current styles created from the default file or from a prior load will be replaced. The styles will not be combined when loading several files.

The default styles file located in FGLDIR/lib should not be modified directly: your changes would be lost if you upgrade the product. Make a copy if the original file into the program directory of your application, then modify the copied file.

Combining TTY and style attributes

TTY attributes can be specific to a form element or can be inherited by an element from a parent node (such as the form or window).

Specific element TTY attributes are directly set in the element node in the AUI tree; they can, for example, be defined with the COLOR attribute of form items. Inherited TTY attributes are taken from the parent nodes of the leaf element to be displayed. For example, when a form is displayed with DISPLAY FORM followed by an ATTRIBUTE clause containing TTY color, font option and/or video attributes, all static labels will be displayed with the TTY attributes of the form. Note however that the form elements controlled by interactive instructions (i.e. form fields) will explicitly get the TTY attributes defined by the ATTRIBUTE clause of OPEN WINDOW, OPEN FORM, DISPLAY TO / BY NAME or the current dialog statement, and must be considered specific TTY attributes for the element.

Specific TTY attributes defined for a form element have a higher priority than style attributes, while inherited TTY attributes (set on one of the parent elements) have a lower priority than style attributes defined for the element.

To illustrate this rule, imagine a form defining two static labels and two fields, with all items using the *mystyle* presentation style, and one of the labels and fields defining a specific TTY attribute with COLOR=BLUE:

```
LABEL lab01: TEXT="Field 1:", COLOR = BLUE, STYLE = "mystyle";
EDIT fld01 = FORMONLY.field01, COLOR = BLUE, STYLE = "mystyle";
LABEL lab02: TEXT="Field 2:", STYLE = "mystyle";
EDIT fld02 = FORMONLY.field02, STYLE = "mystyle";
```

The program displays the form (or window) with an ATTRIBUTES clause using a red color, and the fields are used by an INPUT dialog, with no ATTRIBUTES clause, so the default TTY attributes are gotten from the OPEN FORM instruction:

```
OPEN FORM f FROM "ttyform"
DISPLAY FORM f ATTRIBUTES(RED)
INPUT BY NAME field01, field02 WITHOUT DEFAULTS
```

The .4st styles file defines the *mystyle* attributes as follows:

```
<StyleList>
  <Style name="Edit.mystyle">
    <StyleAttribute name="textColor" value="green" />
  </Style>
  <Style name="Label.mystyle">
    <StyleAttribute name="textColor" value="magenta" />
  </Style>
</StyleList>
```

The text in the form field *fld01* is displayed in blue (from the specific `COLOR` attribute), while *fld02* is displayed in red (the TTY attribute of the form, the style *Edit.mystyle* being ignored).

Since labels are not used by the interactive instructions, *lab01* is displayed in blue (from the specific `COLOR` attribute), while *lab02* is displayed in magenta (from the style *Label.mystyle*, the form TTY attribute red being ignored).

Element types
Styles may apply to any graphical elements of the user interface, such as `Button`, `Edit`, `ComboBox`, `ButtonEdit`, `Table`, `Window`.

The name of the element when used in a style file is case-sensitive (use `CheckBox`, not `checkbox`).

For example, in the following style definition uses the "Window" element type in the style name:

```
<Style name="Window.dialog">
   <StyleAttribute name="position" value="center" />
</Style>
```

The supported element types is defined by the style attributes, for more details, see Style attributes reference on page 818.

Predefined attribute values
This section decribes the values that must be used for some style attributes.

- Colors on page 807
- Fonts on page 812
- Statusbar types on page 817

Colors
When providing a value for style attributes that define a color, you can specify a generic color name or its RGB value.

This section describes how to specify a value for style attributes defining colors, such as `textColor`.

Syntax

```
{ generic-color | #rrggbb }
```

1. *generic-color* is any of the predefined colors supported by the language.
2. *#rrggbb* is a numerical color defined by a red/green/blue specification.

Usage

In most cases it is not possible to know what a potential end-user might expect regarding the font family. Therefore, your application should avoid the usage of explicit font families and use only the `fontWeight`/`fontStyle`/`fontSize` properties. A specific font family should be used only if the client can't determine a proper default font family for the desired platform.

The language defines a set of generic color names, interpreted by the front end according to the graphical capability of the workstation.

Generic color names

Use generic color names, to keep your style definitions portable accros several front-end types.

Table 230: Generic color names

Generic color name	Visual result (1)	RGB value
`black`		`#000000`
`blue`		`#0000FF`
`cyan`		`#00FFFF`
`darkBlue`		`#00008B`
`darkCyan`		`#008B8B`
`darkGray`		`#A9A9A9`
`darkGreen`		`#006400`
`darkMagenta`		`#8B008B`

Generic color name	Visual result (1)	RGB value
darkOlive		#505000
darkOrange		#FF8C00
darkRed		#8B0000
darkTeal		#005050
darkYellow		#AAAA00
gray		#808080
green		#008000
lightBlue		#ADD8E6
lightCyan		#E0FFFF
lightGray		#D3D3D3

Generic color name	Visual result (1)	RGB value
`lightGreen`		`#90EE90`
`lightMagenta`		`#FFC0FF`
`lightOlive`		`#AAAA44`
`lightOrange`		`#FFCC00`
`lightRed`		`#FF8080`
`lightTeal`		`#33CCCC`
`lightYellow`		`#FFFFE0`
`magenta`		`#FF00FF`
`olive`		`#808000`

Generic color name	Visual result (1)	RGB value
`orange`		`#FFA500`
`red`		`#FF0000`
`teal`		`#008080`
`white`		`#FFFFFF`
`yellow`		`#FFFF00`

Note:

1. The exact rendered color depends on front-end type.

System color names

System color names can be used to get a color from the current theme of the workstation windowing system:

Table 231: System color names

System color name	Meaning
`appWorkSpace`	Background color of multiple document interface
`background`	Desktop background
`buttonFace`	Face color for three-dimensional display elements.
`buttonText`	Text on push buttons.
`grayText`	Grayed (disabled) text.
`highLight`	Item(s) selected in a control.
`highLightText`	Text of item(s) selected in a control
`infoBackground`	Background color for tooltip controls.
`infoText`	Text color for tooltip controls.
`systemAlternateBackground`	Background color of the alternate row in listviews
`window`	Window background.
`windowText`	Text in windows.

RGB notation

In some cases, you may also specify a color with the RGB notation, starting with a # hash character.

Each value of the RGB color specification must be provided in hexadecimal, in the range [00-FF].

Example

```
<StyleAttribute name="textColor" value="blue" />
<StyleAttribute name="textColor" value="#00FF45" />
```

Fonts

A graphical application should follow the front-end platform theme. The front-end tries to determine the default font for the application screens.

- Font families on page 813
- Font sizes on page 814

- Font styles on page 815
- Font weights on page 816

Font families
Use the `fontFamily` style attribute to define a generic or specific font family.

This section describes the possible values of the `fontFamily` style attribute.

Syntax

```
font-family [,...]
```

1. *font-family* defines a generic or a native font family.

Usage

A set of generic font families is supported, that are interpreted by the front end according to the graphical capability of the paltform.

If the `fontFamily` is not a generic font family, it is interpreted as a native font family, which identifies a local font supported by the front-end. Usually, it is one of the fonts installed on the platform operating system. See front-end documentation for a list of supported native fonts.

A native font family should be used only if the front-end can't determine a proper default font family for the desired platform.

> **Important:** A font family containing white-spaces must be single quoted. In the XML definition of the style, this leads to a single quoted string that is, in turn, enclosed in double quotes:
>
> ```
> <StyleAttribute name="fontFamily" value="'Courier New'" />
> ```

When specifying a comma-separated list of font families, the front-end will use the best matching font available on the platform. You can mix generic and native font families:

```
<StyleAttribute name="fontFamily" value="'Times New Roman',Times,serif" />
```

Table 232: Generic font families to front-end platform fonts

Generic font family name	GDC	HTML5	GMA	GMI
`serif`	Times	serif (CSS)	Serif	Times New Roman
`sans-serif`	Arial	sans-serif (CSS)	Sans-Serif	Helvetica Neue
`cursive`	Comic Sans Ms	cursive (CSS)	N/A (keeps defauft font)	Marker Felt
`fantasy`	Algerian	fantasy (CSS)	N/A (keeps defauft font)	Papyrus
`monospace`	Courier New	monspace (CSS)	Monospace	Courier

> **Note:**

- The HTML5 front-end used the font family as `font-family` property in a CSS style. For more details, see CSS generic-font-families
- The GMI front-end tries to find a font family in the available fonts of the application (i.e. the iOS built-in fonts and any application specific fonts) which matches the `fontFamily` given in the styles. If none is found, the fallback is "Helvetica Neue".
- The GMA front-end maps generic font family names to Android™ generic font names (Serif, Monospace), these are then mapped to real font names. The real font name depends from the Android brand. For example Sans-serif is usually implemented with the "Roboto" font.

Example

```
<StyleAttribute name="fontFamily" value="sans-serif" />
<StyleAttribute name="fontFamily" value="'Courier New'" />
<StyleAttribute name="fontFamily" value="'Times New
 Roman',Times,serif" />
```

Font sizes

Use the `fontSize` style attribute to influence the size of a font.

Syntax

```
{ generic-size | pointspt | sizeem }
```

1. *generic-size* is one of the generic font size names (such as '`small`' or '`xx-large`) listed in Table 233: Generic font sizes on page 815.
2. *points* defines an absolute size in points. Specify a number followed immediately by `pt`, e.g., `3pt`.
3. *size* defines an relative size. Specify a number followed immediately by `em`, e.g., `3em`.

Usage

Specify either a generic font size, an absolute size in points with the "pt" unit, or a relative size with the "em" unit.

Absolute sizes (using the "pt" suffix) define a font size in physical points. Physical points are much like pixels, in that they are fixed-size units and cannot scale in size. For example, on HTML pages using CSS styles, one point is equal to 1/72 of an inch.

Relative sizes (using the "em" suffix) define a font size in a scalable size unit that adapts to the front-end platform, where one "em" unit results in the same size as the size of the default font on the platform. For example, if the size of the platform default font is 16 points, `1em = 16pt`, `2em = 32pt`, etc.

Generic font sizes are interpreted by the front end according to the graphical capability of the platform.

> **Note:** Use generic font sizes such as `medium`, `large`, `small`, or sizes relative to the user-chosen font (using `em` units), rather than absolute point values. In an HTML browser you can choose two fonts (proportional/fixed), and a well-designed document should not use more than 2 fonts. This is also valid for applications.

Table 233: Generic font sizes

Generic font size name	Definition
`xx-small`	Tiny font size
`x-small`	Extra-small font size
`small`	Small font size
`medium`	Medium font size
`large`	Large font size
`x-large`	Extra-large font size
`xx-large`	Huge font size

You can also specify an absolute font size, by giving a numeric value followed by the units such as `pt` or `em`:

Example

```
<StyleAttribute name="fontSize" value="medium" />
<StyleAttribute name="fontSize" value="xx-large" />
<StyleAttribute name="fontSize" value="12pt" />
<StyleAttribute name="fontSize" value="1em" />
```

Font styles

Use the `fontSize` style attribute to define the style of a font.

Syntax

```
{ italic | roman | oblique }
```

Usage

The style of a font can be specified with a generic name, interpreted by the front end according to the graphical capabilities of the platform. For example, on "Android™ devices, `italic` and `oblique` result in the same font aspect.

Table 234: Generic font style

Generic font style name	Definition
`italic`	Specifies an italic font style, using a typefact that slants slightly to the right. Uses a different glyph as the roman style.
`oblique`	Specifies an oblique font style. This style is similar to italic, except that it uses the same glyphs as the roman type, but distorted.
`roman`	Specifies a roman font style. This is the typical default font style in Latin-script typography.

Example

```
<StyleAttribute name="fontStyle" value="italic" />
```

Font weights

Use the `fontWeight` style attribute to define the aspect of a font.

Syntax

```
{ black
| bold
| book
| condensed
| condensedbold
| condensedlight
| demibold
| extrablack
| heavy
| light
| medium
| normal
| regular
| semibold
| thin
}
```

Usage

The availability of the weight depends on the chosen font family. For example, if the font family is defined as `AmericanTypewriter`, and the front-end platform supports the following set of font names (for this font family): AmericanTypewriter, AmericanTypewriter-Light, AmericanTypewriter-Bold, AmericanTypewriter-CondensedLight, AmericanTypewriter-CondensedBold, AmericanTypewriter-Condensed, you can only use the `condensed`, `light` and `bold` font weights.

Before using a font weight, make sure that the target platform supports the value. For example, on "Android™ devices, only `normal` and `bold` are supported.

Example

```
<StyleAttribute name="fontWeight" value="bold" />
```

Statusbar types

Possible values for Window status bar type.

This section describes how to specify a value for the `Window.statusBarType` style attribute.

Syntax

```
{ statusbar-type }
```

1. *statusbar-type* is a predefined status bar type name.

Usage

The `statusBarType` style attribute can get one of the values listed in the following table, to customize the rendering of error and message texts.

> **Important:** This style attribute is mainly used for desktop application using the GDC front-end.

Table 235: Possible status bar types for the statusBarType attribute

Value	Screenshot
`default`	`lines1`	
`lines2`	
`lines3`	
`lines4`	
`lines5`	
`lines6`	
`panels1`	
`panels2`	`panels3`	`panels4`	`panels5`	
Value	Screenshot
`panels6`	
`panels7`	
`none`	

Example

```
<StyleAttribute name="Windows.statusBarType" value="panels2" />
```

Style attributes reference

A presentation style attribute may be a common attribute that can be applied to any graphical element. Other presentation style attributes apply only to a specific graphical element.

- Common style attributes on page 818
- Button style attributes on page 821
- ButtonEdit style attributes on page 822
- CheckBox style attributes on page 822
- ComboBox style attributes on page 823

- HBox style attributes on page 827
- Image style attributes on page 828
- Label style attributes on page 828
- Menu style attributes on page 829
- Message style attributes on page 829
- ProgressBar style attributes on page 830
- RadioGroup style attributes on page 831
- Scrollgrid style attributes
- Table style attributes on page 831
- TextEdit style attributes on page 834
- Toolbar style attributes on page 838
- Window style attributes on page 839

Common style attributes

Common style presentation attributes apply to any graphical element, such as windows, layout containers, or form items.

For a complete list of AUI element types, refere to the `FGLDIR/src/aui.xa` definition file.

> **Important:** Common style attribute apply to basic layout elements such as containers (Group) and form widgets (Label, Button, Edit, CheckBox). According to the front-end platform, common style attributes typically do not apply to advanced graphical elements such as TopMenu or ToolBar, especially when such widget can be configured with the a user interface theme of the front-end platform. Consider using common style attribute only for elements inside the form layout.

Table 236: Common style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`backgroundColor` Defines the color to be used to fill the background of the object. For possible values, see Colors on page 807. Default is no value (default color of the object). **Note:** To set the background color of GMI/iOS specific GUI elements like toolbars, tab bars and navigation bars, use the `ios*TintColor` attributes for Windows.	Yes	Yes	Yes	Yes (see note)
`border` Defines the border for the widget. If Value is `"none"`, it removes the border. Default is no value (the widget gets its default appearance). This attribute especially applies to widgets such as Image, Edit, ButtonEdit, Button.	Yes	Yes	No	No
`fontFamily` Defines the name of the font. For possible values, see Font families on page 813. Default is no value (default object font or inherited font).	Yes	Yes	Yes	Yes
`fontSize` Defines the size of the characters. For possible values, see Font sizes on page 814. Default is no value (default object font or inherited font).	Yes	Yes	Yes	Yes
`fontStyle` Defines the style of characters. For possible values, see Font styles on page 815. Default is no value (default object font or inherited font).	Yes	Yes	Yes	Yes
`fontWeight` Defines the weight of the characters. Possible values for font weights depend from the front-end native font names, see Font weights on page 816 for details. Default is no value (default object font or inherited font).	Yes	Yes	Yes	Yes
`imageCache` For form items displaying an image, defines if the image can be cached of not by the front end.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
If value is `"yes"` the front-end can cache the image locally. By default, Image for image fields are not cached and image for form items (Button, TopMenu item, Toolbar item) are cached.				

`localAccelerators`
For form items using shortcuts, defines how the widget must behave regarding keyboard accelerators.
If value is `"yes"` (default), the local accelerators have higher priority.
Ex: "HOME" key moves the cursor to the first position.
If value is `"no"`, the application accelerators have higher priority.
Ex: "HOME" key selects the first row of the current array.
The following keys are managed "locally" if attribute defined to `"yes"`.
`TEXTEDIT`: `left, right, up, down, (control+)home, (control+)end, (control+)backspace, (control+)delete`
`EDIT`, `BUTTONEDIT`, `DATEEDIT`, etc: `left, right, home, end, (control+)backspace, (control+)delete`
`TABLE`, `TREE`: `(control+)left, (control+)right`
	Yes	No	No	No

`showAcceleratorInToolTip` Defines if the accelerator key(s) for an action should be shown in the tooltip of the corresponding action view (Button, Toolbar Item, and so on.) If value is `"yes"` the tooltip shows the accelerator key(s) after the action name, between brackets. By default, the tooltip only shows the action name.	Yes	No	No	No
`textColor` Defines the color to be used to paint the text of the object. For possible values, see Colors on page 807. Default is no value (default object color or inherited color). **Note:** In GMI, `textColor` affects the widgets they are defined on, not the labels in the form used to display the widgets. It is also used to set the tint of checkbox, radio group (horizontal) and spin edit.	Yes	Yes	Yes	Yes (see note)
`textDecoration` Defines the decoration for the text. Values can be `"overline"`, `"underline"` or `"line-through"`. Default is no value (default object font or inherited font).	Yes	Yes	No	No

Button style attributes

Button style presentation attributes apply to a button element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 237: Button style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`buttonType` Defines the rendering of a button. Values can be: • `"normal"` (default): The button is rendered as a regular push button. • `"link"`: the button is rendered as an HTML hyper-link. In contrast to the label hyper-link support, clicking on a "link" button does not start the default browser, but triggers the corresponding action, like a normal button. • `"commandLink"`: the button is rendered as a "Command Link" button on Microsoft™ Windows™ Vista and Windows™ 7.	Yes	Yes	No	No
`scaleIcon` Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget. **Note:** On GDC and GWC, if the `scaleIcon` attribute is undefined, the behavior depends on the kind of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`. Values can be: • `"no"`: No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GWC. • `"yes"`: Image are scaled down according to the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI. • `"`*nnn*`px"`: Image are scaled down according to the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not. Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is when the image come from an SVG file which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment.	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.				

ButtonEdit style attributes

ButtonEdit style presentation attributes apply to a buttonedit element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 238: ButtonEdit style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`scaleIcon` Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget. > **Note:** On GDC and GWC, if the `scaleIcon` attribute is undefined, the behavior depends on the kind of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`. Values can be: • `"no"`: No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GWC. • `"yes"`: Image are scaled down according to the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI. • `"`*nnn*`px"`: Image are scaled down according to the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not. Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is when the image come from an SVG file which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment. If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.	Yes	Yes	No	No

CheckBox style attributes

CheckBox style presentation attributes apply to a checkbox element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 239: CheckBox style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`iosCheckBoxOnTintColor` On iOS devices, defines the color for the checkbox marker when on. This is different from backgroundColor, which is used for the tint of the whole switch.	N/A	N/A	N/A	Yes

ComboBox style attributes

ComboBox style presentation attributes apply to a combobox element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 240: ComboBox style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`autoSelectionStart` Defines the item from which the auto-selection will start, when pressing keys. Valid can be: • `"current"` (default): the auto-selection looks for the first corresponding item after the current item of the object. • `"first"`: the auto-selection looks for the first corresponding item after the first item of the object.	Yes	No	No	No
`comboboxCompleter` Activate the ComboBox completer mode. Possible values are `"yes"` and `"no"` (default). When this attribute is set to yes, the ComboBox will have the following behavior: • The ComboBox is editable, but only characters that match an item in the list are allowed (if the list contains the item `"aa"` and the item `"ab"`, you can type `"a"`, `"aa"`, `"ab"`, but nothing else. If you paste text in the field, it will be truncated until the rule is fulfilled. • The drop-down list will only display item which starts with the same characters as the edit field. It is dynamically updated as you type (if the list contains the item `"aa"` and the item `"ab"` and you type `"a"`, you will see both item displayed, but if you continue to type another `"a"`, you will only see `"aa"` in the list. • The best match is automatically selected when leaving the field (thus performing an `"on change"`) as soon as you hit `"TAB"` key, even if the input is not complete.	Yes	No	No	No
`completionTimeout` Defines the timeout (in milliseconds) to build the character sequence for item lookup when the user presses several keys successively. When pressing multiple keys, a character	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
sequence is build for item lookup. After the timeout delay has expired, the character sequence is reset.				

DateEdit style attributes

DateEdit style presentation attributes apply to a dateedit element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 241: DateEdit style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`buttonIcon` Defines the icon name to use for the button.	Yes	Yes	No	No
`daysOff` Defines the days of the week that are grayed out. Possible values are `"monday"`, `"tuesday"`, `"wednesday"`, `"thursday"`, `"friday"`, `"saturday"`, `"sunday"`. Default is `"saturday sunday"`. The days of week can be combined, as shown.	Yes	Yes	No	No
`firstDayOfWeek` Defines the first day of the week to be displayed in the calendar. Possible values are `"monday"`, `"tuesday"`, `"wednesday"`, `"thursday"`, `"friday"`, `"saturday"`, `"sunday"`. Default depends on the front-ends platform language settings: For example, the default first day of week will be Sunday for an English/US locale, Monday for a French or German locale.	Yes	Yes	No	No
`showCurrentMonthOnly` Defines if dates of the previous and next months are shown. Values can be `"yes"`, `"no"` (default).	Yes	Yes	No	No
`showGrid` Indicates if the grid lines between dates must be visible in the calendar. Values can be `"yes"`, `"no"` (default).	Yes	No	No	No
`showWeekNumber` Defines if the week numbers are displayed. Values can be `"yes"`, `"no"` (default).	Yes	No	No	No

Default action view style attributes

These style attributes apply to default action views (`MenuAction` and `Action` classes).

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 242: Action style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`androidActionPosition` On Android™, defines if the option corresponding to the action must be displayed in the menu bar. Values can be: • `"button"`: The action view will be displayed in the Android action bar as a button, if there is no room in the action bar, the action view is not displayed. • `"overflow"`: The action view will be displayed in the Android action bar overflow dropdown list. • `"default"`: The action view will be displayed in the Android action bar, or in the overflow dropdown, if there is no room in the action bar. **Note:** See also Default action views decoration on Android devices on page 1288.	N/A	N/A	Yes	N/A
`androidActionWithIcon` On Android, defines if the icon (default icon or icon specified with the `IMAGE` attribute) must be displayed for the action view. Values can be: • `"yes"` (default): The icon is visible (default). • `"no"`: The icon is not shown.	N/A	N/A	Yes	N/A
`androidActionWithText` On Android, defines if a label (specified with the `TEXT` attribute) must be displayed for the action view. Values can be: • `"yes"` (default): Option text is visible (if there is an icon) • `"no"`: Option text is not shown. **Note:** If the device orientation is in portrait mode, Android may not display the text, even if you force it with this attribute.	N/A	N/A	Yes	N/A
`scaleIcon` Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget. **Note:** On GDC and GWC, if the `scaleIcon` attribute is undefined, the behavior depends on the	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
kind of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`. Values can be: • `"no"`: No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GWC. • `"yes"`: Image are scaled down according to the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI. • `"`*nnn*`px"`: Image are scaled down according to the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not. Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is when the image come from an SVG file which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment. If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.				

Edit style attributes

Edit style presentation attributes apply to an edit element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 243: Edit style attributes

Attribute	GDC	GWC-JS	GMA	GMI

`dataTypeHint`
 	
Defines the type of the input, to let the front-end render a field behavior suitable for the particular data type. This attribute is especially useful on mobile devices.
 	
Values can be:
• `"email"` (for email addresses)
• `"url"` (for URLs)
• `"tel"` (for telephone numbers)
• `"search"` (for search box fields)
 	
For example, on a smart phone, entering data into an edit field with `datatypeHint="tel"` makes the numeric keyboard appear.
 	
`<Style name="Edit.hintPhone">`
	No	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
<StyleAttribute name="dataTypeHint" value="tel"/> </Style>				
`spellCheck` Defines if the edit field includes a spelling checker. **Note:** • With GDC, the possible values are the two dictionary files needed for each language (one .aff and one .dic). These files can be downloaded here. Only the files available for OpenOffice.org 2.x are working (files for OpenOffice.org 3.x are not supported yet). Specify in the style the two files for the "spellCheck" StyleAttribute, using one of the file formats. The local directory of dictionary files can be asked to the GDC with the `standard.feInfo` frontcall with the `dictionariesDirectory` parameter. • With GWC-JS, the attribute is not applicable: Edit fields use the web browser spellchecker. • With GMI, available values are `"yes"`, `"no"`. If this attribute is not set, iOS will decide if spellchecking is enabled, depending on the global auto-correction setting on the device.	No (see note)	No (see note)	No	Yes (see note)

HBox style attributes
HBox style presentation attributes apply to an HBox element.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 244: HBox style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`splitViewRendering` Indicates if the HBox must be displayed as a splitview. • in landscape mode, panes are side by side and scroll independently • in portrait mode, user navigates between the panes by swiping left or right Values can be `"yes"`, `"no"` (default is no)	No	No	Yes	No

Folder style attributes
Folder style presentation attributes apply to a folder tab element.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 245: Folder style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`position` Defines the position of the folder tabs. Values can be `"top"` (default), `"left"`, `"right"`, `"bottom"`.	Yes	Yes	No	No

Image style attributes

Image style presentation attributes apply to an image element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 246: Image style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`alignment` Defines the image alignment when the container is bigger than the image itself. Possible values are a pair of horizontal (`"left"`, `"horizontalCenter"`, `"right"`) and vertical alignments (`"top"`, `"verticalCenter"`, `"bottom"`). To combine alignment options, use a space as separator. Value can also be `"center"`, which is equivalent to `"horizontalCenter verticalCenter"`. The default value is `"top left"`.	Yes	Yes	No	No
`imageContainerType` **Important:** This attribute is deprecated. Consider using URL-based Web Components instead of `IMAGE` fields with the `imageContainerType` style attribute: URL Web Components are much easier to use and more powerful. When set to `"browser"`, defines an image container as a browser. To use the image field as a browser, set a URL instead of an image name. **Note:** This feature uses the WebKit Open Source project as provided with Qt, and has limitations such as no Java™ or ActiveX support. It will display HTML / rich text, but may encounter difficulties with more complex Web pages.	Yes	No	No	No

Label style attributes

Label style presentation attributes apply to a label.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 247: Label style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`textFormat` Defines the rendering of the content of the label widget. Possible values are: • `"plain"` (default): the value assigned to this widget is interpreted as plain text. • `"html"`: it is interpreted as HTML (with hyperlinks).	Yes	Yes	No	No

Menu style attributes

Menu style presentation attributes apply to a menu element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

This table shows the presentation attributes for Menu:

Table 248: Menu style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`position` Defines the position of the automatic menu for "popup" menus. Values can be: • `"cursor"` (default): the popup menu appears at the cursor position. • `"field"`, the popup menu appears below the current field. • `"center"`, the popup menu appears at the center of the screen. • `"center2"`, the popup menu appears at the center of the current window.	Yes	No	No	No

Message style attributes

Message style presentation attributes apply to an error or message.

The element type for both ERROR and MESSAGE is `Message`. To distinguish `ERROR` from `MESSAGE`, the `":error"` or `":message"` pseudo-selectors can be used to specify a different style for the rendereing of each instruction: `"Message:error"` corresponds to the `ERROR` instruction, and `"Message:message"` corresponds to the `MESSAGE` instruction.

The `ERROR` and `MESSAGE` instructions can get a `STYLE` attribute in the `ATTRIBUTES` clause, to specify a particular style name:

```
MESSAGE "No rows have been found." ATTRIBUTES(STYLE="info")
```

A limited set of common style attributes are supported for error/message display. In addition to the attributes described in the section, you can only define font style attributes for messages.

Like simple form fields, TTY attributes have a higher priority than style attributes. By default, `ERROR` has the TTY attribute `REVERSE`, which explains why `ERROR` messages have a reverse background, even

when you use a backgroundColor style attribute. Use the NORMAL attribute in ERROR, to avoid the default REVERSE TTY attribute and define your own background color with a style.

Consider centralizing your ERROR and MESSAGE instruction calls in a function, to simplify global modifications:

```
FUNCTION my_error(m, s)
   DEFINE m, s STRING
   IF s IS NULL THEN
       ERROR m ATTRIBUTES(NORMAL)
   ELSE
       ERROR m ATTRIBUTES(NORMAL, STYLE=s)
   END IF
END FUNCTION
```

This table shows the presentation attributes for ERROR and MESSAGE instructions:

Table 249: Presentation attributes for ERROR and MESSAGE instructions

Attribute	GDC	GWC-JS	GMA	GMI
`position` Defines the output type of the status bar message field. Values can be: • `"statusbar"` (default): will display the text in the regular statusbar of the window. • `"popup"`: will bring a window popup to the front; it should be used with care, since it can annoy the user. • `"statustip"`: will add a small "down" arrow button that will show the popup once the user clicks on it. This can be useful to display very long text. • `"both"`: will display the text in a popup window and then in the status bar.	Yes	No	No	No
`textFormat` Defines the rendering of the content of the widget. Possible values are: • `"plain"` (default): the value assigned to this widget is interpreted as plain text. • `"html"`, it is interpreted as HTML (with hyper-links).	Yes	No	No	No

ProgressBar style attributes
ProgressBar style presentation attributes apply to a progressbar element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 250: ProgressBar style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`percentageVisible` Defines whether the current progress value is displayed. Possible values are:	Yes	Yes (see note)	No	No

Attribute	GDC	GWC-JS	GMA	GMI
• `"no"` (default): no progress value is displayed. • `"center"`: the progress will be displayed in the middle of the progressbar. • `"system"`: it will follow the system theme. **Note:** GWC-JS: This attribute is only supported if the browser allows this option in the progressbar widget.				

RadioGroup style attributes

RadioGroup style presentation attributes apply to a radiogroup element.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 251: RadioGroup style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`autoSelectionStart` Defines the item from which the auto-selection will start, when pressing keys. Possible values are: • `"current"` (default): it will look for the first corresponding item after the current item of the object. • `"first"`, the auto-selection will look for the first corresponding item after the first item of the object.	Yes	No	No	No
`completionTimeout` Defines the timeout (in milliseconds) to build the character sequence for item lookup when the user presses several keys successively. When pressing multiple keys, a character sequence is build for item lookup. After the timeout delay has expired, the character sequence is reset.	Yes	No	No	No

Table style attributes

Table style presentation attributes apply to a table element.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 252: Table style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`forceDefaultSettings` By default, tables are reopened with column positions, visibility and sizes they had when the window was closed. By setting this attribute to true, the saved settings are ignored and the table gets the initial column layout. Note that the saved settings include also the sort columns, that will impact on the order of the rows in the table.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Values can be `"yes"`,`"no"` (default).				
`headerAlignment` Defines the column header alignment in a table. Values can be: • `"default"` (default): will use the system default. In most case it is left aligned. • `"left"` will force all column headers to be left aligned. • `"center"` will force all column headers to be centered. • `"right"` will force all column headers to be right aligned. • `"auto"` will first try to align each column header according to the `"justify"` attribute of the column. If no `"justify"` attribute is set, the column header will be aligned according to the type of data: right for numeric data, left for text data.	Yes	Yes	No	No
`headerHidden` Defines if the horizontal header must be visible in a table. Values can be `"yes"`,`"no"` (default).	Yes	Yes	No	No
`highlightColor` Defines the highlight color of rows for the table, used for selected rows. For possible values, see Colors.	Yes	Yes	No	No
`highlightCurrentCell` Indicates if the current cell must be highlighted in a table. Values can be `"yes"`,`"no"` (default). By default the current edit cell in table has a white background. You can change this behavior by setting this attribute to `"yes"`, to use the same color as when highlightCurrentRow is used. Only some type of cells, checkboxes for example, can be highlighted. Normal editor cells stay in white, because this is the editor background color.	Yes	Yes	No	No
`highlightCurrentRow` Indicates if the current row must be highlighted in a table during an `INPUT ARRAY`. Values can be `"yes"`,`"no"` (default). By default, when a table is in read-only mode (`DISPLAY ARRAY`), the front-end automatically highlights the current row. But in editable mode (`INPUT ARRAY`), no row highlighting is done by default. You can change this behavior by setting this attribute to `"yes"`.	Yes	Yes	No	No
`highlightTextColor`	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Defines the highlighted text color of rows for the table, used for selected rows. For possible values, see Colors.				
`leftFrozenColumns` Requires `"tableType"` set to `"frozenTable"`. Defines how many columns are frozen, starting from the left of the Table. Values can be any numeric value matching with the number of columns. Default is `"0"`.	Yes	Yes	No	No
`resizeFillsEmptySpace` Defines if the resize of the table adapts the size of the last column to avoid unused space. Values can be `"yes"`,`"no"` (default).	Yes	No	No	No
`rightFrozenColumns` Requires `"tableType"` set to `"frozenTable"`. Defines how many columns are frozen, starting from the right of the Table. Values can be any numeric value matching with the number of columns. Default is `"0"`.	Yes	Yes	No	No
`showGrid` Indicates if the grid lines must be visible in a table. Values can be `"yes"` (default when `INPUT ARRAY`),`"no"` (default when `DISPLAY ARRAY`). By default, when a Table is in editable mode (`INPUT ARRAY`), the front-end displays grid lines in the table. You can change this behavior by setting this attribute to `"no"`. By default, when a Table is in editable mode (`DISPLAY ARRAY`), the front-end does not display grid lines in the table. You can change this behavior by setting this attribute to `"yes"`.	Yes	Yes	No	No
`summaryLineAlwaysAtBottom` Defines the placement of the summary row containing aggregate fields. When set to "yes", the row containing aggregate fields is rendered in the last line of the table. When set to "no", the row containing aggregate fields is rendered immediately after the values being aggregated. This is the default.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
`tableType` Defines the rendering type of the table. Values can be: • `"normal"` (default): Regular table rendering. • `"pictureFlow"`: The first column of the table will be used to define the list of images to be used in the picture flow. • `"frozenTable"`: Users can "freeze" some columns from scrolling, so that they always remain visible. Default frozen columns can be defined with `"leftFrozenColumns"` and `"rightFrozenColumns"` attributes.	Yes	Yes	No	No

TextEdit style attributes
Textedit style presentation attributes apply to a textedit element.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 253: TextEdit style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`customWidget` Defines a specific widget to be used by the front end for the textedit field. Values can be: • `"TinyMCE"`: Uses a specific HTML text editor (for HTML5, uses the TinyMCE™ HTML editor when set).	No	Yes	No	No
`integratedSearch` Defines if the textedit field allows search facility (Control-F). Values can be `"yes"`, `"no"` (default).	Yes	No	No	No
`showEditToolBox` Defines if the toolbox for the rich text editing should be shown. Possible values are `"auto"`(default), `"yes"`, `"no"`. Only available if `textFormat` style attribute is set to `"html"`.	Yes	Yes	No	No
`spellCheck` Defines if the textedit field includes a spelling checker. **Note:** • With GDC, the possible values are the two dictionary files needed for each language (one .aff and one .dic). These files can be downloaded here. Only the files available	Yes (see note)	No (see note)	No	Yes (see note)

Attribute	GDC	GWC-JS	GMA	GMI
for OpenOffice.org 2.x are working (files for OpenOffice.org 3.x are not supported yet). Specify in the style the two files for the "spellCheck" StyleAttribute, using one of the file formats. The local directory of dictionary files can be asked to the GDC with the `standard.feInfo` frontcall with the `dictionariesDirectory` parameter. • With GWC-JS, the attribute is not applicable: Edit fields use the web browser spellchecker. • With GMI, available values are `"yes"`, `"no"`. If this attribute is not set, iOS will decide if spellchecking is enabled, depending on the global auto-correction setting on the device.				
`textFormat` Defines the rendering of the content of the widget. Values can be: • `"plain"` (default): the value assigned to this widget is interpreted as plain text. • `"html"`, the value is interpreted as HTML (with hyper-links), with rich text input feature enabled. Note that a specific HTML editor widget can be specified with the `customWidget` style attribute.	Yes	Yes	No	No
`wrapPolicy` Defines where the text can be wrapped in word wrap mode. Values can be: • `"atWordBoundary"` (default): the text will wrap at word boundaries. • `"anywhere"`: the text breaks anywhere, splitting words if needed.	Yes	Yes	No	No

File Formats for `spellCheck`:

- `"my_affix_file.aff|my_dictionnary_file.dic"`
- an absolute path such as `"file:///c:/dics/my_dictionnary_file.aff|file:///c:/dics/my_dictionnary_file.dic"`
- a Web server path such as `http://mywebserver.com/my_affix_file.aff|http://mywebserver.com/my_dictionnary_file.dic`

Rich Text Editing

Some Genero clients support a rich text editing interface, which can display a toolbox with classic editing actions (bold, italic, font size, and so on). Local actions are also created.

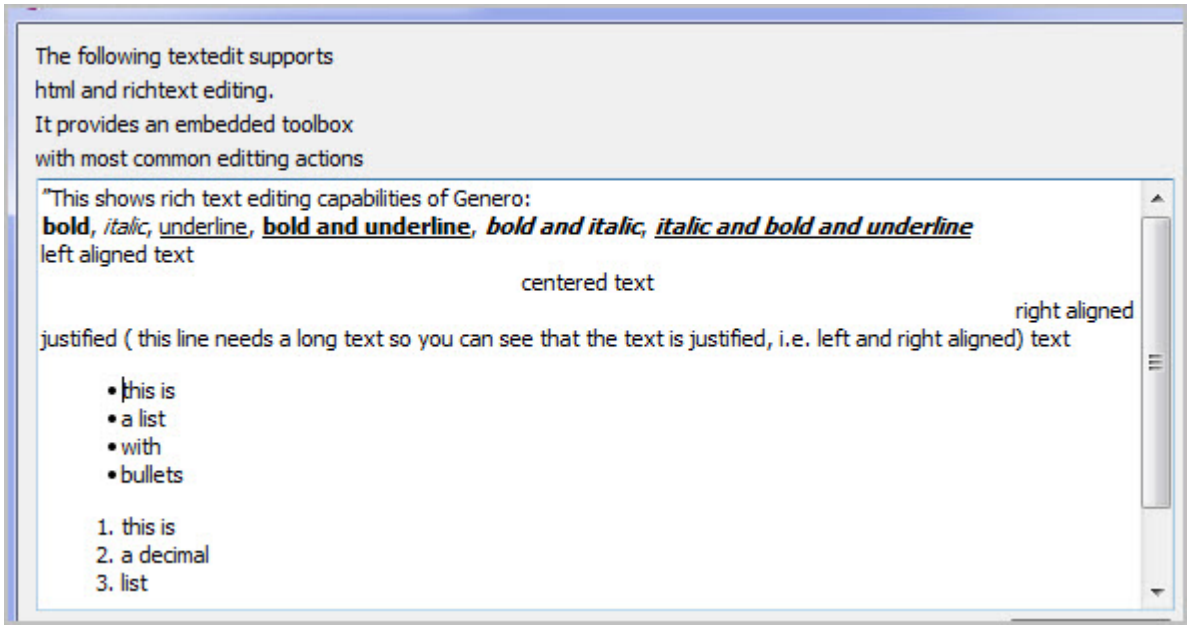

Figure 43: Rich text editing interface

Rich text editing provides:

- Text format: bold, italic, underline
- Paragraph alignment: left, center, right, justify
- Lists: bullet, decimal
- Paragraph indentation
- Font size

To enable rich text editing, set the `textFormat` styleAttribute to `html` .

```
<Style name="TextEdit.richText">
  <StyleAttribute name="textFormat" value="html" />
</Style>
```

If you are using the Genero Web Client for HTML5, you can specify the TinyMCE™ editor for rich text editing with the `customWidget` style attribute. If the `customWidget` attribute is not specified, the default editor is used.

```
<Style name="TextEdit.richText">
  <StyleAttribute name="textFormat" value="html" />
  <StyleAttribute name="customWidget" value="TinyMCE" />
</Style>
```

Richtext toolbox

By default, when the mouse reaches the top border of the textedit field where rich text editing has been enabled, a toolbox appears. The toolbox disappears when the mouse leaves the top border area. This implementation is useful if you only use the textedit field to display rich text, as the toolbox is only visible in input.

If you want always display the toolbox, you can set the `showEditToolBox` styleAttribute.

```
<Style name="TextEdit.richText">
```

```
  <StyleAttribute name="textFormat" value="html" />
  <StyleAttribute name="showEditToolBox" value="yes" />
</Style>
```

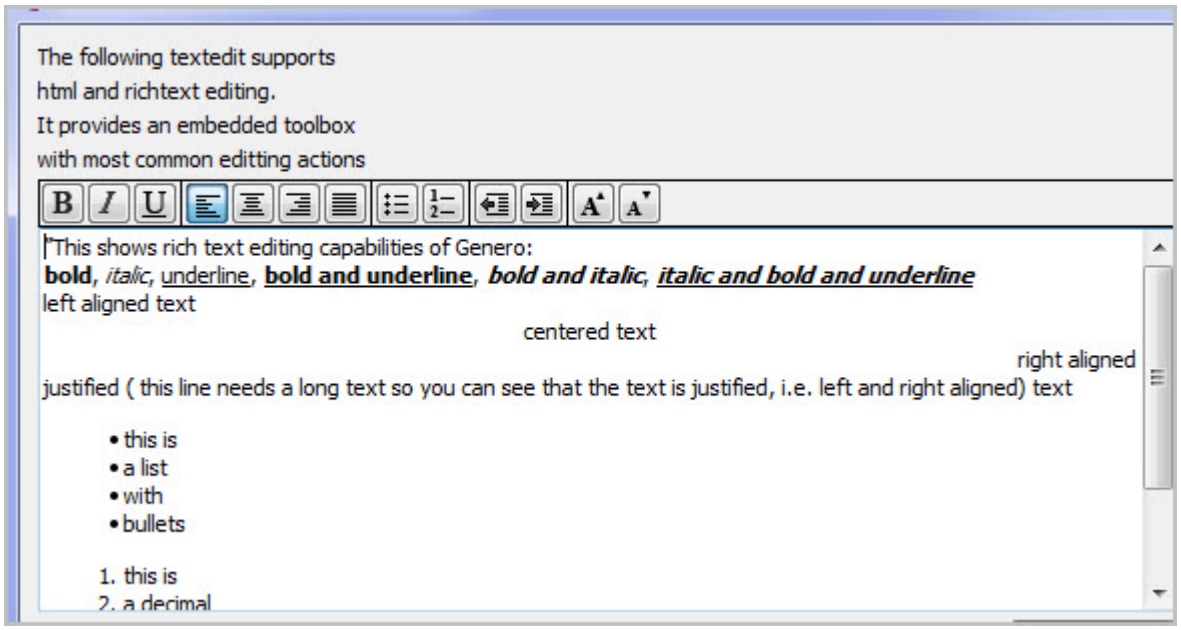

Figure 44: Rich text editing interface with toolbox always displayed.

> **Tip:** The textedit will be wide enough to display the toolbox in its entirety, even if you define a small width in your form definition file. Take this in account when designing your form.
>
> **Tip:** The textedit will be high enough to display the number of lines defined in the form definition file (using the textedit font) and the toolbox when required. A textedit with a height of 1 will display the toolbox and one line, which is much higher than without the toolbox.
>
> **Important:** The behavior of the attribute `showEditToolBox` with the value `auto` differs between the Genero Desktop Client and the Genero Web Client. With the Genero Desktop client, '`auto`' is interpreted as '`no`'. With the Genero Web Client, '`auto`' is interpreted as '`yes`'.

Rich text local actions

Local actions have been created for each rich text capability. As with any local action, you can configure accelerator keys, or you can bind them to action views like toolbar buttons.

Table 254: Local action names, accelerators, and icons

Name	Default Accelerator	Icon Name	Icon
`richtextbold`	Ctrl-b	textbold	B
`richtextitalic`	Ctrl-i	textitalic	*I*
`richunderline`	Ctrl-u	textunder	U
`richtextalignleft`	Ctrl-l	textleft	
`richtextaligncenter`	Ctrl-e	textcenter	

Name	Default Accelerator	Icon Name	Icon
`richtextalignright`	Ctrl-r	textright	
`richtextalignjustify`	Ctrl-j	textjustify	
`richtextlistbullet`	None	textlistbullet	
`richtextlistdecimal`	None	textlistnumbered	
`richtextdecreaseident`	None	textindentdecrease	
`richtextincreaseident`	None	textindentincrease	
`richtextdecreasefontsize`	None	textfontsizedown	
`richtextincreasefontsize`	None	textfontsizeup	

You can hide the toolbox using the `showEditToolBox` styleAttribute.

```
<StyleAttribute name="textFormat" value="html" />
<StyleAttribute name="showEditToolBox" value="no" />
```

Toolbar style attributes
Toolbar style presentation attributes apply to a toolbar.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 255: ToolBar style attributes

Attribute	GDC	GWC-JS	GMA	GMi
`iosSeparatorStretch` Stretches the SEPARATORs between toolbar items on iOS devices. When this attribute is set to `yes`, separators are acting like springs between the individual toolbar items. Values can be: • `"no"` (default): do not stretch toolbar item separators. • `"yes"`: stretch toolbar item separators.	N/A	N/A	N/A	Yes
`scaleIcon` Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget. **Note:** On GDC and GWC, if the `scaleIcon` attribute is undefined, the behavior depends on the kind of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`. Values can be:	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMi
• `"no"`: No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GWC. • `"yes"`: Image are scaled down according to the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI. • `"`*nnn*`px"`: Image are scaled down according to the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not. Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is when the image come from an SVG file which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment. If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.				
`toolBarTextPosition` Defines the text position of a ToolBarItem. Values can be: • `"textBesideIcon"` • `"textUnderIcon"` (default)	Yes	Yes	No	No

Window style attributes
Window style presentation attributes apply to a window.

> **Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 256: Window style attributes

Attribute	GDC	GWC-JS	GMA	GMI
`actionPanelButtonSize` Defines the width of buttons. Values can be `"normal"`, `"shrink"`, `"tiny"`, `"small"`, `"medium"`, `"large"` or `"huge"`. When using `"normal"` and `"shrink"`, buttons are sized according to the text or image, where `"shrink"` uses the minimum size needed to display the content of the button. Default is `"normal"`.	Yes	No	No	No
`actionPanelButtonSpace` Defines the space between buttons.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Values can be "none", "tiny", "small", "medium", "large" or "huge". Default is "medium".				
actionPanelButtonTextAlign Defines the text alignment inside buttons. Values can be "left", "center", "right". Default is "left" when the button have an icon, "center" otherwise.	Yes	Yes	No	No
actionPanelButtonTextHidden Defines the text visibility inside buttons. Values can be "yes" or "no". Default is "yes".	Yes	Yes	No	No
actionPanelDecoration Defines the decoration of the action panel. Values can be "auto", "yes", "no" and "dockable". Default is "auto".	Yes	No	No	No
actionPanelHAlign Defines the alignment of the action panel when actionPanelPosition is "top" or "bottom". Values can be "left", "right" or "center". Default is "left".	Yes	No	No	No
actionPanelPosition Defines the position of the action button frame (OK/Cancel). Values can be "none", "top", "left", "bottom" or "right". Default is "right".	Yes	Yes	No	No
actionPanelScroll Defines if the action panel is "ring" - that is, when the last button is shown, pressing on the "down" button will show the first one again. Values can be "0" or "1". Default is "1".	Yes	No	No	No
actionPanelScrollStep Defines how the action panel should scroll when clicking the "down" button, to shown the next visible buttons. Values can be: • "line" (default): the panel will scroll by one line, and then show only the next button.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
• `"page"`: the scrolling will be done page by page.				
`allowedOrientations` Defines possible orientations for modile device. Values can be: • `"all"`: Any orientations are allowed. • `"landscape"`: Landscape orientation (the display is wider than it is tall). • `"portrait"`: Portrait orientation (the display is taller than it is wide). • `"landscape_reverse"`: Landscape orientation in the opposite direction from normal landscape. • `"portrait_reverse"`: Portrait orientation in the opposite direction from normal portrait. • `"landscape_all"`: Normal and reverse landscape orientations are allowed. • `"portrait_all"`: Normal and reverse portrait orientation are allowed. Default is `"all"`. **Note:** This attribute is supported at the Window level only by GMA.	N/A	N/A	Yes	No
`border` Defines the border type of the window. Values can be: • `"normal"` (default): the border is standard, with a normal window header with a caption. • `"frame"`: only a frame appears, typically without a window header. • `"tool"`: a small window header is used. • `"none"`: the window gets no border. On Mac platforms, using `"tool"` is not effective.	Yes	No	No	No
`commentPosition` Defines the rendering for field comments. Values can be: • `"statusbar"` (default): displays the comment in the window status bar. • `"popup"` will bring a window popup to the front; to be used with care, as it can annoy the end user. • `"statustip"` will add a small "down" arrow button that will show the popup once the user clicks on it; useful to display very long text. • `"both"` will display the comment text in a popup window and then in the status bar.	Yes	No	No	No
`defaultTTFColor`	Yes	Yes	Yes	Yes

Attribute	GDC	GWC-JS	GMA	GMI
Defines the default color to be used for TTF icons. All icons displayed in the window using this style will by default get the color specified in the defaultTTFColor attribute. The value for this attribute must and RGB specification or a named color as listed in Colors on page 807. For more details about TTF icon usage see Using a simple image name (centralized icons) on page 785.				
`errorMessagePosition` Defines the rendering of program errors displayed with the ERROR instruction. Values can be: • `"statusbar"` (default): displays the comment in the window status bar. • `"popup"` will bring a window popup to the front; to be used with care, as it can annoy the end user. • `"statustip"` will add a small "down" arrow button that will show the popup once the user clicks on it; useful to display very long text. • `"both"` will display the comment text in a popup window and then in the status bar.	Yes	No	No	No
`forceDefaultSettings` Indicates if the window content must be initialized with the saved positions and sizes. By default, windows are reopened at the position and with the size they had when they were closed. You can force the use of the initial settings with this attribute. This applies also to column position and width in tables. Values can be `"yes"` or `"no"`. Default is `"no"`.	Yes	Yes	No	No
`formScroll` Defines if scrollbars should always be displayed when the form is bigger than the screen, or only when the window is maximized. Values can be `"yes"` or `"no"`. Default is `"yes"`.	Yes	No	No	No
`ignoreMinimizeSetting` Defines if the stored settings "state=minimize" must be ignored when loading settings. To be used when minimized windows should not be shown minimized when reopened. Values can be `"yes"` or `"no"`.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Default is `"no"`.				
`iosTintColor` On iOS devices, defines the color for items used in the navigation bar, toolbar, and some items in the forms (Buttons, SpinEdit, Radiogroups, and row checkmark and disclosure indicators in list views). This style attribute does not apply to `MENU` with `STYLE=dialog/popup`.	N/A	N/A	N/A	Yes
`iosNavigationBarTextColor` On iOS devices, defines the text color of the navigation bar.	N/A	N/A	N/A	Yes
`iosNavigationBarTintColor` On iOS devices, defines the background color of the navigation bar.	N/A	N/A	N/A	Yes
`iosToolBarTintColor` On iOS devices, defines background color of the toolbar.	N/A	N/A	N/A	Yes
`iosTabBarTintColor` On iOS devices, defines the background color of the tab bar. The iOS tab bar is created with a `TYPE=NAVIGATOR` window.	N/A	N/A	N/A	Yes

`materialFABActionList`
Defines a comma-separated list of action names that will be bound to the Floating Action Button (FAB button), on a device following the material design guidelines. To be used in conjunction with the `materialFABType` attribute. The order of the actions will define which action is triggered when the FAB button is tapped, and several matching actions are active.
The default list of actions is:
`"new,append,insert,update,edit"`
	No	No	Yes	No

`materialFABType` Controls the Floating Action Button (FAB button), on a device following the material design guidelines. Possible values are: • `"single"` (default) - the FAB button is shown and maps to the first active action defined in the `materialFABActionList` attribute. • `"none"` - no FAB button must be displayed.	No	No	Yes	No
`menuPopupPosition` Defines the position of the automatic menu for "popup" menus. Values can be:	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
• `"cursor"` (default) - the popup menu appears at the cursor position. • `"field"` - the popup menu appears below the current field. • `"center"` - the popup menu appears at the center of the screen. • `"center2"` - the popup menu appears at the center of the current window.				
`messagePosition` Defines the rendering for program messages displayed with the `MESSAGE` instruction. Values can be: • `"statusbar"` (default): displays the comment in the window status bar. • `"popup"` will bring a window popup to the front; to be used with care, as it can annoy the end user. • `"statustip"` will add a small "down" arrow button that will show the popup once the user clicks on it; useful to display very long text. • `"both"` will display the comment text in a popup window and then in the status bar.	Yes	No	No	No
`position` Indicates the initial position of the window. Values can be: • `"default"` (default): the windows are displayed according to the window manager rules. • `"field"`: the window is displayed below the current field (works as `"default"`, when current field does not exist). • `"previous"` the window is displayed at the same position (top left corner) as the previous window. (works as `"default"` when there is no previous window). • `"center"`: the window is displayed in the center of the screen. • `"center2"`: the window is displayed in the center of the current window. For front-ends using stored settings, `"field"`, `"previous"` and `"previous"` have higher priority than the settings.	Yes	No	No	No
`ringMenuButtonSize` Defines the width of buttons. Values can be `"normal"`, `"shrink"`, `"tiny"`, `"small"`, `"medium"`, `"large"` or `"huge"`. When using `"normal"` and `"shrink"`, buttons are sized according to the text or image, where `"shrink"` uses the minimum size needed to display the content of the button.	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Default is `"normal"`.				
`ringMenuButtonSpace` Defines the space between buttons. Values can be `"none"`, `"tiny"`, `"small"`, `"medium"`, `"large"` or `"huge"`. Default is `"medium"`.	Yes	No	No	No
`ringMenuButtonTextAlign` Defines the text alignment inside buttons. Values can be `"left"`, `"center"`, `"right"` Default is `"left"` when the button have an icon, `"center"` otherwise.	Yes	Yes	No	No
`ringMenuButtonTextHidden` Defines the text visibility inside buttons. Values can be "`yes`" or "`no`". Default is "`yes`".	Yes	Yes	No	No
`ringMenuDecoration` Defines the decoration of the menu panel. Values can be `"auto"`, `"yes"`, `"no"` and `"dockable"`. Default is `"auto"`.	Yes	No	No	No
`ringMenuHAlign` Defines the alignment of the ring menu when `ringMenuPosition` is `"top"` or `"bottom"`. Values can be `"left"`, `"right"` or `"center"`. Default is `"left"`.	Yes	No	No	No
`ringMenuPosition` Defines the position of the ring menu frame for a MENU instruction. Values can be `"none"`, `"top"`, `"left"`, `"bottom"` or `"right"`. Default is `"right"`.	Yes	Yes	No	No
`ringMenuScroll` Defines if the focus can wrap in the ring menu default actions when pressing up or down keys. Values can be `"0"` or `"1"`. Default is `"1"`.	Yes	No	No	No
`ringMenuScrollStep`	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
Defines how the ring menu must scroll when moving to a next button that is not visible. Values can be: • `"line"` (default): the menu will scroll by one line, and show only the next button. • `"page"`, the scrolling will be done page by page.				
`sizable` Defines if the window can be resized by the user. Values can be `"yes"`, `"no"` or `"auto"`. With the GDC, when using `"auto"`, the window becomes resizeable if the content of the first displayed form has resizeable elements, for example when using a form with a TABLE container or an TEXTEDIT with STRETCH attribute. With GWC, the behavior is applied to the form instead of the window. When set to `"no"`, the form content is not stretched even if the form contains stretchable items. **Note:** On Linux™ and Mac platforms, most of window managers don't take into account `sizable` when it is set to `"no"`. Default is `"yes"`.	Yes	Yes	No	No
`startMenuAccelerator` Defines the shortcut keys to execute the selected start menu item, when the position is defined as `"tree"` or `"poptree"`. By default, `"space"`, `"enter"` and `"return"` start the application linked to the current item.	Yes	No	No	No
`startMenuExecShortcut2` Defines the shortcut keys to execute the selected start menu item, when the position is defined as `"tree"` or `"poptree"`. By default, `"space"`, `"enter"` and `"return"` start the application linked to the current item.	Yes	No	No	No
`startMenuPosition` Indicates the position of the start menu, when one is defined. Values can be: • `"none"` (default): the startmenu is not displayed. • `"tree"`: the start menu is displayed as a treeview, always visible on the right side of the window. • `"menu"`: the start menu is displayed as a pull-down menu, always visible at the top of the window. • `"poptree"`: the start menu is displayed as a tree view in a popup window that can be opened with a shortcut (see `startMenuShortcut`).	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
`startMenuShortcut` Defines the shortcut key to open a start menu, when the position is defined as `"poptree"`. Default is `"control-shift-F12"`.	Yes	No	No	No
`startMenuSize` Defines the size of the start menu, when one is defined and the position is defined as `"tree"` or `"poptree"`. Values can be `"tiny"`, `"small"`, `"medium"`, `"large"` or `"huge"`. Default is `"medium"`. **Note:** The size will also depend on the font used for the startmenu.	Yes	No	No	No
`statusBarType` Defines the type of status bar the window will display. See Statusbar types on page 817 for all possible values. Default is `"default"`.	Yes	No	No	No
`tabbedContainer` For the GDC, defines if the WCI container must display the child application windows in a folder tab. For the GWC, this attribute specifies whether child applications are to be displayed inside the same browser window as the parent, or in a new window. WCI is not supported by GWC. Values can be `"yes"` or `"no"`. Default is `"no"`.	Yes	Yes	No	No
`tabbedContainerCloseMethod` Defines the folder tab method of the container when `tabbedContainer` is set to `"yes"`. Values can be: • `"container"` (default): container gets a close button in the tab. • `"page"`: each page has its own close button. • `"both"`: each page and the container has its close button. • `"none"`: no close button is shown.	Yes	No	No	No
`thinScrollbarDisplayTime` Defines the display time (in seconds) of the automatic scrollbar displayed when scrolling on fixed screen array (a.k.a. "Matrix") and SCROLLGRIDs (for some front-ends). After the delay, the scrollbar will disappear. A value of zero specifies an infinite time: The thin scrollbar remains	Yes	Yes	No	No

Attribute	GDC	GWC-JS	GMA	GMI
visible while the record list can be scrolled (i.e. during dialog execution). Default is 1 second.				
`toolBarDocking` Defines if the toolbar is movable and floatable. Values can be `"yes"` or `"no"`. Default is `"yes"`.	Yes	No	No	No
`toolBarPosition` Indicates the position of the toolbar, when a toolbar is defined. Values can be `"none"`, `"top"`, `"left"`, `"bottom"` or `"right"`. Default is `"top"`.	Yes	No	No	No
`windowMenu` Defines if the WCI container should display an automatic "Window" menu, with *Cascade* and *Tile* features, and list of child windows. Values can be `"yes"` or `"no"`. Default is `"no"`.	Yes	No	No	No
`windowOptionClose` Defines if the window can be closed with a system menu option or window header button. Values can be `"yes"`, `"no"` or `"auto"`. Default is `"auto"`. When value is `"auto"`, the option is enabled according to the window type. This attribute may have different behavior depending on the front end operating system. For example, when no system menu is used, it may not be possible to have this option enabled.	Yes	Yes	No	No
`windowOptionMaximize` Defines if the window can be maximized with a system menu option or window header button. Values can be `"yes"`, `"no"` or `"auto"`. Default is `"auto"`. When value is `"auto"`, the option is enabled according to the window type. This attribute may have different behavior depending on the front end operating system. For example, when no system	Yes	No	No	No

Attribute	GDC	GWC-JS	GMA	GMI
menu is used, it may not be possible to have this option enabled.				
`windowOptionMinimize` Defines if the window can be minimized with a system menu option or window header button. Values can be `"yes"`, `"no"` or `"auto"`. Default is `"auto"`. When value is `"auto"`, the option is enabled according to the window type. This attribute may have different behavior depending on the front end operating system. For example, when no system menu is used, it may not be possible to have this option enabled.	Yes	No	No	No
`windowState` Defines the initial state of a window. Values can be `"normal"`, `"maximized"` or `"minimized"`. Default is `"normal"`.	Yes	No	No	No
`windowSystemMenu` Defines if the window shows a system menu. Values can be `"yes"`, `"no"` or `"auto"`. Default is `"auto"`. When value is `"auto"`, the system menu is enabled according to the window type. **Note:** HTML5: Only `"auto"` is supported.	Yes	No (see note)	No	No
`windowType` Defines the basic type of the window. Values can be: • `"normal"` (default): Normal windows are displayed as typical application windows. • `"modal"`: Modal windows are displayed at the top of all other windows, typically used for temporary dialogs.	Yes	Yes	No	No

Examples

Code examples that use style file entries, form definition files, and source code to illustrate how presentation styles are applied.

Example 1: Defining styles for grid elements

This example shows how to define styles for grid elements.

The presentation style definition file:

```
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <!-- Applies to all type of elements -->
```

```
  <Style name=".bigfont">
     <StyleAttribute name="fontSize" value="large" />
  </Style>
  <!-- Default text color and font family for all labels -->
  <Style name="Label">
     <StyleAttribute name="textColor" value="blue" />
     <StyleAttribute name="fontFamily" value="sans-serif" />
  </Style>
  <!-- Background color for Edits having focus -->
  <Style name="Edit:focus">
     <StyleAttribute name="backgroundColor" value="yellow" />
  </Style>
  <!-- Text color for Edits with STYLE="mandatory" -->
  <Style name="Edit.mandatory">
     <StyleAttribute name="textColor" value="red" />
  </Style>
</StyleList>
```

The form definition file:

```
LAYOUT
GRID
{
[l1    ][f1            ]
[l2    ][f2            ]
[l3    ][f3            ]
}
END
ATTRIBUTES
LABEL l1: TEXT="Label 1:";
EDIT  f1 = FORMONLY.field1;
LABEL l2: TEXT="Label 2:";
EDIT  f2 = FORMONLY.field2;
LABEL l3: TEXT="Label 3:", STYLE="bigfont";
EDIT  f3 = FORMONLY.field3, STYLE="bigfont mandatory";
END
```

Program source file:

```
MAIN
    DEFINE rec RECORD
                field1 STRING,
                field2 STRING,
                field3 STRING
           END RECORD

    LET rec.field1 = "Field 1"
    LET rec.field2 = "Field 2"
    LET rec.field3 = "Field 3"

    CALL ui.Interface.loadStyles("styles")

    OPEN FORM f1 FROM "form"
    DISPLAY FORM f1

    INPUT BY NAME rec.* WITHOUT DEFAULTS

END MAIN
```

Graphical result:

Figure 45: Form displayed based on styles applied

How the styles were applied

1. All labels get a blue text color and sans-serif font family because of the `name="Label"` style.
2. Label 3 and Edit 3 defined with the `bigfont` style name get a large font because of the `name=".bigfont"` style.
3. The Edit field having the focus gets a yellow background color because of the `name="Edit:focus"` style (using the `focus` pseudo-selector).
4. Edit fields defined with the `mandatory` style name get a red text color because of the `name="Edit.mandatory"` style.

Example 2: Defining styles for table rows
This example shows how to define styles for tables and table rows.

The presentation style definition file:

```
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <!-- Applies to all type of elements -->
  <Style name=".bigfont">
     <StyleAttribute name="fontSize" value="large" />
  </Style>
  <!-- Background color form odd rows in tables -->
  <Style name="Table:odd">
     <StyleAttribute name="backgroundColor" value="yellow" />
  </Style>
</StyleList>
```

The form definition file:

```
LAYOUT
TABLE
{
[c1   |c2            |c3                ]
[c1   |c2            |c3                ]
[c1   |c2            |c3                ]
[c1   |c2            |c3                ]
}
END
ATTRIBUTES
EDIT c1 = FORMONLY.col1, TITLE="C1";
EDIT c2 = FORMONLY.col2, TITLE="C2";
EDIT c3 = FORMONLY.col3, TITLE="C3", STYLE="bigfont";
END
```

```
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

Program source file:

```
MAIN
    DEFINE arr DYNAMIC ARRAY OF RECORD
                col1 INTEGER,
                col2 STRING,
                col3 STRING
            END RECORD,
            i INTEGER

    FOR i=1 TO 20
        LET arr[i].col1 = i
        LET arr[i].col2 = "Item #"||i
        LET arr[i].col3 = IIF(i MOD 2, "odd", "even")
    END FOR

    CALL ui.Interface.loadStyles("styles")

    OPEN FORM f1 FROM "form"
    DISPLAY FORM f1

    DISPLAY ARRAY arr TO sr.*

END MAIN
```

Graphical result:

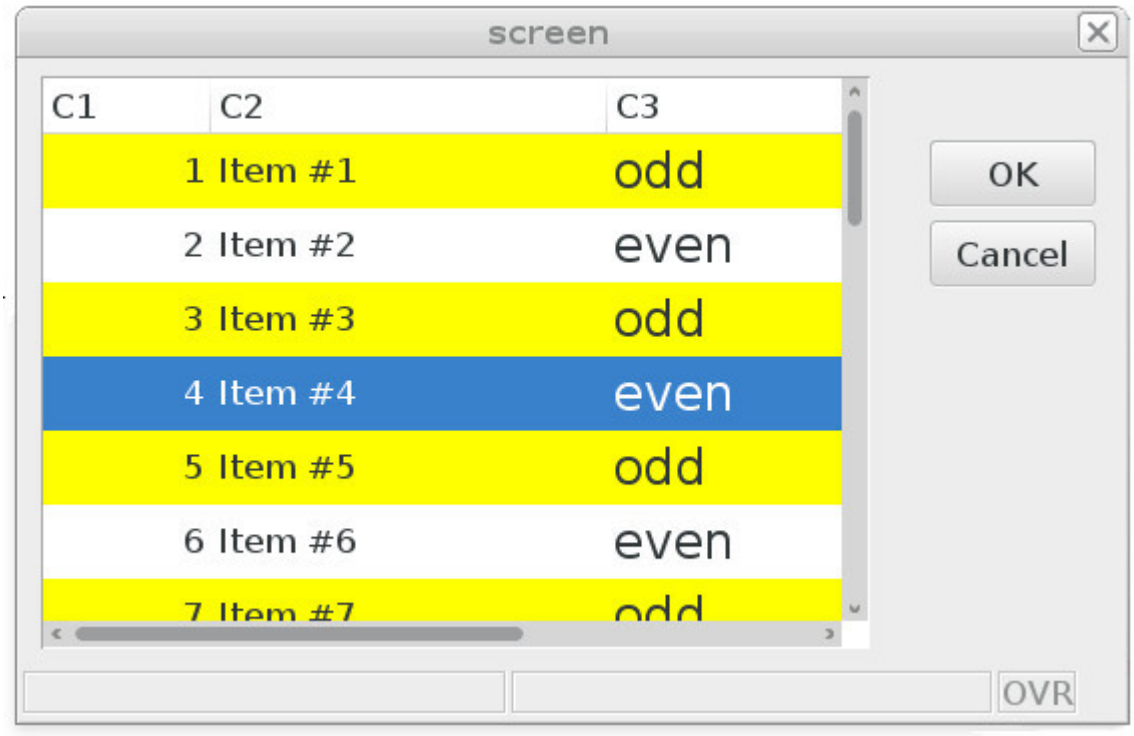

Figure 46: Form displayed based on styles applied

hat has the focus and

How the styles were applied

1. The odd rows get a yellow background because of the `name="Table:odd"` style (using the `odd` pseudo-selector).
2. Column 3 defined with the `bigfont` style name gets a large font because of the `name=".bigfont"` style.

Form specification files

Form specification files are the source files defining the layout and content of application forms.

- Understanding form files on page 853
- Form file concepts on page 853
- Form file structure on page 901
- Form item attributes on page 951
- Form rendering on page 1002
- Examples on page 1001

Understanding form files

A *form specification file* is a source file that defines an application form, to let the end user interact with the program.

The form file defines the disposition, presentation (i.e. decoration), and behavior of screen elements called form items.

The source file must have the `.per` file extension: `myform.per`. Programs load the `.42f` compiled version of the form files, and use interactive instructions (dialogs) to control the form.

To compile a `.per` source file to a `.42f` format, use the `fglform` form compiler. When a `SCHEMA` is specified in the form file, fglform requires that the database schema files already exist. Compiled form files depend on both the source files and the database schema files.

Compiled forms will be loaded by the programs with the `OPEN FORM` or the `OPEN WINDOW WITH FORM` instructions. The FGLRESOURCEPATH environment variable must contain the directory where the compiled form files are located at runtime, if the form file is not in the current directory.

Once a form is loaded, the program can manipulate forms to display or let the user edit data, with interactive instructions such as `INPUT` or `DISPLAY ARRAY`. Program variables are used as display and/or input buffers.

The content of a `.per` form file must follow a specific syntax as described in Form file structure on page 901.

Form file concepts

To write a form specification file, you need to understand the concepts described in this section.

- Form items on page 853
- External form inclusion on page 900
- Boolean expressions in forms on page 901

Form items

The concept of *form item* includes all elements used in the definition of a form.

Definition

A form item can be an input field such as an `EDIT` field, a push `BUTTON` or a `GROUPBOX` or `TABLE` container. A form item can also be an element of a `TOOLBAR`, `TOPMENU` and `ACTION DEFAULTS` definition.

A form item can be:

- A satellite item
- A static item

- A layout item
- A stack item
- An action view
- A form field

Form item types

A form item is defined by its type, called a *form item type*. For example, a form field can be an `EDIT`, or a `COMBOBOX`, a form layout container can be a `GROUP`, or a `GRID`, a toolbar item can be an `ITEM` or a `SEPARATOR`.

For a detailed description, see Form item types on page 878.

Form items in grid-based containers

In a grid-based container such as `GRID`, form items (typically, form fields) must be defined with a form tag in the `LAYOUT` section, bound by the tag name to a definition in the `ATTRIBUTES` section.

The form tag defines the position and length of the form item, while the appearance and the behavior the form item is defined by a set of attributes in the `ATTRIBUTES` section:

```
LAYOUT
GRID
{
   [f1            ]
   ...
}
END
END
...
ATTRIBUTES
EDIT f1 = customer.cust_name, ... ;
END
```

Form items in stack-based forms

In a stack-based container (`STACK`), form items (typically, form fields), are grouped and arranged in a given order, that will define their position in the stacked layout. The appearance and the behavior the form item is defined by a list of attributes in the stack item definition:

```
LAYOUT
 STACK
  GROUP
    EDIT customer.cust_name, ... ;
  END
 END
END
```

Satellite form items

Other kind of form items are defined in the section it belongs to (for example, an `ITEM` element of a `TOOLBAR` definition).

Satellite items
Satellite items are display elements defined outside the `LAYOUT` section.

Satellite items like the TOOLBAR section are form elements independent from the main form layout, and are defined additionally to the `LAYOUT` section.

```
TOOLBAR -- Toolbar section
```

```
...
END
LAYOUT -- Main layout section
...
END
```

Static items
A *static item* defines a simple form item as a final grid element (i.e. that does not change).

A static item is a form element that is defined directly in a grid of the form `LAYOUT` section, such as a text (typically, a field label).

Static items are identified by the `fglform` compiler and converted to a AUI tree node element in the resulting `.42f` file.

Simple texts

It is possible to define simple texts and field labels in the form layout:

```
LAYOUT
GRID
{
A simple text
}
END
END
```

> **Note:** To simplify internationalization, consider using named static labels instead of hard-coded text in the form layout.

Horizontal lines

You define a horizontal line with a sequence of hyphen-minus (`-`) characters in a grid:

```
LAYOUT
GRID
{
This is a horizontal line: ------------
}
END
END
```

> **Note:** Horizontal lines are mainly provided for TUI mode applications. While horizontal lines will be represented by some GUI front-ends, it is not a typical practice in common graphical applications.

Layout items
Layout items are containers with a body that can hold other form items, in a grid-based layout form.

Layout items can be specified as a tree of nested containers, or as layout tags within a single `GRID` container.

The next example shows a tree of nested containers, where a `GRID` and `TABLE` are included in a `VBOX`:

```
LAYOUT
VBOX
 GRID ...
 {
 }
 END
 TABLE ...
 {
 }
```

```
 END
END
```

The next example shows a GRID container including layout tags. The layout tags group form fields in dedicated areas. This syntax is usually more convenient to describe application forms:

```
LAYOUT
GRID
{
<g g1                       >
 Name: [f01                ]
<                           >
<t t1                       >
[c1  |c2                    ]
<                           >
}
END
END
```

Stack items
Stack items are form elements used to define a stack-based layout in a STACK container.

To define a stacked layout within a STACK container, leaf stack items (typically, form fields, labels, buttons) are specified inside grouping stack items such as GROUP or TABLE.

The next example shows a stack-based form definition with a GROUP stack item containing two EDIT stack items:

```
LAYOUT
 STACK
   GROUP g1
       EDIT customer.cust_num, NOENTRY;
       EDIT customer.cust_name, REQUIRED;
   END
 END
END
```

Action views
An *action view* defines a form item that can trigger an action in the program.

Action views as satellite items

Below is TOOLBAR section defining a toolbar button using the close action name. Here no layout tag is used because the toolbar item is part of the toolbar graphical object (it will not appear in the form layout area):

```
TOOLBAR
  ITEM close (TEXT="Close")
END
```

Action views in grid-based container

The position and size of the element is defined with an item tag, while the rendering and behavior is defined in the ATTRIBUTES section. Both parts are bound by the name of the item tag. The item tag name is local to the .per file and is not available at runtime.

The next example defines a BUTTON form item, where the item tag name is "b_close", and the button name (and the action name) is "close":

```
LAYOUT
GRID
```

```
{
  ...
  [b_close     ]
}
END
END
...
ATTRIBUTES
BUTTON b_close: close, TEXT="Close";
END
```

Action views in stack-based layout

In a stack-based container, action views are defined as stack items, with the attribute defining the rendering and behavior:

```
LAYOUT
STACK
 GROUP group1 ( TEXT="Customer" )
  ...
  BUTTON print, TEXT="Print Report", IMAGE="printer";
  ...
```

Form fields
Form fields are form elements designed for data input and/or data display.

Purpose of form fields

A form field is a form item dedicated to data management. It associates a form item with a screen record field. The screen record field will be used to bind program variables in interaction instructions (i.e. dialogs). The program variables will be the data models for the form fields.

There are different sort for form fields:

- Database column fields on page 858
- Formonly fields on page 860
- Phantom fields on page 861
- Aggregate fields on page 863

Form fields can be used in a grid-based layout or in a stack-based layout.

Form fields are identified by the field name in programs, and are grouped in screen records (or screen arrays in case of list containers). The interactive instruction must mediate between screen record fields and database columns by using program variables.

Form fields are usually related to database column, which types are defined in the database schema file.

Forms fields in grid-based containers

In a grid-based container, the position and size of a form field is defined with an item tag in the form layout, while the rendering and behavior is defined in the `ATTRIBUTES` section. Both parts are bound by the name of the item tag. The item tag name is local to the `.per` file and is not available at runtime: It is just the key to bind the item tag (position) with the item definition (attributes).

In the next example, the "`f1`" item tag (in the `LAYOUT` section) is linked to the "`vehicle.num`" form field definition (in the `ATTRIBUTES` section), which references a column of the "`vehicle`" table, defined in the "`carstore`" database schema:

```
SCHEMA carstore
LAYOUT
GRID
```

```
{
Number:   [f1           ]
Name:     [f2                       ]
}
END
END
TABLES
  vehicle
END
ATTRIBUTES
  EDIT f1 = vehicle.num, STYLE="keycol";
  EDIT f2 = vehicle.name, UPSHIFT;
END
```

Forms fields in stack-based containers

In a stack-based container, the visual position of a form field is defined by the ordinal position of the stack item in the stack definition, while the rendering and behavior are defined with stack item attributes.

In the next example, the "`vehicle.num`" form field definition references a column of the "`vehicle`" table, defined in the "`carstore`" database schema:

```
SCHEMA carstore
LAYOUT
  STACK
  GROUP
    EDIT vehicle.num, REQUIRED, STYLE="keycol";
  END
  END
END
TABLES
  vehicle
END
```

Database column fields

Form fields defined with a table and column name get data type from the database schema file.

Syntax 1: In grid-based container

```
item-type item-tag = [table.]column
    [ , attribute-list ]  ;
```

Syntax 2: In stack-based container

```
item-type [table.]column
    [ , attribute-list ]  ;
```

1. *item-type* references an item type like `EDIT`.
2. *item-tag* identifies the layout location of the field.
3. *table* is the name or alias of a table, synonym, or view, as declared in the `TABLES` section.
4. *column* is the name of a database column.
5. *attribute-list* is a list of field attributes.

Usage

A form field is typically based on the definition of a database column found in the database schema specified with the `SCHEMA` clause at the beginning of the form file. The database column defines the data type of the form field.

> **Important:** The data type of a form field is only used by the `CONSTRUCT` interactive statement to do database queries. When using the form field with an `INPUT`, `INPUT ARRAY` or `DISPLAY ARRAY` dialog, the type of the program variable defines the data type of the form field.

In order to reference database columns, the table name must be listed in the `TABLES` section of the form.

Fields are associated with database columns only during the compilation of the form specification file: The form compiler examines the database schema file to identify the data type of the column, and defines the form field with this type. This technique allows to centralize form field data types in the schema files: If the data type of a column changes, extract the schema again and recompile your forms to take the new type into account.

> **Note:** The compilers do also grab other field attributes like validation rules and video display attributes from `.val` and `.att` schema files. However, this is supported for backward compatibility only (formerly stored in syscolval and syscolatt database tables). Consider reviewing programs using this feature.

After the form compiler identifies data types from the schema file, the association between fields and database columns is broken, and the form cannot distinguish the name or synonym of a table or view from the name of a screen record.

The programs only have access to screen record fields, in order to display or input data using program variables. Regardless of how you define them, there is no implicit relationship between the values of program variables, form fields, and database columns. Even, for example, if you declare a variable `lname LIKE customer.lname`, the changes that you make to the variable do not imply any change in the column value. Functional relationships among these entities must be specified in the program code, through screen interaction statements, and through SQL statements. It is up to the programmer to determine what data a form displays and what to do with data values that the user enters into the fields of a form. You must indicate the binding explicitly in any statement that connects variables to forms or to database columns.

If a form field is declared with a table column using the SERIAL, SERIAL8 or BIGSERIAL SQL type, the field will automatically get the `NOENTRY` attribute, except if the field is defined with the `TYPE LIKE` syntax.

Example

Grid-based container database form field definition:

```
SCHEMA stores  -- Database schema
LAYOUT
GRID
{
 [f001             ]
 ...
}
END
END
TABLES
  customer  -- Database table
END
ATTRIBUTES
EDIT f001 = customer.fname,  -- DB-col form field
     REQUIRED, COMMENTS="Customer name";
...
```

Stack-based container database form field definition:

```
SCHEMA stores  -- Database schema
TABLES
  customer  -- Database table
END
LAYOUT
```

```
  STACK
  GROUP
    EDIT customer.fname, -- DB-col form field
         REQUIRED, COMMENTS="Customer name";
  ...
```

Formonly fields

FORMONLY form fields define their data type explicitly, with or without referencing a database columns.

Syntax 1: In grid-based container

```
item-type item-tag = FORMONLY.field-name
   [ TYPE
      { LIKE [table.]column
      | data-type [NOT NULL] }
   ]
     [ , attribute-list ]  ;
```

Syntax 2: In stack-based container

```
item-type FORMONLY.field-name
   [ TYPE
      { LIKE [table.]column
      | data-type [NOT NULL] }
   ]
     [ , attribute-list ]  ;
```

where *data-type* is one of:

```
{ CHAR
| DECIMAL [(p[,s])]
| SMALLFLOAT
| REAL
| FLOAT
| MONEY [(p[,s])]
| INTEGER
| SMALLINT
| DATE
| VARCHAR
| TEXT
| BYTE
| INTERVAL interval-qualifier
| DATETIME datetime-qualifier
| BIGINT
| BOOLEAN
}
```

1. *table* is the name or alias of a table, synonym, or view, as declared in the TABLES section.
2. *column* is the name of a database column.
3. *field-name* is the identifier that will be used in programs to handle the field.
4. *interval-qualifier* is an INTERVAL qualification clause such as HOUR(5) TO SECOND.
5. *datetime-qualifier* is a DATETIME qualification clause such as DAY TO SECOND.

Usage

Form fields can be specified with the FORMONLY prefix, when there is no corresponding database column, or when the field must be defined with another name as the database column.

Important: The data type of a form field is only used by the CONSTRUCT interactive statement to do database queries. When using the form field with an INPUT, INPUT ARRAY or DISPLAY ARRAY dialog, the type of the program variable defines the data type of the form field.

When using the LIKE [table.]column syntax, the form field will get the data type of the specific table column as defined in the database schema. The table name must be specified in the TABLES section.

When using the TYPE *data-type* clause, you explicitly specify the type of the field. Note that for CHAR/VARCHAR data types, the size is defined by the item tag length in the layout.

If no data type is specified, and no database column is referenced, the default data type is CHAR.

Specifying a data type followed by the NOT NULL keywords is equivalent to the NOT NULL attribute.

The STRING data type is not supported in formonly form field definitions.

The definition of FORMONLY fields can be completed by using the DISPLAY LIKE and VALIDATE LIKE attributes, to get the display and validation attributes from the .att and .val database schema files.

Example

Grid-based container FORMONLY form field definition (in the ATTRIBUTES section):

```
LAYOUT
GRID
{
 [f001             ]
 [f002             ]
 ...
}
END
END
ATTRIBUTES
EDIT f001 = FORMONLY.total TYPE DECIMAL(10,2), NOENTRY ;
EDIT f002 = FORMONLY.name TYPE LIKE customer.cust_name,
            VALIDATE LIKE customer.cust_name ;
```

Stack-based container FORMONLY form field definition:

```
LAYOUT
  STACK
  GROUP
    EDIT FORMONLY.total TYPE DECIMAL(10,2), NOENTRY ;
    EDIT FORMONLY.name TYPE LIKE customer.cust_name, REQUIRED;
```

Phantom fields

A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

Syntax

```
PHANTOM { [table.]column
        | FORMONLY.field-name
            [ TYPE
              { LIKE [table.]column
              | data-type [NOT NULL] }
            ]
    } ;
```

where *data-type* is one of:

```
{ CHAR
| DECIMAL [(p[,s])]
```

```
| SMALLFLOAT
| REAL
| FLOAT
| MONEY [(p[,s])]
| INTEGER
| SMALLINT
| DATE
| VARCHAR
| TEXT
| BYTE
| INTERVAL interval-qualifier
| DATETIME datetime-qualifier
| BIGINT
| BOOLEAN
}
```

1. *table* is the name or alias of a table, synonym, or view, as declared in the `TABLES` section.
2. *column* is the name of a database column.
3. *field-name* is the identifier that will be used in programs to handle the field.
4. *interval-qualifier* is an `INTERVAL` qualification clause such as `HOUR(5) TO SECOND`.
5. *datetime-qualifier* is a `DATETIME` qualification clause such as `DAY TO SECOND`.

Usage:

A `PHANTOM` field defines a form field listed in a screen-record or screen-array, that has no corresponding layout element. It is only used for the screen-record (or screen-array) definition, to bind with program variables used by dialogs, typically to match a given database table definition.

Phantom fields will be used by dialog instructions as regular form fields, but will not be displayed to the end user, and the end user will not be able to enter values for these fields. Data hold by phantom fields is never send to the front-ends: They can be used to store critical data that must not go out of the application server.

Phantom fields can be based on columns defined in a database schema file, or as `FORMONLY` field.

For example, if you want to implement a screen-array with all the columns of a database table defined in the database schema file, but you don't want to display all the columns in the `TABLE` container of the `LAYOUT` section, you must use `PHANTOM` fields. With the screen-array matching the database table, you can easily write program code to fetch all columns into an array defined with a `LIKE` clause.

Example (grid-based layout)

Form file:

```
SCHEMA carstore
LAYOUT( TEXT = "Vehicles" )
GRID
{
<T t1                                    >
 Num      Name            Price
[c1      |c2             |c3            ]
[c1      |c2             |c3            ]
[c1      |c2             |c3            ]
}
END
END
TABLES
  vehicle
END
ATTRIBUTES
  TABLE t1: table1;
  EDIT c1 = vehicle.num;
```

```
  EDIT c2 = vehicle.name;
  EDIT c3 = vehicle.price;
  PHANTOM vehicle.available;  -- not used in layout
END
INSTRUCTIONS
  SCREEN RECORD sr(vehicle.*);
END
```

Program code:

```
SCHEMA carstore
...
DEFINE vl DYNAMIC ARRAY OF RECORD LIKE vehicle.*
...
DISPLAY ARRAY vl TO sr.*
...
```

Aggregate fields

An AGGREGATE field defines a screen-record field to display summary information for a TABLE column.

Syntax

```
AGGREGATE item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Usage

An AGGREGATE field defines a form field that is used to display a summary cell for a given column of a TABLE container. The aggregate fields are displayed after the last data line of the table. Such fields are typically used to show computed values for the corresponding column which appears above the aggregate cell.

> **Important:** This feature is not supported on mobile platforms.

An aggregate field can be based on a database column defined in a schema file, or as FORMONLY field.

The AGGREGATETYPE attribute defines how the value of the field will be computed. For example, the SUM keyword (the default) can be used to instruct the runtime system to automatically compute the total of the associated column. By using the PROGRAM keyword, you indicate that the value of the aggregate field will be computed and displayed by program code. A simple DISPLAY BY NAME or DISPLAY TO can be used to show the summary value.

The value displayed in the AGGREGATE field follows the FORMAT attribute of the corresponding column, if defined. The FORMAT attribute is applied for automatically computed values, as well as for values displayed by user code with DISPLAYBY NAME or DISPLAY TO.

The label of an aggregate field can be specified with the AGGREGATETEXT attribute. The text defined with this attribute will be displayed on the left of the aggregate value (in the aggregate cell), except if there is no room to display the label (for example if the aggregate value is too large or if the column values are aligned to the left). An aggregate label can be a localized string with the %"..." string syntax. You can also specify an AGGREGATETEXT attribute at the TABLE level, to get a global label for the summary line. If no text is defined for an aggregate field, the global aggregate text will appear on the left in the summary line.

Table aggregate decoration can be modified with a presentation style. Use the summaryLine pseudo-selector to change the font type and color, as well as the background of the summary line. Use the

`summaryLineAlwaysAtBottom` table style attribute to force the summary line to stay on the bottom of the table.

Aggregate fields in grid-based layout

The item tag of an aggregate field must appear in the last line in the layout block of the`TABLE` container, and must be aligned vertically with a table column item tag. You can specify several aggregate item tags for the same table:

```
TABLE
{
[c1      |c2       |c3           |c4       |c5      ]
[c1      |c2       |c3           |c4       |c5      ]
[c1      |c2       |c3           |c4       |c5      ]
[c1      |c2       |c3           |c4       |c5      ]
         [cnt      ]             [tot_c4   |tot_c5  ]
}
END
```

Aggregate fields in stack-based layout

Important: Aggregate fields are not supported in tables defined in a `STACK` container.

Example (grid-based layout)

```
SCHEMA stores
LAYOUT( TEXT = "Orders" )
GRID
{
<T t1                                    >
 Num      Date            Order total
[c1      |c2             |c3           ]
[c1      |c2             |c3           ]
[c1      |c2             |c3           ]
[c1      |c2             |c3           ]
                         [total        ]
}
END
END
TABLES
  orders
END
ATTRIBUTES
  TABLE t1: table1;
  EDIT c1 = orders.o_num;
  EDIT c2 = orders.o_date;
  EDIT c3 = orders.o_tot;
  AGGREGATE total = FORMONLY.o_total,
                        AGGREGATETEXT = "Total:",
                        AGGREGATETYPE = SUM;
END
INSTRUCTIONS
  SCREEN RECORD sr(orders.*);
END
```

Identifying form items

Elements defined in a form file can be identified with a name, to be used in programs.

Form fields are implicitely identified by the `tabname.colname` specification after the equal sign, while other (non-field) form items such as static labels and group boxes can get an optional item name.

The form item name defined in the form file will be copied to the `name` attribute of the corresponding node in the `.42f` file. It can then be used by programs to select a form element at runtime, to introspect or modify its attributes.

For example, specify the name for a `GROUP` container by writing an identifier after the layout container type:

```
GROUP group1 (TEXT="Customer")
```

Here the group name is '`group1`', and it can be used in a program to identify the group element:

```
DEFINE w ui.Window
DEFINE g om.DomNode
LET w = ui.Window.getCurrent()
LET g = w.findNode("Group","group1")
CALL g.setAttribute("text","Another text")
```

Helper methods are provided for common tasks on form elements. For example, to hide a group with the identifier `group1`, you can use the `setElementHidden()` method on a `ui.Form` object:

```
DEFINE f ui.Form
...
   LET f = DIALOG.getForm()
   ...
   CALL f.setElementHidden("group1", TRUE)
```

> **Note:** Consider defining unique names to form elements to be identified, to simplify the search at runtime. A good practice is the use a prefix based on the type of form element (`g_` for groups, `l_` for labels for example).

Static items in a grid-based layout container cannot get a name, because these are self-defined with the layout part of the item:

```
GRID
{
Name: [f1              ]
...
}
END
```

In the above example, the label "Name:" cannot be identified. In order to give a name to such label, use an item tag and add a `LABEL` line in the `ATTRIBUTES` section, and specify the name of the label after the colon:

```
GRID
{
[l1   ][f1              ]
...
}
END
...
ATTRIBUTES
LABLE l1: l_name, TEXT="Name:";
...
```

Screen records

Form fields can be grouped in a *screen record* or *screen array* definition. A screen array is a screen record with a dimension, to handle a list of records.

Syntax

```
SCREEN RECORD record-name [ size ] ( field-list )
```

where *field-list* is:

```
{ table.*
| field-name
| first-field [ {THROUGH|THRU} last-field ]
[,...] }
```

1. *record-name* is the name of an explicit screen record or screen array.
2. *size* is an integer representing the number of records in the screen array.
3. *field-name* is a field identifier as defined in the right operand of a field definition in the `ATTRIBUTES` section.
4. *first-field* and *last-field* are field identifiers like *field-name*. This notation instructs the form compiler to take all the fields defined between the first and last field (inclusive).
5. *table* is the name or alias of a table, synonym, or view, as declared in the `TABLES` section. This notation instructs the form compiler to build the screen record with all fields declared in the `ATTRIBUTES` section for the given table.

Usage

Screen records and screen arrays are defined with the `SCREEN RECORD` keywords in the `INSTRUCTIONS` section of a form specification file to name a group of fields.

Screen records

A screen record is a named group of fields that screen interaction statements of the program can reference as a single object. By establishing a correspondence between a set of screen fields (the screen record) and a set of program variables (typically a program record), you can pass values between the program and the fields of the screen record. In many applications, it is convenient to define a screen record that corresponds to a row of a database table.

Like the name of a screen field, the identifier of a screen record must be unique within the form, and it has a scope that is restricted to when its form is open. Interactive statements can reference *record-name* only when the screen form that includes it is being displayed. The form compiler returns an error if *record-name* is the same as the name or alias of a table in the TABLES section.

```
SCHEMA videoshop
LAYOUT
GRID
{
  Customer id: [f001     ]
  Name:        [f002                          ]
  Create date: [f003     ]
}
END
END
TABLES
customer
END
INSTRUCTIONS
SCREEN RECORD sr_customer
(
```

```
 customer.cust_id,
 customer.cust_name,
 customer.cust_crea
);
END
```

Default screen records

The form compiler builds default screen records that consist of all the screen fields linked to the same database table within a given form. A default screen record is automatically created for each table that is used to reference a field in the `ATTRIBUTES` section.

The components of the default record correspond to the set of display fields that are linked to columns in that table. The name of the default screen record is the table name (or the alias, if you have declared an alias for that table in the `TABLES` section). For example, all the fields linked to columns of the "customer" table constitute a default screen record whose name is "customer".

If a form includes one or more `FORMONLY` fields, those fields constitute a default screen record called "formonly".

Screen arrays

A screen array is similar to a screen record, except that it defines a additional *size*. Screen arrays are typically used to reference rows in a static list of fields defined in the `LAYOUT` section. Each row of a screen array is a screen record. Each column of a screen array consists of fields with the same field tag in the `LAYOUT` section.

The *size* value must be equal to the number of lines of the static list of field tags in the layout of the form. For example, a `GRID` container might represent a set fields organized in columns like this:

```
LAYOUT
GRID
{
  OrdId      Date        Total Price
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
}
END
END
```

This example requires a *size* of 4 when defining the corresponding screen array:

```
INSTRUCTIONS
SCREEN RECORD sr_orders[4]
(
 order.ord_id,
 order.ord_date,
 order.ord_total
);
END
```

You cannot define multiple screen arrays for the same `TABLE` definition. Only one `SCREEN RECORD` specification is allowed.

Screen arrays must specify a size when referencing fields that define a static list in the layout. When referencing the columns of a variable-size record list container such as a TABLE or a TREE, the corresponding screen array must be defined without a size:

```
LAYOUT
```

```
TABLE
{
  OrdId      Date        Total Price
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
 [f001      |f002       |f003       ]
}
END
END
```

This TABLE layout does not require a *size* specification when defining the corresponding screen array:

```
INSTRUCTIONS
SCREEN RECORD sr_orders
(
 order.ord_id,
 order.ord_date,
 order.ord_total
);
END
```

Using screen records and screen arrays in programs

Screen records and screen arrays can display program records. If the fields in the screen record have the same sequence of data types as the columns in a database table, you can use the screen record to simplify operations that pass values between program variables and rows of the database.

Screen records are usually not referenced in programs within single record input statements, because program variable to form field binding is typically done by name with the `INPUT BY NAME` instruction.

Screen array names are typicaly referenced in programs within interactive dialog controlling a list of records such as `DISPLAY ARRAY` and `INPUT ARRAY`. The current form must include that named screen array.

Form tags
Form tags define layout elements inside a grid-based container.

Form tags are place holders used inside a grid of the layout section, to define the position and the relation between form items.

The syntax and purpose of a form tag depends on the type of form tag.

The different sort of form tags are:

- Layout tags on page 868
- Item tags on page 873
- Hbox tags on page 875

Layout tags
Layout tags define layout areas for containers inside the frame of a grid-based container.

Syntax

```
  <type  [identifier]      >
    content
[ <                        > ]
```

1. *type* defines the kind of layout tag to be inserted at this position.
2. *identifier* references a form item definition in the `ATTRIBUTES` section, it must be unique, but is optional.
3. *content* defines other form items inside the layout tag.

4. The (< >) ending the layout tag body is optional.

Usage

A layout tag defines a layout region of a container, in the body frame of a `GRID` container.

While complex layout with nested frames can be defined with `HBOX` and `VBOX` containers, it is sometimes more convenient to define a form with a complex layout by using layout tags within a `GRID` container.

A layout tag has a type that defines what kind of container will be generated in the compiled form.

A layout tag is delimited by angle braces (<>), and contains the tag type (`G`/`GROUP`, `T`/`TABLE`, etc) and an optional identifier.

Table 257: Types of layout tags

Tag Type	Abbr.	Description
`GROUP`	`G`	Defines a group box layout tag, resulting in the same presentation as the GROUP container.
`TABLE`	`T`	Defines a table view layout tag, resulting in the same presentation as the TABLE container.
`TREE`	*N/A*	Defines a tree-view list view layout tag, resulting in the same presentation as the TREE container.
`SCROLLGRID`	`S`	Defines a scrollable grid layout tag, resulting in the same presentation as the SCROLLGRID container.

The details of the layout tag definition are specified in the `ATTRIBUTE` section. Layout tags must be identified by an item tag name. In the next example, the layout tag named "g1" is defined in the `ATTRIBUTE` section with the `GROUP` form item type to set the name and text:

```
LAYOUT
GRID
{
<GROUP g1        >
[text1           ]
[                ]
[                ]
<                >
}
END
END
ATTRIBUTES
GROUP g1:group1, TEXT="Description";
TEXTEDIT text1=FORMONLY.text1;
END
```

The layout region is a rectangle, in which the width is defined by the length of the layout tag, and the height by a closing tag (< >) . In the next example, the layout region is defined by the layout tag named "group1".

```
<GROUP group1            >
```

```
<                        >
```

Form items must be placed inside the layout region. The [ ] square brackets are not part of the form item width and can be place at the same X position as the layout tag delimiters:

```
<GROUP group1             >
 Item:     [f001          ]
 Quantity: [f002    ]
 Date:     [f003          ]
<                         >
```

The [ ] square brace delimiters are not counted to define the width of an item tag. The width of the item is defined by the number of character between the square braces. Thus, this layout is valid and can be compiled:

```
<GROUP group1            >
[f001                    ]
[f002                    ]
 Static labels must fit!!
<                        >
<TABLE table1            >
[colA  |colB              ]
[colA  |colB              ]
[colA  |colB              ]
[colA  |colB              ]
```

You can place several layout tags on the same layout line in order to split the frame horizontally. This example defines six layout regions (four group boxes and two tables):

```
<GROUP group1      ><GROUP group2              ><GROUP group4 >
 FName: [f001      ] Phone: [f004              ][f012         ]
 LName: [f002      ] EMail: [f005              ][             ]
<                  ><                          >[             ]
<GROUP group3                                  >[             ]
[f010                                          ][             ]
<                                              ><             >
<TABLE table1               ><TABLE table2                    >
[c11   |c12   |c13          ][c21   |c22                      ]
[c11   |c12   |c13          ][c21   |c22                      ]
[c11   |c12   |c13          ][c21   |c22                      ]
[c11   |c12   |c13          ][c21   |c22                      ]
<                           ><                                >
```

The < > closing layout tag is optional. When not specified, the end of the layout region is defined by the underlying layout tag or by the end of the current grid. However, the ending tag must be specified if the form compiler cannot detect the end of the layout region. This is usually the case with group layout tags. In the next example, the table does not need an ending layout tag because it is defined by the starting tag of the group, but the group needs and ending tag otherwise it would include the last field (*field3*). Additionally, if *field3* would have a different size, the form compiler would raise an error because the group and the last field geometry would conflict.

```
<TABLE table1     >
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
<GROUP group2     >
[field1           ]
```

```
[field2           ]
<                 >
[field3           ]
```

It is possible to mix container layout tags with singular form items. You typically put form items using a large area of the form, such as `IMAGE` fields or `TEXTEDIT` fields. The `[ ]` square brace delimiters are not used to compute the size of the singular form items:

```
<GROUP group1             >[image1         ]
 FName: [f001             ][               ]
 LName: [f002             ][               ]
<                         >[               ]
[textedit1                  |               ]
[                           |               ]
[                           |               ]
```

Table layout tags can be embedded inside group layout tags:

```
<GROUP group1             >
 <TABLE table1           >
 [colA  |colB            ]
 [colA  |colB            ]
 [colA  |colB            ]
 [colA  |colB            ]
<                          >
```

Hbox or vbox containers with splitter are automatically created by the form compiler in these conditions:

- Hbox is created when two or more stretchable elements are stacked side by side and touch each other (no space between).
- Vbox is created when two or more stretchable elements are stacked vertically and touch each other (no space between).

Stretchable elements are containers such as `TABLE` containers, or form items like `IMAGE` fields with the `STRETCH` attribute.

No hbox or vbox object will be created if the elements are in a `SCROLLGRID` container.

This example defines two tables stacked vertically, generating a VBox with splitter (note that ending tags are omitted):

```
<TABLE table1     >
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
<TABLE table2     >
[colC  |colD      ]
[colC  |colD      ]
```

In this example, the layout defines two stretchable `TEXTEDIT` fields placed side by side which would generate an automatic hbox with splitter. To make both textedits touch you need to use a pipe delimiter in between:

```
[textedit1         |textedit2               ]
[                  |                        ]
[                  |                        ]
[                  |                        ]
```

The next layout example would make the form compiler create an automatic vbox with splitter to hold *table2* and *textedit1* , plus an hbox with splitter to hold *table1* and the first VBox (We must use a pipe character to delimit the end of *colB* and *textedit1* so that both tables can be placed side by side):

```
<TABLE table1     ><TABLE table2           >
[colA  |colB      ][colC|colD              ]
[colA  |colB      ][colC|colD              ]
[colA  |colB      ][colC|colD              ]
[colA  |colB      |textedit1                ]
[colA  |colB      |                         ]
[colA  |colB      |                         ]
```

If you want to avoid automatic hbox or vbox with splitter creation, you must add blanks between elements:

```
<TABLE table1     >  <TABLE table2           >
[colA  |colB      ]  [colC|colD              ]
[colA  |colB      ]  [colC|colD              ]
[colA  |colB      ]  [colC|colD              ]
[colA  |colB      ]
[colA  |colB      ] [textedit1                ]
[colA  |colB      ] [                         ]
[colA  |colB      ] [                         ]
```

Examples

The typical OK/Cancel window:

```
LAYOUT
GRID
{
<GROUP g1                    >
[com                         ]
<                            >
[            :bok   |bno     ]
}
END
END
ATTRIBUTES
LABEL com: comment;
BUTTON bok: accept;
BUTTON bno: cancel;
...
```

This example shows multiple uses of layout tags:

```
LAYOUT
GRID
{
<GROUP g1                              ><GROUP g2          >
 Ident: [f001   ] [f002                ] [text1            ]
 Addr:  [f003                          ] [                 ]
<                                      ><                  >
<GROUP g3                                                  >
[text2                                                     ]
[                                                          ]
[                                                          ]
<                                                          >
<TABLE t1                                                  >
  Num      Name                 State  Value
[col1    |col2                |col3  |col4                ]
[col1    |col2                |col3  |col4                ]
[col1    |col2                |col3  |col4                ]
```

```
[col1    |col2              |col3  |col4              ]
<                                                     >
}
END
END
ATTRIBUTES
GROUP g1:group1, TEXT="Customer";
GROUP g2:group2, TEXT="Comments";
TABLE t1:table1, UNSORTABLECOLUMNS;
...
```

Item tags

Item tags define the position and size in a grid-based container.

An item tag defines the position and size of a simple form item in a *grid-area* of a `GRID` or `SCROLLGRID` container. Form item defined with item tags are leafs in the structure of a form definition, such as a form field (i.e. it is not a container form item).

Syntax

```
[identifier [-] [|...]]
```

1. *identifier* references a form item definition in the `ATTRIBUTES` section.
2. The optional `-` dash defines the real width of the element.
3. The `|` pipe can be used as item tag separator (equivalent to `][`).

Usage

An item tag is delimited by square braces (`[]`) or pipes (`|`) and contains an identifier used to reference the description of the form item in the `ATTRIBUTES` section. In the next example, the identifier of the form item is "`f01`", and the form item type is `BUTTONEDIT`:

```
LAYOUT
GRID
{
   ...
   [f01            ]
   ...
}
END
...
ATTRIBUTES
BUTTONEDIT f01 = customer.cust_name, ACTION=zoom;
...
```

Each item tag must be indicated by left and right delimiters to show the length of the item and its position within the container layout. Both delimiters must appear on the same line. You must use left and right braces (`[]`) to delimit item tags. The number of characters and the delimiters define the width of the region to be used by the item:

```
GRID
{
  Name:  [f001                              ]
}
END
```

The form item position starts after the open square brace and the length is defined by the number of characters between the square braces. The following example defines a form item starting at position 3, with a length of 2:

```
GRID
{
1234567890
 [f1]
}
END
```

By default, the real width of the form item is defined by the number of characters used between the tag delimiters.

For some special items like `BUTTONEDIT`, `COMBOBOX` and `DATEEDIT`, the width of the field is adjusted to include the button. The form compiler computes the width as: *width=nbchars*-2 if *nbchars*>2:

```
GRID
{
 1234567
[f1     ]  -- this EDIT gets a width of 7
[f2     ]  -- this BUTTONEDIT gets a width of 5 (7-2)
}
END
```

If the default width generated by the form compiler does not fit, the `-` dash symbol can be used to define the real width of the item. In this example, the form item occupies 7 grid cells, but gets a real width of 5 (i.e. for an EDIT field, you would be able to enter 5 characters):

```
GRID
{
 1234567
[f1   - ]
}
END
```

To make two items appear directly next to each other, you can use the pipe symbol (`|`) to indicate the end of the first item and the beginning of the second item:

```
GRID
{
  Info:  [f001    |f002            |f003    ]
}
END
```

If you need the form to support items with a specific height (more that one line), you can specify *multiple-segment* item tags that occupy several lines of a *grid-area*. To create a multiple-segment item, repeat the item tag delimiters without the item *identifier* on successive lines:

```
GRID
{
  Multi-segment: [f001                            ]
                 [                                ]
                 [                                ]
                 [                                ]
                 [                                ]
}
END
```

The notation applies to the new LAYOUT section only. For backward compatibility (when using a SCREEN section), multiple-segment items can be specified by repeating the *identifier* in sub-lines.

If the same item tag (i.e. using the same *identifier*) appears more than once in the layout, it defines a column of a screen array:

```
GRID
{
  Single-line static screen array:
    [f001          ] [f002          ]  [f003          ]
    [f001          ] [f002          ]  [f003          ]
    [f001          ] [f002          ]  [f003          ]
    [f001          ] [f002          ]  [f003          ]
}
END
```

You can even define a multi-line list of fields:

```
GRID
{
  Multi-line static screen array:
    [f001          ]  [f002          ]
        [f003                                          ]
    [f001          ]  [f002          ]
        [f003                                          ]
    [f001          ]  [f002          ]
        [f003                                          ]
    [f001          ]  [f002          ]
        [f003                                          ]
}
END
```

Hbox tags

Hbox tags group several item tags within the same horizontal layout box, in a grid-based container.

An hbox tag defines the position and size in a GRID container for an horizontal box containing several leaf form items. The elements in the hbox tag can use additional alignment rules to get the required visual affect.

Syntax

```
[ element: [...] ]
```

where *element* can be:

```
{ identifier  [-] | string-list }
```

where *string-list* is:

```
{ string-literal | spacer } [...]
```

1. *identifier* references a form item definition in the ATTRIBUTES section.
2. The optional - dash defines the real width of the element.
3. string-list is a combination of string-literals
4. *string-literal* is a quoted text that defines a static label.
5. *spacer* is one or more blanks that define an invisible element that expands automatically.
6. The colon is the delimiter for hbox tag elements.

Usage

Hbox tags are provided to control the alignment of form items in a grid. Hbox tags allow you to stack form items horizontally without the elements being influenced by elements above or below. In an hbox, you can mix form fields, static labels and spacers. A typical use of the hbox is to have zip-code / city form fields side by side with predictable spacing in-between.

An hbox tag is delimited by square braces (`[]`) and must contain at least one *string-list* or an *identifier* preceded or followed by a colon (`:`). A *string-list* is combination of *string-literals* (quoted text) and *spacers* (blank characters). The delimiter for hbox tag elements is the colon.

Hbox tags are not allowed for fields of screen arrays; you will get a form compiler error. The client needs a matrix element directly in a grid or a scrollgrid to perform the necessary positioning calculations for the individual fields.

The following example shows simple hbox tags:

```
GRID
{
 ["Customer info:":    ]
 [f001       :         ]
 [  :f002              ]
 ["Name: "  :f003      ]
}
END
```

In this example:

1. The first hbox tag contains two elements: a static label and a spacer.
2. The second hbox tag contains two elements: a form field and a spacer.
3. The third hbox tag contains two elements: a spacer and a form field.
4. The fourth hbox tag contains two elements: a static label and a form field.

An hbox tag defines the position and width (in grid cells) of several form items grouped inside an horizontal box. The position and width (in grid cells) of the horizontal box is defined by the square braces (`[]`) delimiting the hbox tag.

When using an *identifier*, you define the position of a form item which is described in the `ATTRIBUTES` section. When using a *string-list*, you can define static labels and/or spacers. The following example defines an hbox tag generating 7 items (a static label, a spacer, a form item identified by `num`, a spacer, a static label, a spacer and a form item identified by `name`):

```
GRID
{
 ["Num:"  :num  :  :"Name:"  :name        ]
}
END
```

A *spacer* is an invisible element that automatically expands. It can be used to align elements left, right or center in the hbox. The following example defines 3 hboxes with the same width. Each hbox contains one field. The first field is aligned to the left, the second is aligned to the right and third is centered:

```
GRID
{
 [left :              ]
 [         :right     ]
 [     :centered:     ]
}
END

ATTRIBUTES
 LABEL left: label1, TEXT="LEFT";
```

```
 LABEL right: label2, TEXT="RIGHT";
 LABEL centered: label3, TEXT="CENTER";
END
```

When you use string literals, the quotes define where the label starts and stops. If there is free space after the quote that ends the label, then it is filled by a spacer. Consider this example:

```
GRID
{
 [    :"Label1"     ]
 [         :"Label2"]
}
END
```

In this example:

1. The first line contains a spacer, followed by the static label, followed by another spacer. The quotation marks end the string literal; a colon is not required to delimit the label from the final spacer.
2. The second line contains a spacer, followed by the static label. Because there is no empty space between the end of the static label and the closing bracket of the hbox Tag ( ]).

A typical use of hbox tags is to vertically align some form items - that must appear on the same line - with one or more form items that appear on the other lines:

```
GRID
{
 Id:      [num  :"Name: ":name        ]
 Address: [street                  : ]
          [zip-code:city             ]
 Phones:  [phone       :fax          ]
}
END
```

In this example, the form compiler will generate a grid containing 7 elements (3 labels and 4 hboxes):

1. The label "Id:",
2. A first hbox which defines 3 cells, where:
   - The field 'num' will occupy the cell (1,1),
   - The label "Name:" will occupy the cell (2,1),
   - The field 'name' will occupy the cell (3,1).
3. The label "Address:" will occupy cell (1,2),
4. A second hbox which defines 1 cell, where:
   - The field 'street' will occupy the cell (1,1).
5. A third hbox which defines 2 cells, where:
   - The field 'zip-code' will occupy the cell (1,1),
   - The field 'city' will occupy the cell (2,1).
6. The label "Phones:" will occupy cell (1,4),
7. A fourth hbox which defines 2 cells, where:
   - The field 'phone' will occupy the cell (1,1),
   - The field 'fax' will occupy the cell (2,1).

Inside an hbox tag, the positions and widths of elements are independent of other hboxes. It is not possible to align elements over hboxes. The position of items inside an hbox depends on the spacer and the real size of the elements. The following example does not align the items as you would expect, following the character positions in the layout definition:

```
GRID
```

```
{
  ["Num:     " :fnum :        ]
  ["Name:    " :fname         ]
}
END
```

A big advantage in using elements in an hbox is that the fields gets their real sizes according to the .per definition. The following example illustrates the case:

```
GRID
{
 MMMMM
[f1   ]
[f2 : ]
}
END
```

Here all items will occupy the same number of grid columns (5). The MMMMM static label will have the largest width and define the width of the 5 grid cells. The first field is defined with a normal item tag, and expands to the width of the 5 grid cells. The line 5 defines an hbox that will expand to the size of the 5 grid cells, according to the static label, but its child element - the field f2 - gets a size corresponding to the number of characters used before the ':' colon (i.e. 3 characters).

If the default width generated by the form compiler does not fit, the `-` dash symbol can be used to define the real width of the item. In this example, the hbox tag occupies 20 grid cells, the first form item gets a width of 5, and the second form item gets a width of 3:

```
GRID
{
 12345678901234567890
[f1   - :f2 -    :   ]
}
END
```

The `-` dash size indicator is especially useful in `BUTTONEDIT`, `DATEEDIT` and `COMBOBOX` form fields, for which the default width computed by the form compiler may not fit.

In the next example, a static label is positioned above a `TEXTEDIT` field. The label will be centered over the `TEXTEDIT` field, and will remain centered as the field expands or contracts with the resizing of the window.

```
GRID
{
 [ :"label": ]
 [textedit   ]
}
END

ATTRIBUTES
 TEXTEDIT textedit = formonly.textedit, STRETCH=BOTH;
END
```

Form item types

The *form item types* defines the purpose of form elements.

BUTTON item type

Defines a push-button that can trigger an action.

BUTTON item basics

The `BUTTON` form item type defines a standard push button with a label and/or an icon.

Defining a BUTTON

The label of a BUTTON form item is defined with the TEXT attribute. The COMMENT attribute can be used to define a hint for the button. Consider using localized strings for these attributes.

The picture is defined by the IMAGE attribute. Consider using centralized icons for button images.

```
BUTTON ...
   TEXT = %"common.button.text.ok",
   IMAGE = "accept",
   COMMENT = %"common.button.hint.ok";
```

BUTTON form items can inherit action default attributes, to avoid having to specify the TEXT, COMMENT and IMAGE attributes in all elements bound to the same action. For more details, see Configuring actions on page 1318.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Button style attributes on page 821.

Detecting BUTTON action

A BUTTON form item acts as an action view for a dialog action, and is bound to the ON ACTION handler by name. The action name can be prefixed with a sub-dialog identifier and/or a field name, to define a qualified action view:

```
-- Form file (grid layout)
BUTTON b1: print;

-- Program file:
ON ACTION print
   -- Execute code related to the print action
```

> **Note:** When controlled by a COMMAND action handler in a DIALOG interactive instruction, form buttons can get the focus and thus be part of the tabbing list (TABINDEX attribute).

For more details, see Binding action views to action handlers on page 1278.

Where to use a BUTTON

A BUTTON form item can be defined in two different ways:

1. With an item tag and a BUTTON item definition on page 934 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a BUTTON stack item on page 915 in a STACK container.

BUTTONEDIT item type

Defines a line-edit with a push-button that can trigger an action.

BUTTONEDIT item basics

The BUTTONEDIT form item defines an edit field that get user input, with an additional push button that can fire an action.

This type of form field is typically used to open a secondary window, to let the user choose from a large list of items and set the field value.

Defining a BUTTONEDIT

The IMAGE attribute of a BUTTONEDIT form item defines the picture to be displayed on the button.

By default, the text editor of a BUTTONEDIT allows the user to change the field value. Use the NOTEDITABLE attribute to deny text modification. The field still gets the focus, and the action button remains active, if there is a corresponding action handler in the current dialog.

```
BUTTONEDIT ...
   IMAGE = "zoom",
   NOTEDITABLE;
```

The button of BUTTONEDIT form items can inherit action default attributes, to avoid having to specify the IMAGE attributes in all elements bound to the same action. For more details, see Configuring actions on page 1318.

Most of the attributes described in the EDIT item type on page 886 can also be used with the BUTTONEDIT.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and ButtonEdit style attributes on page 822.

Detecting BUTTONEDIT button action

The button of a BUTTONEDIT form element acts as an action view for a dialog action, and is bound to the ON ACTION handler by the ACTION attribute. The ACTION attribute defines the name of the action to be sent to the program when the user clicks on the button. It can be prefixed with a sub-dialog identifier and/or field name, to define a qualified action view:

```
-- Form file
BUTTONEDIT ...
   ACTION = open_city_list;

-- Program file:
ON ACTION open_city_list
   -- Execute code related to the buttonedit button
```

For more details, see Binding action views to action handlers on page 1278.

Where to use a BUTTONEDIT

A BUTTONEDIT form item can be defined in two different ways:

1. With an item tag and a BUTTONEDIT item definition on page 935 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a BUTTONEDIT stack item on page 916 in a STACK container.

Defining the widget size

In a grid-based layout, the size of a BUTTONEDIT widget is computed according to layout rules as described in Widget size within hbox tags on page 1016.

In a stack-based layout, the widget will take the full width available in the parent container.

Field input length

In grid-based layout, the input length in a BUTTONEDIT fields is defined by the item tag and may need to get the SCROLL attribute. For more details, see Field input length on page 1260.

Defines a boolean or three-state checkbox field.

CHECKBOX item basics

The CHECKBOX form item defines a field with a check box and a text label.

Defining a CHECKBOX

The TEXT attribute defines the label to be displayed near the check box. Consider using localized strings for this attribute.

The box shows a checkmark when the form field contains the value defined in the VALUECHECKED attribute (for example: "Y"), and shows no checkmark if the field value is equal to the value defined by the VALUEUNCHECKED attribute (for example: "N"). If you do not specify the VALUECHECKED or VALUEUNCHECKED attributes, they respectively default to TRUE (integer 1) and FALSE (integer 0).

By default, during an INPUT dialog, a CHECKBOX field can have three states:

- Grayed (NULL value)
- Checked (VALUECHECKED value)
- Unchecked (VALUEUNCHECKED value)

If the field is declared as NOT NULL, the initial state can be grayed if the default value is NULL; once the user has changed the state of the CHECKBOX field, it switches only between checked and unchecked states.

During a CONSTRUCT, a CHECKBOX field always has three possible states (even if the field is NOT NULL), to allow the end user to clear the search condition:

- Grayed (No search condition)
- Checked (Condition column = VALUECHECKED value)
- Unchecked (Condition column = VALUEUNCHECKED value)

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and CheckBox style attributes on page 822.

Detecting CHECKBOX modification

To inform the dialog immediately when the value changes, define an ON CHANGE block for the CHECKBOX field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
CHECKBOX cb1 = order.ord_valid,
   ITEMS = ... ;

-- Program file:
ON CHANGE ord_valid
   -- The checkbox field has been modified
```

For more details, see Reacting to field value changes on page 1267.

Where to use a CHECKBOX

A CHECKBOX form item can be defined in two different ways:

1. With an item tag and a CHECKBOX item definition on page 936 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a CHECKBOX stack item on page 916 in a STACK container.

COMBOBOX item type

Defines a line-edit with a drop-down list of values.

COMBOBOX item basics

The COMBOBOX form item defines a field that can open a list of possible values the end user can choose from.

> **Note:** Such form field should be used for a short list of possible values (10 to 50, maximum).

Defining a COMBOBOX

The values of the drop-down list are defined by the ITEMS attribute. Define a simple list of values like ("A","B","C","D", ...) or a list of key/label pairs like in ((1,"Paris"),(2,"Madrid"), (3,"London")). In the second case, the labels (i.e. the city names) display according to the key value (the city number) held by the field.

```
COMBOBOX ...
   ITEMS=((1,"Paris"),(2,"Madrid"),(3,"London"));
```

Consider using localized strings when defining key/value pairs in the combobox items:

```
COMBOBOX ...
   ITEMS=((1,%"cities.paris"),
          (2,%"cities.madrid"),
          (3,%"cities.london"));
```

The INITIALIZER attribute allows you to define an initialization function for the COMBOBOX. This function will be invoked at runtime when the form is loaded, to fill the item list dynamically, for example with database records. It is recommended that you use the TAG attribute, so you can identify in the program the kind of COMBOBOX form item to be initialized. The initialization function name is converted to lowercase by fglform.

```
COMBOBOX ...
   TAG = "city", INITIALIZER=cmb_init;
```

If neither ITEMS nor INITIALIZER attributes are specified, the form compiler automatically fills the list of items with the values of the INCLUDE attribute, when specified. However, the item list will not automatically be populated with include range values (i.e. values defined using the TO keyword). The INCLUDE attribute can be specified directly in the form or indirectly in the schema files.

```
COMBOBOX ...
   INCLUDE=("A","B","C","D","E");
```

During an input dialog, a COMBOBOX field value can only be one of the values specified in the ITEMS attribute. If the field allows NULL values, consider adding an item to reference the NULL value. However, the best practice is to deny nulls with the NOT NULL attribute, and add a special item such as (0,"<Undefined>") to specify a non-specified-value:

```
COMBOBOX ...
   NOT NULL,
   ITEMS=((0,"<Undefined>"),
          (1,"Red"),
          (2,"Yellow"),
          (3,"Green"));
```

> **Note:** If one of the items is explicitly defined with NULL; In INPUT, selecting the corresponding combobox list item sets the field value to null. In CONSTRUCT, selecting the list item corresponding to null will be equivalent to the = query operator, which will generate a "*colname* is null" SQL

condition. During an CONSTRUCT, a COMBOBOX field gets an additional 'empty' item (even if the field is NOT NULL), to let the user clear the search condition.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and ComboBox style attributes on page 823.

Detecting COMBOBOX item selection

To inform the dialog when the value changes, define an ON CHANGE block for the COMBOBOX field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
COMBOBOX cb1 = customer.cust_city,
   ITEMS = ... ;

-- Program file:
ON CHANGE cust_city
   -- An new item was selected in the combobox list
```

For more details, see Reacting to field value changes on page 1267.

Where to use a COMBOBOX

A COMBOBOX form item can be defined in two different ways:

1. With an item tag and a COMBOBOX item definition on page 937 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a COMBOBOX stack item on page 917 in a STACK container.

Defining the widget size

In a grid-based layout, the size of a COMBOBOX widget is computed according to the SIZEPOLICY and SAMPLE attributes, and according to layout rules as described in Widget size within hbox tags on page 1016.

In a stack-based layout, the widget will take the full width available in the parent container.

COMBOBOX on mobile devices

On a mobile devices, COMBOBOX form items should be used for a short list of values that can be displayed on a single page; for example, 4 to 6 elements. When a list will expand to more than one page, it is recommended that you use a BUTTONEDIT with a zoom, which you can improve with a search button to find an exact item or to reduce the list of items to scroll.

DATEEDIT item type

Defines a line-edit with a calendar widget to pick a date.

DATEEDIT item basics

The DATEEDIT form item defines a field that can open a calendar to ease date input.

To store the field value, use a DATE program variable with this form item.

> **Important:** DATEEDIT fields are dedicated for DATE value input. Some front-ends (especially on mobile devices) deny data types different from DATE. If the front-end does not support the data type used for the DATEEDIT field, the runtime system will raise an error and stop the program. Consider testing your application with all types of front-ends.

Defining a DATEEDIT

The DATEEDIT form item type allows the user to edit date values with a specific widget for date input. A DATEEDIT field typically provides a calendar widget, to let the end user pick a date from it.

When using a DATE variable as recommended, with desktop front-ends, the format of DATEEDIT fields is by default defined by the DBDATE environment variable as for other editor fields. Specific format can be defined with the FORMAT attribute, but it is recommended to use the default date formatting. On mobile platforms, the date format is defined by the device OS language settings.

On some front-end platforms, the native widget used for DATEEDIT fields allows only pure date value input, and therefore cannot be used with a CONSTRUCT instruction, where it must be possible to enter search filters like ">=24/03/2014".

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and DateEdit style attributes on page 824.

Detecting DATEEDIT calendar selection

To inform the dialog when a date is picked from the calendar widget, define an ON CHANGE block for the DATEEDIT field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
DATEEDIT de1 = order.ord_shipdate,
   NOT NULL;

-- Program file:
ON CHANGE ord_shipdate
   -- An new date value was picked from the calendar
```

For more details, see Reacting to field value changes on page 1267.

Where to use a DATEEDIT

A DATEEDIT form item can be defined in two different ways:

1. With an item tag and a DATEEDIT item definition on page 938 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a DATEEDIT stack item on page 917 in a STACK container.

Defining the widget size

In a grid-based layout, the size of a DATEEDIT widget is computed according to layout rules as described in Widget size within hbox tags on page 1016.

In a stack-based layout, the widget will take the full width available in the parent container.

Field input length

The input length in a DATEEDIT fields is defined by the (DATE) program variable. In a grid-based layout, define an item tag with 10 positions, to be able to display dates with 4 year digits. For more details, see Field input length on page 1260.

DATETIMEEDIT item type

Defines a line-edit with a calendar widget to pick a datetime.

DATETIMEEDIT item basics

The DATETIMEEDIT form item defines a field that can open a calendar to ease date-time input.

To store the field value, use a `DATETIME YEAR TO MINUTE` or `DATETIME YEAR TO SECOND` program variable with such form item.

> **Important:** `DATEEDIT` fields are dedicated for `DATETIME` value input. Some front-ends (especially on mobile devices) deny data types different from `DATE`. If the front-end does not support the data type used for the `DATEEDIT` field, the runtime system will raise an error and stop the program. Consider testing your application with all types of front-ends.

Defining a DATETIMEEDIT

The `DATETIMEEDIT` form item type allows the user to edit date-time values with a specific widget for date-time input. A `DATETIMEEDIT` field typically provides a calendar and clock widget, to let the end user pick a date and time from it.

The display and input precision (time part with or without seconds) of the `DATETIMEEDIT` widget depends from the front-end. On some platforms, native date-time editors do not handle the seconds. Further, some front-ends (especially on mobile devices) deny data types different from `DATETIME YEAR TO {MINUTE|SECOND}`.

On some front-end platforms, the native widget used for `DATETIMEEDIT` fields allows only pure date-time value input, and therefore cannot be used with a `CONSTRUCT` instruction, where it must be possible to enter search filters like "`>= 2014-01-23 11:00`".

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818.

Detecting DATETIMEEDIT calendar selection

To inform the dialog when a date-time is picked from the calendar widget, define an `ON CHANGE` block for the `DATETIMEEDIT` field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
DATETIMEEDIT dt1 = order.ord_shipdate,
   NOT NULL;

-- Program file:
ON CHANGE ord_shipdate
   -- An new date-time value was picked from the calendar
```

For more details, see Reacting to field value changes on page 1267.

Where to use a DATETIMEEDIT

A `DATETIMEEDIT` form item can be defined in two different ways:

1. With an item tag and a DATETIMEEDIT item definition on page 939 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a DATETIMEEDIT stack item on page 918 in a `STACK` container.

Defining the widget size

In a grid-based layout, the size of a `DATETIMEEDIT` widget is computed according to layout rules as described in Widget size within hbox tags on page 1016.

In a stack-based layout, the widget will take the full width available in the parent container.

Field input length

The input length in a `DATETIMEEDIT` fields is defined by the (`DATETIME`) program variable. In a grid-based layout, define an item tag with enough positions, to be able to display dates with 4 year digits. For more details, see Field input length on page 1260.

EDIT item type

Defines a simple line-edit field.

EDIT item basics

The EDIT form item defines a field to enter a single-line text, for any data type.

This item type is typically used to define character string and numeric form fields.

Defining an EDIT

The EDIT item type can be used for any data type that can be converted to an editable text.

To show a hint to the user when the field has the focus, use the COMMENT attribute.

If the field is mandatory for an input, combine the NOT NULL with the REQUIRED attribute.

The value accepted for the field can be limited with the INCLUDE attribute.

To provide a default value, define the DEFAULT attribute for the field.

Use the DOWNSHIFT or UPSHIFT attributes to force the letter case during input.

Input can be hidden (for example for password fields), with the INVISIBLE attribute.

Especially for mobile devices, use the KEYBOARDHINT attribute to get a specific keyboard when entering values into the field.

Input completion proposals can be implemented with the COMPLETER attribute.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Edit style attributes on page 826.

Where to use an EDIT

An EDIT form item can be defined in two different ways:

1. With an item tag and a EDIT item definition on page 939 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a EDIT stack item on page 918 in a STACK container.

Field input length

In grid-based layout, the input length in an EDIT fields is defined by the item tag and may need to get the SCROLL attribute. For more details, see Field input length on page 1260.

FOLDER item type

Defines a layout area to hold folder pages.

FOLDER item basics

A FOLDER form item type groups folder pages together. Folder pages are defined with the PAGE form item.

Defining an FOLDER

The FOLDER form item is just a container for PAGE items.

```
FOLDER ...
   PAGE ...
      ...
   PAGE ...
      ...
```

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818.

Where to use a FOLDER

A FOLDER form item can be defined in two different ways:

1. In as a FOLDER container in a LAYOUT tree, within a grid-based layout.
2. As a FOLDER stack item, inside a STACK container, within a stack-based layout.

GRID item type

Defines a layout area based on a grid of cells.

GRID item basics

A GRID form item defines an area in the layout section to place children form items by X,Y position in layout cells.

Defining an GRID

The GRID container declares a formatted text block defining the dimensions and the positions of the form items contained in the grid.

You can specify the position of labels, form fields for data entry or additional interactive objects such as buttons.

A GRID container can hold static text, item tags, field tags, hbox tags, and layout tags to define other containers such as TABLE, TREE and SCROLLGRID.

A GRID can hold form items such as labels, fields, or buttons at a specific position. Form items are located with item tags in the grid layout area. You can use layout tags to place some type of containers inside a grid.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Grid style attributes.

Where to use a GRID

A GRID form item can only be defined as a GRID container in a LAYOUT tree.

GRID layout definition

For more details about grid layout concept, see Grid-based layout on page 1004.

GROUP item type

Defines a layout area to group other layout elements together.

GROUP item basics

A GROUP form item type groups other form items together, typically in a groupbox widget.

Defining an GROUP

The GROUP form item typically gets a TEXT attribute, to define the title of the group. Consider using localized strings for this attribute:

```
GROUP ...
  TEXT=%"customer.info";
```

Note: Some front-ends render group containers as a groupbox widget, displaying a title on the top of the child elements, while other front-ends may not show a group title.

Consider identifying group elements with a name, in order to manipulate the group during program execution. For example use the `ui.Form.setElementHidden()` method to hide or show groups in a form:

```
GROUP g1: g_cust_info, ... ;   -- grid-based layout
GROUP g_cust_info, ... ;       -- stack-based layout
```

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818 and Group style attributes.

Groups in grid-based layout

In a `LAYOUT` tree with `GROUP` containers, if you want to include several children in a `GROUP`, you can add a `VBOX` or `HBOX` into the `GROUP`, to define how these form items are aligned.

> **Note:** When defining a `GROUP` container, you cannot set the `GRIDCHILDRENINPARENT` attribute. This attribute makes sense only for a group item defined with a layout tag contained in a `GRID` area.

Consider using a group layout tag inside a `GRID` container, this layout specification technique is often more appropriate to define forms:

```
GRID
{
<G g1              ><G g2        >
[l1  :f1           ][f4          ]
 ...
<G g3                             >
 ...
```

Groups in stack-based layout

In a `STACK` container, `GROUP` form items are one of the base concepts used to put stack items together. For more details see Stacked group rendering on page 1019.

Groups on mobile devices

On mobile devices, groups render according to the platform standards:

- With GMA/Android™, groups are visualized by a simple separator under the group title. Complex layout construction is supported: groups in groups, groups in a grid, and so on.
- With GMI/iOS, the layout is limited by the platform GUI standards. The only visible grouping container element is a group. Groups within groups are not allowed. GMI enforces each form item as a member in a group. There can be group headers and footers, but no elements in between groups.

Where to use a GROUP

A `GROUP` form item can be defined in three different ways:

1. As a `GROUP` container in a `LAYOUT` tree, within a grid-based layout.
2. As a `<GROUP >` layout tag with a `GROUP` item definition in the `ATTRIBUTES` section, within a grid-based layout.
3. As a `GROUP` stack item, inside a `STACK` container, within a stack-based layout.

IMAGE item type

Defines a area that can display an image resource.

IMAGE item basics

The `IMAGE` item type defines an area where a picture resource can be displayed.

Defining an IMAGE

An IMAGE form item can be defined as a form field image or as a static image. Use a form field image when the content of the image will change often during program execution (for example, to display images from the database). Use a static image if the image remains the same during program execution.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Image style attributes on page 828.

Form field IMAGE item

Use a form field image item to display values that change often during program execution, for example if the image is stored in the database.

The picture resource is defined by the value of the field.

The value can be changed from the program by using the DISPLAY BY NAME / DISPLAY TO instruction, or just by changing the value of the program variable bound to the image field when using the UNBUFFERED mode in an interactive instruction.

When defining the IMAGE item in the form, use a field name to identify the element in programs:

```
-- Grid-based layout (ATTRIBUTES item definition)
IMAGE f001 = cars.picture, SIZEPOLICY=FIXED, AUTOSCALE;

-- Stack-based layout (STACK item)
IMAGE cars.picture, SIZEPOLICY=FIXED, AUTOSCALE;
```

Static IMAGE item

Use a static image item to display an image that does not change during program execution, such as form decoration pictures and logos.

The resource of the image is defined by the IMAGE attribute; the item is not a form field. This kind of item is not affected by instructions such as CLEAR FORM or the DISPLAY TO instruction.

```
-- Grid-based layout (ATTRIBUTES item definition)
IMAGE img1: logo, IMAGE="fourjs.png", STRETCH=BOTH;

-- Stack-based layout (STACK item)
IMAGE logo, IMAGE="fourjs.png", AUTOSCALE;
```

Providing the image resource

To display an image, the front-end needs the image data, which can be provided in different ways.

For example, you can specify an URL, a mapped icon, or a plain image file (centralized on the application server).

For more details about image resource specification, see Providing the image resource on page 784.

Detecting IMAGE clicks

To inform the dialog immediately when an image was clicked, define the ACTION attribute in the IMAGE item, and implement the corresponding ON ACTION handler in the dialog:

```
-- Form file (grid layout)
IMAGE : logo, IMAGE="fourjs.png",
   ACTION=show_about;

-- Program file:
```

```
ON ACTION show_about
   -- The image was clicked
```

The program can then react immediately when the user selects the image element.

Where to use a IMAGE

A IMAGE form item can be defined in two different ways:

1. With an item tag and a IMAGE item definition on page 941 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a IMAGE stack item on page 920 in a STACK container.

Defining the widget size

The size of an IMAGE widget can be controlled in grid-based or stack-based layout, according to several attributes such as SIZEPOLICY, AUTOSCALE and STRETCH.

For more details about image sizing, see Controlling the image layout on page 783.

LABEL item type

Defines a simple text area to display a read-only value.

LABEL item basics

The LABEL form item defines a read-only text area.

Defining a LABEL

A LABEL form item can be defined as a form field image or as a static label. Use a form field label when the text changes often during program execution (for example, to display text from the database). Use a static label if the text remains the same during program execution.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Label style attributes on page 828.

Form field LABEL item

Use a form field label item to display values that change often during program execution, for example if the text is stored in the database.

The label text is defined by the value of the field.

The value can be changed from the program by using the DISPLAY BY NAME / DISPLAY TO instruction, or just by changing the value of the program variable bound to the label field when using the UNBUFFERED mode in an interactive instruction.

When defining the LABEL item in the form, use a field name to identify the element in programs:

```
-- Grid-based layout (ATTRIBUTES item definition)
LABEL f001 = cars.description;

-- Stack-based layout (STACK item)
LABEL cars.description;
```

Static LABEL item

Use a static label item to display a text that does not change during program execution.

This kind of item is not affected by instructions such as `CLEAR FORM` or the `DISPLAY TO` instruction.

```
-- Grid-based layout (ATTRIBUTES item definition)
LABEL lab1: label1, TEXT="Name:";

-- Stack-based layout (STACK item)
LABEL label1, TEXT="Name:";
```

Consider using localized strings to ease application internationalization:

```
LABEL ...
   TEXT = %"label.customer.name";
```

Static labels display only character text values, and therefore do not follow any justification rule as form field labels.

Multi-line text in LABELs

In order to display label text on several lines, the text must contain `\n` line-feed characters:

```
LABEL lab1: label1,
      TEXT="First line.\nSecond line.";
```

Where to use a LABEL

A `LABEL` form item can be defined in two different ways:

1. With an item tag and a LABEL item definition on page 942 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a LABEL stack item on page 921 in a `STACK` container.

PAGE item type

Defines the content of a folder page.

PAGE item basics

A `PAGE` form item type groups other form elements together, to define a folder page of a parent `FOLDER` form item.

Defining an PAGE

A `PAGE` form item can only be a child of a `FOLDER` form item.

By default, `PAGE` form items are used to group elements for decoration only.

> **Note:** Use the `TABINDEX` attribute of form fields inside the folder page, to define which field gets the focus when a folder page is selected.

The `TEXT` attributes defines the label of the folder page. Consider using localized strings for this attribute.

The `IMAGE` attribute can be used to specify which image to use as an icon.

Detecting folder page selection

If needed, you can use the `ACTION` attribute to bind an action to a folder page. When the page is selected, the program gets the corresponding action event.

> **Note:** This feature should be used with care: It exists to implement different singular dialog statements (such as `INPUT`) in each folder page. You should use a `DIALOG` statement to control all folder pages simultaneously.

Bring a folder page to the top

To bring a folder page to the top, use the `NEXT FIELD` program instruction to give the focus to one of the active fields of the page, or use the `ui.Form.ensureFieldVisible()` method if the fields are disabled/unused, or use the `ui.Form.ensureElementVisible()` method if the page does not contain focusable form items.

For more details, see Giving the focus to a form element on page 1272.

Where to use a PAGE

A `PAGE` form item can be defined in two different ways:

1. As a `PAGE` container in a `LAYOUT` tree, within a grid-based layout.
2. As a `PAGE` stack item, inside a `STACK` container, within a stack-based layout.

PROGRESSBAR item type

Defines a progress indicator field.

PROGRESSBAR item basics

The `PROGRESSBAR` form item defines a field that shows a progress indicator.

> **Note:** Use a `SMALLINT` or `INTEGER` variable with a `PROGRESSBAR` form item. Larger types like `BIGINT` or `DECIMAL` are not supported.

Defining a PROGRESSBAR

The `VALUEMIN` and `VALUEMAX` attributes define respectively the lower and upper integer limit of the progress information. Any value outside this range will not be displayed. Default values are `VALUEMIN=0` and `VALUEMAX=100`.

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818 and ProgressBar style attributes on page 830.

Displaying PROGRESSBAR values

The position of the progress bar indicator is defined by the value of the corresponding form field. The value can be changed from the program by using the `DISPLAY TO` instruction, to set the value of the field, or by changing the program variable bound to the field when using the `UNBUFFERRED` dialog mode.

Progress information is typically displayed during non-interactive program code. To show changes to the end user in this context, you need to use the `ui.Interface.refresh()` method to force a refresh. To provide the best feedback to the user, consider calling the `refresh()` method regularly but not to often, otherwise you will overload the network traffic and bring down the front-end component.

For example, if you have to process 1000 rows, define `VALUEMIN=0` and `VALUEMAX=1000` in the `PROGRESSBAR` item, and perform a refresh every 50 rows:

```
FOR row=1 TO 1000
    ...
    IF (row MOD 50) == 0 THEN
       LET myprogbar = row
       CALL ui.Interface.refresh()
    END IF
END FOR
```

Where to use a PROGRESSBAR

A `PROGRESSBAR` form item can be defined in two different ways:

1. With an item tag and a PROGRESSBAR item definition on page 942 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a PROGRESSBAR stack item on page 923 in a `STACK` container.

RADIOGROUP item type

Defines a mutual exclusive set of options field.

RADIOGROUP item basics

The `RADIOGROUP` form item defines a field that provides several options that the user can make a selection from. Checking one radio button unchecks any previously checked button within the same group.

Defining a RADIOGROUP

A `RADIOGROUP` defines a set of radio buttons where each button is associated with a value defined in the `ITEMS` attribute.

The text associated with each item value will be used as the label of the corresponding radio button, for example: `ITEMS=((1,"Beginner"), (2,"Normal"), (3,"Expert"))` will create three radio buttons with the texts `Beginner`, `Normal` and `Expert`, respectively.

```
RADIOGROUP ...
   ITEMS=((1,"Beginner"),(2,"Normal"),(3,"Expert"));
```

Consider using localized strings when defining key/value pairs in the radiogroup items:

```
COMBOBOX ...
   ITEMS=((1,%"skills.beginner"),
          (2,%"skills.normal"),
          (3,%"skills.expert"));
```

If the `ITEMS` attribute is not specified, the form compiler automatically fills the list of items with the values of the `INCLUDE` attribute, when specified. However, the item list will not automatically be populated with include range values (i.e. values defined using the `TO` keyword). The `INCLUDE` attribute can be specified directly in the form or indirectly in the schema files.

During an `INPUT`, a `RADIOGROUP` field value can only be one of the values specified in the `ITEMS` attribute. During an `CONSTRUCT`, a `RADIOGROUP` field allows to uncheck all items (even if the field is `NOT NULL`), to let the user clear the search condition.

If one of the items is explicitly defined with `NULL` and the `NOT NULL` attribute is omitted: In `INPUT`, selecting the corresponding radio button sets the field value to null. In `CONSTRUCT`, selecting the radio button corresponding to null will be equivalent to the = query operator, which will generate a "*`colname`* `is null`" SQL condition.

Use the `ORIENTATION` attribute to define if the radio group must be displayed vertically or horizontally:

```
COMBOBOX ...
   ITEMS=(...),
   ORIENTATION = HORIZONTAL;
```

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818 and RadioGroup style attributes on page 831.

Detecting RADIOGROUP item selection

To inform the dialog when a value change, define an `ON CHANGE` block for the `RADIOGROUP` field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
RADIOGROUP rg1 = user.user_skill,
   ITEMS = ... ;

-- Program file:
ON CHANGE user_skill
   -- An new item was selected in the radiogroup
```

For more details, see Reacting to field value changes on page 1267.

Where to use a RADIOGROUP

A `RADIOGROUP` form item can be defined in two different ways:

1. With an item tag and a RADIOGROUP item definition on page 943 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a RADIOGROUP stack item on page 923 in a `STACK` container.

SCROLLGRID item type

Defines a scrollable grid view widget.

SCROLLGRID item basics

A `SCROLLGRID` form item type defines a grid to show a scrolling list of data records in a set of positioned form fields.

Defining an SCROLLGRID

The `SCROLLGRID` form item declares a formatted text block defining the dimensions and the position of the logical elements of a screen for a multi-record presentation.

A `SCROLLGRID` is similar to the `GRID`, except that you can only specify form fields, that repeat on several "row-templates", in order to design a multiple-record view that appears with a vertical scrollbar.

> **Note:** When using a `SCROLLGRID` container, you cannot set the `GRIDCHILDRENINPARENT` attribute. This attribute makes sense only for a scrollgrid defined with a layout tag contained in a `GRID` area.

The same layout rules apply as in a `GRID` container.

By default, a `SCROLLGRID` container is not resizable in height. Use the `WANTFIXEDPAGESIZE=NO` attribute to allow the scrollgrid to stretch vertically.

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818.

Where to use a SCROLLGRID

Within a grid-based layout, a `SCROLLGRID` form item can be defined in two different ways:

1. As a `SCROLLGRID` container in a `LAYOUT` tree.
2. As a `<SCROLLGRID >` layout tag with a `SCROLLGRID` item definition in the `ATTRIBUTES` section.

SCROLLGRID view programming

A `SCROLLGRID` is similar to a `TABLE` form item in terms of list programming. For more details about list view programming, see Table views on page 1345.

SLIDER item type

Defines a slider form item.

SLIDER item basics

The `SLIDER` form item defines a field where the user can set a value in a given range, such as a typical audio volume control widget where you can grab the slider handle to change the value.

Use a `SMALLINT` or `INTEGER` variable with a `SLIDER` form item, larger types like `BIGINT` or `DECIMAL` are not supported.

Defining a SLIDER

A `SLIDER` field lets the user move a handle along a horizontal or vertical groove and translates the handle's position into a value within the legal range.

The `VALUEMIN` and `VALUEMAX` attributes define respectively the lower and upper integer limit of the slider information. Any value outside this range will not be displayed. The step between two marks is defined by the `STEP` attribute. If `VALUEMIN` and/or `VALUEMAX` are not specified, they default respectively to 0 (zero) and 5.

The `ORIENTATION` attribute defines whether the `SLIDER` is displayed vertically or horizontally.

This item type is not designed for `CONSTRUCT`, as the user can only select one value.

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818.

Detecting SLIDER item selection

To inform the dialog when a value changes, define an `ON CHANGE` block for the `SLIDER` field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
SLIDER s1 = options.opts_volume,
   VALUEMIN=0, VALUEMAX=100;

-- Program file:
ON CHANGE opts_volume
   -- An value changed in the slider
```

For more details, see Reacting to field value changes on page 1267.

Where to use a SLIDER

A `SLIDER` form item can be defined in two different ways:

1. With an item tag and a SLIDER item definition on page 945 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a SLIDER stack item on page 924 in a `STACK` container.

SPINEDIT item type

Defines a spin box widget to enter integer values.

SPINEDIT item basics

The `SPINEDIT` form item defines a field where the users can increase or decrease the number value by a specific increment by clicking an up or down arrow button, or by typing the value directly into the text edit box.

Use a `SMALLINT` or `INTEGER` variable with a `SLIDER` form item. Larger types like `BIGINT` or `DECIMAL` are not supported.

Defining a SPINEDIT

The increment between two values is defined by the STEP attribute:

```
SPINEDIT ...
   STEP = 5;
```

The VALUEMIN and VALUEMAX attributes define respectively the lower and upper integer limit of the spin-edit range. There is no default minimum or maximum value for the SPINEDIT widget.

This widget is not designed for CONSTRUCT, as you can only enter an integer value.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818.

Detecting SPINEDIT modification

To inform the dialog when a value changes, define an ON CHANGE block for the SPINEDIT field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
SLIDER s1 = options.opts_rate,
   VALUEMIN=0, VALUEMAX=100;

-- Program file:
ON CHANGE opts_rate
   -- The value of the spinedit has changed
```

For more details, see Reacting to field value changes on page 1267.

Where to use a SPINEDIT

A SPINEDIT form item can be defined in two different ways:

1. With an item tag and a SPINEDIT item definition on page 945 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a SPINEDIT stack item on page 924 in a STACK container.

TABLE item type

Defines a list view widget.

TABLE item basics

A TABLE form item type defines a listview to show a scrolling list of data records in a set of columns.

Defining an TABLE

The TABLE form item defines list view widget to show a set of data records, bound to a screen array.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and Table style attributes on page 831.

Where to use a TABLE

A TABLE form item can be defined in three different ways:

1. As a TABLE container in a LAYOUT tree, within a grid-based layout.
2. As a <TABLE > layout tag with a TABLE item definition in the ATTRIBUTES section, within a grid-based layout.
3. As a TABLE stack item, inside a STACK container, within a stack-based layout.

TABLE view programming

For more details about table view programming, see Table views on page 1345.

TEXTEDIT item type
Defines a multi-line edit field.

TEXTEDIT item basics

The TEXTEDIT form item defines a text input field with multiple lines. This type of element is typically used to handle large text values such as comments or addresses that would not fit in a single-line edit field.

Use a VARCHAR(N) or STRING variable to hold the data for a TEXTEDIT form item.

Defining a TEXTEDIT

Use the SCROLLBARS attribute to define vertical and/or horizontal scrollbars for the TEXTEDIT form field. By default, this attribute is set to VERTICAL for TEXTEDIT fields.

The STRETCH attribute can be used to force the TEXTEDIT field to stretch when the parent container is re-sized. Values can be NONE, X, Y or BOTH. By default, this attribute is set to NONE for TEXTEDIT fields.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818 and TextEdit style attributes on page 834.

TAB and RETURN

By default, when the focus is in a TEXTEDIT field, the Tab key moves to the next field, while the Return key adds a newline (ASCII 10) character in the text.

To control the user input when the Tab and Return keys are pressed, specify the WANTTABS and WANTNORETURNS attributes.

With WANTTABS, the Tab key is consumed by the TEXTEDIT field, and a Tab character (ASCII 9) is added to the text. The user can still jump out of the field with the Shift-Tab combination.

With WANTNORETURNS, the Return key is not consumed by the TEXTEDIT field, and the action corresponding to the Return key is triggered. The user can still enter a newline character with Shift-Return or Ctrl-Return.

Where to use a TEXTEDIT

A TEXTEDIT form item can be defined in two different ways:

1. With an item tag and a TEXTEDIT item definition on page 947 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a TEXTEDIT stack item on page 925 in a STACK container.

Defining the widget size

In a grid-based layout, the layout behavior of the TEXTEDIT widget can be controlled with the STRETCH and SCROLLBARS attributes.

In a stack-based layout, the TEXTEDIT widget always adapts to the field value to avoid scrollbars. You can control the minimum height of the TEXTEDIT widget by using the HEIGHT attribute. If the field content is null and the HEIGHT attribute is not defined, the minimum size defaults to one line.

Field input length

By default, the input length in an TEXTEDIT fields is defined by the program variable. There is no need to define the SCROLL attribute, except if you explicitly specify SCROLLBARS=NONE (in a grid-based layout).

For more details about the SCROLL attribute, see Field input length on page 1260.

Rich Text HTML support

Some front-ends can also support different text formattings, according to a style attribute. You can for example display and input HTML content in a TEXTEDIT with the Genero Desktop Client. When this feature is enabled, the TEXTEDIT support rich text editing. Depending on the front-end, different formatting options are available (bold, font size, and so on) and can be controlled using either an integrated toolbox or via local actions.

Note:

- Each front-end uses its own technology to provide HTML support in TEXTEDIT fields. The HTML representation may vary between front-ends. As a result, the same HTML content may display in a different way on another front-end.
- When using rich text, the FGL_DIALOG_SETCURSOR() and FGL_DIALOG_SETSELECTION() functions must be called carefully. Because of the rich text format, having a corresponding cursor position / selection between displayed text and HTML representation may be difficult, especially in the case of hidden parts.

TIMEEDIT item type

Defines a line-edit with a clock widget to pick a time.

TIMEEDIT item basics

The TIMEEDIT form item defines a field that allows the user to edit 24H time values, or time duration (intervals), with a specific clock widget for time input.

To store TIMEEDIT field values, consider using the appropriate DATETIME HOUR TO MINUTE or DATETIME HOUR TO SECOND data type according to the target front-end.

Important: The display and input precision (with or without seconds) of the TIMEEDIT widget depends from the front-end. On some platforms, native time editors do not handle the seconds. Further, some front-ends (especially on mobile devices) deny data types different from DATETIME HOUR TO {MINUTE|SECOND}. If the front-end does not support the data type used for the TIMEEDIT field, the runtime system will raise an error and stop the program. Consider testing your application with all types of front-ends.

On some front ends, TIMEEDIT fields can also be used to handle INTERVAL values of the class HOUR TO {MINUTE|SECOND}, in order to input a time duration. Note however that in most cases the time interval pickers are limited to 24H hours and allow only positive values. As result, not all values allowed in an INTERVAL HOUR TO MINUTE variable (such as -86 hours 23 minutes) can be displayed by such widgets.

Defining a TIMEEDIT
