No specific attribute is needed to define the rendering and behavior of a TIMEEDIT field. Common data validation attributes such NOT NULL, REQUIRED, DEFAULT are allowed.

Note: The time display format is automatically taken from the front-end platform settings. For example, time values can display in the 0-12 hour clock format (with AM/PM indicators), or in the 0-24 hour clock format.

The native widget used for TIMEEDIT fields usually allows only exact time value input, and therefore cannot be used with a CONSTRUCT instruction, where it must be possible to enter search filters like ">=11:00".

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818.

Detecting TIMEEDIT modification

To inform the dialog when a date is picked from the clock widget, define an `ON CHANGE` block for the `TIMEEDIT` field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
TIMEEDIT de1 = order.ord_shiptime,
   NOT NULL;

-- Program file:
ON CHANGE ord_shiptime
   -- An new time value was picked from the clock widget
```

For more details, see Reacting to field value changes on page 1267.

Where to use a TIMEEDIT

A `TIMEEDIT` form item can be defined in two different ways:

1. With an item tag and a TIMEEDIT item definition on page 947 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a TIMEEDIT stack item on page 926 in a `STACK` container.

Field input length

The input length in a `TIMEEDIT` fields is defined by the (`DATETIME`) program variable. In a grid-based layout, define an item tag with enough positions, to be able to display all time value digits (5 positions for HH:MM, 7 positions for HH:MM:SS). For more details, see Field input length on page 1260.

TREE item type

Defines a tree view widget.

TREE item basics

A `TREE` form item type defines a treeview to show a structured tree of data records with an optional a set of columns.

Defining an TREE

The `TREE` form item defines tree view widget to show a structured set of data records, bound to a screen array.

Tree view definitions are very similar to regular `TABLE` elements; before reading further about tree views, you should be familiar with table elements.

The first column in the `TREE` must be the field defining the text of the tree-view nodes.

The screen array definition must have exactly the same number of columns as the `TREE` form item.

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818 and Table style attributes on page 831.

Where to use a TREE

In a grid-based layout, a `TREE` form item can be defined in two different ways:

1. As a TREE container in a `LAYOUT` tree.
2. As a `<TREE >` layout tag with a TREE item definition in the `ATTRIBUTES` section.

TREE view programming

For more details about tree view programming, see Tree views on page 1384.

WEBCOMPONENT item type
Defines a specialized form item that holds an external component.

WEBCOMPONENT item basics

The `WEBCOMPONENT` form item defines a form field that will hold an external component, implemented with a front-end plug-in mechanism.

This topic describes the `WEBCOMPONENT` item type in form definition files, a complete section is dedicated to web component programming.

Defining a WEBCOMPONENT

The `COMPONENTTYPE` attribute identifies gICAPI external objects to be used for the field. The `PROPERTIES` attribute is typically used to define attributes that are specific to a given gICAPI-based web component. For example, a chart component might have properties to define x-axis and y-axis labels. For more details, see Using a gICAPI web component on page 1422.

If the `COMPONENTTYPE` attribute is not used, the web component will be a URL-based web component. For more details, see Using a URL-based web component on page 1419.

Some front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 818.

Where to use a WEBCOMPONENT

A `WEBCOMPONENT` form item can be defined in two different ways:

1. With an item tag and a WEBCOMPONENT item definition on page 949 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a WEBCOMPONENT stack item on page 927 in a `STACK` container.

Defining the widget size

The size of a `WEBCOMPONENT` widget can be controlled in grid-based or stack-based layout, according to several attributes such as `SIZEPOLICY` and `STRETCH`.

For more details about image sizing, see Controlling the web component layout on page 1418.

External form inclusion
Form inclusion allows to reuse the same form part in different forms.

In some cases, application forms can become very complex, or can have a common layout part that repeats across forms. In such case, some parts of the form can be defined in a external .per file, that will be included in the final forms by using the `FORM` clause inside the `LAYOUT` section.

Further, the external form parts can be controlled by a declarative dialog instruction that can be attached to any procedural dialog instruction, with the `SUBDIALOG` clause of `DIALOG`.

```
LAYOUT
  VBOX
    GRID g1
    {
       Customer information
       Name:  [f001                ]
       ...
    }
    END
    FORM "orders"
```

```
  END
END
```

Boolean expressions in forms
Some form item definitions can include boolean expressions with a form file specific syntax.

Syntax

```
[(] bool-expr {AND|OR} bool-expr [)] [...]
```

where *bool-expr* is:

```
[NOT]
{ field-tag
    {  =  expression
    |  <> expression
    |  != expression
    |  <= expression
    |  >= expression
    |  <  expression
    |  >  expression
    |  IS [NOT] NULL
    |  [NOT] BETWEEN expression AND expression
    |  [NOT] MATCHES "string"
    |  [NOT] LIKE "string"
    }
}
```

1. *field-tag* is the name of the current field tag in form line with the attribute definition.
2. *expression* can be the a character string, numeric or date-time literal.

Usage

Some form specification file attributes such as `COLOR WHERE` require a boolean expression. These boolean expressions are different from the language boolean expressions, and have a limited syntax which is specific to the form files.

When a *field-tag* is used in the boolean expression, the runtime system replaces *field-tag* at runtime with the current value in the screen field and evaluates the expression.

Example

```
EDIT f001 = item.price,
     COLOR=RED
          WHERE f001 >= 100 AND f001 < 1000;
```

Form file structure
A form specification file is defined by a set of sections.

The sections of a form specification file must appear in the following order:

1. SCHEMA section on page 902
2. ACTION DEFAULTS section on page 903
3. TOPMENU section on page 903
4. TOOLBAR section on page 905
5. TABLES section on page 931
6. LAYOUT section on page 907
7. ATTRIBUTES section on page 932

8. INSTRUCTIONS section on page 950

Each section must begin with the keyword for which it is named, only the LAYOUT section is mandatory.

SCHEMA section
Defines the database schema file to be used to compile the form.

Each form specification file can begin with a SCHEMA section identifying the database schema (if any) on which the form is based. This can be any database schema that is defined with a database schema file. Form field data types can be automatically extracted from the schema file if you specify the table and column name in the form field definition (see ATTRIBUTES section).

Syntax 1

```
SCHEMA { database[@dbserver] | string | FORMONLY }
```

1. *database* is the name of the database schema to be used for the form compilation.
2. *dbserver* identifies the Informix® database server (INFORMIXSERVER).
3. *string* can be a string literal containing the database name.

Syntax 2: (supported for backward compatibility)

```
DATABASE {  database[@dbserver] | string | FORMONLY } [ WITHOUT NULL INPUT ]
```

The DATABASE syntax is supported for compatibility with Informix® 4gl; using SCHEMA is recommended.

1. *database* is the name of the database schema to be used for the form compilation.
2. *dbserver* identifies the Informix® database server (INFORMIXSERVER)
3. *string* can be a string literal containing the database name.

Usage

The SCHEMA (or DATABASE) defines the database schema to be used to resolve data types for database column-based fields.

> **Note:** The DATABASE instruction is supported for backward compatibility, we recommend using SCHEMA instead.

The SCHEMA section must appear in the sequence described in form file structure.

The SCHEMA section is optional; if you do not specify it, database schema specification defaults to SCHEMA FORMONLY.

You can create a form that is not related to any database schema by using the FORMONLY keyword after SCHEMA/DATABASE. When using this option, you must omit the TABLES section and define field data types explicitly in the ATTRIBUTES section.

The *database* and *dbserver* specifications are supported (but ignored) for backward compatibility with Informix® form specifications.

When using a specific database schema, the field data types are taken from the schema file **during compilation**. Make sure that the database schema file of the development database corresponds to the production database; otherwise the form fields defined in the compiled version of your forms will not match the table structures of the production database.

The use of the WITHOUT NULL INPUT option in the DATABASE syntax is supported for backward compatibility, but is ignored.

Example

```
SCHEMA stores
```

```
LAYOUT
  ...
```

ACTION DEFAULTS section

The `ACTION DEFAULTS` section defines local action view default attributes for the form elements.

Syntax

```
ACTION DEFAULTS
   ACTION action-identifier ( action-attribute [,...] )
   [...]
END
```

1. *action-identifier* defines the name of the action.
2. *action-attribute* defines an attribute for the action.

Attributes

`ACCELERATOR`, `ACCELERATOR2`, `ACCELERATOR3`, `ACCELERATOR4`, `DEFAUTVIEW`, `COMMENT`, `CONTEXTMENU`, `IMAGE`, `TEXT`, `VALIDATE`.

Usage

The `ACTION DEFAULTS` section centralizes action view attributes (text, comment, image, accelerators) at the form level.

The `ACTION DEFAULTS` section must appear in the sequence described in form file structure.

The `ACTION DEFAULTS` section is optional.

The section holds a list of `ACTION` elements and specify attributes for each action. The action is identified by the name following the `ACTION` keyword, and attributes are specified in a list between parenthesis.

The attributes defined in this section are applied to form action views like buttons, toolbar buttons, or topmenu options, if the individual action views do not explicitly define their own attributes.

Action attributes can be defined at different levels, see action configuration for more details.

Example

```
ACTION DEFAULTS
  ACTION accept ( COMMENT="Commit order record changes",
                  CONTEXTMENU=NO )
  ACTION cancel ( TEXT="Stop", IMAGE="stop",
                  ACCELERATOR=SHIFT-F2, VALIDATE=NO )
  ACTION print ( COMMENT="Print order information",
                 ACCELERATOR=CONTROL-P,
                 ACCELERATOR2=F5 )
  ACTION zoom1 ( COMMENT="Open items list", VALIDATE=NO )
  ACTION zoom2 ( COMMENT="Open customers list", VALIDATE=NO )
END
```

TOPMENU section

The `TOPMENU` section defines a pull-down menu with options that are bound to actions.

Syntax

```
TOPMENU [menu-identifier] ( menu-attribute [,...] )
  group
  [...]
```

```
END
```

where *group* is:

```
GROUP group-identifier ( group-attribute [,...] )
  { command
  | group
  |  separator
  } [...]
END
```

where *command* is:

```
COMMAND command-identifier ( command-attribute [,...] )
```

and *separator* is:

```
SEPARATOR [separator-identifier] ( separator-attribute [,...] )
```

1. *menu-identifier* defines the name of the top menu (optional).
2. *group-identifier* defines the name of the group.
3. *command-identifier* defines the name of the action to bind to.
4. *separator-identifier* defines the name of the separator (optional).
5. *menu-attribute* can be: `STYLE`, `TAG`.
6. *group-attribute* is one of: `STYLE`, `TEXT`, `IMAGE`, `COMMENT`, `TAG`, `HIDDEN`.
7. *command-attribute* is one of: `STYLE`, `TEXT`, `IMAGE`, `COMMENT`, `TAG`, `HIDDEN`, `ACCELERATOR`.
8. *separator-attribute* is one of: `STYLE`, `TAG`, `HIDDEN`.

Attributes

`ACCELERATOR`, `COMMENT`, `HIDDEN`, `IMAGE`, `STYLE`, `TEXT`, `TAG`.

Usage

The `TOPMENU` section is used to define a pull-down menu in a form.

The `TOPMENU` section must appear in the sequence described in form file structure.

The `TOPMENU` section is optional.

In a `TOPMENU` section, you build a tree of `GROUP` elements to design the pull-down menu. A `GROUP` can contain `COMMAND`, `SEPARATOR` or `GROUP` children. A `COMMAND` defines a pull-down menu option that triggers an action when it is selected. In the topmenu specification, *command-identifier* defines which action a menu option is bound to. For example, if you define a topmenu option as "`COMMAND zoom`", it can be controlled by an "`ON ACTION zoom`" clause in an interactive instruction.

The topmenu commands are enabled according to the actions defined by the current interactive instruction. For example, you can define a topmenu option with the action name "cancel" to bind the pull-down item to this predefined dialog action.

An accelerator name can be defined for a topmenu command; this accelerator name will be used for display in the command item. You must define he same accelerator in the action defaults section for the action name of the topmenu command.

`TOPMENU` elements can get a `STYLE` attribute in order to use a specific rendering/decoration following presentation style definitions.

Example

```
TOPMENU tm ( STYLE="mystyle" )
```

```
  GROUP form (TEXT="Form")
    COMMAND help (TEXT="Help", IMAGE="quest")
    COMMAND quit (TEXT="Quit")
  END
  GROUP edit (TEXT="Edit")
    COMMAND accept (TEXT="Validate", IMAGE="ok",
 TAG="acceptMenu")
    COMMAND cancel (TEXT="Cancel", IMAGE="cancel")
    SEPARATOR
    COMMAND editcut   -- Gets its decoration from action
 defaults
    COMMAND editcopy  -- Gets its decoration from action
 defaults
    COMMAND editpaste -- Gets its decoration from action
 defaults
  END
  GROUP records (TEXT="Records")
    COMMAND append (TEXT="Add", IMAGE="plus")
    COMMAND delete (TEXT="Remove", IMAGE="minus")
    COMMAND update (TEXT="Modify", IMAGE="accept")
    SEPARATOR (TAG="lastSeparator")
    COMMAND search (TEXT="Search", IMAGE="find")
  END
END
```

TOOLBAR section

The TOOLBAR section defines a toolbar with buttons that are bound to actions.

Syntax

```
TOOLBAR [toolbar-identifier] [ ( toolbar-attribute [,...] ) ]
  { ITEM item-identifier  [ ( item-attribute [,...] ) ]
  | SEPARATOR [separator-identifier] [ (separator-attribute [,...] ) ]
  } [...]
END
```

1. *toolbar-identifier* defines the name of the toolbar (optional).
2. *item-identifier* defines the name of the action to bind to.
3. *separator-identifier* defines the name of the separator (optional).
4. *toolbar-attribute* is one of: STYLE, TAG, BUTTONTEXTHIDDEN.
5. *item-attribute* is one of: STYLE, TAG, TEXT, IMAGE, COMMENT, HIDDEN.
6. *separator-attribute* is one of: STYLE, TAG, HIDDEN.

Attributes

BUTTONTEXTHIDDEN, COMMENT, HIDDEN, IMAGE, STYLE, TEXT, TAG.

Usage

The TOOLBAR section defines a toolbar in a form.

The TOOLBAR section must appear in the sequence described in form file structure.

The TOOLBAR section is optional.

A TOOLBAR section defines a set of ITEM elements that can be grouped by using a SEPARATOR element. Each ITEM defines a toolbar button associated to an action by name. The SEPARATOR keyword specifies a vertical line.

The toolbar buttons are enabled according to the actions defined by the current interactive instruction. For example, you can define a toolbar button with the action name "cancel" to bind the toolbar item to this predefined dialog action.

Toolbar button labels are visible by default. The TOOLBAR supports the BUTTONTEXTHIDDEN attribute to hide the labels of buttons.

TOOLBAR elements can get a STYLE attribute in order to use a specific rendering/decoration following presentation style definitions.

Example

```
TOOLBAR tb ( STYLE="mystyle" )
  ITEM accept ( TEXT="Ok", IMAGE="ok" )
  ITEM cancel ( TEXT="Cancel", IMAGE="cancel" )
  SEPARATOR
  ITEM editcut   -- Gets its decoration from action defaults
  ITEM editcopy  -- Gets its decoration from action defaults
  ITEM editpaste -- Gets its decoration from action defaults
  SEPARATOR ( TAG="lastSeparator")
  ITEM append ( TEXT="Append", IMAGE="add" )
  ITEM update ( TEXT="Update", IMAGE="modify" )
  ITEM delete ( TEXT="Delete", IMAGE="del" )
  ITEM search ( TEXT="Search", IMAGE="find" )
END
```

SCREEN section

The SCREEN section defines the form layout for TUI mode forms.

Syntax

```
SCREEN [ SIZE lines [ BY chars ] ] [ TITLE "title" ]
{
  { text | [ item-tag [ | item-tag ] [...] ] }
  [...]
}
[END]
```

1. *lines* is the number of characters the form can display vertically. The default is 24.
2. *chars* is the number of characters the form can display horizontally. The default is the maximum number of characters in any line of the screen definition.
3. *title* is the title for the top window.
4. *item-tag* and *text* define form elements in the layout.

Usage

The SCREEN section must be used to design TUI mode screens. For a GUI mode application, use a LAYOUT or STACKED LAYOUT section instead.

The SCREEN section must appear in the sequence described in form file structure.

This section is mandatory, unless you use a LAYOUT section.

The END keyword is optional.

Inside the SCREEN section, you can define the position of text labels and form fields in the area delimited by the {} curly braces.

Horizontal lines can be specified with a set of dash characters.

Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blanks by fglform.

Example

```
SCREEN
{
  CustId : [f001   ] Name: [f002               ]
  Address: [f003                               ]
           [f003                               ]
  ---------------------------------------------
}
END
```

LAYOUT section

The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

Syntax

```
LAYOUT [ ( layout-attribute [,...] ) ]
  root-container
     child-container
     [...]
  END
[END]
```

1. *layout-attribute* is an attribute for the whole form.
2. *root-container* is the first container that holds *child-containers*.

Attributes

IMAGE, MINHEIGHT, MINWIDTH, SPACING, STYLE, TEXT, TAG, VERSION, WINDOWSTYLE.

Can hold

FORM, VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, STACK, TABLE, TREE.

Usage

The LAYOUT section is used to define a a tree of layout containers, it can mix grid-based layout containers (GRID), with stack-based layout containers (STACK).

The LAYOUT section must appear in the sequence described in form file structure.

This section is mandatory, unless you use a SCREEN section.

Indentation is supported in the LAYOUT section.

The END keyword is optional.

The layout tree of the form is defined by associating layout containers. Different kinds of layout containers are provided, each of them having a specific role. Some containers such as VBOX, HBOX and FOLDER can hold children containers, while others such as GRID and TABLE define a screen area. Containers using a screen area define a formatted region containing static text labels, item tags and layout tags. External form files can be included in the current layout with the FORM clause.

```
LAYOUT (VERSION="12", STYLE="regular")
  VBOX
    GRID grid1
      grid-area
    END
```

```
    GROUP group1
      HBOX
        GRID grid2
          grid-area
        END
        TABLE table1
          table-area
        END
      END
    END
  END
END
```

The definition would result in a layout tree that looks like this:

```
-- VBOX
   |
   +-- GRID grid1
   |
   +-- GROUP group1
       |
       +-- HBOX
           |
           +-- GRID grid2
           |
           +-- TABLE table1
```

The layout section can also contain a simple `GRID` container (equivalent to a V3 SCREEN definition):

```
LAYOUT
  GRID
    grid-area
  END
END
```

Description of LAYOUT attributes

The `VERSION` attribute can be used to specify a version for the form. This allows you to indicate that the form content has changed. Typically used to avoid having the front-end reload the saved window settings.

The `MINHEIGHT`, `MINWIDTH` attributes can be used to specify a minimum width and height for the form. You typically use these attributes to force the form to get a bigger size as the default when it is first rendered. If the front-end stores window sizes, these attributes will only be significant the first time the form is opened, or each time the `VERSION` attribute is changed.

The `IMAGE` attribute can be used to define the icon of the window that will display the form. This attribute will automatically be applied to the parent window node when a form is loaded.

The `TEXT` attribute can be used to define the title of the window that will display the form. This attribute will automatically be applied to the parent window node when a form is loaded.

The `SPACING` attribute can be used to give a hint to the front-end to define the gad between form elements.

The `STYLE` attribute defines the presentation style for form elements, you can for example define a font property for all form elements.

With the `WINDOWSTYLE` attribute, you can define the window type and decoration. This attribute will automatically be applied to the parent window when a form is loaded. For backward compatibility, the `STYLE` attribute is used as the default `WINDOWSTYLE` if this attribute is not used.

FORM clause
Reuse the definition of a form in the current form.

Syntax

```
FORM "form-file"
```

1. *form-file* is the form to be included (without .per extension).

Attributes

None.

Usage

The FORM clause includes an external form at the current layout position, enforcing form re-usability, or to solve form complexity when using a DIALOG instruction. For example to define a common form header for several application forms.

Wherever a layout container can be specified, the layout of an external form can be merged into the layout of the current form, with the FORM clause.

The .per source of the included form must be readable. If the compiled version (.42f) does not exist, or is older as the .per source, fglform will automatically compile the included form.

The form compiler searches for the external form relative to the path of the current compiled form.
For example, with `fglform dir1/dir2/main.per`, when the main form includes an external form with `FORM "../otherdir/subform"`, fglform will include the form file located in `dir1/otherdir/subform.per`.

The form compiler performs an up to date test of the compiled form. Error -6842 will the thrown if the up to date test fails.

If the external form contains a TOOLBAR or a TOPMENU section, error -6841 will be thrown.

The external form must not define a SCREEN RECORD or use a TABLE already been defined in the current form, otherwise error -2024 will be thrown. Consider using the table alias syntax to avoid duplicate table names in merged forms.

The external form can define its own ACTION DEFAULTS section. The action defaults of the external file will be merged into the action defaults of the current form.

The TABINDEX attributes of the elements of the result form will be adjusted. As the result tabbing (OPTIONS FIELD ORDER FORM in programs) keeps the visual order of the layout.

Example

```
LAYOUT
  FOLDER
  PAGE page1 (TEXT = "Customer")
    FORM "customer"
  END
  PAGE page2 (TEXT = "Orders")
    FORM "orders"
  END
  END
END
```

HBOX container
Packs child layout elements horizontally.

Syntax

```
HBOX [identifier]  [ ( attribute [,...] ) ]
  layout-container
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *layout-container* is another child container.

Attributes

COMMENT, FONTPITCH, HIDDEN, STYLE, SPLITTER, TAG.

Can hold

VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, STACK, TABLE, TREE.

Usage

The HBOX container automatically packs the contained elements horizontally from left to right.

Contained elements are packed in the order in which they appear in the LAYOUT section of the form file.

No decoration is added when you use a HBOX container.

By combining VBOX and HBOX containers, you can define any alignment you choose.

Example

```
HBOX
  GROUP ( TEXT = "Customer" )
  {
   ...
  }
  END
  TABLE
  {
   ...
  }
  END
END
```

VBOX container
Packs child layout elements vertically.

Syntax

```
VBOX [identifier]  [ ( attribute [,...] ) ]
  layout-container
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.

3. *layout-container* is another child container.

Attributes

COMMENT, FONTPITCH, HIDDEN, STYLE, SPLITTER, TAG.

Can hold

VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, STACK, TABLE, TREE.

Usage

The VBOX container automatically packs the contained elements vertically from top to bottom.

Contained elements are packed in the order in which they appear in the LAYOUT section of the form file.

No decoration is added when you use a VBOX container.

By combining VBOX and HBOX containers, you can define any alignment you choose.

Example

```
VBOX
  GROUP ( TEXT = "Customer" )
  {
   ...
  }
  END
  TABLE
  {
   ...
  }
  END
END
```

GROUP container
Defines a layout area to group other layout elements together, in a grid-based layout.

Syntax

```
GROUP [identifier] [ ( attribute [,...] ) ]
  layout-container
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *layout-container* is another child container.

Attributes

COMMENT, FONTPITCH, STYLE, TAG, HIDDEN, TEXT.

Can hold

VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, TABLE, TREE.

Usage

In a LAYOUT tree definition, use a GROUP container to hold other containers such as a VBOX with children, or a GRID container.

For more details about this item type, see GROUP item type on page 887.

Example

```
GROUP ( TEXT = "Customer" )
  VBOX
    GRID
    {
     ...
    }
    END
    TABLE
    {
     ...
    }
    END
  END
END
```

FOLDER container
Defines the parent container for folder pages, in a grid-based layout.

Syntax

```
FOLDER [identifier] [ ( attribute [,...] ) ]
   folder-page
   [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *folder-page* defines a folder page that contains other form elements.

Attributes

COMMENT , FONTPITCH , STYLE , TAG , HIDDEN.

Can hold

PAGE

Usage

A FOLDER container including PAGE elements defines a folder tab widget.

Define each folder page with a PAGE container inside the FOLDER container.

For more details about this item type, see FOLDER item type on page 886.

PAGE container
Defines the content of a folder page, in a grid-based layout.

Syntax

```
PAGE [identifier] [ ( attribute [,...] ) ]
```

```
   layout-container
   [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *layout-container* is another child container.

Attributes

ACTION, COMMENT, HIDDEN, IMAGE, STYLE, TAG, TEXT.

Can hold

VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, TABLE, TREE.

Usage

In a LAYOUT tree definition, use a PAGE container to define a folder page that holds other containers such as a VBOX with children, or a GRID container.

A PAGE container always belongs to a parent FOLDER container.

For more details about this item type, see PAGE item type on page 891.

Example

```
FOLDER
  PAGE p1 ( TEXT="Global info" )
    GRID
    {
     ...
    }
    END
  END
  PAGE p2 ( IMAGE="list" )
    TABLE
    {
     ...
    }
    END
  END
END
```

GRID container
Defines a layout area based on a grid of cells.

Syntax

```
GRID [identifier] [ ( attribute [,...] ) ]
{
  { text
  | item-tag
  | hbox-tag
  | layout-tag
  | horizontal-line }
  [...]
}
END
```

1. *text* is literal text that will appear in the form as a static label.
2. *item-tag* defines the position and length of a form item.
3. *hbox-tag* defines the position and length of several form items inside an horizontal box.
4. *layout-tag* defines the position and length of a layout tag.
5. *horizontal-line* is a set of dash characters defining a horizontal line.

Attributes

COMMENT, FONTPITCH, HIDDEN, STYLE, TAG.

Usage

The GRID container declares a formatted text block, defining the dimensions and the positions of children form items.

> **Note:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blanks by fglform.

For more details about this item type, see GRID item type on page 887.

Example

```
GRID
{
<GROUP g1                                      >
 Id:   [f1] Name: [f2                         ]
 Addr: [f3                                    ]
<                                              >
}
END
```

STACK container

The STACK container holds stack items defining a logical alignment of form items.

> **Important:** This feature is experimental, the syntax/name and semantics/behavior may change in a future version.
>
> **Important:** STACK layout was introduced for mobile application programming (GMA/GMI). This type of layout is not supported by GWC-JS and GDC.

Syntax

```
STACK
  { scalable-item
  | container-list
  }
END
```

where *container-list* is:

```
grouping-item
   leaf-item
   [...]
END
[...]
```

1. *scalable-item* is a leaf element of the stacked layout, for widgets with a scalable width and height.
2. *grouping-item* is a stacked layout grouping element that holds a list of *leaf-items*.
3. *leaf-item* is a leaf element of the stacked layout, for widgets with a fixed size (non-scalable).

Can hold

Scalable stack items: IMAGE, TEXTEDIT, WEBCOMPONENT.

or:

Grouping stack items: FOLDER, GROUP, TABLE.

Usage

The STACK container is used to define a stack-based layout.

> **Note:** Unlike grid-based containers (GRID) where element definition is splitted in the LAYOUT and ATTRIBUTES sections, the items in a STACK container define both the position and attributes.

The STACK container typically defines a list of elements (such as GROUP, FOLDER, TABLE), grouping leaf stack items (such as form fields) together:

```
LAYOUT
 STACK
  GROUP custinfo (TEXT="Customer info")
    EDIT customer.cust_num, TITLE="Num:", NOENTRY;
    EDIT customer.cust_name, TITLE="Name:", SCROLL;
    ...
  END
  TABLE cust_orders (STYLE="compact_list", DOUBLECLICK=select)
    LABEL orders.ord_num, TITLE="Num";
    LABEL orders.ord_ship, TITLE="Ship date";
    LABEL orders.ord_value, TITLE="Value";
    ...
  END
  ...
 END
END
```

A stack container can also define a single scalable stack item, such as an IMAGE, TEXTEDIT or WEBCOMPONENT:

```
STACK
  IMAGE FORMONLY.picture;
END
```

BUTTON stack item

Defines a push-button that can trigger an action, in a stack-based layout.

Syntax

```
BUTTON item-name [ , attribute-list ] ;
```

1. *item-name* defines the form item name and the action name.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COMMENT, DISCLOSUREINDICATOR, FONTPITCH, HIDDEN, IMAGE, SAMPLE, SIZEPOLICY, STYLE, TABINDEX, TAG, TEXT.

Usage

Define the rendering and behavior of a button stack item, with a BUTTON element inside a STACK container.

For more details about this item type, see BUTTON item type on page 878.

Example

```
BUTTON print, TEXT="Print Report", IMAGE="printer";
```

BUTTONEDIT stack item

Defines a line-edit with a push-button that can trigger an action, in a stack-based layout.

Syntax

```
BUTTONEDIT field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

ACTION, AUTONEXT, CENTURY, COLOR, COMPLETER, COLOR WHERE, COMMENT, DEFAULT, DISPLAY LIKE, DOWNSHIFT, FONTPITCH, HIDDEN, FORMAT, IMAGE, INCLUDE, INVISIBLE, JUSTIFY, KEY, KEYBOARDHINT, NOT NULL, NOTEDITABLE, NOENTRY, PICTURE, PROGRAM, REVERSE, SAMPLE, SCROLL, STYLE, REQUIRED, TAG, TITLE, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, VERIFY.

Usage

Define the rendering and behavior of a buttonedit stack item, with a BUTTONEDIT element inside a STACK container.

For more details about this item type, see BUTTONEDIT item type on page 879.

Example

```
BUTTONEDIT customer.state,
    REQUIRED, IMAGE="smiley", ACTION=zoom;
```

CHECKBOX stack item

Defines a boolean or three-state checkbox field, in a stack-based layout.

Syntax

```
CHECKBOX field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TEXT, TITLE, VALIDATE LIKE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALUECHECKED, VALUEUNCHECKED.

Usage

Define the rendering and behavior of a checkbox stack item, with a CHECKBOX element inside a STACK container.

For more details about this item type, see CHECKBOX item type on page 880.

Example

```
CHECKBOX customer.active,
   REQUIRED, TEXT="Active",
   VALUECHECKED="Y", VALUEUNCHECKED="N";
```

COMBOBOX stack item

Defines a line-edit with a drop-down list of values, in a stack-based layout.

Syntax

```
COMBOBOX field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, KEY, INCLUDE, INITIALIZER, ITEMS, JUSTIFY, NOT NULL, NOENTRY, QUERYEDITABLE, REQUIRED, SAMPLE, SCROLL, SIZEPOLICY, STYLE, UPSHIFT, TAG, TABINDEX, UNSORTABLE , UNSIZABLE , UNHIDABLE , UNMOVABLE, TITLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a combobox stack item, with a COMBOBOX element inside a STACK container.

For more details about this item type, see COMBOBOX item type on page 881.

Example

```
COMBOBOX customer.city,
   ITEMS=((1,"Paris"),
          (2,"Madrid"),
          (3,"London"));
COMBOBOX customer.sector,
   REQUIRED,
   ITEMS=("SA","SB","SC");
COMBOBOX customer.state,
   NOT NULL,
   INITIALIZER=myinit;
```

DATEEDIT stack item

Defines a line-edit with a calendar widget to pick a date, in a stack-based layout.

Syntax

```
DATEEDIT field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, CENTURY, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a date edit stack item, with a DATEEDIT element inside a STACK container.

For more details about this item type, see DATEEDIT item type on page 883.

Example

```
DATEEDIT order.shipdate;
```

DATETIMEEDIT stack item

Defines a a line-edit with a calendar widget to pick a datetime, in a stack-based layout.

Syntax

```
DATETIMEEDIT field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, IMAGECOLUMN, JUSTIFY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a date-time edit stack item, with a DATETIMEEDIT element inside a STACK container.

For more details about this item type, see DATETIMEEDIT item type on page 884.

Example

```
DATETIMEEDIT package.modts;
```

EDIT stack item

Defines an element to enter a single-line text, in a stack-based layout.

Syntax

```
EDIT [identifier] [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PROGRAM, REQUIRED, SAMPLE, SCROLLBARS, STYLE, STRETCH, TAG, TABINDEX, TITLE, UPSHIFT, VALIDATE LIKE, WANTTABS, WANTNORETURNS.

Usage

Define the rendering and behavior of an edit stack item, with an EDIT element inside a STACK container.

For more details about this item type, see EDIT item type on page 886.

Example

```
EDIT customer.cust_name, NOT NULL;
```

FOLDER stack item

Defines a stack area to hold a set of folder pages, in a stack-based layout.

Syntax

```
FOLDER [identifier] [ ( attribute-list  ) ]
  folder-page
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute-list* defines the aspect and behavior of the form item.
3. *folder-page* is a page element in the folder definition.

Attributes

COMMENT , FONTPITCH , STYLE , TAG , HIDDEN.

Can hold

PAGE.

Usage

Use a FOLDER stack layout element to define a set of folder pages with a folder tab widget.

Define each folder page with a PAGE stack item inside the FOLDER container.

For more details about this item type, see FOLDER item type on page 886.

Example

```
FOLDER folder1 ( STYLE="common" )
   PAGE page1 ( TEXT="Order details" )
      ...
   END
   PAGE page2 ( TEXT="Order items" )
      ...
   END
   ...
END
```

GROUP stack item

Defines a stack area to group other layout elements together, in a stack-based layout.

Syntax

```
GROUP [identifier] [ ( attribute-list ) ]
  stack-item
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute-list* defines the aspect and behavior of the form item.
3. *stack-item* is child element in the stack container.

Attributes

COMMENT, FONTPITCH, HIDDEN, STYLE, TAG, TEXT.

Can hold

BUTTON, BUTTONEDIT, CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, EDIT, IMAGE, LABEL, PROGRESSBAR, PHANTOM, SLIDER, SPINEDIT,TEXTEDIT, TIMEEDIT, RADIOGROUP, WEBCOMPONENT.

Usage

Use a GROUP stack layout element to group other stack items together.

For more details about this item type, see GROUP item type on page 887.

Example

```
GROUP group1 (TEXT="Customer info")
   EDIT ...
   BUTTONEDIT ...
   ...
END
```

IMAGE stack item

Defines an element to display an image resource, in a stack-based layout.

Syntax 1: Defining a *form field image*

```
IMAGE field-name [ , attribute-list ] ;
```

Syntax 2: Defining a *static image*

```
IMAGE : item-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *item-name* identifies the form item for a static image.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

ACTION, AUTOSCALE, COMMENT, HEIGHT, HIDDEN, STYLE, STRETCH, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, WIDTH.

Static image only: IMAGE.

Image field only: JUSTIFY, SIZEPOLICY, SAMPLE.

Usage

Define the rendering and behavior of an image stack item, with a IMAGE element inside a STACK container.

> **Note:** The IMAGE stack item can be used inside a stack container like a group, or as root element of the STACK container: When used directly under the STACK container, the IMAGE stack item must be the only element in the container. It will be rendered a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see IMAGE item type on page 888.

Example

```
IMAGE cars.picture, COMMENT="Picture of the car";
```

LABEL stack item

Defines a simple text area to display a read-only value, in a stack-based layout.

Syntax 1: Defining a *form field label*

```
LABEL field-name [ , attribute-list ] ;
```

Syntax 2: Defining a *static label*

```
LABEL : item-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *item-name* identifies the form element (name attribute in .42f) of a static label.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, IMAGECOLUMN, JUSTIFY, REVERSE, SIZEPOLICY, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.

Form field label only: FORMAT, SAMPLE.

Static label only: TEXT.

Usage

Define the rendering and behavior of an label stack item, with a LABEL element inside a STACK container.

For more details about this item type, see LABEL item type on page 890.

Example

```
LABEL vehicle.description, STYLE="normal";
```

PAGE stack item

Defines the content of a folder page stack item.

Syntax

```
PAGE [identifier] [ ( attribute-list ) ]
  { scalable-item
```

```
  [ grouping-item
          leaf-item
          [...]
      END
  ]
END
```

1. *identifier* defines the name of the element.
2. *attribute-list* defines the aspect and behavior of the form item.
3. *scalable-item* is a stacked layout items that can grow and shrink.
4. *grouping-item* is a stacked layout grouping element that holds a list of *stack-items*.
5. *leaf-item* is a leaf element of the stacked layout, for widgets with a fixed size (non-scalable).

Attributes

ACTION, COMMENT, HIDDEN, IMAGE, STYLE, TAG, TEXT.

Can hold

GROUP, IMAGE, TABLE, TEXTEDIT, WEBCOMPONENT.

Usage

Use a PAGE stack layout element to group other stack items together.

A PAGE stack item always belongs to a parent FOLDER stack item.

For more details about this item type, see PAGE item type on page 891.

Example

```
FOLDER folder1 ( STYLE="common" )
   PAGE page1 ( TEXT="Customer info" )
      GROUP
          EDIT ...
          EDIT ...
          EDIT ...
      END
   END
   PAGE page2 ( TEXT="Picture" )
      IMAGE FORMONLY.cust_pic;
   END
   PAGE page3 ( TEXT="Comments" )
      TEXTEDIT customer.cust_desc;
   END
   ...
END
```

PHANTOM stack item

Defines a form field in a stack-based container, that must not be displayed to the end user.

Syntax

```
PHANTOM [field-name] ;
```

1. *field-name* identifies the name of the screen record field.

Usage

Define a PHANTOM leaf element in a stack container, to declare a form field to be used by a dialog, without beeing displayed to the user.

For more details, see Phantom fields on page 861.

Example

```
PHANTOM customer.cust_name;
```

PROGRESSBAR stack item

Defines a progress indicator field, in a stack-based layout.

Syntax

```
PROGRESSBAR field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, JUSTIFY, VALUEMIN, VALUEMAX, SAMPLE, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.

Usage

Define the rendering and behavior of an progress bar stack item, with an PROGRESSBAR element inside a STACK container.

For more details about this item type, see PROGRESSBAR item type on page 892.

Example

```
PROGRESSBAR workstate.position,
  VALUEMIN=-100, VALUEMAX=+100;
```

RADIOGROUP stack item

Defines a mutual exclusive set of options field, in a stack-based layout.

Syntax

```
RADIOGROUP field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, ITEMS, JUSTIFY, KEY, NOT NULL, NOENTRY, ORIENTATION, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a radio group stack item, with an `EDIT` element inside a `STACK` container.

For more details about this item type, see RADIOGROUP item type on page 893.

Example

```
RADIOGROUP player.level,
  ITEMS=((1,"Beginner"),
         (2,"Normal"),
         (3,"Expert"));
```

SLIDER stack item

Defines a slider element, in a stack-based layout.

Syntax

```
SLIDER field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

`COLOR`, `COLOR WHERE`, `COMMENT`, `DEFAULT`, `FONTPITCH`, `HIDDEN`, `INCLUDE`, `JUSTIFY`, `ORIENTATION`, `SAMPLE`, `STEP`, `STYLE`, `TABINDEX`, `TAG`, `TITLE`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVABLE`, `VALIDATE LIKE`, `VALUEMIN`, `VALUEMAX`.

Usage

Define the rendering and behavior of a slider stack item, with an `SLIDER` element inside a `STACK` container.

For more details about this item type, see SLIDER item type on page 895.

Example

```
SLIDER workstate.duration,
  VALUEMIN=0, VALUEMAX=5,
  STEP=1;
```

SPINEDIT stack item

Defines a spin box widget to enter integer values, in a stack-based layout.

Syntax

```
SPINEDIT field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

`AUTONEXT`, `COLOR`, `COLOR WHERE`, `COMMENT`, `DEFAULT`, `FONTPITCH`, `HIDDEN`, `IMAGECOLUMN`, `INCLUDE`, `JUSTIFY`, `NOT NULL`, `NOENTRY`, `REQUIRED`, `SAMPLE`, `STEP`, `STYLE`, `TABINDEX`, `TAG`, `TITLE`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVABLE`, `VALIDATE LIKE`, `VALUEMIN`, `VALUEMAX`.

Usage

Define the rendering and behavior of a spin edit stack item, with an SPINEDIT element inside a STACK container.

For more details about this item type, see SPINEDIT item type on page 895.

Example

```
SPINEDIT command.nbitems, STEP=5;
```

TABLE stack item

Defines a re-sizable table designed to display a list of records, in a stack-based layout.

Syntax

```
TABLE identifier [ ( attribute-list ) ]
  stack-item
  [...]
END
```

1. *identifier* defines the name of the element.
2. *attribute-list* defines the aspect and behavior of the form item.
3. *stack-item* is child element in the stack container defining a column in the table.

Attributes

AGGREGATETEXT, COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT.

Can hold

BUTTONEDIT, CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, EDIT, IMAGE, LABEL, PROGRESSBAR, PHANTOM, SLIDER, SPINEDIT, TIMEEDIT, RADIOGROUP.

Usage

The TABLE stack layout element defines defines a list view element, in a stack-based layout.

To create a table view in a stacked layout, define the following elements in the form file:

1. The layout of the list, with a TABLE stack item.
2. The columns definitions as stack items inside the TABLE item.

Note: The TABLE item must get an identifier, that will be used as screen-array in list dialogs.

For more details about table view programming, see Table views on page 1345

Example

```
TABLE custlist (STYLE="regular")
   EDIT ...
   BUTTONEDIT ...
   ...
END
```

TEXTEDIT stack item

Defines an multi-line edit field, in a stack-based layout.

Syntax

```
TEXTEDIT [identifier] [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PROGRAM, REQUIRED, SAMPLE, SCROLLBARS, STYLE, STRETCH, TAG, TABINDEX, TITLE, UPSHIFT, VALIDATE LIKE, WANTTABS, WANTNORETURNS.

Usage

Define the rendering and behavior of a text edit stack item, with a TEXTEDIT element inside a STACK container.

> **Note:** The TEXTEDIT stack item can be used inside a stack container like a group, or as root element of the STACK container: When used directly under the STACK container, the TEXTEDIT stack item must be the only element in the container. It will be rendered a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see TEXTEDIT item type on page 897.

Example

```
TEXTEDIT customer.cust_address, HEIGHT=3, REQUIRED;
```

TIMEEDIT stack item

Defines a line-edit with a clock widget to pick a time, in a stack-based layout.

Syntax

```
TIMEEDIT field-name [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a time edit stack item, with a TIMEEDIT element inside a STACK container.

For more details about this item type, see TIMEEDIT item type on page 898.

Example

```
TIMEEDIT package.arrtime;
```

WEBCOMPONENT stack item

Defines a generic form field that can receive an external widget, in a stack-based layout.

Syntax

```
WEBCOMPONENT [identifier] [ , attribute-list ] ;
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMPONENTTYPE, COMMENT, DEFAULT, FONTPITCH, HEIGHT, HIDDEN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PROPERTIES, REQUIRED, SCROLLBARS, SIZEPOLICY, STYLE, STRETCH, TAG, TABINDEX, TITLE, VALIDATE LIKE, WIDTH.

Usage

Define the rendering and behavior of a web component stack item, with a WEBCOMPONENT element inside a STACK container.

> **Note:** The WEBCOMPONENT stack item can be used inside a stack container like a group, or as root element of the STACK container: When used directly under the STACK container, the WEBCOMPONENT stack item must be the only element in the container. It will be rendered a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see WEBCOMPONENT item type on page 900.

Example

```
-- URL-based web component (recommended):
WEBCOMPONENT FORMONLY.mymap;

-- gICAPI web component:
WEBCOMPONENT FORMONLY.mycal,
     COMPONENTTYPE="Calendar", -- lookup "Calendar.html"
     STYLE="regular";
```

SCROLLGRID container

Defines a scrollable grid view widget, in a grid-based layout.

Syntax

```
SCROLLGRID [identifier] [ ( attribute [,...] ) ]
{
  row-template
  [...]
}
END
```

where *row-template* is a text block containing:

```
 item-tag
```

```
[...]
```

1. *item-tag* defines the position and length of a form item. This item tag must define a form field.

Attributes

COMMENT, FONTPITCH, STYLE, TAG, HIDDEN, WANTFIXEDPAGESIZE.

Usage

The SCROLLGRID container declares a formatted text block defining the dimensions and the position of the logical elements of a screen for a multi-record presentation.

> **Important:** This feature is not supported on mobile platforms.

Scrollgrids are by default non-resizable; The number of visible rows is defined by the number of repeated form items inside the SCROLLGRID area. To implement a resizable scrollgrid, define a single scrollgrid row in the form layout, and use the WANTFIXEDPAGESIZE=NO attribute. Resizable scrollgrids is the recommended way to implement scrollgrids.

> **Note:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blanks by fglform.

For more details about this item type, see SCROLLGRID item type on page 894.

Example 1: Resizable scrollgrid (using WANTFIXEDPAGESIZE=NO):

```
SCROLLGRID (WANTFIXEDPAGESIZE=NO)
{
 [f001   ]   [f002                          ]
 [f003                                      ]
}
END
```

Example 2: Scrollgrid with fixed page size, using four rows:

```
SCROLLGRID
{
 [f001   ]   [f002                          ]
 [f003                                      ]

 [f001   ]   [f002                          ]
 [f003                                      ]

 [f001   ]   [f002                          ]
 [f003                                      ]

 [f001   ]   [f002                          ]
 [f003                                      ]

}
END
```

TABLE container
Defines a re-sizable table designed to display a list of records.

Syntax

```
TABLE [identifier] [ ( attribute [,...] ) ]
{
```

```
 title [...]
[col-name   [|...]     ]
[...]
[aggr-name  [|...]     ]
}
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *title* is the text to be displayed as column title.
4. *col-name* is an identifier that references a form field.
5. *aggr-name* is an identifier that references an aggregate Field.

Attributes

AGGREGATETEXT, COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT.

Usage:

The TABLE container defines a list view element in a grid-based layout.

To create a table view in a grid layout, define the following elements in the form file:

1. The layout of the list, with a TABLE container in the LAYOUT section.
2. The column data types and field properties, in the ATTRIBUTES section.
3. The field list definition to group form fields together with a screen array, in the INSTRUCTIONS section.

For more details about this item type, see TABLE item type on page 896.

Example

```
SCHEMA videolab
LAYOUT ( TEXT="Customer list" )
TABLE ( TAG="normal" )
{
 [c1     |c2                          |c3        |c4 ]
 [c1     |c2                          |c3        |c4 ]
 [c1     |c2                          |c3        |c4 ]
 [c1     |c2                          |c3        |c4 ]
}
END
END
TABLES
  customer
END
ATTRIBUTES
  EDIT c1 = customer.cust_num, TITLE="Num";
  EDIT c2 = customer.cust_name, TITLE="Customer name";
  EDIT c3 = customer.cust_cdate, TITLE="Date";
  CHECKBOX c4 = customer.cust_status, TITLE="Status";
END
INSTRUCTIONS
  SCREEN RECORD custlist( cust_num, cust_name, cust_cdate,
 cust_status )
END
```

TREE container
The TREE container defines the presentation of a list of ordered records in a tree-view widget.

Syntax

```
TREE [identifier] [ ( attribute [,...] ) ]
{
 title [...]
 [name_column   [|identifier   [|...]] ]
[...]
}
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *title* is the text to be displayed as column title.
4. *name_column* is a mandatory column referencing a form item defining the node text.
5. *identifier* references a form item.

Attributes

COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT, PARENTIDCOLUMN, IDCOLUMN, EXPANDEDCOLUMN, ISNODECOLUMN, IMAGEEXPANDED, IMAGECOLLAPSED, IMAGELEAF.

Usage

To create a tree view in a grid-based layout, you must define the following elements in the form file:

1. The layout of the tree-view, with a TREE container in the LAYOUT section.
2. The column data types and field properties, in the ATTRIBUTES section.
3. The field list definition to group form fields together with a screen array, in the INSTRUCTIONS section.

For more details about this item type, see TREE item type on page 899.

Example

```
LAYOUT
GRID
{
<Tree t1                        >
 Name                    Index
[c1                      |c2    ]
[c1                      |c2    ]
[c1                      |c2    ]
[c1                      |c2    ]
}
END
END

ATTRIBUTES
LABEL c1 = FORMONLY.name;
LABEL c2 = FORMONLY.idx;
PHANTOM FORMONLY.pid;
PHANTOM FORMONLY.id;
TREE t1: tree1
    PARENTIDCOLUMN = pid,
    IDCOLUMN = id;
END
```

```
INSTRUCTIONS
SCREEN RECORD sr_tree(name, pid, id, idx);
END
```

TABLES section
Defines the list of database tables referenced by form field definitions.

Syntax

```
TABLES
[ alias = [database[@dbserver]:][owner.] ] table [,...]
[END]
```

1. *alias* represents an alias name for the given table.
2. *table* is the name of the database table.
3. *database* is the name of the database of the table (see warnings).
4. *dbserver* identifies the Informix® database server (INFORMIXSERVER)
5. *owner* is the name of the table owner (see warnings).

Usage

The TABLES section lists every database table or view referenced the form specification file. This section is mandatory when form fields reference database columns defined in the database schema file.

The TABLE section must appear in the sequence described in form file structure.

The END keyword is optional.

The SCHEMA section must also exist to define the database schema.

Field identifiers in programs or in other sections of the form specification file can reference screen fields as *column*, *alias.column*, or *table.column*.

The same *alias* must also appear in screen interaction statements of programs that reference screen fields linked to the columns of a table that has an *alias*.

If a table requires the name of an *owner* or of a *database* as a qualifier, the TABLES section must also declare an alias for the table. The *alias* can be the same identifier as *table*.

For backward compatibility with the Informix® form specification, the comma separator is optional and the *database*, *dbserver* and *owner* specifications are ignored.

Example

```
SCHEMA stores
LAYOUT
GRID
{
  ...
}
END
TABLES
 customer, orders
END
ATTRIBUTES
...
END
```

ATTRIBUTES section

The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

Syntax

```
ATTRIBUTES
 { form-field-definition
 | phantom-field-definition
 | form-item-definition }
[...]
[END]
```

where *form-field-definition* is:

```
item-type item-tag = field-name [ , attribute-list ] ;
```

where *phantom-field-definition* is:

```
PHANTOM field-name ;
```

where *form-item-definition* is:

```
item-type item-tag: item-name [ , attribute-list ] ;
```

1. *item-type* defines the type of the Form Item.
2. *item-tag* is the name of the screen element used in the LAYOUT section.
3. *field-name* defines the name of the screen record field.
4. *item-name* identifies the form item that is not a form field containing data.
5. *attribute-list* defines the aspect and behavior of the form item.

where *attribute-list* is:

```
attribute [,...]
```

1. The attribute list is a comma-separated list of attributes.

where *attribute* is:

```
attribute-name [ = { value | value-list } ]
```

1. *attribute* identifies the attribute of the form item.

where *value-list* is:

```
( { value | sub-value-list } [,...])
```

1. *value* is a string, date or numeric literal, or predefined constant like TODAY.
2. *sub-value-list* is a set of values separated by comma, to support subset definitions as in "(1,(21,22),(31,32,33))".

Usage

The ATTRIBUTES section is required to define the attributes for the form items used in grid-based containers of the LAYOUT section.

The ATTRIBUTES section must appear in the sequence described in form file structure.

The END keyword is optional.

Every item-tag used in the LAYOUT section must get an item definition in the ATTRIBUTES section.

A form item definition is associated by name to an item tag or layout tag defined in the grid-based container.

In order to define a form field, the form item definition must use the equal sign notation to associate a screen record field with the form item. If the form item is not associated with a screen record field (for example, a push button), you must use the colon notation.

To match the complete structure of a database table record, additional fields can be defined as phantom fields, when no corresponding item tag is used in the layout.

Form item definitions can optionally include an *attribute-list* to specify the appearance and behavior of the item. For example, you can define acceptable input values, on-screen comments, and default values for fields.

When no screen record is defined in the `INSTRUCTION` section, a default screen record is built for each set of form items declared with the same table name.

The order in which you list the form items determines the order of fields in the default screen records that the form compiler creates for each table.

To define form items as form fields, you are not required to specify *table* unless the name *column* is not unique within the form specification. However, it is recommended that you always specify *table.column* rather than the unqualified *column* name. As you can refer to field names collectively through a screen record built upon all the fields linked to the same table, your forms might be easier to work with if you specify *table* for each field.

When used in a table, some widgets are rendered only when the user enters in the field. For example `RadioGroup`, `CheckBox`, `ComboBox`, `ProgressBar`.

Example

```
SCHEMA game
LAYOUT
GRID
{
  ...
}
END
TABLES
 player
END
ATTRIBUTES
 EDIT f001 = player.name, REQUIRED,
               COMMENT="Enter player's name";
 EDIT f002 = player.ident, NOENTRY;
 COMBOBOX f003 = player.level, NOT NULL,
      ITEMS=((1,"Beginner"), (2,"Normal"),(3,"Expert"));
 CHECKBOX f004 = FORMONLY.winner,
      VALUECHECKED=1, VALUEUNCHECKED=0,
      TEXT="Winner";
 BUTTON b1: print, TEXT="Print Report";
 GROUP g1: print, TEXT="Description";
END
```

AGGREGATE item definition
Defines screen-record fields that hold computed values to be displayed as footer cells in a `TABLE` container.

Syntax

```
AGGREGATE item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AGGREGATETEXT, AGGREGATETYPE.

Usage

Aggregate fields used as must be declared with an AGGREGATE element in the ATTRIBUTES section.

Important: This feature is not supported on mobile platforms.

For more details see Aggregate fields on page 863.

Example

```
AGGREGATE total = FORMONLY.o_total,
                  AGGREGATETEXT = "Total:",
                  AGGREGATETYPE = SUM;
```

PHANTOM item definition
Defines a form field in a grid-based container, that must not be displayed to the end user.

Syntax

```
PHANTOM [field-name] ;
```

1. *field-name* identifies the name of the screen record field.

Usage

Define a phantom form field (that will be used by a dialog, but not displayed in the form layout), with a PHANTOM element in the ATTRIBUTES section.

For more details, see Phantom fields on page 861.

Example

```
PHANTOM customer.cust_name;
```

BUTTON item definition
Defines a push-button that can trigger an action, in a grid-based layout.

Syntax

```
BUTTON item-tag: item-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *item-name* defines the form item name and the action name.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COMMENT, DISCLOSUREINDICATOR, FONTPITCH, HIDDEN, IMAGE, SAMPLE, SIZEPOLICY, STYLE, TABINDEX, TAG, TEXT.

Usage

Define the rendering and behavior of a button item tag, with a `BUTTON` element in the `ATTRIBUTES` section.

For more details about this item type, see BUTTON item type on page 878.

Example

```
LAYOUT
GRID
{
[btn1         ]
 ...

}
END
END

ATTRIBUTES
BUTTON btn1: print, TEXT="Print Report", IMAGE="printer";
...
```

BUTTONEDIT item definition
Defines a line-edit with a push-button that can trigger an action, in a grid-based layout.

Syntax

```
BUTTONEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

ACTION, AUTONEXT, CENTURY, COLOR, COMPLETER, COLOR WHERE, COMMENT, DEFAULT, DISPLAY LIKE, DOWNSHIFT, FONTPITCH, HIDDEN, FORMAT, IMAGE, INCLUDE, INVISIBLE, JUSTIFY, KEY, KEYBOARDHINT, NOT NULL, NOTEDITABLE, NOENTRY, PICTURE, PROGRAM, REVERSE, SAMPLE, SCROLL, STYLE, REQUIRED, TAG, TITLE, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, VERIFY.

Usage

Define the rendering and behavior of a buttonedit item tag, with a `BUTTONEDIT` element in the `ATTRIBUTES` section.

For more details about this item type, see BUTTONEDIT item type on page 879.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END
```

```
ATTRIBUTES
BUTTONEDIT f1 = customer.state,
   REQUIRED, IMAGE="smiley", ACTION=zoom;
...
```

CANVAS item definition
Defines an area in which you can draw shapes, in a grid-based layout.

Syntax

```
CANVAS item-tag: item-name [  , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COMMENT, HIDDEN, TAG.

Usage

Define the rendering and behavior of a canvas drawing area item tag, with a CANVAS element in the ATTRIBUTES section.

Note: The CANVAS feature is deprecated, consider using a WEBCOMPONENT with SVG graphics.

Example

```
LAYOUT
GRID
{
[cvs1             ]
[                 ]
[                 ]
 ...

}
END
END

ATTRIBUTES
CANVAS cvs1: canvas1;
...
```

CHECKBOX item definition
Defines a boolean or three-state checkbox field, in a grid-based layout.

Syntax

```
CHECKBOX item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TEXT, TITLE, VALIDATE LIKE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALUECHECKED, VALUEUNCHECKED.

Usage

Define the rendering and behavior of a checkbox item tag, with a CHECKBOX element in the ATTRIBUTES section.

For more details about this item type, see CHECKBOX item type on page 880.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
CHECKBOX f1 = customer.active,
   REQUIRED, TEXT="Active",
   VALUECHECKED="Y", VALUEUNCHECKED="N";
...
```

COMBOBOX item definition
Defines a COMBOBOX item in a grid-based layout, in a grid-based layout.

Syntax

```
COMBOBOX item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, KEY, INCLUDE, INITIALIZER, ITEMS, JUSTIFY, NOT NULL, NOENTRY, QUERYEDITABLE, REQUIRED, SAMPLE, SCROLL, SIZEPOLICY, STYLE, UPSHIFT, TAG, TABINDEX, UNSORTABLE , UNSIZABLE , UNHIDABLE , UNMOVABLE, TITLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a combobox item tag, with a COMBOBOX element in the ATTRIBUTES section.

For more details about this item type, see COMBOBOX item type on page 881.

Example

```
LAYOUT
```

```
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
COMBOBOX f1 = customer.city,
   ITEMS=((1,"Paris"),
          (2,"Madrid"),
          (3,"London"));
...
```

DATEEDIT item definition
Defines a line-edit with a calendar widget to pick a date, in a grid-based layout.

Syntax

```
DATEEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, CENTURY, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a date edit item tag, with a DATEEDIT element in the ATTRIBUTES section.

For more details about this item type, see DATEEDIT item type on page 883.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
DATEEDIT f1 = order.shipdate;
...
```

DATETIMEEDIT item definition
Defines a line-edit with a calendar widget to pick a datetime, in a grid-based layout.

Syntax

```
DATETIMEEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, IMAGECOLUMN, JUSTIFY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a date edit item tag, with a DATETIMEEDIT element in the ATTRIBUTES section.

For more details about this item type, see DATETIMEEDIT item type on page 884.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
DATETIMEEDIT f1 = package.modts;
...
```

EDIT item definition
Defines a simple line-edit field, in a grid-based layout.

Syntax

```
EDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, CENTURY, COLOR, COMPLETER, COLOR WHERE, COMMENT, DEFAULT, DISPLAY LIKE, DOWNSHIFT, HIDDEN, FONTPITCH, FORMAT, IMAGECOLUMN, INCLUDE, INVISIBLE, JUSTIFY, KEYBOARDHINT, KEY, NOT NULL, NOENTRY, PICTURE, PROGRAM, REQUIRED, REVERSE, SAMPLE, STYLE, SCROLL, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, VERIFY.

Usage

Define the rendering and behavior of an edit item tag, with an `EDIT` element in the `ATTRIBUTES` section.

For more details about this item type, see EDIT item type on page 886.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
EDIT f1 = customer.cust_state,
   REQUIRED,
   COMMENT = %"customer.cust_state.comment",
   INCLUDE=(0,1,2);
...
```

GROUP item definition
Defines a groupbox layout tag, in a grid-based layout.

Syntax

```
GROUP layout-tag: item-name [  , attribute-list ] ;
```

1. *layout-tag* is an identifier that defines the name of the layout tag.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

`COMMENT`, `FONTPITCH`, `GRIDCHILDRENINPARENT`, `HIDDEN`, `STYLE`, `TAG`, `TEXT`.

Usage

Define the rendering and behavior of a group layout tag, with an `GROUP` element in the `ATTRIBUTES` section.

For more details about this item type, see GROUP item type on page 887.

Example

```
LAYOUT
GRID
{
<GROUP g1             >
 Num: [f001         ]
 ...

}
END
END
```

```
ATTRIBUTES
GROUP g1: group1,
   TEXT="Description",
   GRIDCHILDRENINPARENT;
...
```

IMAGE item definition
Defines an area that can display an image resource, in a grid-based layout.

Syntax 1: Defining a *form field image*

```
IMAGE item-tag = field-name [ , attribute-list ] ;
```

Syntax 2: Defining a *static image*

```
IMAGE item-tag: item-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *item-name* identifies the form item for a static image.
4. *attribute-list* defines the aspect and behavior of the form item.

Attributes

ACTION, AUTOSCALE, COMMENT, HEIGHT, HIDDEN, STYLE, STRETCH, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, WIDTH.

Image field only: JUSTIFY, SIZEPOLICY, SAMPLE.

Static image only: IMAGE.

Usage

Define the rendering and behavior of an image item tag, with an IMAGE element in the ATTRIBUTES section.

For more details about this item type, see IMAGE item type on page 888.

Example

```
LAYOUT
GRID
{
[f1                    ]
[                      ]
[                      ]
[                      ]
 ...

}
END
END

ATTRIBUTES
IMAGE f1 = cars.picture,
      SIZEPOLICY=FIXED, AUTOSCALE,
      COMMENT="Picture of the car";
...
```

LABEL item definition
Defines a simple text area to display a read-only value, in a grid-based layout.

Syntax 1: Defining a *form field label*

```
LABEL item-tag = field-name [ , attribute-list ] ;
```

Syntax 2: Defining a *static label*

```
LABEL item-tag: item-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *item-name* identifies the form element (name attribute in .42f) of a static label.
4. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, IMAGECOLUMN, JUSTIFY, REVERSE, SIZEPOLICY, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.

Form field label only: FORMAT, SAMPLE.

Static label only: TEXT.

Usage

Define the rendering and behavior of an label item tag, with an LABEL element in the ATTRIBUTES section.

For more details about this item type, see LABEL item type on page 890.

Example

```
LAYOUT
GRID
{
[l1  :f1         ]
 ...

}
END
END

ATTRIBUTES
LABEL l1: label1, TEXT="Desc:"; -- This is a static label
LABEL f1 = vehicle.description; -- This is a form field label
...
```

PROGRESSBAR item definition
Defines a progress indicator field, in a grid-based layout.

Syntax

```
PROGRESSBAR item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.

3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, JUSTIFY, VALUEMIN, VALUEMAX, SAMPLE, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.

Usage

Define the rendering and behavior of an progress bar item tag, with an PROGRESSBAR element in the ATTRIBUTES section.

For more details about this item type, see PROGRESSBAR item type on page 892.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
PROGRESSBAR f1 = workstate.position,
  VALUEMIN=-100, VALUEMAX=+100;
...
```

RADIOGROUP item definition
Defines a mutual exclusive set of options field, in a grid-based layout.

Syntax

```
RADIOGROUP item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, ITEMS, JUSTIFY, KEY, NOT NULL, NOENTRY, ORIENTATION, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a radio group item tag, with a RADIOGROUP element in the ATTRIBUTES section.

For more details about this item type, see RADIOGROUP item type on page 893.

Example

```
LAYOUT
GRID
```

```
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
RADIOGROUP f1 = player.level,
  ITEMS=((1,"Beginner"),
         (2,"Normal"),
         (3,"Expert"));
...
```

SCROLLGRID item definition
Defines a scrollgrid layout tag, in a grid-based layout.

Syntax

```
SCROLLGRID layout-tag: item-name [  , attribute-list ] ;
```

1. *layout-tag* is an identifier that defines the name of the layout tag.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COMMENT, FONTPITCH, GRIDCHILDRENINPARENT, HIDDEN, STYLE, TAG.

Usage

The SCROLLGRID form item type to specify the attributes of a scrollgrid container defined with a layout tag.

Important: This feature is not supported on mobile platforms.

For more details about this item type, see SCROLLGRID item type on page 894.

Example

```
LAYOUT
GRID
{
<SCROLLGRID sg1             >
 [f001         ]
 ...

}
END
END

ATTRIBUTES
SCROLLGRID sg1: scrollgrid1,
  GRIDCHILDRENINPARENT;
```

SLIDER item definition
Defines a slider element, in a grid-based layout.

Syntax

```
SLIDER item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, ORIENTATION, SAMPLE, STEP, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, VALUEMIN, VALUEMAX.

Usage

Define the rendering and behavior of a slider item tag, with an SLIDER element in the ATTRIBUTES section.

For more details about this item type, see SLIDER item type on page 895.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
SLIDER f1 = workstate.duration,
  VALUEMIN=0, VALUEMAX=50,
  STEP=1;
...
```

SPINEDIT item definition
Defines a spin box widget to enter integer values, in a grid-based layout.

Syntax

```
SPINEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STEP, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, VALUEMIN, VALUEMAX.

Usage

Define the rendering and behavior of a spin edit item tag, with an SPINEDIT element in the ATTRIBUTES section.

For more details about this item type, see SPINEDIT item type on page 895.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
SPINEDIT f1 = command.nbitems, STEP=5;
...
```

TABLE item definition
Defines attributes for a table layout tag, in a grid-based layout.

Syntax

```
TABLE layout-tag: item-name [  , attribute-list ] ;
```

1. *layout-tag* is an identifier that defines the name of the layout tag.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AGGREGATETEXT, COMMENT, DOUBLECLICK, FONTPITCH, HEIGHT, HIDDEN, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH.

Usage

Define a TABLE element in the ATTRIBUTES section, to configure a table layouted with a <TABLE > layout tag.

For more details about this item type, see TABLE item type on page 896.

Example

```
LAYOUT
GRID
{
<TABLE t1                    >
[c1  |c2        |c3          ]
[c1  |c2        |c3          ]
 ...

}
END
END
```

```
ATTRIBUTES
TABLE t1: table1, UNSORTABLECOLUMNS;
...
```

TEXTEDIT item definition
Defines a multi-line edit field, in a grid-based layout.

Syntax

```
TEXTEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PROGRAM, REQUIRED, SAMPLE, SCROLLBARS, STYLE, STRETCH, TAG, TITLE, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, WANTTABS, WANTNORETURNS.

Usage

Define the rendering and behavior of a text edit item tag, with an TEXTEDIT element in the ATTRIBUTES section.

For more details about this item type, see TEXTEDIT item type on page 897.

Example

```
LAYOUT
GRID
{
[f1                    ]
[                      ]
[                      ]
[                      ]
 ...

}
END
END

ATTRIBUTES
TEXTEDIT f1 = customer.address,
   WANTTABS, SCROLLBARS=BOTH;
...
```

TIMEEDIT item definition
Defines a line-edit with a clock widget to pick a time, in a grid-based layout.

Syntax

```
TIMEEDIT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.

2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a text edit item tag, with an TEXTEDIT element in the ATTRIBUTES section.

For more details about this item type, see TIMEEDIT item type on page 898.

Example

```
LAYOUT
GRID
{
[f1         ]
 ...

}
END
END

ATTRIBUTES
TIMEEDIT f1 = package.arrtime;
...
```

TREE item definition
Defines attributes for a tree layout tag, in a grid-based layout.

Syntax

```
TREE layout-tag: item-name [  , attribute-list ] ;
```

1. *layout-tag* is an identifier that defines the name of the layout tag.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT, PARENTIDCOLUMN, IDCOLUMN, EXPANDEDCOLUMN, ISNODECOLUMN, IMAGEEXPANDED, IMAGECOLLAPSED, IMAGELEAF.

Usage

The TREE form item type can be used to specify the attributes of a tree container defined with a layout tag.

For more details about this item type, see TREE item type on page 899.

WEBCOMPONENT item definition
Defines a generic form field that can receive an external widget, in a grid-based layout.

Syntax

```
WEBCOMPONENT item-tag = field-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMPONENTTYPE, COMMENT, DEFAULT, FONTPITCH, HEIGHT, HIDDEN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PROPERTIES, REQUIRED, SCROLLBARS, SIZEPOLICY, STYLE, STRETCH, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, WIDTH.

Usage

Define the rendering and behavior of a web component item tag, with an WEBCOMPONENT element in the ATTRIBUTES section.

For more details about this item type, see WEBCOMPONENT item type on page 900.

Example

```
LAYOUT
GRID
{
[f1             ]
[               ]
[               ]
 ...
[f2             ]
[               ]
[               ]
 ...

}
END
END

ATTRIBUTES

-- URL-based web component (recommended):
WEBCOMPONENT f1 = FORMONLY.mymap,
     STRETCH=BOTH;

-- gICAPI web component:
WEBCOMPONENT f2 = FORMONLY.mycal,
     COMPONENTTYPE="Calendar", -- lookup "Calendar.html"
     STRETCH=BOTH, STYLE="regular";
```

INSTRUCTIONS section

The INSTRUCTIONS section is used to define screen arrays, non-default screen records and global form properties.

Syntax

```
INSTRUCTIONS
{ screen-record-definition [;...] }
[ DELIMITERS AB [;] ]
[ DEFAULT SAMPLE = "string" ]
[END]
```

1. *screen-record-definition* is the definition of a screen record or screen array.
2. *A* and *B* define the opening and closing field delimiters for character based terminals.

Usage

The INSTRUCTIONS section must appear in the sequence described in form file structure.

The INSTRUCTIONS section is optional in a form definition.

The END keyword is optional.

This section is mainly used to define screen records, to group fields using tables, tree views, scrollgrids or traditional static field arrays.

Screen records (or screen arrays)

A *screen record* is a named group of form fields.

See Screen records on page 866 for more details.

Field delimiters

Use the DELIMITER keyword to specify the characters to be displayed as field delimiters on the screen.

This option is especially used for TUI mode applications.

Default sample

The DEFAULT SAMPLE directive defines the default sample text for all fields.

```
DEFAULT SAMPLE = "MMM"
```

See SAMPLE attribute on page 981 for more details.

Example

```
SCHEMA stores
LAYOUT
GRID
{
  ...
}
END
TABLES
 stock, items
END
ATTRIBUTES
...
END
INSTRUCTIONS
  SCREEN RECORD s_items[10]
```

```
    ( stock.*,
      items.quantity,
      FORMONLY.total_price )
  DELIMITERS "[]"
END
```

KEYS section
The KEYS section can be used to define default key labels for the current form.

Syntax

```
KEYS
key-name = [%]"label"
[...]
[END]
```

1. *key-name* is the name of a key (like `F10`, `Control-z`).
2. *label* is the text to be displayed in the button corresponding to the key.

Usage

The KEYS section can be used to define default key labels at the form level.

The KEYS section must appear in the sequence described in form file structure.

The KEYS section is optional in a form definition.

The END keyword is optional.

> **Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

Example

```
KEYS
  F10 = "City list"
  F11 = "State list"
  F15 = "Validate"
END
```

Form item attributes
The form item attributes reference.

ACCELERATOR attribute
The `ACCELERATOR` is an action attribute defining the primary accelerator key for an action.

Syntax

```
ACCELERATOR = key
```

1. *key* defines the accelerator key.

Usage

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see ACCELERATOR action attribute on page 1323.

ACCELERATOR2 attribute
The `ACCELERATOR2` is an action attribute defining the secondary accelerator key for an action.

Syntax

```
ACCELERATOR2 = key
```

1. *key* defines the accelerator key.

Usage

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see ACCELERATOR2 action attribute on page 1324.

ACCELERATOR3 attribute
The `ACCELERATOR3` is an action attribute defining the third accelerator key for an action.

Syntax

```
ACCELERATOR3 = key
```

1. *key* defines the accelerator key.

Usage

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see ACCELERATOR3 action attribute on page 1325.

ACCELERATOR4 attribute
The `ACCELERATOR4` is an action attribute defining the fourth accelerator key for an action.

Syntax

```
ACCELERATOR4 = key
```

1. *key* defines the accelerator key.

Usage

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see ACCELERATOR4 action attribute on page 1325.

ACTION attribute
The `ACTION` attribute defines the action associated to the form item.

Syntax

```
ACTION = action-name
```

1. *action-name* is an identifier that defines the name of the action to be sent.

Usage

The `ACTION` attribute defines the name of the action to be sent to the program when the user activates the form item.

This attribute can for example be used in a `BUTTONEDIT` field to identify the corresponding action handle to be executed in the program when the button is pressed.

The action name can be prefixed with a sub-dialog identifier and/or field name, to define a qualified action view (see action handler binding rules for more details).

Example

```
BUTTONEDIT f001 = customer.state, ACTION = print;
```

AGGREGATETEXT attribute

The AGGREGATETEXT attribute defines a label to be displayed for aggregate fields.

Syntax

```
AGGREGATETEXT = [%]"string"
```

1. *string* defines the label to be associated with the aggregate cell, with the % prefix it is a localized string.

Usage

The AGGREGATETEXT attribute can be specified at the AGGREGATE field level, or globally at the TABLE level, to define a label for the whole summary line. When defining the AGGREGATETEXT attribute at the aggregate field level, the text will be anchored to the value cell. If the AGGREGATETEXT attribute is specified at the TABLE level, the label will appear on the left in the summary line. When an aggregate text is defined at both levels, the global aggregate text of the table will be ignored.

Example

```
AGGREGATE tot = FORMONLY.total, AGGREGATETEXT="Total:";
```

AGGREGATETYPE attribute

The AGGREGATETYPE attribute defines how the aggregate field value is computed.

Syntax

```
AGGREGATETYPE = { PROGRAM | SUM | AVG | MIN | MAX | COUNT }
```

Usage

PROGRAM specifies that the aggregate value will be computed and displayed by the program code.

An aggregate type different from PROGRAM specifies that the aggregate value is computed automatically:

- SUM computes the total of all values of the corresponding numeric column.
- AVG computes the average of all values of the corresponding numeric column.
- MIN displays the minimum value of the corresponding numeric column.
- MAX displays the maximum value of the corresponding numeric column.
- COUNT computes the number of rows.

The SUM and AVG aggregate types apply to data types that can be used as operand for an addition, such as INTEGER, DECIMAL, INTERVAL.

The MIN and MAX aggregate types apply to data types that can be compared, such as INTEGER, DECIMAL, INTERVAL, CHAR, DATETIME.

Example

```
AGGREGATE tot = FORMONLY.total, AGGREGATETYPE=PROGRAM;
```

AUTOSCALE attribute
The AUTOSCALE attribute causes the form element contents to automatically scale to the size given to the item.

Syntax

```
AUTOSCALE
```

Usage

For images, this attribute forces the image to be stretched to fit in the area reserved for the image.

AUTONEXT attribute
The AUTONEXT attribute forces the cursor to automatically leave the current field when full.

Syntax

```
AUTONEXT
```

Usage

With AUTONEXT, when the user types a character that completely fills the current field, the focus goes automatically to the next field in the input order.

If data values entered in the field do not meet the requirements of other field attributes like INCLUDE or PICTURE, the cursor does not automatically move to the next field. It remains in the current field, and an error message displays.

AUTONEXT is particularly useful with character fields in which the input data is of a standard length, such as numeric postal codes. It is also useful if a character field has a length of 1, as only one keystroke is required to enter data and move to the next field.

BUTTONTEXTHIDDEN attribute
The BUTTONTEXTHIDDEN attribute indicates that the button labels for an element should not be displayed.

Syntax

```
BUTTONTEXTHIDDEN
```

Usage

Use BUTTONTEXTHIDDEN in a TOOLBAR definition to hide the labels of toolbar buttons.

CENTURY attribute
The CENTURY attribute defines expansion of the year in a DATE or DATETIME field.

Syntax

```
CENTURY = { "R" | "C" |"F" | "P" }
```

Usage

The CENTURY attribute specifies how to expand abbreviated one- and two-digit *year* specifications in a DATE and DATETIME field.

Century expansion is based on this attribute and on the current year defined by the system clock.

The CENTURY attribute can specify any of four algorithms to expand abbreviated years into four-digit year values that end with the same digits (or digit) that the user has entered.

CENTURY supports the same settings as the DBCENTURY environment variable, but with a scope that is restricted to a single field.

If the CENTURY and DBCENTURY settings are different, CENTURY takes precedence.

Unlike DBCENTURY, the CENTURY attribute is not case sensitive. However, we recommend that you use uppercase letters in the attribute.

CLASS attribute
The CLASS attribute defines the behavior of a field defined with the WIDGET attribute.

Syntax

```
CLASS = "identifier"
```

1. *identifier* is a predefined keyword defining the class of the field.

Usage

The CLASS attribute can only be used with the WIDGET attribute. It is ignored if WIDGET is not used.

> **Important:** This attribute is deprecated, use new form item types instead.

Table 258: Supported field classes

Class	Description
KEY	Field is used to trigger a keystroke instead of being a normal input field. Only supported with WIDGET="BMP"|"CHECK"|"RADIO"
PASSWORD	Field input is masked by replacing normal character echo by stars.

COLOR attribute
The COLOR attribute defines the foreground color of the text displayed by a form element.

Syntax

```
COLOR = color-name
```

1. *color-name* can be: BLACK, BLUE, CYAN, GREEN, MAGENTA, RED,WHITE, and YELLOW.

Usage

The COLOR attribute defines the logical color of a value displayed in a field.

For backward compatibility, *color-name* can be combined with an intensity keyword: REVERSE, LEFT, BLINK, and UNDERLINE.

Example

```
EDIT f001 = customer.name, COLOR = RED;
```

COLOR WHERE Attribute

The `COLOR WHERE` attribute defines a condition to set the foreground color dynamically.

Syntax

```
COLOR = color-name [...] WHERE bool-expr
```

1. *color-name* can be `BLACK`, `BLUE`, `CYAN`, `GREEN`, `MAGENTA`, `RED`, `WHITE`, or `YELLOW`.
2. *color-name* can also be an intensity keyword: `REVERSE`, `LEFT`, `BLINK`, and `UNDERLINE`.
3. *bool-expr* defines a boolean expression with a restricted syntax.

Usage

The `COLOR WHERE` attribute defines the logical color of the text of a field when the value satisfies the conditional expression.

The condition in `COLOR WHERE` can only reference the field for which the attribute is set.

The boolean expression is automatically evaluated at runtime to check when the color attribute must be set.

Example

```
EDIT f001 = item.price, COLOR=RED WHERE f001 > 100;
```

CONFIG Attribute

The `CONFIG` attribute defines the behavior and decoration of a field defined with the `WIDGET` attribute.

Syntax

```
CONFIG = "parameter [...]"
```

1. *parameter* is the value of a configuration parameter.

Usage

The `CONFIG` attribute can only be used with the `WIDGET` attribute. It is ignored if `WIDGET` is not used.

Configuration parameters are separated by blanks.

If a configuration parameter holds blank characters, you must use `{}` curly braces to delimit the parameter value.

Important: This attribute is deprecated, use new form item types instead.

CONTEXTMENU attribute

The `CONTEXTMENU` attribute defines whether a context menu option must be displayed for an action.

Syntax

```
CONTEXTMENU = [ AUTO | YES | NO ]
```

Usage

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see CONTEXTMENU action attribute on page 1326.

COMMENT attribute

The COMMENT attribute defines hint for the user about the form element.

Syntax

```
COMMENT = [%]"string"
```

1. *string* is the text to display, with the % prefix it is a localized string.

Usage

The most common use of the COMMENT attribute is to give information or instructions to the user.

The COMMENT attribute can be used for different sort of form elements:

- Form field definitions, to show a message when the field gets the focus.
- Action views, to give a hint to the user about the action.

With form fields, this attribute is particularly appropriate when the field accepts only a limited set of values. The screen location where the message is displayed depends on external configuration. It can be displayed in the comment line, or in the status bar when using a graphical user interface. If the OPEN WINDOW statement specifies COMMENT LINE OFF, any output to the comment area is hidden even if the window displays a form that includes fields that include the COMMENT attribute.

This attribute is also an action attribute that can be defined in the ACTION DEFAULTS section of a form or directly in an action view (BUTTON), see COMMENT action attribute on page 1325 for more details.

Example

```
-- As action default
ACTION DEFAULTS
  ACTION print (COMMENT="Print current order information")
END

-- In a form field definition
EDIT f1 = customer.name, COMMENT = "The customer name";

-- In a form buttom
BUTTON b1: print, COMMENT = "Print customer details";
```

COMPLETER attribute

The COMPLETER attribute enables autocompletion for the edit field.

Syntax

```
COMPLETER
```

Usage:

Form fields with COMPLETER attribute provide suggestions while the end-user types text into the field, it can be used in text edit fields such as EDIT and BUTTONEDIT item types.

Normally, the ON CHANGE trigger is fired for text edit fields when leaving the field and if the content was modified. Form fields defined with the COMPLETER attribute will trigger the ON CHANGE control block when the end user modifies the content of the field.

See Enabling autocompletion on page 1274 for more details.

Example

```
EDIT f1 = FORMONLY.custname, COMPLETER;
```

COMPONENTTYPE attribute

The COMPONENTTYPE attribute defines a name identifying the external widget for WEBCOMPONENT fields.

Syntax

```
COMPONENTTYPE = "name"
```

1. *name* defines the HTML file defining the web component.

Usage

The COMPONENTTYPE attribute is used to define the type of a WEBCOMPONENT form item for gICAPI web components.

When this attribute is specified, it defines the name of the HTML file that will be loaded by the front-end. If this attribute is not defined, the web component will be specified by an URL set dynamically by program in the field value. Consider using URL-based web components instead of gICAPI web components.

Example

```
WEBCOMPONENT f001 = FORMONLY.mycal, COMPONENTTYPE="Calendar";
```

DEFAULT attribute

The DEFAULT attribute assigns a default value to a field during data entry.

Syntax

```
DEFAULT = value
```

1. *value* can be any literal expression supported by the form compiler, as long as it matches the form field type.
2. *value* can be TODAY to specify the current system date as default.
3. *value* can be CURRENT to specify the current system datetime as default.

Usage

The literal constant specified after as default value must match the form field type. For example, when defining a numeric field, use a numeric decimal constant, for character string fields, use a double-quoted character literal.

The effect of the DEFAULT attribute depends on the WITHOUT DEFAULTS configuration option of the dialog using the form:

With the INPUT statement, form default values have are ignored when using the WITHOUT DEFAULTS option. With this option, the runtime system displays the values in the program variables to the screen. Otherwise, the form default values will be displayed when the dialog starts.

With the INPUT ARRAY statement, the form default values are always used for new rows inserted by the user. With INPUT ARRAY, the WITHOUT DEFAULTS option indicates if the existing program array elements have to be used.

Defaults values can also be specified in the database schema file, for form fields defined with database column reference.

If the field is FORMONLY, you must also specify a data type when you assign the DEFAULT attribute to a field.

If both the DEFAULT attribute and the REQUIRED attribute are assigned to the same field, the REQUIRED attribute is ignored.

If you do not use the WITHOUT NULL INPUT option in the DATABASE section of a form, all fields default to null values unless you have specified a DEFAULT attribute.

Note that DATETIME and INTERVAL literals are not supported in the DEFAULT attribute.

Example

```
EDIT f001 = order.orderdate, DEFAULT = TODAY;
EDIT f012 = FORMONLY.discount TYPE DECIMAL(5,2), DEFAULT=0.10;
```

DEFAULTVIEW attribute

The DEFAULTVIEW attribute defines if a default view (a button) must be displayed for a given action.

Syntax

```
DEFAULTVIEW = [ AUTO | YES | NO ]
```

Usage

This attribute is an action attribute that can be specified in form ACTION DEFAULTS, for more details, see DEFAULTVIEW action attribute on page 1327.

DISPLAY LIKE attribute

The DISPLAY LIKE attribute applies column attributes defined in the database schema files (.att) to a field.

Syntax

```
DISPLAY LIKE [table.]column
```

1. *table* is the optional table name to qualify the column.
2. *column* is the name of the column to be used to retrieve display attributes.

Usage

Specifying this attribute is equivalent to listing all the attributes that are assigned to *table.column* in the database schema file with the .att extension.

Display attributes are automatically taken from the schema file if the field is linked to *table.column* in the field name specification.

The DISPLAY LIKE attribute is evaluated at compile time, not at runtime. If the database schema file changes, recompile all forms using this attribute. Even if all of the fields in the form are FORMONLY, this attribute requires the form compiler to access the database schema file that contains the description of *table*.

Example

```
EDIT f001 = FORMONLY.fullname, DISPLAY LIKE customer.custname;
```

DISCLOSUREINDICATOR attribute

The DISCLOSUREINDICATOR attribute adds a drill-down decoration to the form item.

Syntax

```
DISCLOSUREINDICATOR
```

Usage

The DISCLOSUREINDICATOR attribute is used on BUTTON form items to add a graphical hint, to indicate that a click on the button will drill down in the application windows, typically to show a detail view of the information displayed in the current window.

This is a simple decoration attribute, with no other functional purpose.

For example, on iOS devices, the buttons defined with this attribute will show a typical > icon on the right.

Example

```
BUTTON b_details : details,
   TEXT="Show details",
   DISCLOSUREINDICATOR;
```

DOUBLECLICK attribute

The DOUBLECLICK attribute defines the action for double-clicks or tap on TABLE/TREE rows.

Syntax

```
DOUBLECLICK = action-name
```

1. *action-name* defines the name of the action to be invoked.

Usage

> **Note:** The double-click/tap action can also be defined as DISPLAY ARRAY dialog attribute. For more details, see Defining the action for a row choice on page 1360.

The DOUBLECLICK attribute is typically used in a TABLE or TREE container, to define the action to be sent when the user double-clicks on a row on a front-end using a mouse device. On mobile front-ends, this attribute corresponds to the action of tapping on the row with the finger.

By default, when the TABLE is driven by a DISPLAY ARRAY, a double-click invokes the "accept" action.

With an INPUT ARRAY, double-click selects the whole text if the current widget is editable. If DOUBLECLICK is defined when using an INPUT ARRAY, the action can only be sent when the user double-clicks on a non-editable widget like a LABEL. It is not recommended to define this attribute when an INPUT ARRAY dialog is used.

DOWNSHIFT attribute

The DOWNSHIFT attribute forces character input to lowercase letters.

Syntax

```
DOWNSHIFT
```

Usage

Assign the DOWNSHIFT attribute to a character field to automatically convert uppercase letters entered by the user to lowercase letters.

Because uppercase and lowercase letters have different values, storing character strings in one or the other format can simplify sorting and querying a database.

The results of conversions between uppercase and lowercase letters are based on the locale settings.

EXPANDEDCOLUMN attribute
The EXPANDEDCOLUMN attribute specifies the form field that indicates whether a tree node is expanded.

Syntax

```
EXPANDEDCOLUMN = column-name
```

1. *column-name* is the name of the form field holding the flag indicating whether a tree node is expanded (opened.)

Usage

This attribute is used in the definition of a TREE container.

You must specify form field column names, not item tag identifiers.

This attribute is optional.

FONTPITCH attribute
The FONTPITCH attribute defines the character font type as fixed or variable when the default font is used.

Syntax

```
FONTPITCH = {FIXED|VARIABLE}
```

Usage

By default, most front ends use variable width character fonts, but some fields might need to use a fixed font.

> **Tip:** Use a STYLE defining a fixed font instead of this attribute.

FORMAT attribute
The FORMAT attribute defines the data formatting for numeric and date time fields, for input and display.

Syntax

```
FORMAT = "format"
```

1. *format* is a string of characters that specifies a data format.

Usage

The FORMAT attribute can be set to define a input and display format for numeric and date fields.

When this attribute is not used, environment variables define the default format:

- For MONEY and numeric fields such as DECIMAL fields, a format can be specified with the DBFORMAT (or DBMONEY) environment variables.
- For DATE fields, the default format is defined by the DBDATE environment variable.

The data format is used when converting the input buffer to the program variable, and when displaying program variable data to form fields. For example, when defining a `FORMAT="yyyy-mm-dd"` for a form field bound to a program variable defined as a `DATE`, the user can input a date as `2013-12-24`, and the date value will be displayed in the same manner.

Do not confuse the `FORMAT` and `PICTURE` attributes: The `PICTURE` attribute is used to define an input mask for character string fields, such as vehicle registration numbers. Do not mix `PICTURE` and `FORMAT` attributes in field defintions.

If the format string is smaller than the field width, you get a compile-time warning, but the form is usable.

The format string can be any valid string expression using formatting characters as described in Formatting numeric values on page 217 and Formatting DATE values on page 220.

Example

```
EDIT f001 = order.thedate, FORMAT = "mm/dd/yyyy";
```

GRIDCHILDRENINPARENT attribute

The `GRIDCHILDRENINPARENT` attribute is used for a container to align its children to the parent container.

Syntax

```
GRIDCHILDRENINPARENT
```

Usage

By default, in a grid-based layout, child elements of a container are aligned locally inside the container layout cells. With the `GRIDCHILDRENINPARENT` attribute, you can force children to be aligned in the vertical or horizontal direction, according to the layout cells in the parent container of the container to which you assign this attribute.

Important: This feature is not supported on mobile platforms.

Note: The `GRIDCHILDRENINPARENT` attribute applies only to `GROUP` and `SCROLLGRID` containers used inside a parent `GRID` container.

When the group or scrollgrid containers are placed vertically over each other, the alignment applies on parent grid columns, and when the containers are placed side by side horizontally, the alignment applies on parent grid rows.

Example

With the next form definition, the elements in the four group boxes will align vertically and horizontally to the parent grid cells:

```
LAYOUT
GRID
{
<G ga       ><G gb       >
 Some text
[a          ]  b[b     ]
<           ><           >
<G gc       ><G gd       >
[c          ]  d[d     ]
<           ><           >
}
END
END
ATTRIBUTES
```

```
GROUP ga: GRIDCHILDRENINPARENT;
GROUP gb: GRIDCHILDRENINPARENT;
GROUP gc: GRIDCHILDRENINPARENT;
GROUP gd: GRIDCHILDRENINPARENT;
EDIT a = FORMONLY.f_a;
EDIT b = FORMONLY.f_b;
EDIT c = FORMONLY.f_c;
EDIT d = FORMONLY.f_d;
END
```

HIDDEN attribute

The `HIDDEN` attribute indicates that the element should not be displayed.

Syntax

```
HIDDEN [ = USER ]
```

1. `HIDDEN` sets the underlying item attribute to 1.
2. `HIDDEN=USER` sets the underlying item attribute to 2.

Usage

By default, all form elements are visible. Specify the `HIDDEN` attribute to hide a form element, such as a form field or a groupbox.

The runtime system detects hidden form fields: If you write an `INPUT` statement using a hidden field, the field is ignored (as if it was declared as `NOENTRY`).

If the `HIDDEN` keyword is specified alone, the underlying item attribute is set to 1. The value 1 indicates that the element is definitvely hidden to the end user, which cannot show the element, for example with the context menu of `TABLE` headers. In this hidden mode, the `UNHIDABLE` attribute is ignored by the front end.

With `HIDDEN=USER`, the underlying item attribute is set to 2. The value 2 indicates that the element is hidden by default, but the end user can show/hide the element as needed. For example, the user can change a hidden column back to visible. Form elements like table columns that are hidden by the user might be automatically re-shown (hidden=0) by the front-end if the program dialog gives the focus to that field for input. In such case the program dialog takes precedence over the hidden attribute.

When you set a hidden attribute for a form field, the model node gets the hidden attribute, not the view node.

Form fields hidden with `HIDDEN=USER` (value 2) might be shown anyway, if the field is needed by a dialog for input.

Programs may also change the visibility of form elements dynamically with the `ui.Form.setElementHidden()` or `ui.Form.setFieldHidden()` methods.

Example

```
EDIT f001 = FORMONLY.field1, HIDDEN;
EDIT col1 = FORMONLY.column1, HIDDEN=USER;
```

HEIGHT attribute

The `HEIGHT` attribute defines an explicit height for a form element.

Syntax

```
HEIGHT = integer [CHARACTERS|LINES|POINTS|PIXELS]
```

1. *integer* defines the height of the element.

Usage

By default, the height of an element is defined by the size of the form item tag in a grid-based layout, or by the type of the form item in a stack-based layout. Use the `HEIGHT` attribute to define a specific height for a form item.

> **Note:** As a general rule, consider not specifying a unit, to default to relative characters/lines/columns, instead of specifying exact pixels or points. This is especially important for mobile devices, where the screen resolution can significantly vary according to the smartphone or tablet model.

In a grid-based layout and stack-based layout, if you don't specify a size unit, it defaults to `CHARACTERS`, which defines a height based on the characters size in the current font.

Grid-based layout

For sizable items like `IMAGE`, the default height is defined by the number of lines of the form item tag in the layout, as a vertical character height. Overwrite this default by specifying the `HEIGHT` attribute.

For `TABLE`/`TREE` containers, the default height is defined by the number of lines used in the table layout. Overwrite the default by specifying the `HEIGHT = x LINES` attribute.

```
IMAGE img1: image1, WIDTH = 20, HEIGHT = 12;
```

Stack-based layout

For `TABLE` containers, the height of a list is defined by the actual number of rows, this cannot be changed.

For `IMAGE` items, by default the image is rendered full size, which means that the actual size of the image is used. Overwrite the default by specifying the `HEIGHT` attribute:

```
IMAGE image1, HEIGHT = 12, ...;
```

By default, `WEBCOMPONENT` items adapt their size to the content. To force a give size, use the `HEIGHT` attribute:

```
WEBCOMPONENT FORMONLY.chart, HEIGHT = 10, ...;
```

A `TEXTEDIT` item always adapts its size to the text value. By using the `HEIGHT` attribute, you can define a minimum height, when the value of the field is empty:

```
TEXTEDIT FORMONLY.comment, HEIGHT = 5, ...;
```

IDCOLUMN attribute

The `IDCOLUMN` attribute specifies the form field that contains the identifier of a tree node.

Syntax

```
IDCOLUMN = column-name
```

1. *column-name* is a form field name.

Usage

This attribute is used in the definition of a `TREE` container, to define the name of the form field containing the identifier of a node in a tree view

You must specify form field column names, not item tag identifiers.

This attribute is mandatory.

IMAGE attribute
The IMAGE attribute defines the image resource to be displayed for the form item.

Syntax

```
IMAGE = "resource"
```

1. *resource* defines the file name, path or URL to the image source.

Usage:

The IMAGE attribute is used to define the image resource to be displayed form items such a BUTTON, BUTTONEDIT, a TOOLBAR button or a static IMAGE item.

For more details about image resource specification, see Providing the image resource on page 784.

This attribute is also an action attribute that can be defined in the ACTION DEFAULTS section of a form or directly in an action view (BUTTON), see IMAGE action attribute on page 1328 for more details.

Example

```
-- As action default
ACTION DEFAULTS
  ACTION print (IMAGE="printer")
END

-- In a form buttonedit or button
BUTTONEDIT f001 = FORMONLY.field01, IMAGE = "zoom";
BUTTON b01: open_file, IMAGE = "buttons/fileopen";
BUTTON b02: accept, IMAGE = "http://myserver/images/accept.png";

-- In a static image form item
IMAGE: img1, IMAGE = "mylogo.png"
```

IMAGECOLUMN attribute
The IMAGECOLUMN attribute defines the form field containing the image for the current field.

Syntax

```
IMAGECOLUMN = column-name
```

1. *column-name* is a form field name.

Usage

The IMAGECOLUMN attribute allows displaying an image on the left of the value of this column value. The image can be different for each row.

A typical usage is the TREE container: IMAGECOLUMN will allow to display a row-specific image left of the tree node text. You defined only one image column for a tree node decoration.

When used in the definition of a TABLE column, the image and the column will be displayed in the same table cell. There can be several TABLE columns using an IMAGECOLUMN.

For TREE containers, the images defined by the IMAGECOLLAPSED, IMAGEEXPANDED and IMAGELEAF attributes take precedence over the images defined by the IMAGECOLUMN cell.

This attribute references form field that contains the name of an image. This form field must be defined as a PHANTOM form field, that will be part of the screen record definition in the INSTRUCTIONS section.

For more details about image resource specification in the `PHANTOM` column, see Providing the image resource on page 784.

Example

```
...
ATTRIBUTES
PHANTOM FORMONLY.icon;
EDIT FORMONLY.file_name, IMAGECOLUMN=icon;
...
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.icon, FORMONLY.file_name, ...);
...
```

IMAGECOLLAPSED attribute

The `IMAGECOLLAPSED` attribute sets the global icon to be used when a tree node is collapsed.

Syntax

```
IMAGECOLLAPSED = "image-name"
```

1. *image-name* is an image resource.

Usage

This attribute is used in the definition of a `TREE` container, to define the icon to be used for nodes that are collapsed.

It overwrites the program array image defined by `IMAGECOLUMN`, if both are used.

This attribute is optional.

For more details about image resource specification, see Providing the image resource on page 784.

IMAGEEXPANDED attribute

The `IMAGEEXPANDED` attribute sets the global icon to be used when a tree node is expanded.

Syntax

```
IMAGEEXPANDED = "image-name"
```

1. *image-name* is an image resource.

Usage

This attribute is used in the definition of a `TREE` container, to define the icon to be used for nodes that are expanded.

It overwrites the program array image defined by `IMAGECOLUMN`, if both are used.

This attribute is optional.

For more details about image resource specification, see Providing the image resource on page 784.

IMAGELEAF attribute

The IMAGELEAF attribute defines the global icon for leaf nodes of a TREE container.

Syntax

```
IMAGELEAF = "image-name"
```

1. *image-name* is an image resource.

Usage

This attribute is used in the definition of a TREE container, to specify the name of the icon that must be used for leaf nodes.

It overwrites the program array image defined by IMAGECOLUMN, if both are used.

This attribute is optional.

For more details about image resource specification, see Providing the image resource on page 784.

INCLUDE attribute

The INCLUDE attribute defines a list of possible values for a field.

Syntax

```
INCLUDE = ( { NULL | literal [ TO literal] } [,...] )
```

1. *literal* can be any literal expression supported by the form compiler.

Usage

The INCLUDE attribute specifies acceptable values for a field and causes the runtime system to check the data before accepting an input value.

If the field is FORMONLY, you must also specify a data type when you assign the INCLUDE attribute to a field.

Include the NULL keyword in the value list to specify that it is acceptable for the user to leave the field without entering any value.

Use the TO keyword to specify an inclusive range of acceptable values. When specifying a range of values, the lower value must appear first. The field value is accepted if it is greater or equal to the first literal, and lower or equal to the second literal.

```
INCLUDE = (1 TO 999)
  is equivalent to:
( field_value >= 1 AND field_value <= 999 )
```

Special consideration must be taken for character string fields:

```
INCLUDE = ("AAA" TO "ZZZ")
  is equivalent to:
( field_value >= "AAA" AND field_value <= "ZZZ" )
  ABC is accepted
  A!! is not accepted
  Zaa is not accepted
```

When combining several ranges and single values, the value entered by the user is verified for each element of the INCLUDE attribute:

```
INCLUDE = (1 TO 999, -1, NULL)
```

```
  is equivalent to:
( field_value >= 1 AND field_value <= 999 )
OR
( field_value == -1 )
OR
( field_value IS NULL )
```

Example

```
EDIT f001 = compute.rate, INCLUDE = ( 1 TO 100, 200, NULL);
EDIT f002 = customer.state, INCLUDE = ( "AL" TO "GA", "IA" TO
 "WY" );
EDIT f003 = FORMONLY.valid TYPE CHAR, INCLUDE = ("Y","N");
```

INITIALIZER attribute

The `INITIALIZER` attribute allows you to specify an initialization function that will be automatically called by the runtime system to set up the form item.

Syntax

```
INITIALIZER = function
```

1. *function* is an identifier defining the program function to be called.

Usage

The initialization function must exist in the program using the form file and must be defined with a `ui.ComboBox` parameter.

The initialization function name is converted to lowercase by fglform.

> **Tip:** Consider defining the initialization function name in lowercase letters. The language syntax allows case-insensitive functions names, but to avoid mistakes, it is recommended to use a common naming convention with lowercase letters.

INVISIBLE attribute

The `INVISIBLE` attribute prevents user-entered data from being echoed on the screen during an interactive statement.

Syntax

```
INVISIBLE
```

Usage

The `INVISIBLE` attribute can be used for `EDIT` and `BUTTONEDIT` fields.

Characters that the user enters in a field with the `INVISIBLE` attribute are not displayed during data entry. Depending on the front end type, the typed characters are displayed using the blank, star, underscore or dot characters.

The `INVISIBLE` attribute has no effect when display data directly to a field with `DISPLAY TO` or `DISPLAY BY NAME`.

ISNODECOLUMN attribute
The `ISNODECOLUMN` attribute specifies the form field that indicates whether a tree node has children.

Syntax

```
ISNODECOLUMN = column-name
```

1. *column-name* is a form field name.

Usage

This attribute is used in the definition of a `TREE` container, to specify the name of the form field indicating whether a tree node has children.

Even if the program node does not contain child nodes for this tree node, this attribute may be used, to implement dynamic filling of tree views.

You must specify form field column names, not item tag identifiers.

This attribute is optional.

ITEMS attribute
The `ITEMS` attribute defines a list of possible values that can be used by the form item.

Syntax

```
ITEMS = { single-value-list | double-value-list }
```

where *single-value-list* is:

```
( value [,...])
```

where *double-value-list* is:

```
( ( value, label-value) [,...])
```

1. *single-value-list* is a comma-separated list of single values.
2. *double-value-list* is a comma-separated list of (a, b) values pairs within parentheses.
3. *value* is a numeric or string literal, or one of the following keywords: `NULL`, `TRUE`, `FALSE`.
4. *label-value* is a numeric literal, a string literal, or a localized string.

Usage

The list must be delimited by parentheses, and each element of the list can be a simple literal value or a pair of literal values delimited by parentheses.

This attribute is not used by the runtime system to validate the field, you must use the `INCLUDE` attribute to force the possible values.

This example defines a list of simple values:

```
ITEMS = ("Paris", "London", "New York")
```

This example defines a list of pairs:

```
ITEMS = ((1,"Paris"),(2,"London"),(3,"New York"))
```

This attribute can be used, for example, to define the list of a COMBOBOX form item:

```
COMBOBOX cb01 = FORMONLY.combobox01,
        ITEMS = ((1,"Paris"), (2,"London"),(3,"New York"));
```

In this example, the first value of a pair (1,2,3) defines the data values of the form field and the second value of a pair ("Paris", "London", "New York") defines the value to be displayed in the selection list.

When used in a RADIOGROUP form item, this attribute defines the list of radio buttons:

```
RADIOGROUP rg01 = FORMONLY.radiogroup01,
        ITEMS = ((1,"Paris"), (2,"London"),(3,"New York"));
```

In this case, the first value of a pair (1,2,3) defines the data values of the form field and the second value of a pair ("Paris", "London", "New York") defines the value to be displayed as the radio button label.

You can specify item labels with localized strings, but this is only possible when you specify a key and a label:

```
ITEMS = ((1,%"item1"),(2,%"item2"),(3,%"item3"))
```

It is allowed to define a NULL value for an item (An empty string is equivalent to NULL):

```
ITEMS = ((NULL,"Enter bug status"),(1,"Open"),(2,"Resolved"))
```

In this case, the behavior of the field depends from the item type used.

JUSTIFY attribute
The JUSTIFY attribute defines the justification of the content of a field and the alignment of table column headers.

Syntax

```
JUSTIFY = { LEFT | CENTER | RIGHT }
```

Usage

With the JUSTIFY attribute, you specify the justification of the content of a field as LEFT, CENTER or RIGHT when the field is in display state.

This attribute is ignored for input (i.e. when the field has the focus); only the default data justification rule applies when a field is in input state. The default data justification depends on the dialog type, the field data type and the FORMAT attribute. For example, a numeric field value is right aligned, while a string field is left aligned. The type of dialog also defines the default justification: In a CONSTRUCT, all input fields are left aligned, for search criteria input.

The JUSTIFY attribute can be used with all form item types: Additionally to the field content/data alignment, JUSTIFY defines the alignment of table column headers indirectly (i.e. table column header follows the alignment of field data). However, column header alignment in tables may not be enabled by default; Check the `headerAlignment` presentation style attribute for the Table class.

With mobile front-ends, tables are rendered as list views with a maximum of two visible columns. By default, the main and the comment columns are displayed vertically in each row (i.e. main is on top of the comment). Use JUSTIFY=RIGHT for the second column, in order to display columns side by side. Note that numeric fields are by default right justified and thus do not need that attribute to be set.

You can also specify the text alignment of static form labels with the JUSTIFY attribute.

Example

```
LABEL t01: TEXT="Hello!", JUSTIFY=RIGHT;
EDIT f01 = order.value, JUSTIFY=CENTER;
```

KEY attribute

The KEY attribute is used to define the labels of keys when the field is made current.

Syntax

```
KEY keyname = [%]"label"
```

1. *keyname* is the name of a key (like F10, "Control-z").
2. *label* is the text to be displayed in the button corresponding to the key.

Usage

Use the KEY attribute to define a label for the accelerator key corresponding to an action when the focus is in the field.

The *keyname* must be specified in quotes if you want to use Control / Shift / Alt key modifiers.

See the KEYS section to define key labels for the whole form.

> **Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

Example

```
EDIT f001 = customer.city, KEY F10 = "City list";
EDIT f002 = customer.state, KEY "Control-z" = "Open Zoom";
```

KEYBOARDHINT attribute

The KEYBOARDHINT attribute gives an indication on the kind of data the form field contains, to let the front-end adapt the keyboard accordingly.

Syntax

```
KEYBOARDHINT = { DEFAULT | EMAIL | NUMBER | PHONE }
```

Usage

The KEYBOARDHINT attribute can be used to give a hint to the front-end, regarding the kind of data the form field will contain. According to this hint, the front-end will open the virtual keyboard adapted to the data type, especially useful when designing application forms for mobile platforms.

Valid values for KEYBOARDHINT are:

- DEFAULT: No hint, the only hint is the data type of the program variable bound to the form field.
- EMAIL: The field is used to enter an e-mail address.
- NUMBER: The field is used to enter a numeric value.
- PHONE: The field is used to enter a phone number.

For example, when defining a numeric field with the attribute KEYBOARDHINT=NUMBER, the iOS device will display a numeric keyboard when entering data into that field.

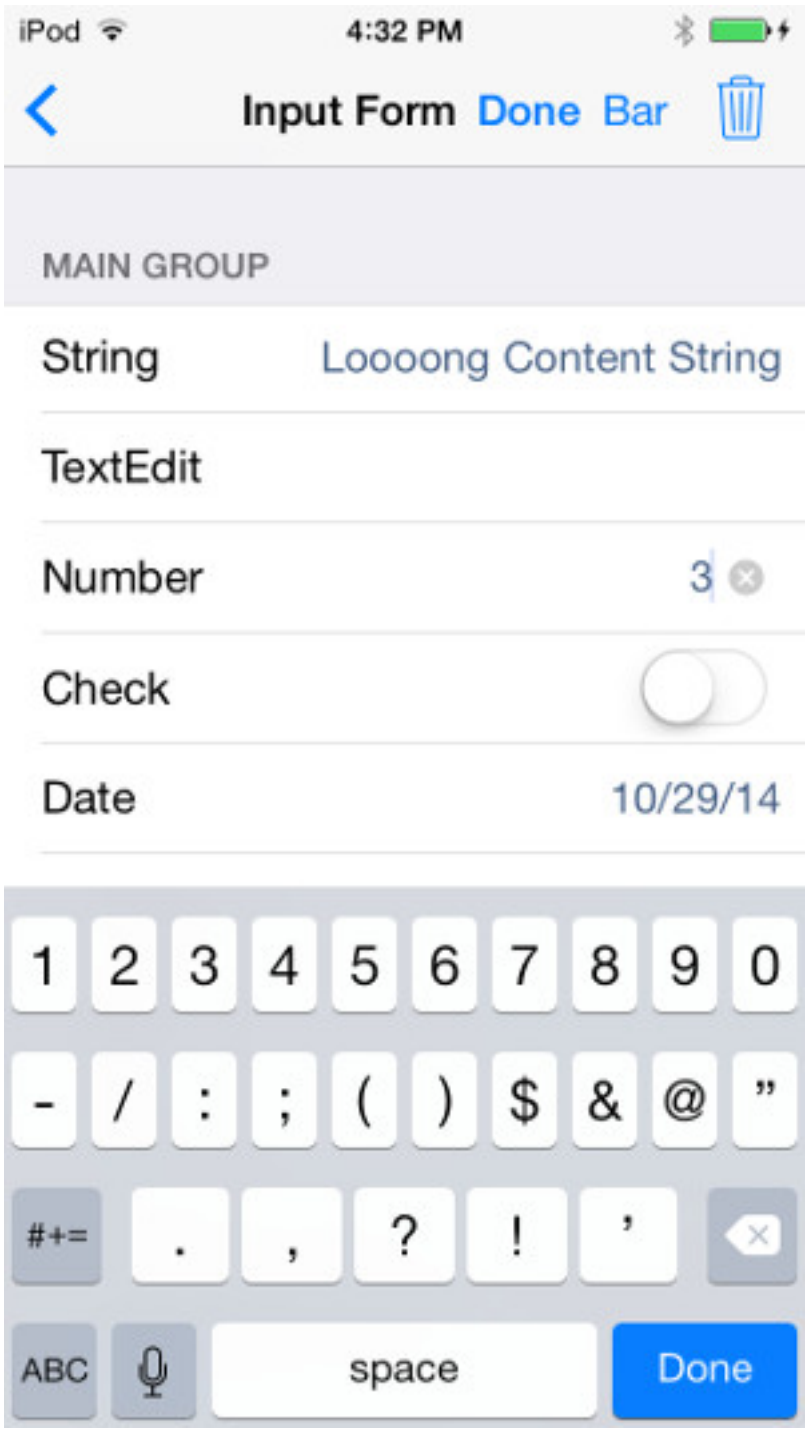

Figure 47: Mobile application using a numeric keyboard

Example

```
EDIT f23 = customer.cust_phone, KEYBOARDHINT=PHONE;
```

MINHEIGHT attribute
The MINHEIGHT attribute defines the minimum height of a form.

Syntax

```
MINHEIGHT = integer
```

1. *integer* defines the minimum height of the element, as a number of grid cells.

Usage

The MINHEIGHT attribute is used to define a minimum height for the form/window. It must be specified in the attributes of the LAYOUT section.

The unit defaults to a number of grid cells. This is the equivalent of the CHARACTERS in the HEIGHT attribute specification.

Example

```
LAYOUT ( MINWIDTH=60, MINHEIGHT=50 )
GRID
  ...
```

MINWIDTH attribute
The MINWIDTH attribute defines the minimum width of a form.

Syntax

```
MINWIDTH = integer
```

1. *integer* defines the minimum width of the element, as a number of grid cells.

Usage

The MINWIDTH attribute is used to define a minimum width for the form/window. It must be specified in the attributes of the LAYOUT section.

The unit defaults to a number of grid cells. This is the equivalent of the CHARACTERS in the WIDTH attribute specification.

Example

```
LAYOUT ( MINWIDTH=60, MINHEIGHT=50 )
GRID
  ...
```

NOENTRY attribute
The NOENTRY attribute prevents data entry in the field during an input dialog.

Syntax

```
NOENTRY
```

Usage

Use the NOENTRY attribute to bypass field input during an INPUT or INPUT ARRAY statement.

A NOENTRY field is like a disabled field, it cannot get the focus.

When compiling a form with a field referencing a SERIAL/BIGSERIAL column in the database schema, the NOENTRY attribute is automatically set. However, the attribute will not be set if the field is defined with a TYPE LIKE syntax.

When using a WITHOUT DEFAULTS dialog option, the content of the corresponding program variable is displayed in the field.

The NOENTRY attribute does not prevent data entry into a field during a CONSTRUCT statement.

Example

```
EDIT f001 = order.totamount, NOENTRY;
```

NOT NULL attribute

The NOT NULL attribute sets that the field does not accept NULL values.

Syntax

```
NOT NULL
```

Usage

The NOT NULL attribute requires that the field contains a non-null value. It can be specified explicitly in the form field definition, or in the corresponding column definition in the database schema file. If not column is associated to the field, the NOT NULL attribute can also be used in the type definition of FORMONLY fields.

The NOT NULL attribute is effective only when the field name appears in the list of screen fields of an INPUT or INPUT ARRAY statement.

If a DEFAULT attribute is used for the field and the input dialog does not use the WITHOUT DEFAULTS option, the runtime system assumes that the default value satisfies the NOT NULL attribute.

Unlike the REQUIRED attribute which has no effect when the INPUT dialog uses the WITHOUT DEFAULTS option, the NOT NULL attribute is always checked when validating a dialog.

Example

```
EDIT f001 = customer.city, NOT NULL;
```

NOTEDITABLE attribute

The NOTEDITABLE attribute disables the text editor.

Syntax

```
NOTEDITABLE
```

Usage:

The NOTEDITABLE attribute can be used in BUTTONEDIT field to disable the text editor. The button of the field remains active, if there is a corresponding active action handler in the current dialog. The field can still get the focus.

Use this attribute if you want to deny text edition in BUTTONEDIT fields, when the value can only be set by the action.

OPTIONS attribute
The OPTION attribute specifies widget options for the field.

Syntax

```
OPTIONS = "option [...]"
```

1. *option* can be -nolist (to indicate that the column should appear as an independent field).

Usage

The OPTIONS attribute specifies parameters for a form item defined with the WIDGET attribute.

Important: This attribute is deprecated, use new form item types instead.

ORIENTATION attribute
The ORIENTATION attribute defines whether an element displays vertically or horizontally.

Syntax

```
ORIENTATION = { VERTICAL | HORIZONTAL }
```

Usage

The ORIENTATION attribute is typically used in the definition of a RADIOGROUP form item, to specify how radio items have to be displayed.

Example

```
RADIOGROUP f001 = customer.status, ORIENTATION=HORIZONTAL;
```

PARENTIDCOLUMN attribute
The PARENTIDCOLUMN attribute specifies the form field that contains the identifier of the parent node of a tree node.

Syntax

```
PARENTIDCOLUMN = column-name
```

1. *column-name* is a form field name.

Usage

This attribute is used in the definition of a TREE container, to define the name of the form field containing the identifier of the tree node that is the parent of the current node in a tree view

You must specify form field column names, not item tag identifiers.

This attribute is mandatory.

PICTURE attribute
The PICTURE attribute specifies a character pattern for data entry in a text field, and prevents entry of values that conflict with the specified pattern.

Syntax

```
PICTURE = "format-string"
```

1. *format-string* defines the data input pattern of the field.

Usage

format-string can be any combination of characters, where the characters "A", "#" and "X" have a special meaning.

- The character "A" specifies any letter (alpha-numeric) character at a given position.
- The character "#" specifies any digit character at a given position.
- The character "X" specifies any character at a given position.

Any character different from "A", "X" and "#" is treated as a literal. Such characters automatically appear in the field and do not have to be entered by the user.

The `PICTURE` attribute does not require data entry into the entire field. It only requires that whatever characters are entered conform to *format-string*.

When `PICTURE` specifies input formats for `DATETIME` or `INTERVAL` fields, the form compiler does not check the syntax of *format-string*, but your form will work if the syntax is correct. Any error in *format-string*, however, such as an incorrect field separator, produces a runtime error.

The typical usage for the `PICTURE` attribute is for (fixed-length) `CHAR` fields. It is not recommended to use `PICTURE` for other data types, especially numeric or date/time fields: The current value of the field must always match (i.e. be formatted according to) `PICTURE`.

Understand that the `PICTURE` attribute defines a mask for data entry. In order to format fields when data is displayed to the field, use the `FORMAT` attribute instead. `FORMAT` is typically used for numeric and date fields, while `PICTURE` is typically used for formatted character string fields requiring input control.

The `PICTURE` attribute is ignored in `CONSTRUCT` and `DISPLAY` / `DISPLAY ARRAY` instructions: It takes only effect in `INPUT` and `INPUT ARRAY` dialogs.

Example

```
EDIT f001 = carinfo.ident, PICTURE = "AA####-AA(X)";
```

PROGRAM attribute

The `PROGRAM` attribute can specify an external application program to edit `TEXT` or `BYTE` fields.

Syntax

```
PROGRAM = "editor"
```

1. *editor* is the name of the program that must be used to edit the special field data.

Usage

You can assign the `PROGRAM` attribute to a `TEXT` or `BYTE` field to call an external program to work with the `BYTE` or `TEXT` values.

This attribute works in TUI mode only.

Users can invoke the external program by pressing the exclamation point (!) key while the screen cursor is in the field.

The external program then takes over control of the screen. When the user exits from the external program, the form is redisplayed with any display attributes besides `PROGRAM` in effect.

When no `PROGRAM` attribute is used, the `DBEDIT` environment variable defines the default editor.

PROPERTIES attribute

The PROPERTIES attribute is used to define a list of widget-specific characteristics.

Syntax

```
PROPERTIES = ( { single-property | array-property | map-property} [,...] )
```

where *single-property* is:

```
identifier = property-value
```

and *array-property* is:

```
identifier = ( property-value [,...])
```

and *map-property* is:

```
identifier = ( item-identifier = property-value[,...] )
```

and *property-value* is:

```
{ numeric-value | "string-value" }
```

1. *numeric-value* is an integer or decimal literal.
2. *string-value* is a string literal delimited by single or double quotes.

Usage

The PROPERTIES attribute is typically used to define the widget-specific attributes of a WEBCOMPONENT form item.

Property names and values are not checked, to let you freely set any characteristic of an external widget. You must verify that the front-end side implementation supports the specified properties.

Example

```
WEBCOMPONENT f01 = FORMONLY.mycalendar,
   COMPONENTTYPE = calendar,
   PROPERTIES = (
               type = "gregorian",
               week_start = 2,
               days_off = ( 1, 7 ),
               dates_off = ( "????-11-25", "????-06-20" ),
               day_titles = ( t1 = "Sunday",
                              t2 = "Monday",
                              t3 = "Tuesday",
                              t4 = "Wednesday",
                              t5 = "Thursday",
                              t6 = "Friday",
                              t7 = "Saturday"
             );
```

QUERYEDITABLE attribute

The QUERYEDITABLE attribute makes a COMBOBOX field editable during a CONSTRUCT statement.

Syntax

```
QUERYEDITABLE
```

Usage

The QUERYEDITABLE attribute is effective only during a CONSTRUCT statement. This attribute is useful when the display values match the real values in the ITEMS attribute, for example when ITEMS=("Paris","London","Madrid"). Do not use this attribute when the real field values are mapped to display values, for example when ITEMS=((1,"Paris"),(2,"London"),(3,"Madrid")).

During a CONSTRUCT, a COMBOBOX is not editable by default: The end-user is forced to set one of the values of the list as defined by the ITEMS attribute, or set the 'empty' item. The QUERYEDITABLE attribute can be used to force the COMBOBOX to be editable during a CONSTRUCT instruction, in order to allow free search criterion input such as "A*". If QUERYEDITABLE is used and the ITEMS are defined with key/label combinations, the text entered by the user will be automatically searched in the list of items. If a label corresponds, the key will be used in the SQL criterion, otherwise the text entered by the user will be used. For example, if the items are defined as ((1,"Paris"),(2,"Madrid"),(3,"London")), and the user enters "Paris" in the field, the item (1,"Paris") will match and will be generate "*colname = 1*". If the user enters ">2", the text does not match any item so it will be used as is and generate the SQL "*colname > 2*". Users may enter values like "Par*", but in this case the runtime system will raise an error because this criterion does is not valid for the numeric data type of the field. To avoid end-user confusion, a COMBOBOX defined with key/label combinations should not use the QUERYEDITABLE attribute.

REQUIRED attribute
The REQUIRED attribute forces the user to modify the content of a field during an input dialog.

Syntax

```
REQUIRED
```

Usage

The REQUIRED attribute forces the user to modify the content of a field controlled by an input dialog (INPUT or INPUT ARRAY), when the INPUT dialog does not use the WITHOUT DEFAULTS option. Within INPUT ARRAY, the REQUIRED attribute always applies to new created rows.

If an INPUT dialog uses the WITHOUT DEFAULTS clause, the current value of the variable linked to the REQUIRED field is considered as a default value; the runtime system assumes that the field satisfies the REQUIRED attribute, even if the variable value is null.

In an INPUT ARRAY dialog, the REQUIRED attribute always applies to new created rows, even if WITHOUT DEFAULTS is used. In other words, when creating a new row, INPUT ARRAY behaves like INPUT without the WITHOUT DEFAULTS clause.

If REQUIRED is effective regarding the WITHOUT DEFAULTS conditions, and a DEFAULT attribute is used for the field, the runtime system assigns the default value to the field and assumes that the REQUIRED attribute is satisfied.

The REQUIRED attribute does not prevent fields to be null; If the field contains a value, and the user subsequently erases this value during the same input, the runtime system considers the REQUIRED attribute satisfied. To insist on a non-null entry, use the NOT NULL attribute.

Example

```
EDIT f001 = orders.ord_shipcmt, REQUIRED;
```

REVERSE attribute

The REVERSE attribute displays any value in the field in reverse video (dark characters in a bright field).

Syntax

```
REVERSE
```

Usage

Use the REVERSE attribute to highlight specific fields in your forms.

On graphical front-ends, the REVERSE attribute is rendered by using the field COLOR attribute as background color.

On character based terminals, the REVERSE video escape sequences must be defined in the TERMINFO or TERMCAP databases.

Example

```
EDIT f001 = customer.name, COLOR = BLUE, REVERSE;
```

SAMPLE attribute

The SAMPLE attribute defines the text to be used to compute the width of a form field.

Syntax

```
SAMPLE = "text"
```

1. *text* is the sample string that will be used to compute the width of the field.

Usage

By default, form fields are rendered by the client with a size determined by the current font and the number of characters used in the layout grid. The field width is computed so that the largest value can fit in the widget.

> **Important:** This feature is not supported on mobile platforms.

Sometimes the default computed width is too wide for the typical values displayed in the field. For example, numeric fields usually need less space as alphanumeric fields. If the values are always smaller, you can use the SAMPLE attribute to provide a hint for the front end to compute the best width for that form field.

When specifying the SAMPLE attribute, you do not have to fill the sample string up to the width of the corresponding field tag: The front-ends will be able to compute a physical width by applying a ratio to fit the best visual result. For example, for a sample of 'XY' used for a field defined with 10 characters, is equivalent to specifying a sample of 'XYXYXYXYXY'.

If the SAMPLE attribute is not used, the first 6 cells are always computed with the pixel width of the 'M' character in the current font. Next cells are computed with the pixel width of the '0' (zero) character. In other words, the default sample model is 'MMMMMM000000.....", reduced to the size of the field tag in the layout:

```
   -123456789-123456789-         default sample
   [f01 ]                        MMMM
   [f02   ]                      MMMMMM
   [f03             ]            MMMMMM0000000000
```

You can define a default sample for all fields used in the form, by specifying a `DEFAULT SAMPLE` option in the `INSTRUCTIONS` section.

Example

```
EDIT cid = customer.custid, SAMPLE="0000";
EDIT ccode = customer.ucode, SAMPLE="MMMMMM";
DATEEDIT be01 = customer.created, SAMPLE="00-00-0000";
```

SCROLL attribute

The `SCROLL` attribute can be used to enable horizontal scrolling in a character field.

Syntax

```
SCROLL
```

Usage

By default, the maximum data input length is defined by the width of the item-tag of the field. For example, if you define an `CHAR` field in the form with a length of 3 characters, users can only enter a maximum of 3 characters, even if the program variable used for input is a `CHAR(20)`.

If you want to let the user input more characters than the width of the item-tag of the field, use the `SCROLL` attribute.

The `SCROLL` attribute applies only to fields with character data input.

Use the `SCROLL` attribute only when the layout of the form does not allow to define an item tag that is large enough to hold all possible character string data that fits in the corresponding program variable. Understand that the end user can miss a part of the displayed data when the field is too small. Therefore, using the `SCROLL` attribute should be rare.

SCROLLBARS attribute

The `SCROLLBARS` attribute can be used to specify scrollbars for a form item.

Syntax

```
SCROLLBARS = { NONE | VERTICAL | HORIZONTAL | BOTH }
```

Usage

This attribute defines scrollbars for the form item, such as a `TEXTEDIT`.

Example

```
TEXTEDIT f001 = customer.fname, SCROLLBARS=BOTH;
```

SIZEPOLICY attribute

The `SIZEPOLICY` attribute is a sizing directive, according to the content of a form item.

Syntax

```
SIZEPOLICY = { INITIAL | FIXED | DYNAMIC }
```

Usage

The SIZEPOLICY attribute defines how the front-ends computes the size of some form elements, according to the content of the form field or form item.

The SIZEPOLICY applies only to leaf elements of the layout. It does not apply to containers. The attribute applies to form elements with sizable content, typically IMAGE, COMBOBOX, WEBCOMPONENT. Elements allowing user input such as EDIT, or elements where the size does not depend from the value content such as PROGRESSBAR, SLIDER do not use this attribute.

Note that the SIZEPOLICY attribute is ignored for columns used in TABLE or TREE containers: In list views, the size policy is implicitly defined by the cell (i.e., the size of the column in the form layout). The SIZEPOLICY attribute is also implicitly fixed for fields inside SCROLLGRID and GRID containers that are controlled by a list dialog, such as a DISPLAY ARRAY. With a list dialog, each row can have a different value, which would imply a different widget size for each row; this is not supported.

When the SIZEPOLICY is not specified, the default behavior depends on the type of the form item. See Table 259: Behavior of SIZEPOLICY=INITIAL, according to the form item type and front-end type on page 984.

SIZEPOLICY = FIXED

When SIZEPOLICY is FIXED, the form element's size is exactly the size defined in the layout of the form specification file.

The size of the element is computed from the width and height in the form grid and the font used on the front-end side.

The element keeps the size, even if the content is modified. However, if the STRETCH attribute is set to X, Y or BOTH, the form element can still stretch when the parent window size changes.

SIZEPOLICY = DYNAMIC

When SIZEPOLICY is DYNAMIC, the size of the element grows and shrinks according to the width of the content, during the lifetime of the application.

This can be used for COMBOBOX or RADIOGROUP fields, when the size of the widget must fit exactly to its content, which can vary during the program execution.

> **Note:** With SIZEPOLICY=DYNAMIC, some element such as BUTTON, LABEL, IMAGE and RADIOGROUP can shrink and grow all the time, while COMBOBOX elements can only grow.

SIZEPOLICY = INITIAL

When SIZEPOLICY is INITIAL, the size is computed from the initial content, the first time the element appears on the screen. Once the widget displays, its size is frozen. However, if the STRETCH attribute is set to X, Y or BOTH, the form element can still stretch when the parent window size changes.

This is typically used when the size of the element must be fixed, but is not known at design time. For example, when populating a COMBOBOX item list from a database table, the size of the COMBOBOX depends on the size of the labels in the drop-down list).

This size policy mode is also useful when the text of labels is unknown at design time because of internationalization.

With SIZEPOLICY=INITIAL, the behavior differs depending on the form element type.

Table 259: Behavior of SIZEPOLICY=INITIAL, according to the form item type and front-end type

Form item	Behavior with SIZEPOLICY=INITIAL
BUTTON	The size defined in the form is a minimum size. If the text is bigger, the size grows (width and height).
COMBOBOX	The width defined in the form is a minimum width. If one of the items in the value list is bigger, the size grows in order for the combobox to fully display the largest item.
LABEL, CHECKBOX, RADIOGROUP	These form items can shrink or grow. The size defined in the form is ignored. The fields are sized according to the element text.
IMAGE	Image form items can shrink and grow according to the picture displayed. Images can use the STRETCH attribute, so that the widget size is dependent on the parent container, overriding the SIZEPOLICY attribute. If the WIDTH and HEIGHT attributes must be used, the SIZEPOLICY attribute must be set to FIXED.
WEBCOMPONENT	The web component is scaled to the right size, after the first web page is loaded. It stays at that size, except if the STRETCH attribute is used, and the parent container size changes.

Keep in mind that after the first display, the element size will be frozen.

Example

```
COMBOBOX f001 = customer.city,
    ITEMS=((1,"Paris"),(2,"Madrid"), (3,"London")),
    SIZEPOLICY=DYNAMIC;

WEBCOMPONENT wc1 = FORMONLY.chart,
    COMPONENTTYPE="chart",
    SIZEPOLICY=FIXED,
    STRETCH=BOTH;
```

SPACING attribute

The SPACING attribute is a spacing directive to display form elements.

Syntax

```
SPACING = { NORMAL | COMPACT }
```

Usage

This attribute defines the global distance between two neighboring form elements. In NORMAL mode, the front end displays form elements consistent with the desktop spacing, which is, for example, 6 and 10 pixels on Microsoft™ Windows™ platforms.

When using the COMPACT mode, large forms that by default do not fit to the screen can be displayed with less space between elements.

By default, forms are displayed with COMPACT spacing.

Example

```
LAYOUT ( SPACING=COMPACT )
```

SPLITTER attribute

The SPLITTER attribute forces the container to use a splitter widget between each child element.

Syntax

```
SPLITTER
```

Usage

This attribute indicates that the container (typically, a VBOX or HBOX) must have a splitter between each child element held by the container. If a container is defined with a splitter and if the children are stretchable (like TABLE or TEXTEDIT), users can resize the child elements inside the container.

Example

```
VBOX ( SPLITTER )
```

STEP attribute

The STEP attribute specifies how a value is increased or decreased in one step (by a mouse click or key up/down).

Syntax

```
STEP = integer
```

1. *integer* defines a positive integer value to be added (for an increase) or subtracted (for a decrease).

Usage

This attribute is typically used with form items allowing the user to change the current integer value by a mouse click like SLIDER, SPINEDIT.

Example

```
SLIDER s01 = FORMONLY.slider, STEP=10;
```

STRETCH attribute

The STRETCH attribute specifies how a widget must resize when the parent container is resized.

Syntax

```
STRETCH = { NONE | X | Y | BOTH }
```

Usage

This attribute is typically used with form items that can be re-sized like IMAGE. TEXTEDIT, or WEBCOMPONENT fields. By default such form items have a fixed width and height, but in some cases you may want to force the widget to resize vertically, horizontally, or in both directions.

- To allow the widget to resize vertically only, use STRETCH=Y.
- To allow the widget to resize horizontally only, use STRETCH=X.
- To allow the widget to resize vertically and horizontally, use STRETCH=BOTH.

Example

```
IMAGE i01 = FORMONLY.image01, STRETCH=BOTH;
```

STYLE attribute

The STYLE attribute specifies a presentation style for a form element.

Syntax

```
STYLE = "string"
```

1. *string* is a user-defined style.

Usage

This attribute specifies a presentation style to be applied to a form element.

The presentation style can define decoration attributes such as a background color, a font type, and so on.

Note: The string used to define this attribute must be a *style-name* only, it must not contain the *element-type* that is typically used to define the style in a .4st file (as CheckBox.important for example)

Example

```
EDIT c01 = item.comment, STYLE = "important";
```

TABINDEX attribute

The TABINDEX attribute defines the tab order for a form item.

Syntax

```
TABINDEX = integer
```

1. *integer* defines the order of the item in the tab sequence.

Usage

This attribute can be used to define the order in which the form items are selected as the user "tabs" from field.

To take TABINDEX attributes into account in dialogs, the program must defined the form tabbing order with the OPTIONS FIELD ORDER FORM instruction. Alternatively, a dialog can use the FIELD ORDER FORM option as well.

The TABINDEX attribute can also be used to define which field must get the focus when a FOLDER page is selected.

By default, form items get a tab index according to the order in which they appear in the LAYOUT section.

Tip: TABINDEX can be set to zero in order to exclude the form item from the tabbing list. The item can still get the focus with the mouse.

Example

```
EDIT f001 = customer.fname, TABINDEX = 1;
EDIT f002 = customer.lname, TABINDEX = 2;
EDIT f003 = customer.comment,
```

```
      TABINDEX = 0; -- Excluded from tabbing list
```

TAG attribute

The TAG attribute can be used to identify the form item with a specific string.

Syntax

```
TAG = "tag-string"
```

1. *tag-string* is free text.

Usage

This attribute is used to identify form items with a specific string. It can be queried in the program to perform specific processing.

You are free to use this attribute as you need. For example, you can define a numeric identifier for each field in the form in order to show context help, or group fields for specific input verification.

If you need to handle multiple data, you can format the text, for example, by using a pipe separator.

Example

```
EDIT f001 = customer.fname, TAG = "name";
EDIT f002 = customer.lname, TAG = "name|optional";
```

TEXT attribute

The TEXT attribute defines the label associated with a form item.

Syntax

```
TEXT = [%]"string"
```

1. *string* defines the label to be associated with the form item, with the % prefix it is a localized string.

Usage

The TEXT attribute is used to define the label of a form item, for example for a CHECKBOX form field or a BUTTON action view.

Consider using localized strings with the %"*string-id*" syntax, if you plan to internationalize your application.

This attribute is also an action attribute that can be defined in the ACTION DEFAULTS section of a form or directly in an action view (BUTTON), see TEXT action attribute on page 1330 for more details.

Example

```
-- As form action default
ACTION DEFAULTS
  ACTION print (TEXT="Print")
END

-- As a CHECKBOX label
CHECKBOX cb01 = FORMONLY.checkbox01,
                TEXT="OK" ... ;

-- As a BUTTON label
```

```
BUTTON b1: print, TEXT="Print";
```

TITLE attribute
The TITLE attribute defines the title of a form item.

Syntax

```
TITLE = [%]"string"
```

1. *string* defines the title to be associated with the form item, with the % prefix it is a localized string.

Usage

The TITLE attribute is typically used to define the title of a form field that will be defined as a TABLE or TREE column, or form items used in a stacked layout, to define the label associated to the item.

> **Note:** Use of the TITLE attribute should be restricted to form fields that make up the columns of a table/tree container, or form items used in a stacked layout.

Consider using localized strings with the %"*string-id*" syntax, if you plan to internationalize your application.

Example

```
EDIT col4 = FORMONLY.ord_shipdate, TITLE="Ship date";
```

UNSORTABLE attribute
The UNSORTABLE attribute indicates that the element cannot be selected by the user for sorting.

Syntax

```
UNSORTABLE
```

Usage

By default, a TABLE container allows the user to sort the columns by a left-click on the column header.

Use the UNSORTABLE attribute to prevent a sort on a specific column.

Makes sense only for a field that is used for the definition of a column in a TABLE container.

Example

```
EDIT c01 = item.comment, UNSORTABLE;
```

UNSORTABLECOLUMNS attribute
The UNSORTABLECOLUMNS attribute indicates that the columns of the table cannot be selected by the user for sorting.

Syntax

```
UNSORTABLECOLUMNS
```

Usage

When using this attribute in a TABLE definition, the end user will not be allowed to sort rows.

Example

```
TABLE t1 ( UNSORTABLECOLUMNS )
```

UNSIZABLE attribute

The UNSIZABLE attribute indicates that the element cannot be resized by the user.

Syntax

```
UNSIZABLE
```

Usage

By default, a TABLE container allows the user to resize the columns by a drag-click on the column header.

Use this attribute to prevent a resize on a specific column.

Makes sense only for a field that is used for the definition of a column in a TABLE container.

Example

```
EDIT c01 = item.comment, UNSIZABLE;
```

UNSIZABLECOLUMNS attribute

The UNSIZABLECOLUMNS attribute indicates that the columns of the table cannot be resized by the user.

Syntax

```
UNSIZABLECOLUMNS
```

Usage

When using this attribute in a TABLE definition, the end user will not be allowed to resize the columns.

Example

```
TABLE t1 ( UNSIZABLECOLUMNS )
```

UNHIDABLE attribute

The UNHIDABLE attribute indicates that the element cannot be hidden or shown by the user with the context menu.

Syntax

```
UNHIDABLE
```

Usage

By default, a TABLE container allows the user to hide the columns by a right-click on the column header.

Use this attribute to prevent the user from hiding a specific column.

The end user is also denied to show columns that are hidden by default with HIDDEN=USER

Makes sense only for a field that is used for the definition of a column in a TABLE container.

Example

```
EDIT c01 = item.comment, UNHIDABLE;
```

UNHIDABLECOLUMNS attribute

The UNHIDABLECOLUMNS attribute indicates that the columns of the table cannot be hidden or shown by the user with the context menu.

Syntax

```
UNHIDABLECOLUMNS
```

Usage

When using this attribute in a TABLE definition, the end user will not be allowed to hide columns, or show columns that are hidden by default with HIDDEN=USER.

Example

```
TABLE t1 ( UNHIDABLECOLUMNS )
```

UNMOVABLE attribute

The UNMOVABLE attribute prevents the user from moving a defined column of a table.

Syntax

```
UNMOVABLE
```

Usage

By default, a TABLE container allows the user to move the columns by dragging and dropping the column header.

Use this attribute to prevent the user from changing the order of a specific column.

Typically, UNMOVABLE is used on at least two columns to prevent the user from changing the order of the input on these columns.

Example

```
EDIT c01 = item.comment, UNMOVABLE;
```

UNMOVABLECOLUMNS attribute

The UNMOVABLECOLUMNS attribute prevents the user from moving columns of a table.

Syntax

```
UNMOVABLECOLUMNS
```

Usage

When using this attribute in a TABLE definition, the end user will not be allowed to move columns around.

Example

```
TABLE t1 ( UNMOVABLECOLUMNS )
```

UPSHIFT attribute

The UPSHIFT attribute forces character input to uppercase letters.

Syntax

```
UPSHIFT
```

Usage

Assign the UPSHIFT attribute to a character field to automatically convert lowercase letters entered by the user to uppercase letters.

Because uppercase and lowercase letters have different values, storing character strings in one or the other format can simplify sorting and querying a database.

The results of conversions between uppercase and lowercase letters are based on the locale settings.

Example

```
EDIT f001 = FORMONLY.name, UPSHIFT;
```

VALIDATE attribute

The VALIDATE action attribute defines the data validation level for a given action.

Syntax

```
VALIDATE = NO
```

Usage

This attribute is an action attribute that can be specified in form ACTION DEFAULTS, for more details, see VALIDATE action attribute on page 1331.

VALIDATE LIKE attribute

The VALIDATE LIKE attribute applies column attributes defined in the .val database schema files to a field.

Syntax

```
VALIDATE LIKE [table.]column
```

Note:

1. *table* is the optional table name to qualify the column.
2. *column* is the name of the column used to search for validation rules.

Usage

Specifying the VALIDATE LIKE attribute is equivalent to writing in the field definition all the attributes that are assigned to *table*.*column* in the .val database schema file.

Note that .val attributes are taken automatically from the schema file if the field is linked to *table*.*column* in the field name specification. The VALIDATE LIKE attribute is usually specified for FORMONLY fields.

The VALIDATE LIKE attribute is evaluated at compile time, not at runtime. If the database schema file changes, you should recompile all your forms.

Even if all of the fields in the form are FORMONLY, the VALIDATE LIKE attribute requires the form compiler to access the database schema file that contains the description of *table*.

Example

```
EDIT f001 = FORMONLY.fullname, VALIDATE LIKE customer.custname;
```

VALUEMIN attribute

The VALUEMIN attribute defines a lower limit of values displayed in widgets (such as progress bars).

Syntax

```
VALUEMIN = integer
```

1. *integer* is a integer literal.

Usage

This attribute is typically used to define the lower limit in PROGRESSBAR, SPINEDIT and SLIDER fields.

This attribute is not used by the runtime system to validate the field. You must use the INCLUDE attribute to control value boundaries.

Example

```
SLIDER s01 = FORMONLY.slider01,
             VALUEMIN=0,
             VALUEMAX=500;
```

VALUEMAX attribute

The VALUEMAX attribute defines a upper limit of values displayed in widgets (such as progress bars).

Syntax

```
VALUEMAX = integer
```

1. *integer* is an integer literal.

Usage

This attribute is typically usedto define the upper limit in PROGRESSBAR, SPINEDIT and SLIDER fields.

This attribute is not used by the runtime system to validate the field. You must use the INCLUDE attribute to control value boundaries.

Example

```
SLIDER s01 = FORMONLY.slider01,
                         VALUEMIN=0,
                         VALUEMAX=500;
```

VALUECHECKED attribute

The VALUECHECKED attribute defines the value associated with a checkbox item when it is checked.

Syntax

```
VALUECHECKED = value
```

1. *value* is a numeric or string literal, or one of the following keywords: NULL, TRUE, FALSE.

Usage

This attribute is used in conjunction with the VALUEUNCHECKED attribute to define the values corresponding to the states of a CHECKBOX.

This attribute is not used by the runtime system to validate the field, you must use the INCLUDE attribute to control value boundaries.

Example

```
CHECKBOX cb01 = FORMONLY.checkbox01,
                TEXT="OK",
                VALUECHECKED=TRUE,
                VALUEUNCHECKED=FALSE;
```

VALUEUNCHECKED attribute

The VALUEUNCHECKED attribute defines the value associated with a checkbox item when it is not checked.

Syntax

```
VALUEUNCHECKED = value
```

1. *value* is a numeric or string literal, or one of the following keywords: NULL, TRUE, FALSE.

Usage

This attribute is used in conjunction with the VALUECHECKED attribute to define the values corresponding to the states of a CHECKBOX.

This attribute is not used by the runtime system to validate the field, you must use the INCLUDE attribute to control value boundaries.

Example

```
CHECKBOX cb01 = FORMONLY.checkbox01,
                TEXT="OK",
                VALUECHECKED="Y",
                VALUEUNCHECKED="N";
```

VERIFY attribute

The VERIFY attribute requires users to enter data in the field twice to reduce the probability of erroneous data entry.

Syntax

```
VERIFY
```

Usage

This attribute supplies an additional step in data entry to ensure the integrity of your data. After the user enters a value into a VERIFY field and presses the Return or Tab key, the runtime system erases the field and requests reentry of the value. The user must enter exactly the same data each time, character for character: 15000 is not exactly the same as 15000.00.

The VERIFY attribute takes effect in INPUT or INPUT ARRAY instructions only, it has no effect on CONSTRUCT statements.

VERSION attribute
The VERSION attribute is used to specify a user version string for an element.

Syntax

```
VERSION = { "string" | TIMESTAMP }
```

1. *string* is a user-defined version string.

Usage

This attribute specifies a version string to distinguish different versions of a form element. You can specify an explicit version string or use the TIMESTAMP keyword to force the form compiler to write a timestamp string into the 42f file.

Typical usage is to specify a version of the form to indicate if the form content has changed. This attribute is used by the front-end to distinguish different form versions and to avoid reloading window/form settings into a new version of a form.

You should use the TIMESTAMP only during development.

Example

```
LAYOUT ( TEXT="Orders", VERSION = "1.23" )
```

WANTFIXEDPAGESIZE attribute
The WANTFIXEDPAGESIZE attribute controls the vertical resizing of a list element.

Syntax

```
WANTFIXEDPAGESIZE [ = NO ]
```

Usage

The WANTFIXEDPAGESIZE attribute can be used for TABLE and SCROLLGRID containers to control the vertical resizing of the list element.

By default, a TABLE container is resizable (vertically and horizontally). To freeze the height of the table to the number of lines defined by the form file, use the attribute WANTFIXEDPAGESIZE.

By default, a SCROLLGRID container is not resizable in height. The number of visible scrollgrid rows is defined by the form file. To allow the scrollgrid to stretch vertically, use the attribute WANTFIXEDPAGESIZE=NO.

WANTNORETURNS attribute
The `WANTNORETURNS` attribute forces a text field to reject newline characters when the user presses the Return key.

Syntax

```
WANTNORETURNS
```

Usage

By default, text fields like `TEXTEDIT` insert a newline (ASCII 10) character in the text when the user presses the Return key. As the Return key is typically used to fire the *accept* action to validate the dialog, you can force the field to reject Return keys with this attribute.

The user can still enter newline characters with Shift-Return or Ctrl-Return, if these keys are not bound to actions.

WANTTABS attribute
The `WANTTABS` attribute forces a text field to insert Tab characters in the text when the user presses the Tab key.

Syntax

```
WANTTABS
```

Usage

By default, text fields like `TEXTEDIT` do not insert a Tab character in the text when the user presses the Tab key, since the Tab key is used to move to the next field. You can force the field to consume Tab keys with this attribute.

The user can still jump out of the field with Shift-Tab, if this key is not bound to an action.

WIDGET attribute
The `WIDGET` attribute specifies the type of graphical widget to be used for the field.

Syntax

```
WIDGET = "identifier"
```

1. *identifier* defines the type of widget, it can be one of the keywords listed in Table 260: Supported widgets on page 996.

Usage

The `WIDGET` attribute defines the type of widget to be used for the form field.

This attribute is used with `CONFIG`, `CLASS` and `INCLUDE` attributes, to parameter the field widget.

> **Important:** This attribute is deprecated, use new form item types instead.

- Instead of `WIDGET="IMAGE"`, you should now use a IMAGE form item.
- Instead of `WIDGET="CANVAS"`, you should now use a CANVAS form item.
- Instead of `WIDGET="CHECK"`, you should now use a CHECKBOX form item.
- Instead of `WIDGET="COMBO"`, you should now use a COMBOBOX form item.
- Instead of `WIDGET="BMP"`, you should now use a BUTTON form item.
- Instead of `WIDGET="FIELD_BMP"`, you should now use a BUTTONEDIT form item.
- Instead of `WIDGET="RADIO"`, you should now use a RADIOGROUP form item.

The *identifier* widget type is case sensitive, only uppercase letters are recognized.

When you use the `WIDGET` attribute, the form cannot be properly displayed on character based terminals, it should only be displayed on graphical front ends.

Table 260: Supported widgets

Symbol	Effect	Other attributes
`Canvas`	The field is used as a drawing area. Field must be declared as `FORMONLY` field.	None.
`BUTTON`	The field is presented as a button widget with a label.	`CONFIG`: The unique parameter defines the key to be sent when the user clicks on the button. Button text is defined in configuration files or from the program with a `DISPLAY TO` instruction. For example: `CONFIG = "Control-z"`
`BMP`	The field is presented as a button with an image.	`CONFIG`: First parameter defines the image file to be displayed, second parameter defines the key to be sent when the user clicks on the button. For example: `CONFIG = "smiley.bmp F11"` **Important:** Image files are not centralized on the machine where the program is executed; image files must be present on the Workstation. See front end specific documentation for more details.

`CHECK`	The field is presented as a checkbox widget. It can be used with the `CLASS` attribute to change the behavior of the widget.	`CONFIG`: First and second parameters define the values corresponding respectively to the state "Checked" / "Unchecked" of the check box, while the third parameter defines the label of the checkbox.
		For example:
		`CONFIG = "Y N Confirmation"`
		If the text part must include spaces, add {} curly braces around the text:
		`CONFIG = "Y N {Order validated}"`
		If the `CLASS` attribute is used with the `"KEY"` value, the first and second parameters defines the keys to be sent respectively when the checkbox is "Checked" / "Unchecked", and the third parameter defines the label of the checkbox as with normal checkbox usage.
		For example (line breaks added for document readability):

Symbol	Effect	Other attributes
		`CLASS = "KEY",` `CONFIG = "F11 F12 Confirmation"`

`COMBO`	The field is presented as a combobox widget. It can be used with the `CLASS` attribute to change the behavior of the widget.	`INCLUDE`: This attribute defines the list of acceptable values that will be displayed in the combobox list.
		For example (line breaks added for document readability):
		`INCLUDE =`
		`("Paris", "London", "Madrid")`
		Important: The `INCLUDE` attribute cannot hold value range definitions, because all items must be explicitly listed to be added to the combobox list.
		The following example is not supported:
		`INCLUDE = (1 TO 10)`

`FIELD_BMP`	The field is presented as a normal editbox, plus a button on the right.	`CONFIG`: The first parameter defines the image file to be displayed in the button; the second parameter defines the key to be sent when the user clicks on the button. For example: `CONFIG = "combo.bmp Control-z"`
`LABEL`	The field is presented as a simple label, a read-only text.	None.

`RADIO`	The field is presented as a radiogroup widget.	`CONFIG`: Parameter pairs define respectively the value and the label corresponding to one radio button.
		For example (line breaks added for document readability):
		`CONFIG =`
		`"AA First BB Second CC Third"`
		If the radio texts must include spaces, add {} curly braces around the texts (line breaks added for document readability):
		`CONFIG = "AA {First option}`
		`BB {Second option} CC {Third option}"`
		If the `CLASS` attribute is used with the value `"KEY"`, the first element of each pairs represents the key to be sent when the user selects a radio button.
		For example (line breaks added for document readability):
		`CLASS = "KEY",`
		`CONFIG = "F11 First F12 Second`

Symbol	Effect	Other attributes
		F13 Third"

Controlling old style widgets activation

The following list of widgets can be enabled or disabled from programs with a DISPLAY TO instruction:

- Text buttons (WIDGET="BUTTON")
- Image buttons (WIDGET="BMP")
- Checkboxes of class "KEY" (WIDGET="CHECK", CLASS="KEY")
- Radio buttons of class "KEY" (WIDGET="RADIO", CLASS="KEY")

If you display an exclamation mark in such fields, the button is enabled, but if you display a star (*), it is disabled:

```
DISPLAY "*" TO button1 # disables the button
DISPLAY "!" TO button1 # enables the button
```

Changing the text of WIDGET="BMP" fields

The text of button fields (WIDGET="BUTTON") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "Click me" TO button1
 # Sets text and enables the button
```

Changing the image of WIDGET="BMP" fields:

The image of button fields (WIDGET="BMP") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "smiley.bmp" TO button1
 # Sets image and enables the button
```

Image files are not centralized on the machine where the program is executed; image files must be present on the Workstation. See front end specific documentation for more details.

Changing the text of WIDGET="LABEL" fields:

The text of label fields (WIDGET="LABEL") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "Firstname" TO l_firstname
 # Sets text of the label field
```

Using WIDGET="Canvas" fields:

The fields declared with the WIDGET="Canvas" attribute can be used by the program as drawing areas. Canvas fields must be defined in the LAYOUT section. A set of drawing functions are provided to fill canvas fields with graphical elements.

WIDTH attribute

The WIDTH attribute defines an explicit width of a form element.

Syntax

```
WIDTH = integer [CHARACTERS|COLUMNS|POINTS|PIXELS]
```

1. *integer* defines the width of the element.

Usage

By default, the width of an element is defined by the size of the form item tag in a grid-based layout, or by the type of the form item in a stack-based layout. Use the WIDTH attribute to define a specific width for a form item.

> **Note:** As a general rule, consider not specifying a unit, to default to relative characters/lines/columns, instead of specifying exact pixels or points. This is especially important for mobile devices, where the screen resolution can significantly vary according to the smartphone or tablet model.

Grid-based layout

For sizable items like IMAGE, the default width is defined by the number of horizontal characters used in the form item tag. Overwrite this default by specifying the WIDTH attribute.

```
IMAGE img1: image1, WIDTH = 20, HEIGHT = 12;
```

For TABLE/TREE containers, the default width is defined by the columns used in the table layout. Overwrite the default by specifying the WIDTH = *x* COLUMNS attribute. This will give a small initial width for tables with a large number of columns.

```
TABLE t1: table1, WIDTH = 5 COLUMNS;
```

In a grid-based layout, if you don't specify a size unit, it defaults to CHARACTERS, which defines a width based on the characters size in the current font.

Stack-based layout

In a stack-based layout, the WIDTH attribute cannot be used: The width of form element are automatically computed.

WINDOWSTYLE attribute

The WINDOWSTYLE attribute defines the style to be used by the parent window of a form.

Syntax

```
WINDOWSTYLE = "string"
```

1. *string* is a user-defined style name.

Usage

The WINDOWSTYLE attribute can be used to specify the style of the parent window that will hold the form. This attribute is specific to the LAYOUT element. Do not confuse this attribute with the STYLE attribute, which is used to specify the decoration style of the form elements.

When a form is loaded by the OPEN WINDOW or DISPLAY FORM instruction, the runtime system automatically assigns the WINDOWSTYLE to the STYLE attribute of the parent window element.

Example

```
LAYOUT ( STYLE="BigFont", WINDOWSTYLE="dialog" )
```

WORDWRAP Attribute

The WORDWRAP attribute enables a multiple-line editor in TUI mode.

Syntax

```
WORDWRAP [ { COMPRESS | NONCOMPRESS } ]
```

Usage

This attribute is provided for backward compatibility with character-based forms, to support word wrapping in multi-line text input.

In GUI mode, you should use a TEXTEDIT form item instead. When used, the WORDWRAP attribute is ignored, because text input and display is managed by the text editor widget. The text data is not automatically modified by the editor by adding blanks to put words on the next line.

In TUI mode, the WORDWRAP attribute has following effects:

- During input and display, the runtime system treats all segments that have that field tag as segments of a single field.
- The multi-line editor can *wrap* long character strings to the next line of a multiple-segment field for data entry, data editing, and data display.
- The COMPRESS option prevents blanks produced by the editor from being included in the program variable. COMPRESS is applied by default and can cause truncation to occur if the sum of intentional characters exceeds the field or column size. Because of editing blanks in the WORDWRAP field, the stored value might not correspond exactly to its multiple-line display.
- Specifying NONCOMPRESS after the WORDWRAP keyword causes any editor blanks to be saved when the string value is saved in a database column, in a variable, or in a file.

Using WORDWRAP fields with character-based terminals results in quite different behavior than with graphical front ends. With character-based terminals, the text input and display is modified by the multi-line editor. This editor can automatically modify the text data by adding blanks to put words to the next line, in order to make the text fit into the form field. In GUI mode, the text input and display is managed by a multi-line edit control.

The maximum number of bytes a user can enter is the width of the form-field multiplied by the height of the form-field. Blank characters may be intentional blanks or fill blanks. Intentional blanks are initially stored in the target variable where entered by the user. Fill blanks are inserted at the end of a line by the editor when a newline or a word-alignment forces a line-break. It is not possible to set the cursor at a fill blank. Intentional blanks are always displayed (even on the beginning of a line; the word-wrapping method used in reports with PRINT WORDWRAP works differently).

When entering characters with Japanese locales, special characters are prohibited from being the first or the last character on a line. If the last character is prohibited from ending a line, this character is wrapped down to the next line. If the first character is prohibited from beginning a line, the preceding character will also wrap down to the next line. This method is called kinsoku. The test for prohibited characters will be done only once for the first and the last character on each line.

Word-wrapping is disabled on the last row of a WORDWRAP field. The last word on the last row may by truncated. The WORDWRAP COMPRESS attribute instructs the editor to remove fill blanks before assigning the field-buffer to the target variable. The WORDWRAP NONCOMPRESS attribute instructs the editor to store fill blanks to the target variable. The WORDWRAP and WORDWRAP NONCOMPRESS attributes are equivalent.

The WORDWRAP attribute is not used by the CONSTRUCT instruction.

Examples

Example 1: Grid-based layout form

```
LAYOUT ( TEXT = "Customer orders" )
  VBOX
    GROUP group1 ( TEXT = "Customer" )
      GRID
      {
        <GROUP Name                                          >
         [f001                                              ]
        <                                                    >
        <GROUP Identifiers       ><GROUP Contact             >
         FCode: [f002           ]  Phone: [f004             ]
         LNumb: [f003           ]  EMail: [f005             ]
        <                         ><                         >
      }
      END
    END
    TABLE
    {
      OrdNo  Date       Ship date   Weight
     [c01   |c02       |c03        |c04        ]
     [c01   |c02       |c03        |c04        ]
     [c01   |c02       |c03        |c04        ]
     [c01   |c02       |c03        |c04        ]
    }
    END
    FOLDER
      PAGE pg1 ( TEXT = "Address" )
        GRID
        {
           Address:  [f011                              ]
           State:    [f012           ]
           Zip Code: [f013      ]
        }
        END
      END
      PAGE pg2 ( TEXT = "Comments" )
        GRID
        {
          [f021                                         ]
          [                                             ]
          [                                             ]
          [                                             ]
        }
        END
      END
    END
  END
END
```

Example 2: Stack-based layout form

```
SCHEMA stores

ACTION DEFAULTS
  ACTION import(TEXT=%"action.import")
END

TABLES
  customer
END
```

```
LAYOUT(TEXT=%"title.customer")
STACK
GROUP
  LABEL, TEXT=%"label.new_customer";
END --GROUP
GROUP
  EDIT customer.customer_num, NOENTRY, TITLE=%"label.number";
  EDIT customer.fname, TITLE=%"label.first_name";
  EDIT customer.lname, TITLE=%"label.last_name";
  EDIT customer.company, TITLE=%"label.company";
END --GROUP
GROUP(TEXT = "group.address")
  EDIT customer.address1, TITLE=%"label.address1";
  EDIT customer.address2, TITLE=%"label.address2";
  EDIT customer.city, TITLE=%"label.city";
  BUTTONEDIT customer.state, TITLE=%"label.state", UPSHIFT,
             NOTEDITABLE, ACTION = zoom;
  EDIT customer.zipcode, TITLE=%"label.zipcode";
END --GROUP
GROUP phone_edit
  EDIT customer.phone, TITLE=%"label.telephone",
       KEYBOARDHINT=PHONE;
END --GROUP
GROUP phone_dial
  BUTTON dial, TEXT=%"button.dial";
END --GROUP
END --STACK
END --LAYOUT
```

Form rendering

The section explains the layout rules to render forms on graphical front-ends.

- Form rendering basics on page 1002
- Grid-based layout on page 1004
- Stack-based layout on page 1017

Form rendering basics

Get the essentials about form rendering.

In the graphical mode (GUI mode), forms are not displayed in a fixed text-mode screen. Application windows can display complex layouts and are resizable by the end user, if the platform allows window resizing (mobile devices versus desktop platforms).

When developing with command line tools, forms are designed with `.per` form specification files, which are text files. In order to display text-based forms in graphical mode, the text-based form definitions must be converted to graphical forms, which implies specific layout rules. These rules are explained in this section.

We distinguish two type of form rendering techniques:

- Grid-based rendering, based on a grid of cells, to place and size form elements.
- Stack-based rendering, where all form elements are place over each other vertically.

Character set usage

The character set used to edit and compile `.per` form specification files is defined by the current locale.

Form elements (typically, labels) can be written with non-ASCII characters of the current codeset.

In a grid-based layout, the form element positions and sizes are determined by counting the width of characters, rather than the number of bytes identifying the characters in the current codeset. This rule can be ignored when using a single-byte character set such as ISO-8859-1 or CP-1252, where each character

has width of 1 and codepoint of 1 byte. This rule is important when using a multibyte character set such as BIG5 or UTF-8.

For example, in the UTF-8 multibyte codeset, a Chinese ideogram is encoded with three bytes, while the visual width of the character is twice the size of a Latin character. In the next example, the labels with three Chinese characters have the same width as the labels using six Latin characters. As a result, all the labels will get the same size (6 cells), and all fields will be aligned properly in a proportional font display:

```
LAYOUT
GRID
{
### [f001  ] abcdef [f002  ]
abcdef [f003  ] ### [f004  ]
}
END
END
```

In a stack-based container, the position of form elements is logical, the current locale does not impact on the form item positions as in a grid-based container:

```
LAYOUT
 STACK
   GROUP
      EDIT customer.cust_num, TITLE="###";
      EDIT customer.cust_name;
      EDIT customer.cust_address;
   END
   ...
 END
END
```

For maximum portability, it is recommended to write all form specification files in ASCII (7 bit), and use localized strings to internationalize your forms.

Adapting to viewport changes

Application forms and functions can be adapted according to the front-end viewport size or mobile device orientation.

Detecting viewport size / orientation changes

When the mobile device orientation changes, or when the current window is resized on desktop/web front-ends, the `windowresized` specific predefined action will be sent, if an `ON ACTION` handler is defined by the current dialog for this action.

> **Note:** The `windowresized` action should only be used to hide/show items on the current form using the standard user interface API (`ui.Form.setElementHidden()`) and not reload forms on the fly.

This predefined action can be used to detect viewport geomatry changes and adapt the application form to the new size:

```
  ON ACTION windowresized
     -- Code to adapt to the new viewport size
```

> **Note:** In dialogs allowing field input (`INPUT` / `INPUT ARRAY` or `CONSTRUCT`), take care of the current field input: The `windowresized` action can force the field validation. Therefore, it is not recommended to use this special action in these dialogs. The action can be safely used in `DISPLAY ARRAY` and `MENU` dialogs.

To control the action view rendering defaults and current field validation behavior when the `windowresized` action is used and fired, consider setting action defaults attribute for this action in your .4ad file as follows:

```
<ActionDefaultList>
  ...
  <ActionDefault name="windowresized" validate="no" defaultView="no"
 contextMenu="no"/>
  ...
</ActionDefaultList>
```

Querying the geometry of the viewport

Use the feInfo/windowSize front call to query the actual size of the front-end view-port (GDC current window, GBC webview, or mobile screen size):

```
DEFINE size STRING
CALL ui.Interface.frontCall("standard","feInfo",["windowSize"],[size])
IF size == "1200x1824" THEN
   ...
END IF
```

Grid-based layout

A form file can define a grid-based layout within a tree of layout items.

In a `.per` form specification file, the `LAYOUT` section defines a tree of layout containers, which hold form items such as labels and form fields.

The `GRID` container can be used to define a grid of cells that hold form items: In the layout tree, the `GRID` container acts as a leaf node, which holds the visible widgets (fields, buttons, and so on).

> **Note:** `SCROLLGRID` and `GROUP` containers defined by layout tags inside a grid without the `GRIDCHILDRENINPARENT` attribute, are similar to `GRID` containers in regards to the layout rules describe in this section.

The `.per` form specification file defines a form layout based on a character grid, each character defines a cell of the grid:

```
GRID
{
First Name [fname  ]
Last Name  [lname  ]
}
END
```

The `.per` file layout specification can be shown in a character grid.

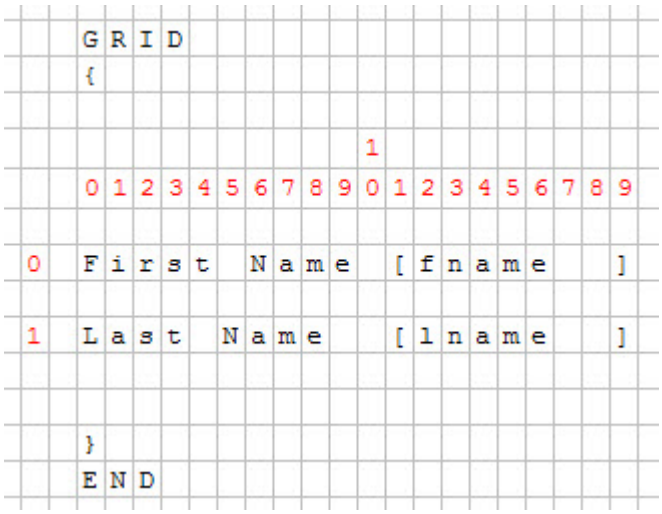

Figure 48: Character grid of a form layout

With a fixed-font based front end (such as a dumb terminal), the forms appear within a screen where each cell is identified by x and y coordinates, as in the SCREEN section of the form specification file. There is no particular layout issue, as all characters can be displayed at the same (relative) position as in the source form file.

With the graphical front-end, text-based forms must be displayed in a graphical window using fonts with a proportional size. In a proportional font, the field label "Key" has a different graphical length than the label "Num", despite having the same number of characters.

In the compiled version of the form specification file, all form items get coordinates in a virtual grid (defined by `posX` and `posY` attributes), and the number of cells the item occupies in the grid (in the `gridWidth` and `gridHeight` attributes):

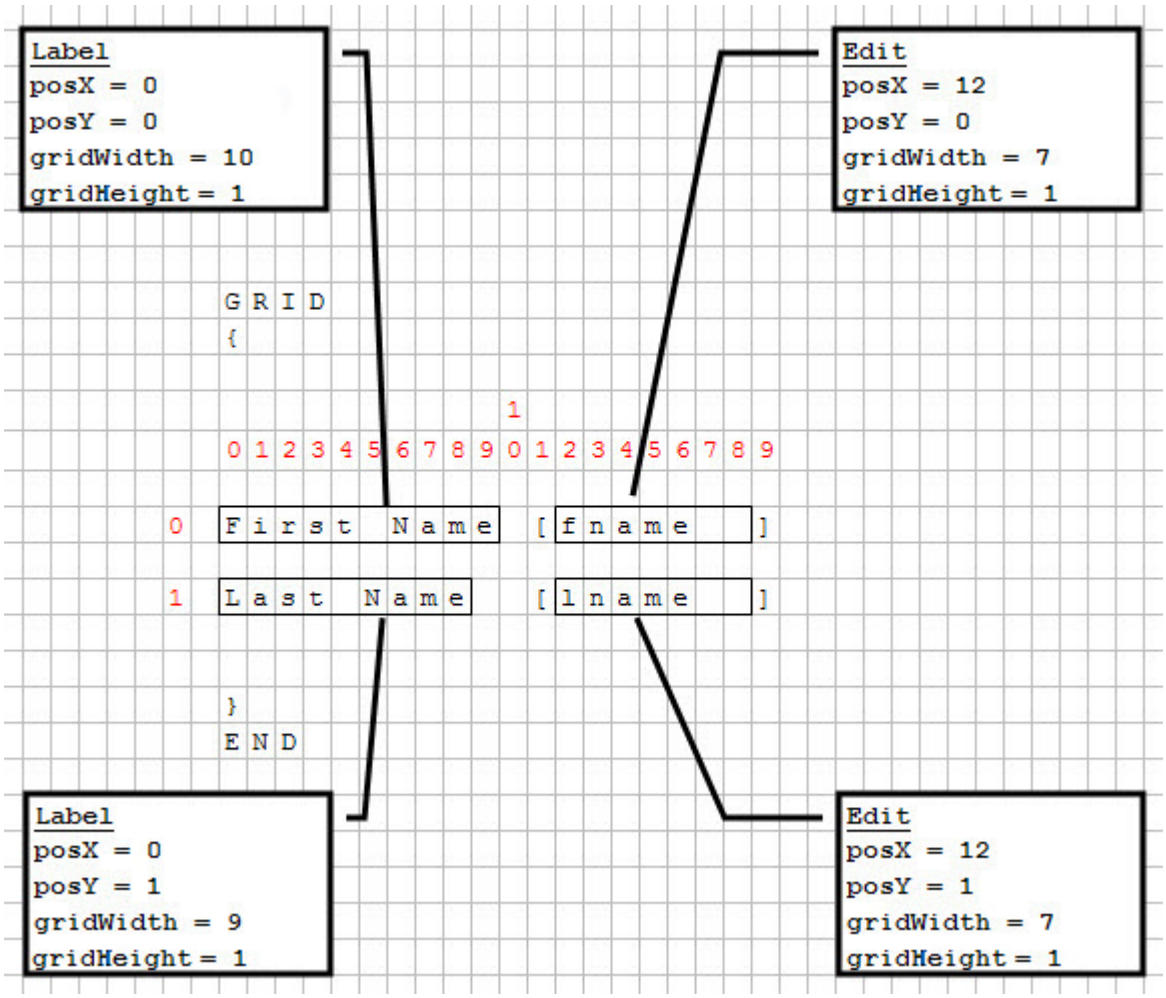

Figure 49: Grid positioning

The "First Name" and "Last Name" texts are identified as whole labels, even if the words "First" and "Name" (or "Last" and "Name") are not joined in the form definition, because the form compiler considers a single blank as a word separator within labels.

Packed and unpacked grids
When resizing a window, the content will either grow with the window or be packed in the top left position.

If elements in the window can grow, they will follow the window container and resize accordingly. Some elements can grow vertically, some can grow horizontally, and some can grow in both directions. The way resizable form items can grow is controlled by the `STRETCH` attribute. The window content is packed horizontally, vertically or in both directions, if none of the elements can grow in that direction.

The following form item types can grow horizontally:

- `TABLE` / `TREE` items
- `IMAGE` items (with `STRETCH=BOTH` or `STRETCH=X`)
- `TEXTEDIT` items (with `STRETCH=BOTH` or `STRETCH=X`)

The following form item types can grow vertically:

- `TABLE` / `TREE` items (without `WANTFIXEDPAGESIZE` attribute)
- `IMAGE` items (with `STRETCH=BOTH` or `STRETCH=Y`)
- `TEXTEDIT` items (with `STRETCH=BOTH` or `STRETCH=Y`)

In general, a `GRID` container can grow if any object inside the `GRID` can grow. The exception to this rule: If there is a single `GROUP` container (defined without the `GRIDCHILDRENINPARENT` attribute) inside a `GRID` and nothing else, the grid can grow even if the objects inside the grid cannot grow.

This exception allows better rendering of a grouped grid.

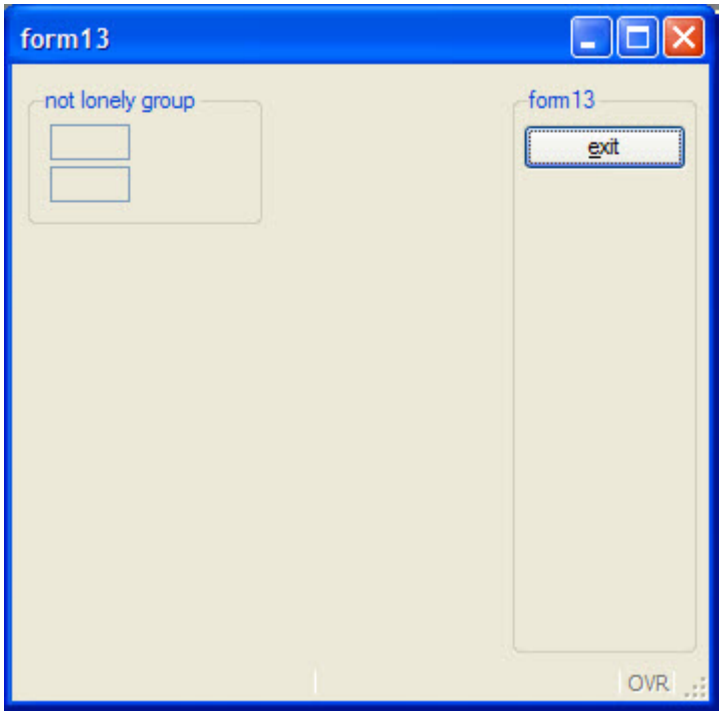

Figure 50: Packed grid

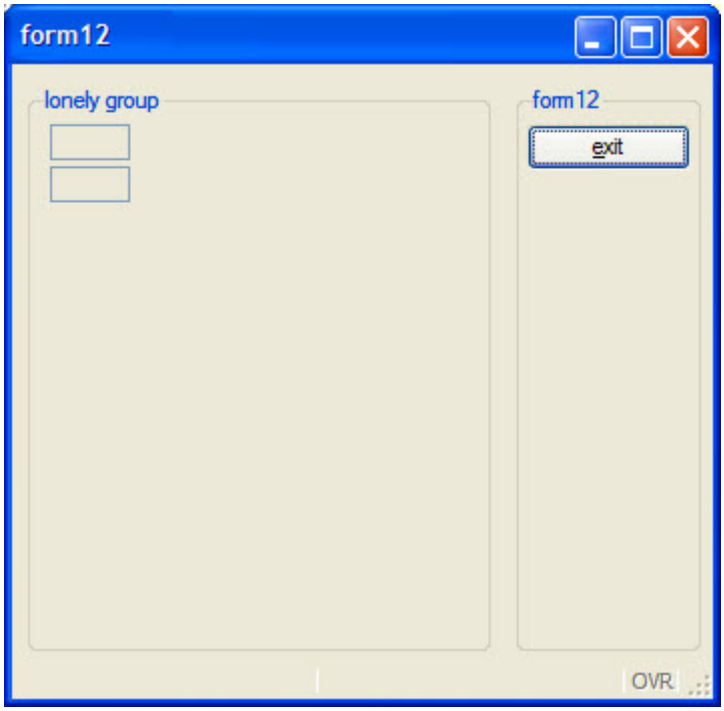

Figure 51: Unpacked grid

Automatic HBoxes and VBoxes
Horizontal and vertical boxes are added automatically when stretchable elements are used.

When using layout tags in a `GRID` container, the `fglform` compiler will automatically add hbox or vbox containers with splitters in the following conditions:

- An hbox is created when two or more stretchable elements are stacked side by side and touch each other (no space between).
- A vbox is created when two or more stretchable elements are stacked vertically and touch each other (no space between).

No hbox or vbox will be created if the elements are in a `SCROLLGRID` container.

This example defines two tables stacked vertically, generating a vbox with splitter. The ending tags for the tables are omitted.

```
<T table1         >
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
[colA  |colB      ]
<T table2         >
[colC  |colD      ]
[colC  |colD      ]
```

This example defines a layout with two stretchable `TEXTEDIT` fields placed side by side, which would generate an automatic hbox with splitter. To make both widgets touch, you need to use a pipe delimiter in between the two widgets.

```
[textedit1         |textedit2                ]
[                  |                         ]
[                  |                         ]
[                  |                         ]
```

Widget position and size in grid
Form items render as widgets in the window, at a given position and with a given size.

To render form items, grid-based rendering follows the layout rules described below:

1. The position of the widgets in the virtual grid is defined by the `posX` and `posY` AUI tree attributes.
2. The number of virtual grid cells occupied by a widget is defined by the `gridWidth` and `gridHeight` AUI tree attributes.
3. The real size (i.e. pixels) of a widget is defined by the `width` and `height` AUI tree attributes.
4. Empty lines and empty columns in the form layout definition take a size of 0 pixels, but this can be configured with `emptyColWidth` and `emptyRowHeight` style attributes (see below).
5. The size of a cell in the virtual grid depends on the real size of the widgets inside the grid.
6. A widget's minimum size is computed via its real size and the `SAMPLE` attribute.
7. The preferred size of the widget is computed according to the `SIZEPOLICY` attribute.
8. The final widget size is computed according to the minimum and preferred size, to fill the cells in the grid.
9. A small spacing is applied in non-empty cells.

The next screen-shot shows 2 labels and 2 fields placed in a grid.

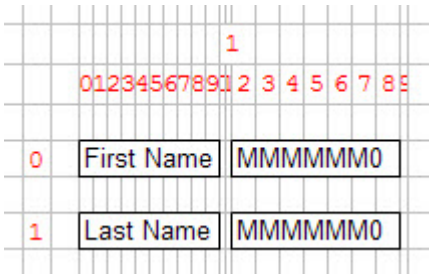

Figure 52: Two labels and two fields placed in a grid: Grid view

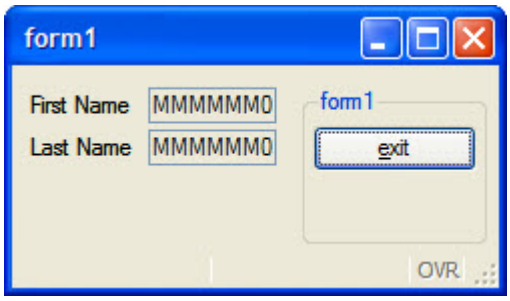

Figure 53: Two labels and two fields placed in a grid: Form view

By default, empty grid rows and empty grid columns get not size when rendering on the front-end. For example, in the above grid sample, the grid columns #10 and #11 are empty.

Form item dependencies in grids
Form items interact with each other in terms of width, according to the front-end widget size.

This example illustrates how form items are dependent of each other inside the grid.

```
GRID
{
  [a      ]
  [b      ]
}
END
```

This `.per` implies that form items a and b start at the same position and have the same size, whatever a and b are.

This rule could lead to very different results, especially when a large widget is assigned into a small number of cells.

Example:

```
LAYOUT
GRID
{
[a|b   ][f     ]
[c|d]   [e     ]
}
END
END

ATTRIBUTES
CHECKBOX a = formonly.a, TEXT="A Checkbox";
EDIT b = formonly.b;
EDIT c = formonly.c;
CHECKBOX d = formonly.d, TEXT="Another Checkbox";
EDIT e = formonly.e;
```

```
EDIT f = formonly.f;
END
```

The grid will be computed regarding characters cells in the form definition:

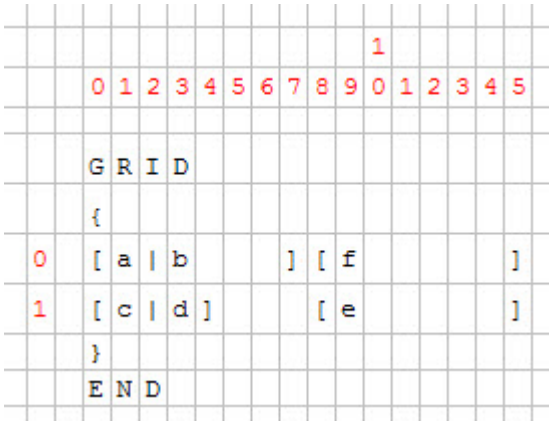

Figure 54: Grid layout

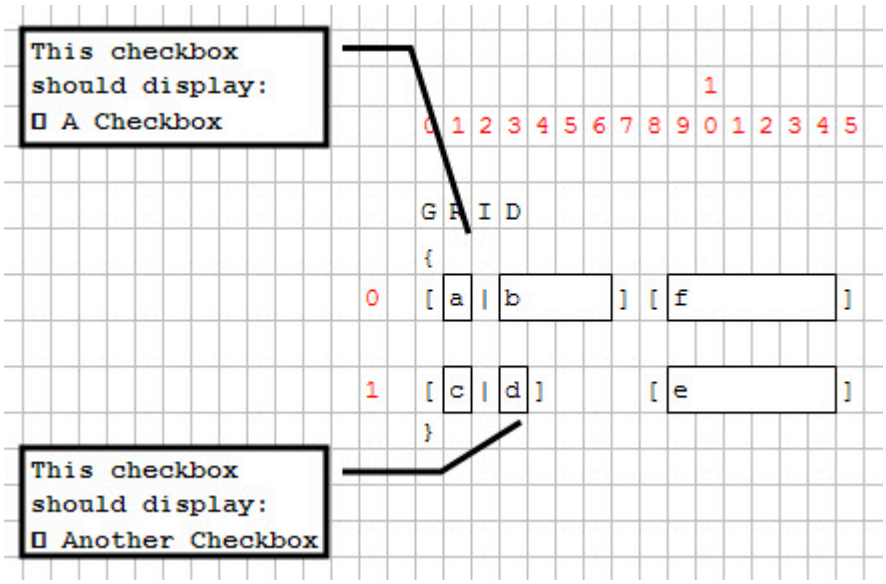

Figure 55: Grid layout with checkboxes

Then the minimum size of each widget and the layout is computed.

Cells (0,1) and (1,3) contain a checkbox; these checkboxes will enlarge columns 1 and 3.

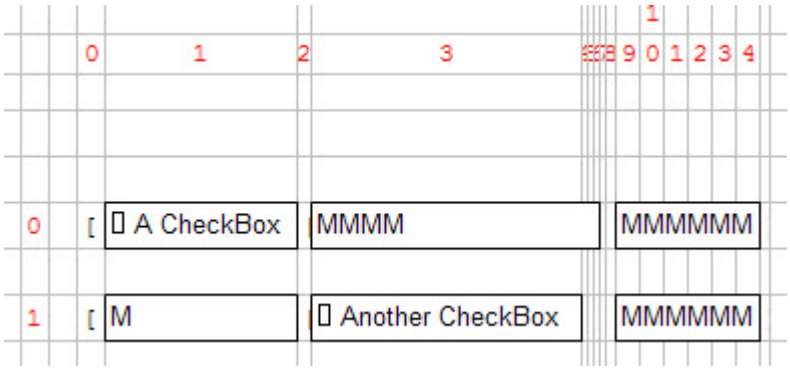

Figure 56: Enlarged columns

Because the `EDIT` field "c" is defined to have the same width as checkbox "a", it will be much larger as expected.

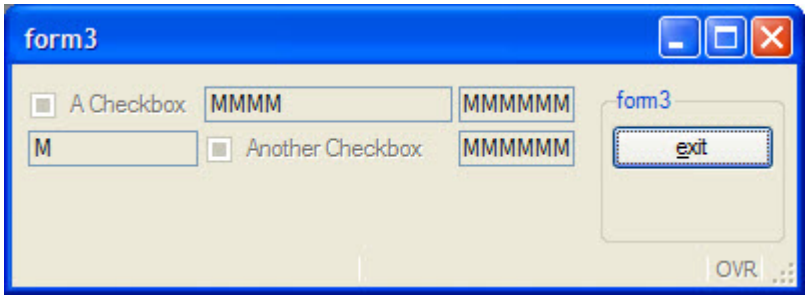

Figure 57: Resulting form

To avoid this visual result, you must assign a realistic number of grid cells for each form item.

```
GRID
{
[a         |b  ][f     ]
[c|d           ][e     ]
}
```

Even if the grid area is wider in the source form file, the real graphical result will be smaller.

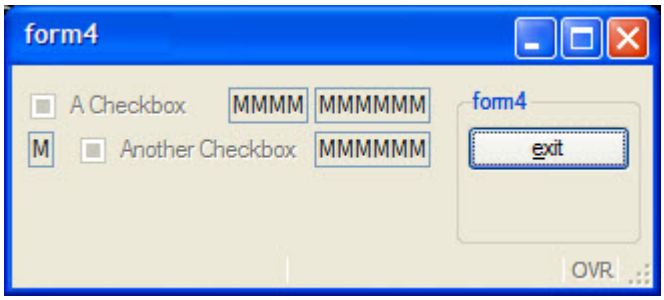

Figure 58: Resulting form

Complex grid layout example
Describes how form item align in grid-based front-ends with an example.

These diagrams show the virtual grid of a complex form, with several field item tags.

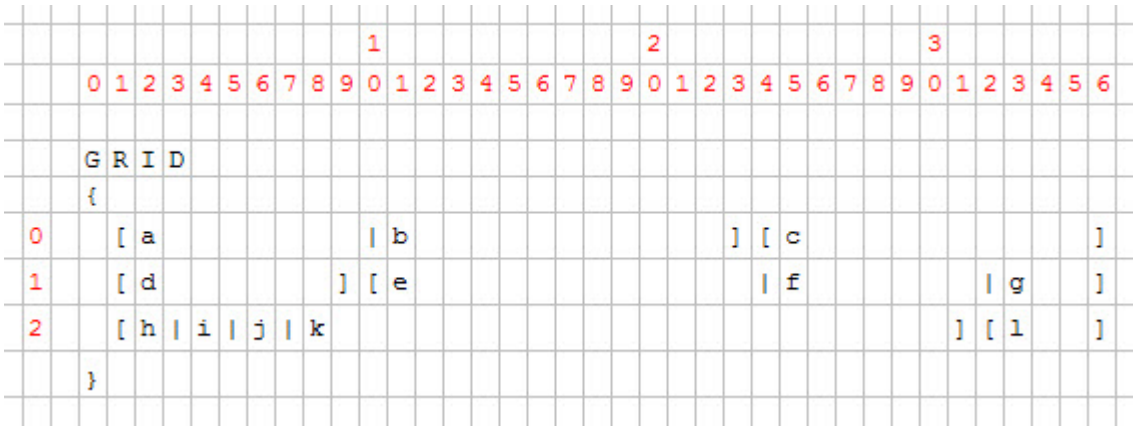

Figure 59: Grid containing several fields

For each form field, the position and the number of cells is computed by the form compiler.

At runtime, the front-end creates the widgets and sets them on the virtual grid.

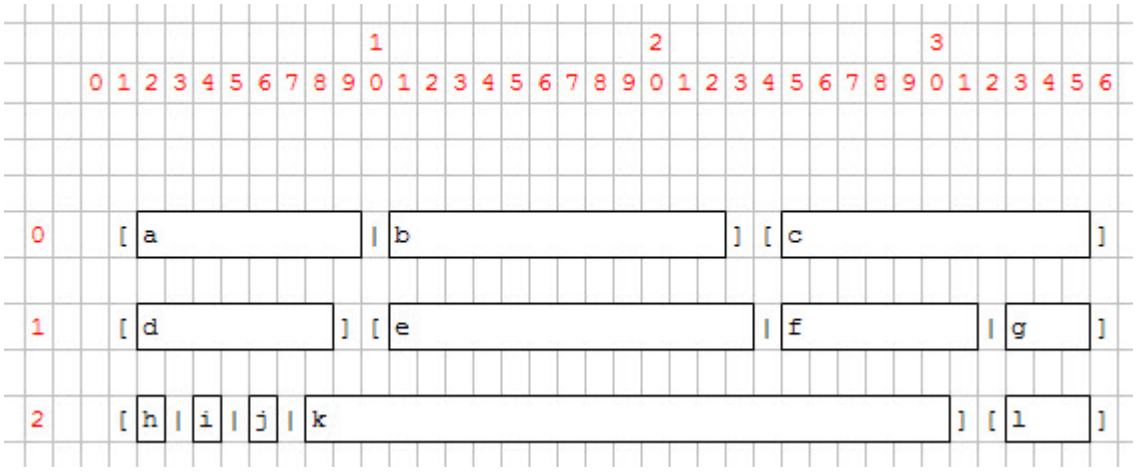

Figure 60: Widgets set on grid

Once widgets are on the grid, their minimum size is computed according to their size, to `SIZEPOLICY` and the `SAMPLE` attributes.

Then the sizes of the grid cells adapt to the size of the widgets.

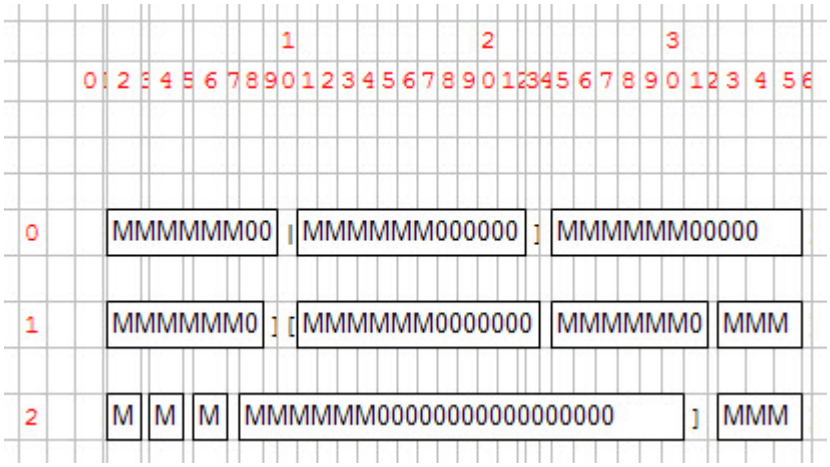

Figure 61: Widget size computations

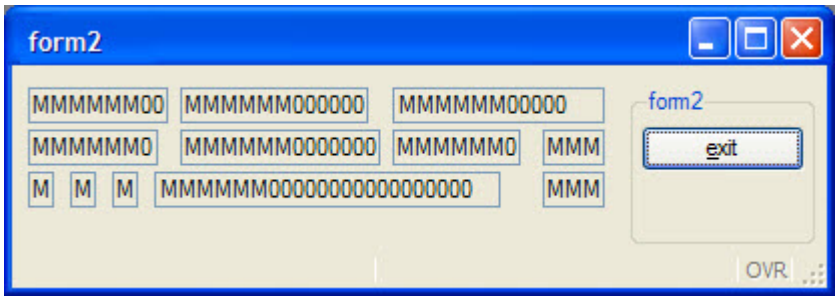

Figure 62: Widgets in rendered form

In this screen shot, the fields k and c are much bigger than expected:

- Field g and l make columns 33, 34 and 35 bigger than the others,
- Field f extends columns 25 to 31.
- As field c has to fill columns 25 to 35, its size grows; the same for field k.

Some fields are proportionally bigger than others because some parameters are variable, while others are fixed.

The width of the widget is the sum of border width, plus the content width (depending on SIZEPOLICY and the SAMPLE attributes).

Since the default SAMPLE is MMMMMM000..., the graphical width of a field is not linearly proportional to the width defined in the form file. For example, a field of 1 will be as wide as 2 borders + 1 'M'. A field of 10 will be as wide as 2 borders + 6 'M' + 4 '0'. This means that a field of 1 is far from being 10 times smaller than a field of 10.

Using hbox tags to align form items

The hbox tag concept has been introduced to bypass the limitations of the character-based grid in forms.

An hbox tag defines a widget container that will gather the child widgets horizontally, like the horizontal box container. All widgets inside this container are no longer dependent on the parent grid.

- Defining hbox tags in grids on page 1013
- Spacer items in hbox tags on page 1015
- Widget size within hbox tags on page 1016

Defining hbox tags in grids

An hbox tag is defined by using a : colon in an item tag delimited by square braces.

This example creates a hbox container containing widgets a, b and c. These widgets won't be aligned in the grid.

```
GRID
{
[a:b:c   ]
[d|e|f   ]
}
END
```

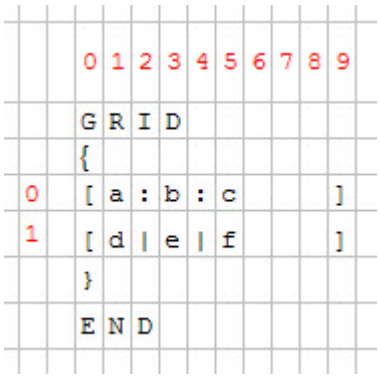

Figure 63: Using an hbox tag

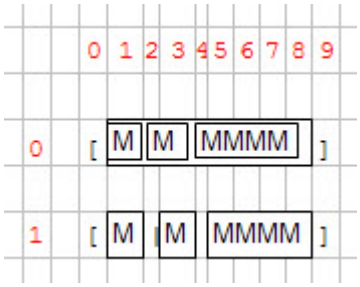

Figure 64: HBox tag rendering

Hbox tags are useful when the form contains large widgets in a small number of cells in one row, and don't want to have dependencies.

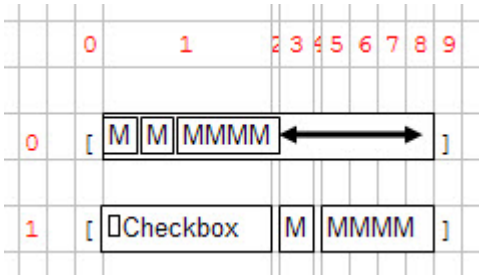

Figure 65: Using an HBox tag

We can modify the Form item dependencies in grids on page 1009 example, using hbox tags:

```
GRID
{
[a:b   ][f     ]
[c:d   ][e     ]
}
END
```

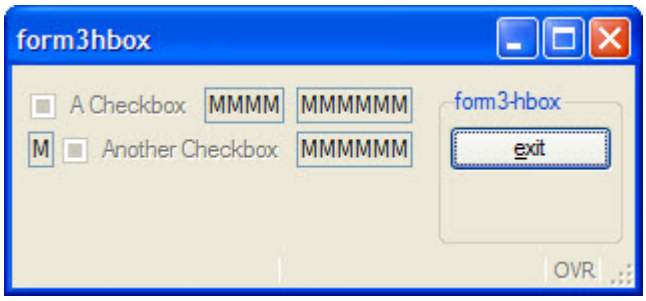

Figure 66: HBox rendering

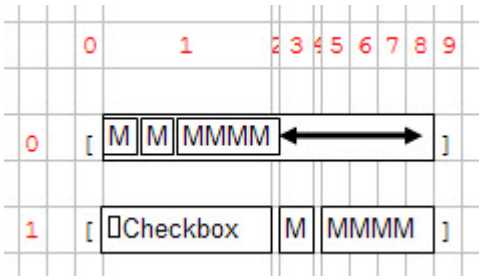
Spacer items in hbox tags

HBox tags also introduces the spacer items concept: when a grid hbox is created, the content may be smaller than the container.

```
GRID
{
[a   :b   :c   ]
[d   :e   :f   ]
}
END

ATTRIBUTES
```

Figure 67: Spacer items



Because of the checkbox, the cell 1 is very large, and then the hbox is larger than the three fields. A spacer item object is automatically created by the form compiler; the role of the spacer item is to take all the free space in the container. Then all the widgets are packed to the left side of the hbox.

By default, a spacer item is created at the right of the container, but the spacer can also be defined in another place:

```
GRID
{
[a      :b      :c       ] <- default: spacer on the right
[ :d    :e      :f       ] <- spacer on the left
[g      :     :h         ] <- spacer between g and h
[i: :j: :k    : :l       ] <- multiple spacers (between i and j, j and k, k
 and l
}
END
```

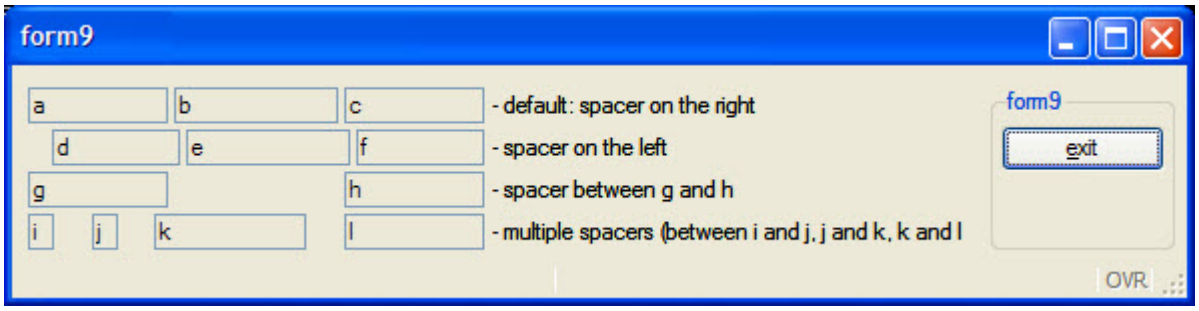


Figure 68: Form using spacers

Widget size within hbox tags

By default, the real width of `BUTTONEDIT`, `DATEEDIT`, `DATETIMEEDIT` and `COMBOBOX` widgets are computed as follows:

```
if item-tag-width > 2
   real-width = item-tag-width - 2
else
   real-width = item-tag-width
```

Where *item-tag-width* represents the number of characters used in the form layout by the item tag, to define the width of the element.

If the default widget size computing does not satisfy the needs, it is possible to specify the exact with of a `BUTTONEDIT`, `DATEDIT` or `COMBOBOX` with an hbox tag, combined to the `SAMPLE` attribute.

The hbox tag can be used with a `:` (colon) and `-` (dash) marker to define the exact number of characters the field can display, while the `SAMPLE` attribute will define the size.

For example:

```
LAYOUT
GRID
{
 ButtonEdit A  [ba     ]
 ButtonEdit B  [bb:    ]
 ButtonEdit C  [bc   : ]
 ButtonEdit D  [bd  -: ]
}
END
END
ATTRIBUTES
BUTTONEDIT ba = FORMONLY.ba, SAMPLE="0",  ACTION=zoom1;
BUTTONEDIT bb = FORMONLY.bb, SAMPLE="M",  ACTION=zoom2;
BUTTONEDIT bc = FORMONLY.bc, SAMPLE="Pi", ACTION=zoom3;
BUTTONEDIT bd = FORMONLY.bd, SAMPLE="0",  ACTION=zoom4;
END
```

Here the `ba` item tag occupies 7 grid columns and gets a real width of 5 (7-2). The `SAMPLE` attribute makes the edit field part as large as 5 characters '0' in the current font, so with this field you can input or display only 5 digits.

The `bb` item tag, which is in an hbox tag that occupies 7 grid columns, gets a width of 2. Since the `SAMPLE` attribute is "M", one can input 2 characters as wide as an "M".

The `bc` item tag, which is in an hbox tag that occupies 7 grid columns, gets a width of 3 (5-2). Since the `SAMPLE` attribute is "Pi", the edit field part will be as large as the word "Pi". (If `SAMPLE` contains more than 1 character it must have the same number of characters as in the field definition).

When using an hbox tag, one can explicitly specify the width of the field with the dash size indicator: The `bd`, which is in an hbox tag that occupies 7 grid columns, gets a width of 4 (because of the dash size indicator). Since the `SAMPLE` attribute is "0", the edit field part will be as large as 4 digits.

Stack-based layout
A form file can define a stack-based layout within a tree of stack items.

In a `.per` form specification file, the `LAYOUT` section defines a tree of layout containers, which hold layout items such as labels and form fields.

Use the `STACK` layout containers, to define a logical grouping of form elements, to be rendered vertically by the front end.

> **Important:** This feature is experimental and specific to mobile programming (STACK layout is not supported by GWC-JS and GDC). The syntax/name and semantics/behavior may change in a future version.

The `STACK` container defines a tree of stack containers, which holds a set of stack items such as form fields:

```
LAYOUT
STACK
   GROUP g1(TEXT="Customer info")
       EDIT customer.cust_num, NOENTRY, TITLE="Id:";
       EDIT customer.cust_name, TITLE="Name:";
       EDIT customer.cust_address, TITLE="Address:";
   END
END
END
```

There is no such thing as x,y coordinates in a stack container: The form element position definition is abstract and relative to other elements. Arranging form elements logically allows more flexibility in the final rendering of the form on the front-end.

Stack-based forms are typically used in mobile application design, to get a similar, but adaptable layout rendering on different mobile device brands.

The visual result of the above form definition would look as follows on an iOS mobile device:

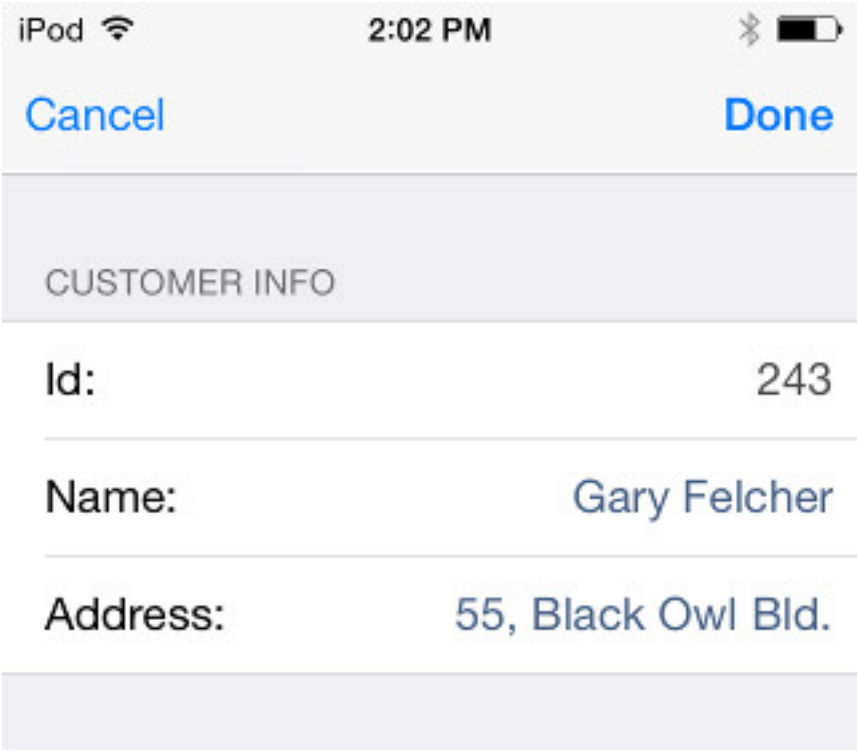

Figure 69: iOS stacked form 2

Label internationalization
Define form files with stacked containers for different languages.

To internationalize your application, define `TITLE` attributes using `%"`*`string-id`*`"` localized strings, in stack containrs and stack item definitions:

```
-- myform.per
LAYOUT
 STACK
   GROUP (TEXT=%"group.custinfo")
       EDIT customer.cust_num, NOENTRY, TITLE=%"cust.label.id";;
       EDIT customer.cust_name, TITLE=%"cust.label.name";
       EDIT customer.cust_address, TIELE=%"cust.label.address";
   END
 END
ED

-- myapp.str
"group.custinfo"     = "Customer information"
"cust.label.id"      = "Id:"
"cust.label.name"    = "Name:"
"cust.label.address" = "Address:"
```

If more space is needed for text fields, remove field labels and add a `COMMENT` attribute to show a grayed text inside empty fields:

```
-- myform.per
LAYOUT
 STACK
   GROUP (TEXT=%"group.custinfo")
       EDIT customer.cust_num, NOENTRY, TITLE=%"cust.label.id";;
       EDIT customer.cust_name, COMMENT=%"cust.comment.name";
       EDIT customer.cust_address, COMMENT=%"cust.comment.address";
```

```
   END
 END
END

-- myapp.str
"group.custinfo"       = "Customer information"
"cust.label.id"        = "Id:"
"cust.comment.name"    = "Customer's name"
"cust.comment.address" = "Customer's address"
```

The visual result for the about stack-based form will look like this on an iOS device:

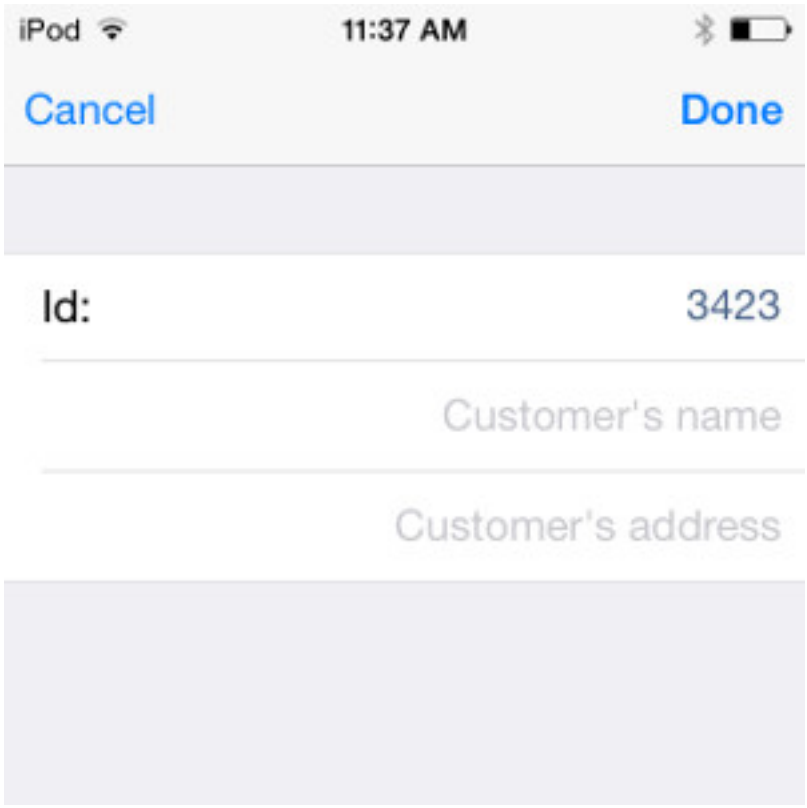

Figure 70: iOS stacked form 3

Stacked group rendering
Groups render in a native way on front-ends supporting the stacked layout.

Use GROUP containers in your form definition, to control the stacked layout: Fields and other form elements such as buttons can be grouped together by domain.

The header of a group box is defined by the TEXT attribute of the GROUP container.

For example, in a form designed for customer data input, customer identification (number, name) should appear in a dedicated group, while address information (street, zip code, state, country fields) should appear under another group:

```
-- myform.per
LAYOUT
 STACK
  GROUP g1 (TEXT=%"cust.group1")
    EDIT FORMONLY.id, TITLE=%"cust.label.id";
    EDIT FORMONLY.name, TITLE=%"cust.label.name";
  END
  GROUP g2  (TEXT=%"cust.group2")
```

```
    LABEL : l_street, TEXT=%"cust.label.street";
    TEXTEDIT FORMONLY.street, HEIGHT=3;
    EDIT FORMONLY.zipcode, TITLE=%"cust.label.zipcode";
    EDIT FORMONLY.state, TITLE=%"cust.label.state";
    EDIT FORMONLY.country, TITLE=%"cust.label.country";
  END
 END
END

-- myapp.str
"cust.group1"        = "Customer id"
"cust.label.id"      = "Id:"
"cust.label.name"    = "Name:"
"cust.group2"        = "Address"
"cust.label.street"  = "Street:"
"cust.label.zipcode" = "Zip Code:"
"cust.label.state"   = "State:"
"cust.label.country" = "Country:"
```

This code example will render as follows on an iOS mobile device:

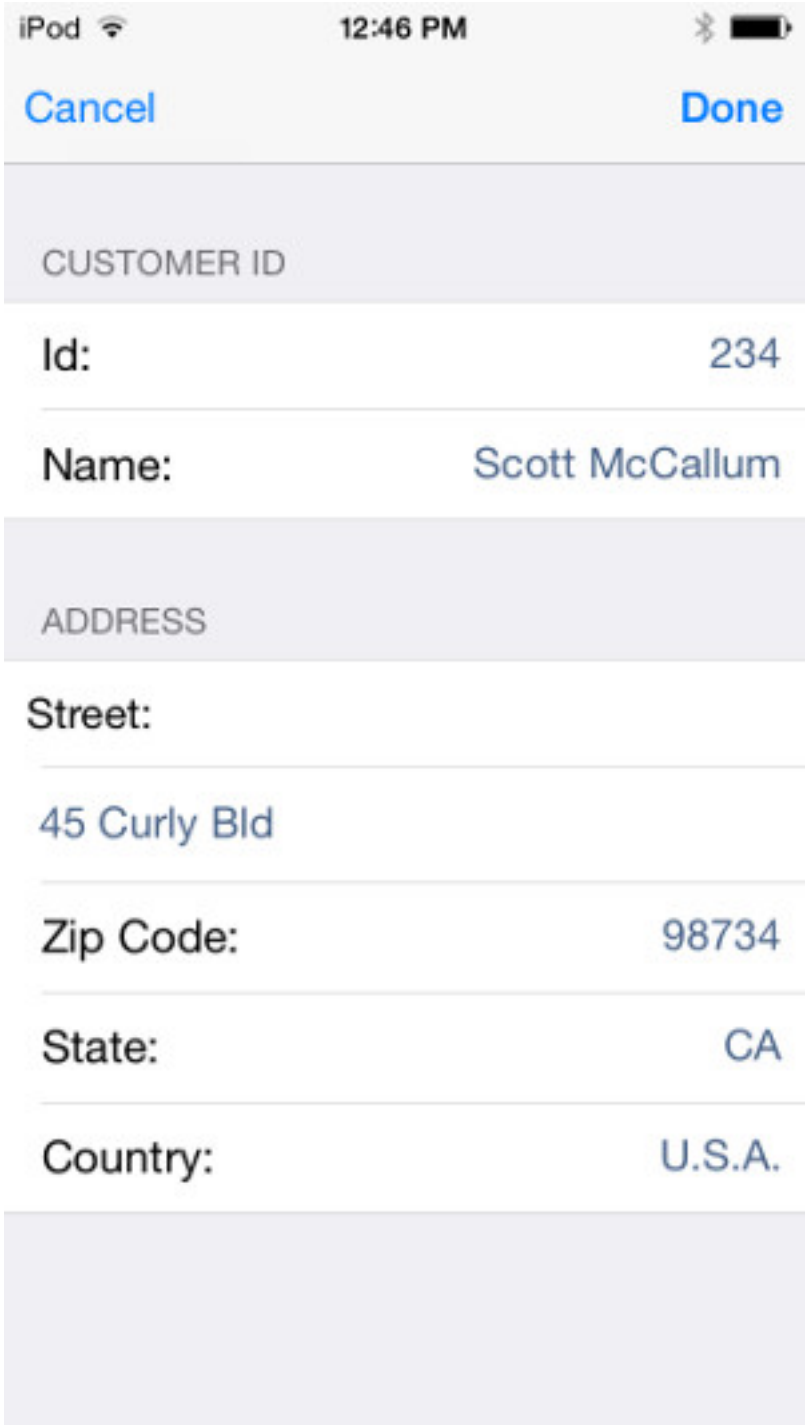

Figure 71: iOS stacked form 4

Toolbars

Toolbars define a bar of buttons that appears at the top of application forms.

- Understanding toolbars on page 1022
- Syntax of a toolbar file (.4tb) on page 1022
- Using toolbars on page 1023
  - Defining toolbars in the form file on page 1024
  - Loading a toolbar from an XML file on page 1024

- Loading a default toolbar from an XML file on page 1024
- Creating the toolbar manually with DOM on page 1024
- Toolbars on mobile devices on page 1025
- Examples on page 1025
  - Example 1: Toolbar in XML format on page 1025
  - Example 2: Toolbar created dynamically on page 1026
  - Example 3: Toolbar section in form file on page 1026

Understanding toolbars

A toolbar defines action views presented as a set of buttons that can trigger events in an interactive instruction.

This section describes how to define toolbars with XML in files or in programs as global/default toolbars; it is also possible to define toolbars in forms with the `TOOLBAR` section, as form-specific toolbars.

Toolbar files can be loaded by a program with the methods `ui.Interface.loadToolBar()` (for default toolbars) or `ui.Form.loadToolBar()` (for form-initializers).

A global toolbar is displayed by default in all windows, or in the global window container when using a window container. The form-specific toolbar is displayed in the form where it is defined. The position and visibility of toolbars can be controlled with a window style attribute. Typical "modal windows" do not display toolbars.

The toolbar items (or buttons) are enabled according to the `ON ACTION` handlers defined by the current interactive instruction. A toolbar item is bound to an action handler by name.. A click on the toolbar button will execute the user code in the action handler.

Toolbar elements can get a `style` attribute in order to use a specific rendering/decoration following presentation style definitions.

The DOM tag names are case sensitive; `Toolbar` is different from `ToolBar`.

When binding to an action, make sure that you are using the right value in the `name` attribute. As `ON ACTION` and `COMMAND` generate lowercase identifiers, it is recommended to use lowercase names.

It is recommended that you define the decoration of toolbar items for common actions with action defaults.

Syntax of a toolbar file (.4tb)

A toolbar file defines a set of buttons in a dedicated area of a window.

Toolbar XML syntax

```
<ToolBar [ toolbar-attribute="value" [...]] >
  { <ToolBarSeparator separator-attribute="value" [...] />
  | <ToolBarItem item-attribute="value" [...] />
  } [...]
</ToolBar>
```

1. *toolbar-attribute* defines a property of the toolbar.
2. *item-attribute* defines a property of the toolbar item.

Toolbar XML attributes

Table 261: ToolBar node attributes

Attribute	Type	Description
`style`	`STRING`	Use to decorate the element with a presentation style.

Attribute	Type	Description
tag	STRING	User-defined attribute to identify the node.
name	STRING	Identifies the toolbar.
buttonTextHidden	INTEGER	Defines if the text of toolbar buttons must appear by default.

Table 262: ToolBarItem node attributes

Attribute	Type	Description
name	STRING	Identifies the action corresponding to the toolbar button. Can be prefixed with the sub-dialog identifier.
style	STRING	Use to decorate the element with a presentation style.
tag	STRING	User-defined attribute to identify the node.
text	STRING	The text to be displayed in the toolbar button.
comment	STRING	The message to be shown as tooltip when the user selects a toolbar button.
hidden	INTEGER	Indicates if the item is hidden.
image	STRING	The icon to be used in the toolbar button.

Table 263: ToolBarSeparator node attributes

Attribute	Type	Description
name	STRING	Identifies the toolbar separator.
style	STRING	Use to decorate the element with a presentation style.
tag	STRING	User-defined attribute to identify the node.
hidden	INTEGER	Indicates if the separator is hidden.

Using toolbars

To use toolbars, you must understand how they work and how to structure the code.

- Understanding toolbars on page 1022
- Defining toolbars in the form file on page 1024
- Loading a toolbar from an XML file on page 1024
- Loading a default toolbar from an XML file on page 1024

- Creating the toolbar manually with DOM on page 1024
- Toolbars on mobile devices on page 1025

Defining toolbars in the form file
Toolbars can be defined in the form specification file within the `TOOLBAR` section.

Form toolbars are only displayed in the window where the form is loaded. Only one toolbar can be defined in a form file. Toolbar button attributes that are common to topmenu options should be centralized in action defaults.

Example

```
TOOLBAR tb
  ITEM accept ( TEXT="Ok", IMAGE="ok" )
  ITEM cancel ( TEXT="Cancel", IMAGE="cancel" )
  SEPARATOR
  ...
END

LAYOUT
GRID
{
  ...
```

Loading a toolbar from an XML file

To load a toolbar definition file (`4tb`) for a form, use the utility method provided by the `ui.Form` built-in class.

```
CALL myform.loadToolbar("standard")
```

Loading a default toolbar from an XML file
To load a default toolbar from an XML definition file, use the utility method provided by the `ui.Interface` built-in class.

```
CALL ui.Interface.loadToolbar("standard")
```

The default toolbar will be displayed in all forms.

Creating the toolbar manually with DOM

This example shows how to create a toolbar in all forms by using the default initialization function and the `om.DomNode` class:

```
CALL ui.Form.setDefaultInitializer("myinit")
OPEN FORM f1 FROM "form1"
DISPLAY FORM f1
...
FUNCTION myinit(form)
  DEFINE form ui.Form
  DEFINE f om.DomNode
  LET f = form.getNode()
  ...
END FUNCTION
```

After getting the DOM node of the form, create a node with the "`ToolBar`" tag name:

```
DEFINE tb om.DomNode
LET tb = f.createChild("ToolBar")
```

For each toolbar button, create a sub-node with the "`ToolBarItem`" tag name and set the attributes to define the button:

```
DEFINE tbi om.DomNode
LET tbi = tb.createChild("ToolBarItem")
CALL tbi.setAttribute("name","update")
CALL tbi.setAttribute("text","Modify")
CALL tbi.setAttribute("comment","Modify the current record")
CALL tbi.setAttribute("image","change")
```

If needed, you can create a "`ToolBarSeparator`" node to separate toolbar buttons:

```
DEFINE tbs om.DomNode
LET tbs = tb.createChild("ToolBarSeparator")
```

Toolbars on mobile devices
Toolbars can be used to control action view rendering on mobile devices.

On mobile devices, actions render usually as default action views, that display implicitly in dedicated panes on the screen. When displaying forms on a mobile front-end, you can use a toolbar to control the rendering of the actions.

Using toolbars for Android™ devices (GMA)

On Android devices, a `TOOLBAR` can be used to define the action views that appear in the Android action bar. Toolbar action views are listed first and ordered as they are defined in the `TOOLBAR` section, followed by the default action views for remaining actions that are not part of the `TOOLBAR` definition.

Using toolbars for iOS devices (GMI)

On iOS devices, a `TOOLBAR` renders as the iOS toolbar panel. This toolbar appears at the bottom of the screen, displaying a icon or text for each toolbar item. If there is not enough space to render all toobar items, a three-dot overflow icon appears on the right, to show up the remaining toolbar items.

The `iosSeparatorStretch` toolbar style attribute can be used to stretch the separators to give more space between action buttons.

Examples
Examples showing the various ways to define a toolbar.

- Example 1: Toolbar in XML format on page 1025
- Example 2: Toolbar created dynamically on page 1026
- Example 3: Toolbar section in form file on page 1026

Example 1: Toolbar in XML format

```
<ToolBar style="mystyle">
   <ToolBarItem name="f5" text="List" image="list" />
   <ToolBarSeparator/>
   <ToolBarItem name="query" text="Query" image="search" />
   <ToolBarItem name="add" text="Append" image="add" />
   <ToolBarItem name="delete" text="Delete" image="delete" />
   <ToolBarItem name="modify" text="Modify" image="change" />
   <ToolBarSeparator/>
   <ToolBarItem name="f1" text="Help" image="list" />
   <ToolBarSeparator/>
   <ToolBarItem name="quit" text="Quit" image="quit" />
</ToolBar>
```

Example 2: Toolbar created dynamically

```
MAIN
  DEFINE aui om.DomNode
  DEFINE tb  om.DomNode
  DEFINE tbi om.DomNode
  DEFINE tbs om.DomNode

  LET aui = ui.Interface.getRootNode()

  LET tb = aui.createChild("ToolBar")

  LET tbi = createToolBarItem(tb,"f1","Help","Show help","help")
  LET tbs = createToolBarSeparator(tb)
  LET tbi = createToolBarItem(tb,"upd","Modify","Modify current
 record","change")
  LET tbi = createToolBarItem(tb,"del","Remove","Remove current
 record","delete")
  LET tbi = createToolBarItem(tb,"add","Append","Add a new record","add")
  LET tbs = createToolBarSeparator(tb)
  LET tbi = createToolBarItem(tb,"xxx","Exit","Quit application","quit")

  MENU "Example"
    COMMAND KEY(F1)
      DISPLAY "F1 action received"
    COMMAND "upd"
      DISPLAY "Update action received"
    COMMAND "Del"
      DISPLAY "Delete action received"
    COMMAND "Add"
      DISPLAY "Append action received"
    COMMAND "xxx"
      EXIT PROGRAM
  END MENU

END MAIN

FUNCTION createToolBarSeparator(tb)
  DEFINE tb om.DomNode
  DEFINE tbs om.DomNode
  LET tbs = tb.createChild("ToolBarSeparator")
  RETURN tbs
END FUNCTION

FUNCTION createToolBarItem(tb,n,t,c,i)
  DEFINE tb om.DomNode
  DEFINE n,t,c,i VARCHAR(100)
  DEFINE tbi om.DomNode
  LET tbi = tb.createChild("ToolBarItem")
  CALL tbi.setAttribute("name",n)
  CALL tbi.setAttribute("text",t)
  CALL tbi.setAttribute("comment",c)
  CALL tbi.setAttribute("image",i)
  RETURN tbi
END FUNCTION
```

Example 3: Toolbar section in form file

```
TOOLBAR ( STYLE="mystyle" )
  ITEM accept ( TEXT="Ok", IMAGE="ok" )
  ITEM cancel ( TEXT="cancel", IMAGE="cancel" )
  SEPARATOR
  ITEM editcut   -- Gets decoration from action defaults
```

```
  ITEM editcopy  -- Gets decoration from action defaults
  ITEM editpaste -- Gets decoration from action defaults
  SEPARATOR
  ITEM append ( TEXT="Append", IMAGE="add" )
  ITEM update ( TEXT="Update", IMAGE="modify" )
  ITEM delete ( TEXT="Delete", IMAGE="del" )
  ITEM search ( TEXT="Search", IMAGE="find" )
END
```

Topmenus

Topmenus define typical pull-down menus that appear at the top of application forms.

- Understanding topmenus on page 1027
- Syntax of a topmenu file (.4tm) on page 1028
- Using topmenus on page 1030
  - Defining the topmenu in a form file on page 1030
  - Loading a topmenu from an XML file on page 1030
  - Loading a default topmenu from an XML file on page 1030
  - Creating the topmenu dynamically on page 1030
  - Topmenus on mobile devices on page 1031
- Examples on page 1033
  - Example 1: Topmenu in XML format on page 1033
  - Example 2: Topmenu section in form file on page 1033

Understanding topmenus

A topmenu defines a graphical menu that holds views for actions controlled in programs with `ON ACTION` handlers. A topmenu renders to the user according to the front-end platform standards. On a desktop / web front-end, the topmenu appears as a typical pull-down menu. On mobile devices, a topmenu displays as a flat list of options (Android™), and as a set of option screens the user can drill down (iOS).

This section describes how to define topmenus with XML in files or in programs as global/default topmenus; it is also possible to define topmenus in forms with the `TOPMENU` section, as form-specific topmenus.

Topmenu files can be loaded by program with the methods `ui.Interface.loadTopMenu()` (for default topmenus) or `ui.Form.loadTopMenu()` (for form-initializers).

In the abstract user interface tree, the `TopMenu` node must be created under the `Form` node, and must contain `TopMenuGroup` nodes. The `TopMenuGroup` nodes group topmenu commands and other topmenu groups. A `TopMenuCommand` is a leaf node in the topmenu tree that will trigger an action:

```
TopMenu
 +- TopMenuGroup
  +- TopMenuCommand
  +- TopMenuCommand
  +- TopMenuCommand
 +- TopMenuGroup
  +- TopMenuGroup
   +- TopMenuCommand
   +- TopMenuCommand
  +- TopMenuGroup
   +- TopMenuCommand
   +- TopMenuCommand
   +- TopMenuCommand
```

The topmenu options are enabled according to the `ON ACTION` handlers defined by the current interactive instruction. A topmenu option is bound to an action handler by name. Selecting the topmenu option will execute the user code in the action handler.

Topmenu elements can get a `style` attribute in order to use a specific rendering/decoration following presentation style definitions.

The DOM tag names are case sensitive; `Topmenu` is different from `TopMenu`.

When binding to an action, make sure that you are using the right value in the `name` attribute. As `ON ACTION` and `COMMAND` generate lowercase identifiers, it is recommended to use lowercase names.

It is recommended that you define the decoration of topmenu options for common actions with action defaults.

Images cannot be displayed for the first level of `TopMenuGroup` elements.

Syntax of a topmenu file (.4tm)
A topmenu file defines a tree of menu options to be displayed in the header of a window.

Topmenu XML syntax

```
<TopMenu [ topmenu-attribute="value" [...] ] >
    group
    [...]
  </TopMenu>
```

where *group* is:

```
<TopMenuGroup group-attribute="value" [...]>
    { <TopMenuSeparator separator-attribute="value" [...] />
    | <TopMenuCommand command-attribute="value" [...] />
    | group
    } [...]
  </TopMenuGroup>
```

1. *topmenu-attribute* defines a property of the `TopMenu`.
2. *group-attribute* defines a property of a `TopMenuGroup`.
3. *command-attribute* defines a property of a `TopMenuCommand`.
4. *separator-attribute* defines a property of a `TopMenuSeparator`.

Topmenu XML attributes

Table 264: TopMenu node attributes

Attribute	Type	Description
`name`	`STRING`	Identifies the topmenu.
`style`	`STRING`	Can be used to decorate the element with a presentation style.
`tag`	`STRING`	User-defined attribute to identify the node.

Table 265: TopMenuCommand node attributes

Attribute	Type	Description
name	STRING	Identifies the action corresponding to the topmenu command. Can be prefixed with the sub-dialog identifier.
style	STRING	Can be used to decorate the element with a presentation style.
tag	STRING	User-defined attribute to identify the node.
text	STRING	The text to be displayed in the pull-down menu option.
comment	STRING	The message to be shown for this element.
hidden	INTEGER	Indicates if the command is hidden.
image	STRING	The icon to be used in the pull-down menu option.
acceleratorName	STRING	Defines the accelerator name to be display on the left of the menu option text. Note this attribute is only used for decoration (you must also define an action default accelerator).

Table 266: TopMenuGroup node attributes

Attribute	Type	Description
name	STRING	Identifies the topmenu group.
style	STRING	Can be used to decorate the element with a presentation style.
tag	STRING	User-defined attribute to identify the node.
text	STRING	The text to be displayed in the pull-down menu group.
comment	STRING	The message to be shown for this element.
hidden	INTEGER	Indicates if the group is hidden.
image	STRING	The icon to be used in the pull-down menu group.

Table 267: Separator-attributes for the TopMenuSeparator node

Attribute	Type	Description
name	STRING	Identifies the topmenu separator.
style	STRING	Can be used to decorate the element with a presentation style.
tag	STRING	User-defined attribute to identify the node
hidden	INTEGER	Indicates if the separator is hidden.

Using topmenus

To use topmenus, you must understand how they work and how to structure the code.

Defining the topmenu in a form file

Topmenus can be defined in the form specification file within the TOPMENU section.

Form topmenus will only be displayed in the window where the form is loaded. Only one topmenu can be defined in a form file. Topmenu item attributes that are common to toolbar buttons should be centralized in action defaults.

Example

```
TOPMENU tm
  GROUP form (TEXT="Form")
    COMMAND help (TEXT="Help", IMAGE="quest")
    COMMAND quit (TEXT="Quit")
  END
  ...
END

LAYOUT
GRID
{
  ...
```

Loading a topmenu from an XML file

To load a .4tm topmenu definition file for a form, use the utility method provided by the ui.Form built-in class:

```
CALL myform.loadTopMenu("standard")
```

Loading a default topmenu from an XML file

To load a default topmenu from an XML definition file, use the utility method provided by the ui.Interface built-in class.

```
CALL ui.Interface.loadTopMenu("standard")
```

The default topmenu will be displayed in all forms.

Creating the topmenu dynamically

This example shows how to create a topmenu in all forms by using the default initialization function and the om.DomNode class:

```
CALL ui.Form.setDefaultInitializer("myinit")
OPEN FORM f1 FROM "form1"
```

```
DISPLAY FORM f1
...
FUNCTION myinit(form)
  DEFINE form ui.Form
  DEFINE f om.DomNode
  LET f = form.getNode()
  ...
END FUNCTION
```

After getting the DOM node of the form, create a node with the "`TopMenu`" tag name:

```
DEFINE tm om.DomNode
LET tm = f.createChild("TopMenu")
```

For each Topmenu group, create a subnode with the "`TopMenuGroup`" tag name and set the attributes to define the group:

```
DEFINE tmg om.DomNode
LET tmg = tm.createChild("TopMenuGroup")
CALL tmg.setAttribute("text","Reports")
```

For each Topmenu option, create a sub-node in a group node with the "`TopMenuCommand`" tag name and set the attributes to define the option:

```
DEFINE tmi om.DomNode
LET tmi = tmg.createChild("TopMenuCommand")
CALL tmi.setAttribute("name","report")
CALL tmi.setAttribute("text","Order report")
CALL tmi.setAttribute("comment","Orders entered today")
CALL tmi.setAttribute("image","smiley")
```

If needed, you can create a "`TopMenuSeparator`" node inside a group, to separate menu options:

```
DEFINE tms om.DomNode
LET tms = tmg.createChild("TopMenuSeparator")
```

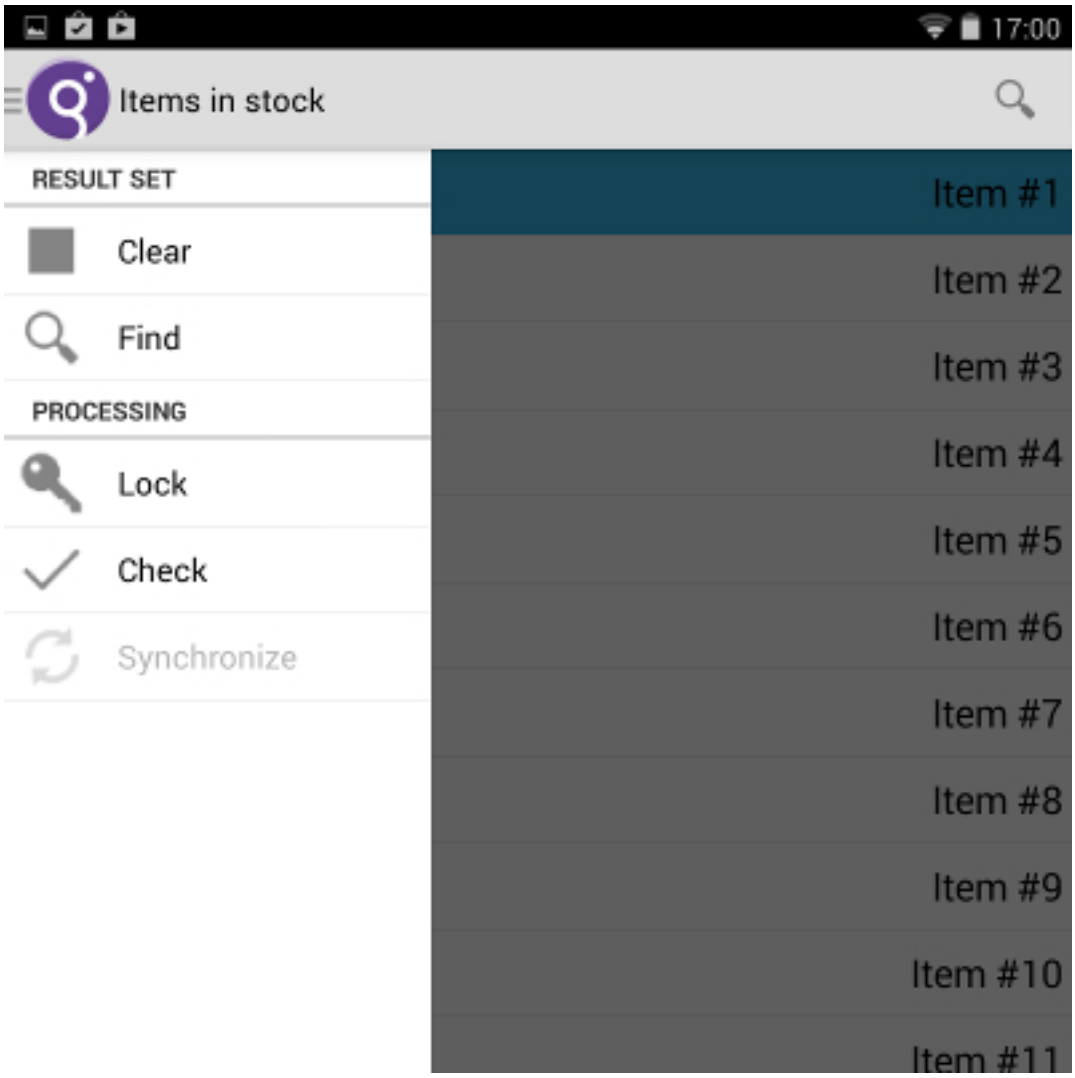
Topmenus on mobile devices
Topmenus can be used to implement a general options menu in mobile apps.

On mobile devices, actions render usually as default action views, that display implicitly in dedicated panes on the screen. When displaying forms on a mobile front-end, you can use a topmenu to get a list of options the end user can choose from.

Using topmenus for Android™ devices (GMA)

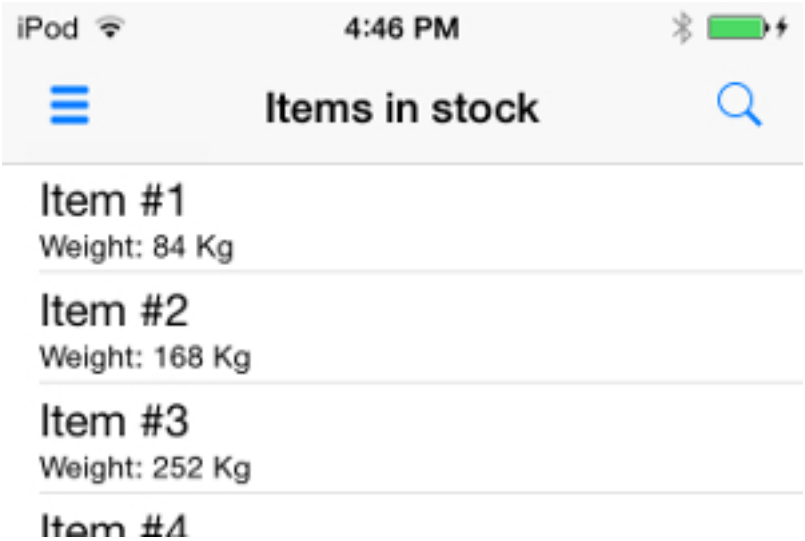
On Android devices, a `TOPMENU` renders as a menu icon on the top left of the screen, in the Android action bar. When the user taps on this icon, a list with topmenu items shows up. Selecting an option fires the corresponding action handler is fired.

> **Note:** On Android, the topmenu can only display one level of options (no tree of options is possible).



Using topmenus for iOS devices (GMI)

On iOS devices, a `TOPMENU` renders as a menu icon on the top left corner of the device screen, in the iOS navigation controller. When the user taps on this icon, a new view appears with the first level of topmenu items. The user can the drill down to a next level, select an option if it's a leaf item, or tap on the back button to move one level up in the topmenu tree. Selecting a leaf item will fire the corresponding action handler and close the menu.



Examples

Example 1: Topmenu in XML format

```
<TopMenu>
   <TopMenuGroup text="Form" style="mystyle">
      <TopMenuCommand name="help" text="Help" image="quest" />
      <TopMenuCommand name="quit" text="Quit" acceleratorName="alt-F4"/>
   </TopMenuGroup>
   <TopMenuGroup text="Edit">
      <TopMenuCommand name="accept" text="Validate" image="ok" />
      <TopMenuCommand name="cancel" text="Cancel" image="cancel" />
      <TopMenuSeparator/>
      <TopMenuCommand name="editcut" text="Cut" />
      <TopMenuCommand name="editcopy" text="Copy" />
      <TopMenuCommand name="editpaste" text="Paste" />
   </TopMenuGroup>
   <TopMenuGroup text="Records">
      <TopMenuCommand name="append" text="Add" image="add" />
      <TopMenuCommand name="delete" text="Remove" image="delete" />
      <TopMenuCommand name="update" text="Modify" image="change" />
      <TopMenuSeparator/>
      <TopMenuCommand name="search" text="Query" image="find" />
   </TopMenuGroup>
</TopMenu>
```

Example 2: Topmenu section in form file

```
TOPMENU
  GROUP form (TEXT="Form", STYLE="mystyle" )
     COMMAND help (TEXT="Help", IMAGE="quest")
     COMMAND quit (TEXT="Quit", ACCELERATOR=ALT-F4)
  END
  GROUP edit (TEXT="Edit")
     COMMAND accept (TEXT="Validate", IMAGE="ok")
     COMMAND cancel (TEXT="Cancel", IMAGE="cancel")
     SEPARATOR
     COMMAND editcut   -- Gets decoration from action defaults
     COMMAND editcopy  -- Gets decoration from action defaults
     COMMAND editpaste -- Gets decoration from action defaults
  END
  GROUP records (TEXT="Records")
     COMMAND append (TEXT="Add", IMAGE="add")
```

```
      COMMAND delete (TEXT="Remove", IMAGE="del")
      COMMAND update (TEXT="Modify", IMAGE="change")
      SEPARATOR
      COMMAND search (TEXT="Search", IMAGE="find")
  END
END
```

Dialog instructions

This section describes the dialog instructions to control application forms and the concepts related to dialog implementation.

- Static display (DISPLAY/ERROR/MESSAGE/CLEAR) on page 1034
- Prompt for values (PROMPT) on page 1042
- Ring menus (MENU) on page 1048
- Record input (INPUT) on page 1060
- Read-only record list (DISPLAY ARRAY) on page 1075
- Editable record list (INPUT ARRAY) on page 1098
- Query by example (CONSTRUCT) on page 1128
- Multiple dialogs (DIALOG) on page 1144
- Parallel dialogs (START DIALOG) on page 1199

Static display (DISPLAY/ERROR/MESSAGE/CLEAR)

This section explains the instructions displaying static information to application forms, such as DISPLAY, ERROR, MESSAGE, CLEAR.

- Display of data and messages on page 1034
- DISPLAY (to stdout) on page 1035
- MESSAGE on page 1035
- ERROR on page 1036
- DISPLAY TO on page 1037
- DISPLAY BY NAME on page 1038
- CLEAR FORM on page 1040
- CLEAR SCREEN ARRAY on page 1040
- CLEAR field-list on page 1041
- SCROLL on page 1042

Display of data and messages

The values contained in program variables can be displayed to the current form with the `DISPLAY BY NAME` or `DISPLAY TO` instruction. Forms can be cleared with the `CLEAR FORM` or `CLEAR` *`field-list`* instructions. Complete record lists (in `SCROLLGRID`, `TABLE` or `TREE` containers) can be cleared with the `CLEAR SCREEN ARRAY` instruction. Application messages and warnings can be displayed to the user with the `MESSAGE` and `ERROR` instructions.

The `DISPLAY BY NAME/TO` instructions are not interactive, and are usually not needed if the program is always in the context of a dialog controlling the form fields: The data of the program variables will be displayed in form fields when the dialog starts, if the `WITHOUT DEFAULTS` option is specified, and during the dialog execution, form fields will be automatically synchronized with the program variables when using the `UNBUFFERED` option.

DISPLAY (to stdout)

The DISPLAY instruction displays text in line mode to the standard output channel.

Syntax

```
DISPLAY expression
```

1. *expression* is any expression supported by the language.

Usage

The DISPLAY instruction can be used to print information to the standard output channel (stdout) of the terminal the program is attached to.

The *expression* is typically a list of string constants and program variables separated by the comma concatenation operator.

Before displaying to the standard output channel, the expression is converted to a character string. The values contained in variables are formatted according to the data types and environment settings such as DBDATE and DBMONEY.

Example

```
MAIN
  DISPLAY "Today's date is: ", TODAY
END MAIN
```

MESSAGE

The MESSAGE instruction displays a message to the user.

Syntax

```
MESSAGE message [,...]
  [ ATTRIBUTES ( display-attribute [,...] ) ]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
| STYLE = "style-name"
}
```

1. *expression* is any expression supported by the language.
2. *style-name* is a presentation style name.

Usage

The MESSAGE instruction displays a message to the user in an interactive program.

In TUI mode, the text is displayed in the comment line of the current window.

In GUI mode, the text is displayed in a specific area, depending on the STYLE attribute.

When you specify the STYLE attribute, you can reference a style defined in the presentation styles file. This allows you to display errors or messages in GUI mode with more sophisticated visual effects as the regular TTY attributes. Advanced automatic rendering can be obtained with message specific style attributes. If

you want to apply automatically a style to all program messages displayed with the MESSAGE instruction, you can use the `:message` pseudo selector in the style definition.

Example

```
INPUT BY NAME custrec.* ...
  BEFORE INPUT
    MESSAGE "Enter customer data."
  ...
```

ERROR
The ERROR instruction displays an error message to the user.

Syntax

```
ERROR expression
  [ ATTRIBUTES ( display-attribute [,...] ) ]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
| STYLE = "style-name"
}
```

1. *expression* is any expression supported by the language.
2. *style-name* is a presentation style name.

Usage

The ERROR instruction displays an error message to the user in an interactive program.

In TUI mode, the error text is displayed in the error line of the current window.

In GUI mode, the text is displayed in a specific area, depending on the STYLE attribute.

When you specify the STYLE attribute, you can reference a style defined in the presentation styles file. This allows you to display errors or messages in GUI mode with more sophisticated visual effects as the regular TTY attributes. Advanced automatic rendering can be obtained with message specific style attributes. If you want to apply automatically a style to all program warnings displayed with the ERROR instruction, you can use the `:error` pseudo selector in the style definition.

Example

```
...
IF sqlca.sqlcode THEN
  ERROR "Database update failed (" || sqlca.sqlcode || ")"
    ATTRIBUTES(STYLE="important")
    ...
END IF
...
```

DISPLAY TO

The DISPLAY TO instruction displays data to form fields explicitly.

Syntax

```
DISPLAY expression [,...] TO field-spec [,...]
  [ ATTRIBUTES ( display-attribute [,...] ) ]
```

where *field-spec* is:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

1. *expression* is any expression supported by the language.
2. *field-name* is the identifier of a field of the current form.
3. *table-name* is the identifier of a database table of the current form.
4. *screen-record* is the identifier of a screen record of the current form.
5. *screen-array* is the screen array that will be used in the form.

Usage

A DISPLAY TO statement copies the data from program variables to the form fields specified after the TO keyword.

When the program variables do not have the same names as the form fields, you must use the TO clause to explicitly map the variables to fields. You can list the fields individually, or you can use the *screen-record*.* or *screen-record*[n].* notation, where *screen-record*[n].* specifies all the fields in line n of a screen array.

In the next example, the values in the p_items program record are displayed in the first row of the s_items screen array:

```
DISPLAY p_items.* TO s_items[1].*
```

The expanded list of screen fields must correspond in order and in number to the expanded list of identifiers after the DISPLAY keyword. Identifiers and their corresponding fields must have the same or compatible data types. For example, the next DISPLAY statement displays the values in the p_customer program record in fields of the s_customer screen record:

```
DISPLAY p_customer.* TO s_customer.*
```

For this example, the p_customer program record and the s_customer screen record require compatible declarations. The following DEFINE statement declares the p_customer program record:

```
DEFINE p_customer RECORD
```

```
  customer_num LIKE customer.customer_num,
  fname LIKE customer.fname,
  lname LIKE customer.lname,
  phone LIKE customer.phone
END RECORD
```

This fragment of a form specification declares the s_customer screen record:

```
ATTRIBUTES
 f000 = customer.customer_num;
 f001 = customer.fname;
 f002 = customer.lname;
 f003 = customer.phone;
END
```

The DISPLAY TO instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

DISPLAY TO changes the touched flag

The DISPLAY TO statement changes the 'touched' status of the target fields. When you modify a field value with this instruction, the FIELD_TOUCHED( ) operator returns true and the ON CHANGE and ON ROW CHANGE triggers may be invoked if the current field value was changed with a DISPLAY BY NAME.

In dialogs controlling field input such as INPUT or INPUT ARRAY, use the UNBUFFERED attribute to display data to fields automatically without changing the 'touched' status of fields. The UNBUFFERED clause will make automatic form field and program variable synchronization. When using the UNBUFFERED mode, the touched flag can be set with DIALOG.setFieldTouched( ) if you want to get the same effect as a DISPLAY BY NAME

Specifying TTY attributes in the DISPLAY BY NAME statement

The ATTRIBUTES clause temporarily overrides any default display attributes or any attributes specified in the OPTIONS or OPEN WINDOW statements for the fields. When the DISPLAY TO statement completes execution, the default display attributes are restored.In a DISPLAY TO statement, any screen attributes specified in the ATTRIBUTES clause apply to all the fields that you specify after the TO keyword.

The REVERSE, BLINK, INVISIBLE, and UNDERLINE attributes are not sensitive to the color or monochrome status of the terminal, if the terminal is capable of displaying these intensity modes. The ATTRIBUTES clause can include zero or more of the BLINK, REVERSE, and UNDERLINE attributes, and zero or one of the other attributes. That is, all of the attributes except BLINK, REVERSE, and UNDERLINE are mutually exclusive.

The DISPLAY TO statement ignores the INVISIBLE attribute, regardless of whether you specify it in the ATTRIBUTES clause.

DISPLAY BY NAME

The DISPLAY BY NAME instruction displays data to form fields explicitly *by name*.

Syntax

```
DISPLAY BY NAME { variable | record.* } [,...]
  [ ATTRIBUTES ( display-attribute [,...] ) ]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | NORMAL
| REVERSE | BLINK | UNDERLINE
```

```
}
```

1. *variable* is a program variable that has the same name as a form field.
2. *record.** is a record variable that has members with the same names as form fields.

Usage

A `DISPLAY BY NAME` statement copies the data from program variables to the form fields associated to the variables by name. The program variables used in `DISPLAY BY NAME` must have the same name as the form fields where they have to be displayed. The language ignores any record structure name prefix when matching the names. The names must be unique and unambiguous; if not, the instruction raises an error.

For example, the following statement displays the values for the specified variables in the form fields with corresponding names (`company` and `address1`):

```
DISPLAY BY NAME p_customer.cust_company,
                p_customer.cust_address1
```

The `DISPLAY BY NAME` instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

DISPLAY BY NAME uses the default screen record

Unlike the `DISPLAY TO` instruction where you can explicitly specify a screen record or screen array, `DISPLAY BY NAME` displays data to the screen fields of the default screen records. The default screen records are those having the names of the tables defined in the `TABLES` section of the form specification file. When the form fields define a record list in the layout, only the first row can be referenced with the default screen record. In the next example, the form contains a static record list definition in the layout.

```
SCHEMA mystock
SCREEN
{
[f01  |f02    |f03          ]
[f01  |f02    |f03          ]
[f01  |f02    |f03          ]
[f01  |f02    |f03          ]
}
END
TABLES
customer
END
ATTRIBUTES
f01 = customer.cust_key;
f02 = customer.cust_name;
f03 = customer.cust_address;
END
```

In the program, a `DISPLAY BY NAME` statement will display the data in the first line of the record list in the form:

```
DISPLAY BY NAME record_cust.*
```

DISPLAY BY NAME changes the touched flag

The `DISPLAY BY NAME` statement changes the 'touched' status of the target fields. When you modify a field value with this instruction, the `FIELD_TOUCHED()` operator returns true and the `ON CHANGE` and `ON ROW CHANGE` triggers may be invoked if the current field value was changed with a `DISPLAY BY NAME`.

In dialogs controlling field input such as `INPUT` or `INPUT ARRAY`, use the `UNBUFFERED` attribute to display data to fields automatically without changing the 'touched' status of fields. The `UNBUFFERED` clause will make automatic form field and program variable synchronization. When using the `UNBUFFERED` mode, the touched flag can be set with `DIALOG.setFieldTouched()` if you want to get the same effect as a `DISPLAY BY NAME` statement.

Specifying TTY attributes in the DISPLAY BY NAME statement

The `ATTRIBUTES` clause temporarily overrides any default display attributes or any attributes specified in the `OPTIONS` or `OPEN WINDOW` statements for the fields. When the `DISPLAY BY NAME` statement completes execution, the default display attributes are restored.

The `REVERSE`, `BLINK`, `INVISIBLE`, and `UNDERLINE` attributes are not sensitive to the color or monochrome status of the terminal, if the terminal is capable of displaying these intensity modes. The `ATTRIBUTES` clause can include zero or more of the `BLINK`, `REVERSE`, and `UNDERLINE` attributes, and zero or one of the other attributes. That is, all of the attributes except `BLINK`, `REVERSE`, and `UNDERLINE` are mutually exclusive.

The `DISPLAY BY NAME` statement ignores the `INVISIBLE` attribute, regardless of whether you specify it in the `ATTRIBUTES` clause.

CLEAR FORM

The `CLEAR FORM` instruction clears all fields in the current form.

Syntax

```
CLEAR FORM
```

Usage

The `CLEAR FORM` instruction clears all form fields of the current form. It has no effect on any part of the screen display except the form fields.

Similarly to `CLEAR field-list`, the `CLEAR FORM` instruction is typically used when the program is not inside a dialog block execution controlling the form fields. For example, after a database query with a `CONSTRUCT` instruction, you might want to clear all search criteria entered by the user with this instruction, to cleanup the form.

The `CLEAR FORM` instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

Example

```
CONSTRUCT BY NAME sql
   ON cust_name, cust_address, ...
   ...
END CONSTRUCT
CLEAR FORM
...
```

CLEAR SCREEN ARRAY

The `CLEAR SCREEN ARRAY` instruction clears the values of all rows of the form list identified by the specified screen array.

Syntax

```
CLEAR SCREEN ARRAY screen-array.*
```

1. *screen-array* is a screen array specified in the form.

Usage

After executing a `DISPLAY ARRAY` or `INPUT ARRAY` instruction, values remain in the form list identified by the screen array.

The `CLEAR SCREEN ARRAY` instruction automatically clears all rows of the list, regardless of the view: a `TABLE`, `TREE`, `SCROLLGRID`, or in a matrix of fields (an old-style/text-mode static screen array).

The `CLEAR SCREEN ARRAY` instruction replaces code which clears each individual row through the use of a loop:

```
-- Clearing each row individually
FOR i=1 TO <screen-array-length>
  CLEAR screen-array[i].*
END FOR
-- Unique instruction to clear a list
CLEAR SCREEN ARRAY screen-array.*
```

Using the `CLEAR SCREEN ARRAY` instruction eliminates the need for calculating the screen array length, a value which can change when using a `TABLE` container, that can be resized.

The `CLEAR SCREEN ARRAY` instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

Example

```
...
   DISPLAY ARRAY cust_arr TO sa.*
   ...
   CLEAR SCREEN ARRAY sa.*
   ...
```

CLEAR *field-list*

The `CLEAR` *`field-list`* instruction clears specific fields in the current form.

Syntax

```
CLEAR field-list
```

where *field-list* is:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
}
[,...]
```

1. *field-name* is the identifier of a field of the current form.
2. *table-name* is the identifier of a database table of the current form.
3. *screen-record* is the identifier of a screen record of the current form.
4. *screen-array* is the screen array that will be used in the form.

Usage

The CLEAR *field-list* instruction can be used to clear the content of the specified form fields

Similarly to CLEAR FORM, the CLEAR *field-list* is typically used when the program is not inside a dialog block execution controlling the form fields. For example, after a database query with a CONSTRUCT instruction, you might want to clear all search criteria entered by the user with this instruction, to cleanup the form.

The CLEAR *field-list* instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

Example

```
CONSTRUCT BY NAME sql
   ON s_customer.*
   ...
END CONSTRUCT
CLEAR s_customer.*
...
```

SCROLL
The SCROLL instruction moves data rows up or down in a screen array.

Syntax

```
SCROLL field-list { UP | DOWN } [ BY lines ]
```

where *field-list* is:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

1. *field-name* is the identifier of a field of the current form.
2. *table-name* is the identifier of a database table of the current form.
3. *screen-record* is the identifier of a screen record of the current form.
4. *screen-array* is the name of the screen array used of the current form.
5. *lines* is an integer expression that specifies how far (in lines) to scroll the display.

Usage

The SCROLL instruction specifies vertical movements of displayed values in all or some of the fields of a screen array within the current form.

The SCROLL instruction is supported for applications running in TUI mode, to scroll screen array rows when no interactive instruction is executing. In a GUI application, use a TABLE container with a DISPLAY ARRAY instruction.

Prompt for values (PROMPT)

The PROMPT instruction provides unique field input in an automatic popup window.

- Understanding the PROMPT instruction on page 1043

- Syntax of PROMPT instruction on page 1043
- Using simple prompt inputs on page 1044
  - PROMPT programming steps on page 1044
  - PROMPT instruction configuration on page 1045
  - Default actions in PROMPT on page 1045
  - Interaction blocks on page 1046
- Examples on page 1047
  - Example 1: Simple PROMPT statements on page 1047
  - Example 2: Simple PROMPT with Interrupt Checking on page 1047
  - Example 3: PROMPT with ATTRIBUTES and ON ACTION handlers on page 1047

Understanding the PROMPT instruction

Use the PROMPT instruction to query for a single value from the user.

PROMPT requires the text of the question to be displayed to the user and the variable that receives the value entered by the user. The variable can be of any simple data type except TEXT and BYTE.

The runtime system displays the question in the prompt area, waits for the user to enter a value, reads whatever value was entered until the user validates (for example with the Enter key), and stores this value in a response variable. The prompt dialog remains visible until the user enters a response.

The prompt finishes after ON IDLE, ON ACTION, or ON KEY block execution (to ensure backwards compatibility).

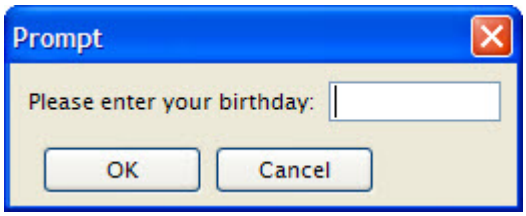
Prompt display in TUI mode

In TUI mode, the PROMPT question and input field is displayed in the prompt line of the current window, which is defined by the OPTIONS PROMPT LINE instruction or with the ATTRIBUTES clause of OPEN WINDOW. If the prompt line is not as wide as the prompt string, runtime error -1146 occurs.

Prompt display in GUI mode

In GUI mode, the PROMPT instruction opens a modal window with an OK and a Cancel button, and waits for input from the user.

Figure 72: PROMPT window



Syntax of PROMPT instruction

The PROMPT statement assigns a user-supplied value to a variable.

Syntax

```
PROMPT question
    [ ATTRIBUTES ( display-attribute [,...] ) ]
    FOR [CHAR[ACTER]] variable
    [ HELP number ]
    [ ATTRIBUTES ( control-attribute [,...] ) ]
```

```
[ dialog-control-block
   [...]
   END PROMPT ]
```

where *dialog-control-block* is one of:

```
{ ON IDLE seconds
| ON TIMER seconds
| ON ACTION action-name
| ON KEY ( key-name [,...] )
}
    statement
    [...]
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

where *control-attribute* is:

```
{ ACCEPT [ = boolean ]
| CANCEL [ = boolean ]
| CENTURY = "century-spec"
| FORMAT = "format-spec"
| PICTURE = "picture-spec"
| SHIFT = { "up" | "down" }
| HELP = help-number
| COUNT = row-count
| UNBUFFERED [ = boolean ]
| WITHOUT DEFAULTS [ = boolean ]
}
```

1. *question* is a string expression displayed as a message for the input of the value.
2. *variable* is the name of the variable that receives the data typed by the user.
3. The `FOR CHAR` clause exits the prompt statement when the first character has been typed.
4. *number* is the help message number to be displayed when the user presses the help key.
5. *key-name* is an hot-key identifier (such as `F11` or `Control-z`).
6. *action-name* identifies an action that can be executed by the user.
7. *seconds* is an integer literal or variable that defines a number of seconds.
8. *statement* is an instruction that is executed when the user presses the key defined by *key-name.*
9. *century-spec* is a string specifying the century input rule, like the `CENTURY` attribute.
10. *format-spec* is a string defining the display format for the prompt field, like the `FORMAT` attribute.
11. *picture-spec* is a string defining the input format for the prompt field, like the `PICTURE` attribute.

Using simple prompt inputs

To use simple prompt inputs, you must understand how they work and how to structure the code.

PROMPT programming steps

To use the `PROMPT` statement, you must:

1. Declare a program variable with the `DEFINE` statement.
2. Set the `INT_FLAG` variable to `FALSE`.
3. Define the `PROMPT` statement, with dialog control blocks to control the instruction. Use the `FOR CHAR` clause if a single character is to be entered.

4. After executing the PROMPT, check the INT_FLAG variable to determine whether the input was validated or canceled by the user.

PROMPT instruction configuration

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help while executing the instruction. The predefined *help* action is automatically created by the runtime system. You can bind action views to the *help* action.

The HELP clause overrides the HELP attribute.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the *accept* default action.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using EXIT INPUT.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

Default actions in PROMPT

When a PROMPT instruction executes, the runtime system creates a set of default actions.

According the invoked default action, field validation occurs and different PROMPT control blocks are executed.

This table lists the default actions created for this dialog:

Table 268: Default actions created for the PROMPT dialog

Default action	Description
accept	Validates the PROMPT dialog (validates field criteria) *Creation can be avoided with the* ACCEPT *attribute.*
cancel	Cancels the PROMPT dialog (no validation, int_flag is set) *Creation can be avoided with the* CANCEL *attribute.*
close	By default, cancels the PROMPT dialog (no validation, int_flag is set) Default action view is hidden. See Implementing the close action on page 1337.
help	Shows the help topic defined by the HELP clause. *Only created when a* HELP *clause is defined.*

Interaction blocks

ON ACTION block

You can use `ON ACTION` blocks to execute a sequence of instructions when the user raises a specific action. This is the preferred solution compared to `ON KEY` blocks, because `ON ACTION` blocks use abstract names to control user interaction.

> **Important:** The `PROMPT` instruction is automatically finished after `ON IDLE`, `ON ACTION`, `ON KEY` block execution.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (`*`key-name`*`)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

Examples

Example 1: Simple PROMPT statements

```
MAIN
  DEFINE birth DATE
  DEFINE chkey CHAR(1)
  PROMPT "Please enter your birthday: " FOR birth
  DISPLAY "Your birthday is: " || birth
  PROMPT "Now press a key... " FOR CHAR chkey
  DISPLAY "You pressed: " || chkey
END MAIN
```

Example 2: Simple PROMPT with Interrupt Checking

```
MAIN
  DEFINE birth DATE
  LET INT_FLAG = FALSE
  PROMPT "Please enter your birthday: " FOR birth
  IF INT_FLAG THEN
    DISPLAY "Interrupt received."
  ELSE
    DISPLAY "Your birthday is: " || birth
  END IF
END MAIN
```

Example 3: PROMPT with ATTRIBUTES and ON ACTION handlers

```
MAIN
  DEFINE birth DATE
  LET birth = TODAY
  PROMPT "Please enter your birthday: " FOR birth
     ATTRIBUTES(WITHOUT DEFAULTS)
        ON ACTION action1
           DISPLAY "Action 1"
  END PROMPT
  DISPLAY "Your birthday is " || birth
END MAIN
```

Ring menus (MENU)

The MENU instruction implements a list of options the end user can choose from.

Understanding ring menus

A *ring menu* defines a list of options that can trigger actions to execute associated program code. Ring menus are implemented with the MENU interactive instruction. A MENU block lists the possible actions that can be triggered in a given place in the program, with the associated program code to be executed.

```
MENU "Sample"
    COMMAND "Say hello"
       DISPLAY "Hello, world!"
    COMMAND "Exit"
       EXIT MENU
END MENU
```

A ring menu can only define a set of options for a given level of the program. You cannot define all menu options of your program in a single MENU instruction; you must implement nested menus.

The MENU instruction is mainly designed for text mode applications, displaying ring menus at the top of the screen. A typical TUI mode application starts with a global menu, defining general options to access subroutines, which in turn implement specific menus with database record handling options such as 'Append', 'Delete', 'Modify', and 'Search'. Ring menus can also be used in a GUI application, however, as this instruction does not handle form fields, other parts of the form are disabled during the menu dialog execution. In GUI applications, ring menus are typically used to open a modal window with Yes / No / Cancel options.

Syntax of the MENU instruction

The MENU instruction defines a set of options the end user can select to trigger actions in a program.

Syntax

```
MENU [title]
```

```
   [ ATTRIBUTES ( menu-attribute [,...] ) ]
   [ BEFORE MENU
       menu-statement
     [...]
   ]
   menu-option
   [...]
END MENU
```

where *menu-option* is one of:

```
{ COMMAND option-name
      [option-comment] [ HELP help-number ]
    menu-statement
    [...]
| COMMAND KEY ( key-name ) option-name
      [option-comment] [ HELP help-number ]
    menu-statement
    [...]
| COMMAND KEY ( key-name )
    menu-statement
    [...]
| ON ACTION action-name
             [ ATTRIBUTES ( action-attributes-menu ) ]
    menu-statement
    [...]
| ON IDLE seconds
    menu-statement
    [...]
| ON TIMER seconds
    menu-statement
    [...]
}
```

where *action-attributes-menu* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
| DISCLOSUREINDICATOR
    [,...] }
```

where *menu-statement* is:

```
{ statement
|  CONTINUE MENU
|  EXIT MENU
|  NEXT OPTION option
|  SHOW OPTION { ALL | option [,...] }
|  HIDE OPTION { ALL | option [,...] }
}
```

where *menu-attribute* is:

```
{ STYLE = { "default" | "popup" | "dialog" }
| COMMENT = "string"
| IMAGE = "string"
}
```

1. *title* is a string expression defining the title of the menu.
2. *menu-attribute* is an attribute that defines the behavior and presentation of the menu.
3. *key-name* is an hot-key identifier (like `F11` or `Control-z`).
4. *option-name* is a string expression defining the label of the menu option and identifying the action that can be executed by the user.
5. *option-comment* is a string expression containing a description for the menu option, displayed when *option-name* is the current.
6. *help-number* is an integer that allows you to associate a help message number with the menu *option.*
7. *action-name* identifies an action that can be executed by the user.
8. *seconds* is an integer literal or variable that defines a number of seconds.
9. *action-name* identifies an action that can be executed by the user.
10. *action-attributes* are dialog-specific action attributes.

MENU programming steps

The following steps describe how to implement a `MENU` statement:

1. Create a `MENU` block with a title and write the end of the menu block with the `END MENU` keywords.
2. According to the type of menu rendering you need, add an `ATTRIBUTES` clause with the required `STYLE` attribute.
3. List all the options that you want to offer to the end user when the menu executes. Typical CRUD programs will implement "Append", "Modify", "Delete" operations for a given database application entity (customers, orders, items tables). Typical dialog box menus have "Yes" / "No" / "Cancel" options.
4. According to TUI or GUI mode, define action views (topmenu, toolbar or form buttons) for each menu action, and use either `COMMAND [KEY]` or `ON ACTION` clauses to define the menu options.
5. When the menu is not a popup or dialog menu, do not forget to implement an option to leave the menu with the `EXIT MENU` control instruction.
6. Implement the code to be executed in every option.

Using ring menus

To use ring menus, you must understand how they work and how to structure the code.

Rendering modes of a menu

When you add a style to a `MENU`'s attributes list, you define the look-and-feel of that menu and how that menu acts.

MENU rendering specification

The rendering mode of a `MENU` instruction can be controlled with the `STYLE` dialog attribute:

```
MENU "Test" ATTRIBUTES ( STYLE = "mode" )
   ...
END MENU
```

> **Note:** `MENU ... ATTRIBUTES(STYLE="mode")` is not a presentation style defined in a `4st` file: It defines a display mode, a rendering hint for front-ends.

The decoration of the different rendering modes of a `MENU` depends from the front-end type and the platform used. Consider testing the menu instruction with all front-ends that must be supported for end users.

Default MENU rendering

By default, if no `STYLE` attribute is used in the `MENU` instruction, each menu option will be displayed as a push button in a dedicated area of the current window, depending on the front end. This dedicated area is called the action frame.

Note that when an explicit action view (for ex, a `BUTTON` in form layout) is associated with a menu option, the default button will not appear in the action frame area.

The default rendering of a `MENU`, including the position of the action frame in the window, can be controlled with window presentation style attributes.

```
MAIN
  MENU "File"
    COMMAND "New"
      DISPLAY "New"
    COMMAND "Open"
      DISPLAY "Open"
    COMMAND "Save"
      DISPLAY "Save"
    COMMAND "Import"
      DISPLAY "Import"
    COMMAND "Quit"
      EXIT MENU
  END MENU
END MAIN
```

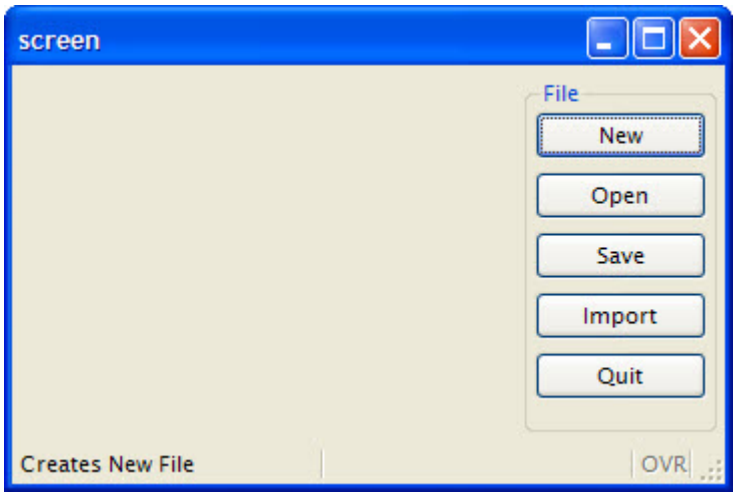

Figure 73: Default rendering of MENU with the Genero Desktop Client

Modal dialog MENU rendering

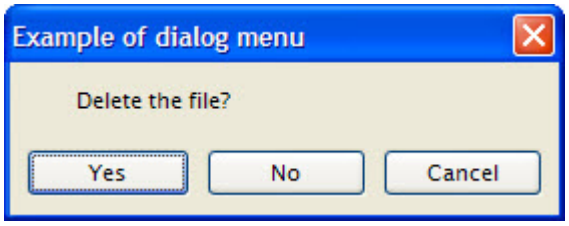
Menus can be rendered in a modal dialog window by specifying the `STYLE="dialog"` attribute in the `MENU` instruction.

```
MAIN
  MENU "Example of dialog menu"
    ATTRIBUTES ( STYLE="dialog", COMMENT="Delete the file?" )
    COMMAND "Yes"
      DISPLAY "Yes"
    COMMAND "No"
      DISPLAY "No"
    COMMAND "Cancel"
      DISPLAY "Cancel"
  END MENU
END MAIN
```

When the user clicks on an option, the `MENU` instruction automatically exits and the modal dialog window closes. There is no need for an `EXIT MENU` command.

With `STYLE="dialog"`, when the user clicks on an option, the `MENU` instruction automatically exits and the popup menu closes. There is no need for an `EXIT MENU` command.

Figure 74: MENU displayed as a modal dialog with the Genero Desktop Client



Popup MENU rendering

Menus can also be displayed as popup choice lists, when the `STYLE="popup"` attribute is used in the `MENU` instruction.

```
MAIN
   DEFINE r INTEGER
   MENU "test"
     COMMAND "popup"
        DISPLAY popup()
     COMMAND "quit"
        EXIT MENU
   END MENU
END MAIN

FUNCTION popup()
   DEFINE r INTEGER
   LET r = -1
   MENU "unused" ATTRIBUTES ( STYLE="popup" )
     COMMAND "Copy all"
        LET r = 1
     COMMAND "Copy current"
        LET r = 2
     COMMAND "Paste all"
        LET r = 3
     COMMAND "Paste current"
        LET r = 4
   END MENU
   RETURN r
END FUNCTION
```

With `STYLE="popup"`, when the user clicks on an option, the `MENU` instruction automatically exits and the popup menu closes. There is no need for an `EXIT MENU` command.

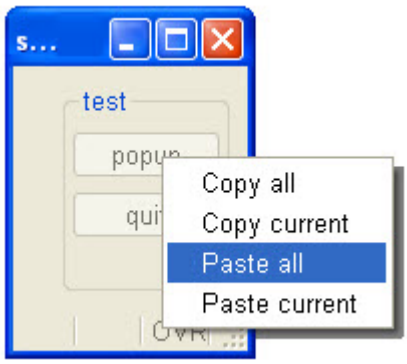


Figure 75: MENU displayed as popup list with the Genero Desktop Client

MENU rendering on mobile platforms

On mobile devices, the rendering of the MENU dialog depends on whether or not the current window has a form.

If a MENU is active and the current Window has no form, then the MENU is shown as a list of actions.

If a MENU is active and has a FORM, then the menu actions are rendered like all other dialog actions.

Binding action views to menu options

A MENU statement is a controller for user actions, defining action handlers triggered by action views. Actions views in the form file (i.e. toolbar buttons, topmenu items or push buttons) are bound to menu options by name. For example, if a MENU instruction defines `ON ACTION sendmail`, a form BUTTON with the name "sendmail" will be attached to that action handler.

When binding action views to menu option clauses, the action name is case sensitive. The compiler converts COMMAND labels and `ON ACTION` identifiers to lowercase to create the action name. It is recommended that you use all lowercase letters when defining the action name for action views and menu options.

Menu options can also be defined with the COMMAND clause. Unlike `ON ACTION`, the COMMAND clause takes a string literal as argument, that defines both the action name and the default text to be displayed in the default action view. For example, `COMMAND "Help"` will define the action name help and the default button text "Help". Action views must be bound with the action name in lower case (`help`).

When the menu is rendered as a popup of dialog box, no explicit action views need to be defined, default action views will be created and will get the decoration specified in action defaults.

MENU instruction configuration

The rendering and behavior of a MENU instruction can be configured with the ATTRIBUTES clause:

```
MENU "Question"
     ATTRIBUTES (
         STYLE="dialog",
         COMMENT="Do you want to commit your changes?"
      )
```

When the STYLE instruction attribute is set to '`default`' or when you do not specify the menu type, the runtime system generates a default decoration as a set of buttons in a specific area of the current window.

When the STYLE attribute is set to '`dialog`', the menu options appear as buttons at the bottom in a temporary modal window, in which you can define the message and the icon with the COMMENT and IMAGE attributes.

When the STYLE is set to '`popup`', the menu appears as a popup menu (contextual menu).

If the menu is a "dialog" or "popup", the dialog is automatically exited after any action clause such as ON ACTION, COMMAND or ON IDLE.

Default actions in MENU

When an MENU instruction executes, the runtime system creates a set of default actions.

Table 269: Default actions created for the MENU instruction

Default action	Control Block execution order
close	Created to execute COMMAND KEY(INTERRUPT) if used (can be overwritten with ON ACTION close) Default action view is hidden. See Implementing the close action on page 1337.
help	Shows the help topic defined by the HELP clause. Default action view is hidden.

Window close events can be trapped with COMMAND KEY(INTERRUPT) clause.

MENU control blocks
BEFORE MENU block

If the MENU block contains a BEFORE MENU clause, statements within this clause will be executed before the menu dialog starts.

This block is typically used to hide or disable some menu options according to the current context of the program. For example, when the current user is not allowed to create new records, the menu options can be disabled as follows:

```
MENU "Orders"
   BEFORE MENU
      CALL DIALOG.setActionActive("append", can_user_append() )
      ...
   COMMAND "Append" -- creates "append" action (lowercase)
      ...
   ...
END MENU
```

In TUI mode, the menu options can also be disabled, but they will still be displayed on the screen. The end user will see the option, but cannot select it. In this case it's more convenient to hide the option to the end user with the DIALOG.setActionHidden() method, instead of disabling the action.

MENU interaction blocks
COMMAND [KEY()] "option" block

The COMMAND [KEY(*key-name*)] "*option-name*" clause defines a menu action handler with a set of instructions to be executed when an action is invoked. The option text (*option-name*), converted to lowercase letters, defines the name of the action.

For example, when defining:

```
COMMAND "Hello"
```

The name of the action will be "hello" (not "Hello" with a capital H).

When used with the KEY() clause, the command specifies both accelerator keys and an option text. For backward compatibility, a coma-separated key list is supported in the KEY() specification. Consider using a single key for new developments, or prefer accelerator definition with action defaults.

Action defaults will be applied by using the action name defined by the option text (converted to lower case).

Explicit action views defined in the form (`BUTTON` in layout, `TOPMENU` or `TOOLBAR` items) will get all action defaults associated to the menu command, while default action views (i.e. buttons in the action frame) will be decorated with the menu option text and comment specified in the program (i.e. the `TEXT` and `COMMENT` attributes of the corresponding action defaults entry are not used for the default action views), however, other attributes such as the `IMAGE` will also be applied to default action views.

For example, when defining:

```
COMMAND "Hello" "This is the Hello option"
```

The name of the action will become "`hello`", the default action view button text will be "`Hello`", and the button hint will be "`This is the Hello option`", even if an action default defines a different text or comment for the "`hello`" action. If the corresponding action default defines a `IMAGE` icon, it will display in the default action view button.

The `KEY()` clause can specify up to four accelerator attributes for the action. The keys defined in the program will take precedence over accelerators defined with action defaults.

The first letter of the display text of a `COMMAND` menu clause can be used as default accelerator. When this first letter is not used by other menu option labels, pressing the key corresponding to that letter will execute that action. When the first letter is also used in other menu options, pressing the key will toggle the focus between all default action views that share the same letter. For example:

```
MENU
  COMMAND "Start"
    DISPLAY "Start"
  COMMAND "Stop"
    DISPLAY "Stop"
  COMMAND "Quit"
    EXIT MENU
END MENU
```

In this example, when pressing S on the keyboard, the focus will toggle between "Start" and "Stop"buttons, and the current option can be selected with the Return or Space key. When pressing Q, the "Quit" action will be fired.

To write abstract code without decoration in your programs, use the `ON ACTION` clause instead of `COMMAND [KEY]`, except if the action view must get the focus.

Note that if you use an ampersand (&) in the command name, some front-ends consider the letter following & as an Alt-key accelerator, and the letter will be underscored. However the ampersand forms part of the action name. For example, `COMMAND "&Save"` will create an action with the name "`&save`".

In TUI mode, actions created with `COMMAND [KEY]` do not get accelerators from action defaults; Only actions defined with `ON ACTION` will get accelerators of action defaults.

COMMAND KEY() block

The `COMMAND KEY(`*`key-name`*`)` block (without an option text) defines a menu action handler with a set of instructions to be executed when an action is invoked. The `KEY()` clause defines one or several accelerator keys separated by a comma. The specified key name must be one of the virtual keys.

For backward compatibility, a coma-separated key list is supported in the `KEY()` specification. Consider using a single key for new developments, or prefer accelerator definition with action defaults.

While a `COMMAND KEY(`*`key-name`*`) "`*`option-name`*`"` (with option text) defines the name of the action with the option text (converted to lowercase), a `COMMAND KEY(`*`key-name`*`)` (without option text), defines the action name from the last key in the `KEY()` list, converted to lowercase letters. For example, with `COMMAND KEY(F10,F12,Control-Z)`, the name of the action will be "`control-z`".

Action defaults will be applied by using the key name of the KEY() clause. With a list of keys, the last key name will be used to apply action defaults, because it defines the action name.

The KEY() clause can specify up to four accelerator attributes for the action. The keys defined in the program will take precedence over accelerators defined with action defaults.

By default, COMMAND KEY(*key-name*) actions are not decorated with a default action (i.e. a button in the action frame will not appear for these actions). However, by defining the text attribute within action defaults, the default action view button will be visible. This allows you to decorate existing COMMAND KEY(*key-name*) clauses with graphical buttons without changing the program code.

To write abstract code without decoration in your programs, use the ON ACTION clause instead of COMMAND [KEY], except if the action view must get the focus.

In TUI mode, actions created with COMMAND [KEY] do not get accelerators from action defaults; Only actions defined with ON ACTION will get accelerators of action defaults.

ON ACTION block

The ON ACTION *action-name* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
   instruction
   ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
   CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
   CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
   CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The ON IDLE *seconds* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON TIMER block

The `ON TIMER` *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

MENU control instructions
SHOW/HIDE OPTION instruction
The `HIDE OPTION` and `SHOW OPTION` to hide or show `MENU` options.

Syntax:

```
{ HIDE | SHOW } OPTION
    { ALL
    | option-name [,...]
    }
```

Usage

The `SHOW OPTION` instruction will show/enable action views corresponding the listed menu options. The default action views (buttons in action frame) are made visible and the explicit action views (buttons in form) are enabled. The `HIDE OPTION` instruction will hide default action views and disable explicit action views.

Use the `ALL` keyword reference all menu options. In a menu that contains many options, you typically do a `HIDE OPTIONS ALL` followed by `HIDE OPTION` to show a subset of the menu options.

The `SHOW OPTION` and `HIDE OPTION` instructions are provided for backward compatibility. To hide and show default action views, use the `DIALOG.setActionHidden()` method instead. In GUI applications, you should rather disable actions, instead of hiding them to the end user.

Example

```
MENU "Customers"
   BEFORE MENU
      HIDE OPTION ALL
      SHOW OPTION "Add", "Exit"
   ...
```

EXIT MENU instruction

`EXIT MENU` terminates the execution of a `MENU` block.

Syntax

```
EXIT MENU
```

Usage

`EXIT MENU` statement terminates the `MENU` block an continues the program flow with the statement after the menu block.

Example

```
MENU "Stock"
  ...
  COMMAND "Exit"
     EXIT MENU
END MENU
```

CONTINUE MENU instruction

`CONTINUE MENU` resumes the execution of a `MENU` block.

Syntax

```
CONTINUE MENU
```

Usage

The `CONTINUE MENU` ignores the remaining instructions in the current program section of a `MENU` block, re-displays the menu options and gives the control back to the user to select a new menu option.

The statements following the `CONTINUE MENU` instruction are skipped.

Example

```
MENU "Stock"
  ...
  COMMAND "Exit"
    IF question("Exit the program?")==FALSE THEN
       CONTINUE MENU
    END IF
    CALL commit_changes()
    EXIT MENU
```

```
END MENU
```

Examples

Example 1: MENU with abstract action options

```
MENU
  ON ACTION new
      CALL newFile()
  ON ACTION open
      CALL openFile()
  ON ACTION save
      CALL saveFile()
  ON ACTION import
      LOAD FROM "infile.dat" INSERT INTO table
  ON ACTION quit
      EXIT PROGRAM
END MENU
```

Example 2: MENU with text-mode options

```
MENU "File"
  COMMAND KEY ( CONTROL-N ) "New" "Creates New File" HELP 101
    CALL newFile()
  COMMAND KEY ( CONTROL-O ) "Open" "Open existing File" HELP 102
    CALL openFile()
  COMMAND KEY ( CONTROL-S ) "Save" "Save Current File" HELP 103
    CALL saveFile()
  COMMAND "Import"
    LOAD FROM "infile.dat" INSERT INTO table
  COMMAND KEY ( CONTROL-Q ) "Quit" "Quit Program" HELP 201
    EXIT PROGRAM
END MENU
```

Example 3: MENU with STYLE="dialog"

The next code example implements typical message box utility functions implemented with `MENU` dialogs:

```
FUNCTION mbox_ync(title,msg)
    DEFINE title, msg STRING
    DEFINE res SMALLINT
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
        ON ACTION yes     LET res = 1
        ON ACTION no      LET res = 0
        ON ACTION cancel  LET res = -1
    END MENU
    RETURN res
END FUNCTION

FUNCTION mbox_yn(title,msg)
    DEFINE title, msg STRING
    DEFINE res BOOLEAN
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
        ON ACTION yes LET res = TRUE
        ON ACTION no  LET res = FALSE
    END MENU
    RETURN res
END FUNCTION

FUNCTION mbox_ok(title,msg)
    DEFINE title, msg STRING
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
```

```
        ON ACTION accept
    END MENU
END FUNCTION
```

Record input (INPUT)

The `INPUT` instruction provides single record input control in an application form.

Understanding the INPUT instruction

The `INPUT` statement binds program variables to screen-records in forms for data entry in form fields. The `INPUT` statement uses the current form in the current window. Before executing the `INPUT` statement, record data must be fetched from the database table into the program variables using by the input statement.

During the `INPUT` statement execution, the user can edit the record fields, while the program controls the behavior of the instruction with control blocks.

To terminate the `INPUT` execution, the user can validate (or cancel) the dialog to commit (or invalidate) the modifications made in the record.

When the statement completes execution, the form is deactivated. After the user terminates the input (for example, with the "accept" key), the program must test the `INT_FLAG` variable to check if the dialog was validated (or canceled), and then can use the `INSERT` or `UPDATE` SQL statements to modify the appropriate database tables.

Syntax of the INPUT instruction

The `INPUT` statement supports data entry into the fields of the current form.

Syntax

```
INPUT { BY NAME { variable | record.* } [,...]
              [ WITHOUT DEFAULTS ]
      | variable | record.* } [,...]
              [ WITHOUT DEFAULTS ]
              FROM field-list
      }
  [ ATTRIBUTES (
         { display-attribute
         | control-attribute
         } [,...] ) ]
  [ HELP help-number ]
  [ dialog-control-block
    [...]
END INPUT ]
```

where *dialog-control-block* is one of:

```
{ BEFORE INPUT
| AFTER INPUT
| BEFORE FIELD field-spec [,...]
| AFTER FIELD field-spec [,...]
| ON CHANGE field-spec [,...]
| ON IDLE seconds
| ON TIMER seconds
| ON ACTION action-name
             [ INFIELD field-spec ]
             [ ATTRIBUTES ( action-attributes-input ) ]
| ON KEY ( key-name [,...] )
}
    dialog-statement
    [...]
```

where *action-attributes-input* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| VALIDATE = NO
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *dialog-statement* is one of:

```
{ statement
| ACCEPT INPUT
| CONTINUE INPUT
| EXIT INPUT
| NEXT FIELD
   { CURRENT
   | NEXT
   | PREVIOUS
   | field-spec
   }
}
```

where *field-list* defines a list of fields with one or more of:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

where *field-spec* identifies a unique field with one of:

```
{ field-name
| table-name.field-name
| screen-array.field-name
| screen-record.field-name
}
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

where *control-attribute* is:

```
{ ACCEPT [ = boolean ]
| CANCEL [ = boolean ]
| FIELD ORDER FORM
| HELP = help-number
| NAME = "dialog-name"
| UNBUFFERED [ = boolean ]
| WITHOUT DEFAULTS [ = boolean ]
}
```

1. *variable* is a program variable that will be filled by the `INPUT` statement.
2. *record.** is a record variable that will be filled by the `INPUT` statement.
3. *help-number* is an integer that allows you to associate a help message number with the instruction.
4. *field-name* is the identifier of a field of the current form.
5. *table-name* is the identifier of a database table of the current form.
6. *screen-record* is the identifier of a screen record of the current form.
7. *screen-array* is the screen array that will be used in the form.
8. *line* is a screen array line in the form.
9. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
10. *dialog-name* is the identifier of the dialog.
11. *seconds* is an integer literal or variable that defines a number of seconds.
12. *action-name* identifies an action that can be executed by the user.
13. *statement* is any instruction supported by the language.
14. *boolean* is a boolean expression evaluated when the dialog starts.
15. *action-attributes* are dialog-specific action attributes.

INPUT programming steps

The following steps describe how to use the `INPUT` statement:

1. Create a form specification file, with an optional screen record.

The screen record identifies the presentation elements to be used by the runtime system to display the records. if you omit the declaration of the screen record in the form file, the runtime system will use the default screen records created by the form compiler for each table listed in the `TABLES` section and for the `FORMONLY` pseudo-table.

2. Make sure that the program controls interruption handling with `DEFER INTERRUPT`, to manage the validation/cancellation of the interactive dialog.
3. Define a program record with the `DEFINE` instruction.

   The members of the program record must correspond to the elements of the screen record, by number and data types.
4. Open and display the form, using an `OPEN WINDOW` with the `WITH FORM` clause or the `OPEN FORM` / `DISPLAY FORM` instructions.
5. If needed, fill the program record with data, for example with a result set cursor.
6. Set the `INT_FLAG` variable to `FALSE`.
7. Write the `INPUT` statement to handle data input.
8. Inside the `INPUT` statement, control the behavior of the instruction with `BEFORE INPUT`, `BEFORE FIELD`, `AFTER FIELD`, `AFTER INPUT` and `ON ACTION` blocks.
9. After the interaction statement block, test the `INT_FLAG` predefined variable to check if the dialog was canceled (`INT_FLAG=TRUE`) or validated (`INT_FLAG=FALSE`).

   If the `INT_FLAG` variable is `TRUE`, you should reset it to `FALSE` to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

Using simple record inputs

To use simple record inputs, you must understand how they work and how to structure the code.

Variable binding in INPUT

The `INPUT` instruction binds program variables (typically, members of a `RECORD`) are bound to the fields of a screen record of the current form, and synchronizes the data between field input buffers and program variables.

Binding variables and fields by name

The `INPUT BY NAME` *`variable-list`* instruction implicitly binds the fields to the program variables that have the same identifiers as the form field names. The program variables are typically defined within a record declared with a `LIKE table.*` based a database schema, to get the same names as the form fields defined with database column references. The runtime system ignores any record name prefix when making the match, only record member names matter. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exception.

```
SCHEMA stock
DEFINE custrec RECORD LIKE customer.*
...
INPUT BY NAME custrec.*
  ...
END INPUT
```

Binding variables and fields by position

The `INPUT` *`variable-list`* `FROM` *`field-list`* clause explicitly binds the variables to form fields by position. The form can include other fields that are not part of the specified variable list, but the number of variables or record members must equal the number of form fields listed in the `FROM` clause. Each variable must be of the same (or a compatible) data type as the corresponding form field. When the user enters

data, the runtime system checks the entered value against the data type of the variable, not the data type of the form field.

```
SCHEMA stock
DEFINE custrec RECORD LIKE customer.*,
       comment VARCHAR(100)
...
INPUT custrec.*, comment FROM sr_cust.*, cmt
  ...
END INPUT
```

When using the FROM clause with a screen record followed by a .* (dot star), keep in mind that program variables are bound to screen record fields by position, so you must make sure that the program variables are defined (or listed) in the same order as the screen array fields.

Serial column support

The program variables can be of any data type: The runtime system will adapt input and display rules to the variable type. If a variable is declared with the LIKE clause and uses a column defined as SERIAL / SERIAL8 / BIGSERIAL, the runtime system will treat the field as if it was defined with the NOENTRY attribute in the form file: Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

The UNBUFFERED mode

The variables act as data model to display data or to get user input through the INPUT instruction. Always use the variables if you want to change some field values by program. When using the UNBUFFERED attribute, the instruction is sensitive to program variable changes: If you need to display new data during the INPUT execution, just assign the values to the program variables; the runtime system will automatically display the values to the screen:

```
INPUT p_items.* FROM s_items.* ATTRIBUTES ( UNBUFFERED )
  ON CHANGE code
    IF p_items.code = "A34" THEN
      LET p_items.desc = "Item A34"
    END IF
END INPUT
```

Handling default field values

When the INPUT instruction executes, any column default values are displayed in the screen fields, unless you specify the WITHOUT DEFAULTS keywords. The column default values are specified in the form specification file with the DEFAULT attribute, or in the database schema files.

If you specify the WITHOUT DEFAULTS option, however, the form fields display the current values of the variables when the INPUT statement begins. This option is available with both the BY NAME and the FROM binding clauses.

```
LET p_items.code = "A34"
INPUT p_items.* FROM s_items.* WITHOUT DEFAULTS
  BEFORE INPUT
    MESSAGE "You should see A34 in field 'code'..."
END INPUT
```

Using PHANTOM fields

If the program record has the same structure as a database table (this is the case when the record is defined with a LIKE clause), you may not want to display/use some of the columns. You can achieve this

by used PHANTOM fields in the screen record definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

INPUT instruction configuration

This section describes the options that can be specified in the ATTRIBUTES clause of the INPUT instruction. The options of the ATTRIBUTES clause override all default attributes and temporarily override any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields. With the INPUT statement, the INVISIBLE attribute is ignored.

NAME option

The NAME attribute can be used to name the INPUT dialog. This is especially used to identify actions of the dialog.

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help while the focus is in any field used by the instruction. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

Indicates if the fields controlled by INPUT must be filled (FALSE) or not (TRUE) with the column default values defined in the form specification file or the database schema files. The runtime system assumes that the field satisfies the REQUIRED attribute when WITHOUT DEFAULTS is used. If the WITHOUT DEFAULT option is not used, all fields defined with the REQUIRED attribute must be visited and modified. Fields not defined as NOT NULL can be left empty.

FIELD ORDER FORM option

By default, the tabbing order is defined by the variable binding list in the instruction description. You can control the tabbing order by using the FIELD ORDER FORM attribute: When this attribute is used, the tabbing order is defined by the TABINDEX attribute of the form fields. If this attribute is used, the Dialog.fieldOrder FGLPROFILE entry is ignored.

The OPTIONS instruction can also change the behavior of the INPUT instruction, with the INPUT WRAP or FIELD ORDER FORM options.

UNBUFFERED option

Indicates that the dialog must be sensitive to program variable changes. When using this option, you bypass the traditional "buffered" mode.

When using the traditional "buffered" mode, program variable changes are not automatically displayed to form fields; You need to execute a DISPLAY TO or DISPLAY BY NAME. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of the current field is to use GET_FLDBUF().

If the "unbuffered" mode is used, program variables and form fields are automatically synchronized. You don't need to display explicitly values with a DISPLAY TO or DISPLAY BY NAME. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using ACCEPT INPUT.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using EXIT INPUT.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

Default actions in INPUT

When an INPUT instruction executes, the runtime system creates a set of default actions.

According the invoked default action, field validation occurs and different INPUT control blocks are executed.

This table lists the default actions created for this dialog:

Table 270: Default actions created for the INPUT dialog

Default action	Description
accept	Validates the INPUT dialog (validates fields and leaves the dialog) *Creation can be avoided with* ACCEPT *attribute.*
cancel	Cancels the INPUT dialog (no validation, INT_FLAG is set to TRUE) *Creation can be avoided with* CANCEL *attribute.*
close	By default, cancels the INPUT dialog (no validation, INT_FLAG is set to TRUE) Default action view is hidden. See Implementing the close action on page 1337.
help	Shows the help topic defined by the HELP clause. *Only created when a* HELP *clause is defined.*

The accept and cancel default actions can be avoided with the ACCEPT and CANCEL dialog control attributes:

```
INPUT BY NAME field1 ATTRIBUTES ( CANCEL=FALSE )
  ...
```

INPUT control blocks

INPUT control blocks execution order

This table shows the order in which the runtime system executes the control blocks in the INPUT instruction, according to the user action:

Table 271: Control Block Execution Order for INPUT

Context / User action	Control Block execution order
Entering the dialog	**1.** BEFORE INPUT **2.** BEFORE FIELD (first field)

Context / User action	Control Block execution order
Moving from field A to field B	**1.** `ON CHANGE` (if value has changed for field A) **2.** `AFTER FIELD` (for field A) **3.** `BEFORE FIELD` (for field B)
Changing the value of a field with a specific field like checkbox	**1.** `ON CHANGE`
Validating the dialog	**1.** `ON CHANGE` (if value has changed in current field) **2.** `AFTER FIELD` **3.** `AFTER INPUT`
Canceling the dialog	**1.** `AFTER INPUT`

BEFORE INPUT block

BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `BEFORE INPUT` is only executed once when the dialog is started.

The `BEFORE INPUT` block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ...
   BEFORE INPUT
       MESSAGE "Input customer information"
       CALL DIALOG.setActionActive("check_info", is_super_user() )
       CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
   ...
```

The fields are initialized with the defaults values before the `BEFORE INPUT` block is executed. When the `INPUT` instruction uses the `WITHOUT DEFAULTS` option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the `DEFAULT` attributes of the form fields are used.

Use the `NEXT FIELD` control instruction in the `BEFORE INPUT` block, to jump to a specific field when the dialog starts.

BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE INPUT` block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `BEFORE INPUT` block.

`BEFORE INPUT` is executed after the `BEFORE DIALOG` block andbefore the `BEFORE ROW`, `BEFORE FIELD` blocks.

In this example, the `BEFORE INPUT` block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
   BEFORE INPUT
       CALL DIALOG.setActionActive("validate_order", TRUE)
```

AFTER INPUT block

AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER INPUT` is only executed once when dialog ends.

The `AFTER INPUT` block is executed after the user has validated or canceled the `INPUT` or `INPUT ARRAY` dialog with the accept or cancel default actions, or when the `ACCEPT INPUT` instruction is executed.

The `AFTER INPUT` block is not executed when the `EXIT INPUT` instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the `NEXT FIELD` instruction to force the dialog to continue. The `CONTINUE INPUT` instruction can be used instead of `NEXT FIELD`, when no particular field has to be select.

Before checking the validation rules, make sure that the `INT_FLAG` variable is `FALSE`: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
  ...

  AFTER INPUT
    IF NOT INT_FLAG THEN
       IF cust_rec.cust_address IS NOT NULL
          AND cust_rec.cust_zipcode IS NULL THEN
          ERROR "Address is incomplete, enter a zipcode."
          NEXT FIELD zipcode
       END IF
    END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER INPUT` block is executed when the focus is lost by a group of fields driven by an `INPUT` or `INPUT ARRAY` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `AFTER INPUT` block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER INPUT` is executed after the `AFTER FIELD`, `AFTER ROW` blocks and before the `AFTER DIALOG` block.

Executing a `NEXT FIELD` in the `AFTER INPUT` control block will keep the focus in the group of fields. Within an `INPUT ARRAY` sub-dialog, `NEXT FIELD` will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the `AFTER INPUT` block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
   AFTER INPUT
      IF NOT check_order_data(DIALOG) THEN
```

```
        NEXT FIELD CURRENT
      END IF
      CALL DIALOG.setFieldActive("validate_order", FALSE)
```

BEFORE FIELD block

For fields controlled by an INPUT, INPUT ARRAY or by a CONSTRUCT instructions, the BEFORE FIELD block is executed every time the cursor enters into the specified field.

For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
   BEFORE FIELD cust_status
     LET p_cust.cust_comment = NULL
     MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block might be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

ON CHANGE block

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set. The ON CHANGE block can only be used for fields controlled by an INPUT or INPUT ARRAY dialog, it is not available in CONSTRUCT.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in

a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
   ON CHANGE order_checked -- Defined as CHECKBOX
      CALL setup_dialog(DIALOG)
```

If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had leaved and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This denies to do field validation in ON CHANGE blocks: you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

AFTER FIELD block

In dialog parts driven by a simple INPUT, INPUT ARRAY or by a CONSTRUCT sub-dialog, the AFTER FIELD block is executed every time the focus leaves the specified field. For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
   AFTER FIELD item_quantity
     IF p_item.item_quantity <= 0 THEN
        ERROR "Item quantity cannot be negative or zero"
        LET p_item.item_quantity = 0
        NEXT FIELD item_quantity
     END IF
```

INPUT interaction blocks
ON ACTION block

The ON ACTION *action-name* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
  ON ACTION action-name
     instruction
```

```
      ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
   ON ACTION zoom
      CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
   ON ACTION zoom INFIELD cust_city
      CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
   ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (`*`key-name`*`)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the

names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

INPUT control instructions

ACCEPT INPUT instruction

The `ACCEPT INPUT` instruction validates the `INPUT` instruction and exits the dialog block if no error is raised.

The `AFTER FIELD`, `ON CHANGE`, etc. control blocks will be executed.

The statements after the `ACCEPT INPUT` instruction will not be executed.

```
INPUT BY NAME cust_rec.*
  ...
  ON ACTION process_order
    CALL set_missing_defaults()
    ACCEPT INPUT
  ...
END INPUT
```

The `INPUT` instruction creates the default accept action to let the user validate the dialog. The `ACCEPT INPUT` instruction should only be used in specific cases when the default accept action is not appropriated.

CONTINUE INPUT instruction

`CONTINUE INPUT` skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog.

If this instruction is called in a control block that is not `AFTER INPUT`, further control blocks might be executed according to the context. `CONTINUE INPUT` instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of `GOTO end_of_control_block`). However, when executed in `AFTER INPUT`, the focus returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field. In this case the `BEFORE FIELD` of the current field will be invoked.

As alternative, use the `NEXT FIELD` control instruction to give the focus to a specific field and force the dialog to continue. However, unlike `CONTINUE INPUT`, the `NEXT FIELD` instruction will skip the further control blocks that are normally executed.

EXIT INPUT instruction

The `EXIT INPUT` instruction terminates the `INPUT` instruction and resumes the program execution at the instruction following the `INPUT` block.

Performing an `EXIT INPUT` instruction during a dialog is equivalent to cancel the dialog: No field validation will occur, and the `AFTER FIELD` or `AFTER INPUT` blocks will not be executed. The dialog is exited immediately. However, `INT_FLAG` will not be set to `TRUE` as when the cancel action is fired.

CLEAR instruction in dialogs

The `CLEAR` *`field-list`* and `CLEAR SCREEN ARRAY` *`screen-array.*`* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. `CLEAR` can be used outside any dialog instruction, such as the `DISPLAY BY NAME / TO` instructions.

When a dialog is configured with the `UNBUFFERED` mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with `DISPLAY` or `CLEAR` instruction in an `UNBUFFERED` dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an `UNBUFEFERED` dialog, just set to `NULL` the variables bound to the dialog. However, when using a `CONSTRUCT`, no program variables are associated to the dialog and no `UNBUFFERED` concept exits, and the `CLEAR` or `DISPLAY TO / BY NAME` instructions are the only way to modify the `CONSTRUCT` fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using `TABLE` containers, you can therefore use the `CLEAR SCREEN ARRAY` instruction to clear all rows of a list.

Examples
Example 1: INPUT with binding by field position

Form definition file (form1.per):

```
SCHEMA office

LAYOUT
GRID
{
  Customer id: [f001    ]
  First Name : [f002                    ]
  Last Name  : [f003                    ]
}
END
END

TABLES
  customer
```

```
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END
```

Program source code:

```
SCHEMA office

MAIN

  DEFINE custrec RECORD LIKE customer.*

  OPTIONS INPUT WRAP

  OPEN FORM f FROM "form1"
  DISPLAY FORM f

  LET INT_FLAG = FALSE
  INPUT custrec.* FROM sr_cust.*

  IF INT_FLAG = FALSE THEN
    DISPLAY custrec.*
    LET INT_FLAG = FALSE
  END IF

END MAIN
```

Example 2: INPUT with binding by field name

Form definition file "custlist.per" (same as in Example 1)

Program source code:

```
SCHEMA shop

MAIN

  DEFINE custrec RECORD LIKE customer.*
  DEFINE upd INTEGER

  DATABASE shop
  OPTIONS INPUT WRAP
  OPEN FORM f FROM "form1"
  DISPLAY FORM f

  LET custrec.id = arg_val(1)
  LET upd = (custrec.id < 0)

  LET INT_FLAG = FALSE
  INPUT BY NAME custrec.* ATTRIBUTES(UNBUFFERED, WITHOUT DEFAULTS=upd)
    BEFORE INPUT
      MESSAGE "Enter customer information..."
      IF upd THEN
         SELECT fname, lname INTO custrec.fname, customer.lname
            FROM customer WHERE customer.id = custrec.id
```

```
      END IF
    AFTER FIELD fname
      IF FIELD_TOUCHED(custrec.fname) AND custrec.fname IS NULL THEN
        LET custrec.lname = NULL
      END IF
    AFTER INPUT
      MESSAGE "Input terminated..."
  END INPUT

  IF INT_FLAG = FALSE THEN
    DISPLAY custrec.*
    LET INT_FLAG = FALSE
  END IF

END MAIN
```

Read-only record list (DISPLAY ARRAY)

The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

  - DISPLAY ARRAY control instructions on page 1095
- Examples on page 1095
  - Example 1: DISPLAY ARRAY using full list mode on page 1095
  - Example 2: DISPLAY ARRAY using paged mode on page 1096
  - Example 3: DISPLAY ARRAY using modification triggers on page 1097

Understanding the DISPLAY ARRAY instruction

The DISPLAY ARRAY is a dialog instruction designed to browse a list of records, binding a static or dynamic array model to a screen array of the current displayed form.

A DISPLAY ARRAY instruction supports additional features such as drag & drop, tree-view management, built-in sort and search, multi-row selection and list modification triggers. For a detailed description of these features, see Table views on page 1345.

Use the DISPLAY ARRAY instruction to let the end user browse in a list of rows, after fetching a result set from the database. The result set is produced with a database cursor executing a SELECT statement. The SELECT SQL statement is usually completed at runtime with a WHERE clause produced from a CONSTRUCT dialog. When the DISPLAY ARRAY statement completes execution, the program must test the INT_FLAG variable to check if the dialog was validated (or canceled) to take into account (or ignore) the row that was chosen by the user.

Syntax of DISPLAY ARRAY instruction

The DISPLAY ARRAY instruction controls the display of a program array on the screen.

Syntax

```
DISPLAY ARRAY array TO screen-array.*
  [ HELP help-number ]
  [ ATTRIBUTES ( { display-attribute
                 | control-attribute }
                    [,...]) ]
  [  dialog-control-block
  [...]
END DISPLAY ]
```

where *dialog-control-block* is one of:

```
{ BEFORE DISPLAY
| AFTER DISPLAY
| BEFORE ROW
| AFTER ROW
| ON IDLE seconds
| ON TIMER seconds
| ON ACTION action-name
             [ ATTRIBUTES ( action-attributes-display-array ) ]
| ON FILL BUFFER
| ON SELECTION CHANGE
| ON SORT
| ON APPEND [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON INSERT [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON UPDATE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON DELETE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON EXPAND ( row-index )
| ON COLLAPSE ( row-index )
| ON DRAG_START ( dnd-object )
| ON DRAG_FINISH ( dnd-object )
| ON DRAG_ENTER ( dnd-object )
| ON DRAG_OVER ( dnd-object )
| ON DROP ( dnd-object )
| ON KEY ( key-name [,...] )
}
  dialog-statement
  [...]
```

where *action-attributes-display-array* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
| ROWBOUND
    [,...] }
```

where *action-attributes-listmod-triggers* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
```

```
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *dialog-statement* is one of:

```
{ statement
| EXIT DISPLAY
| CONTINUE DISPLAY
| ACCEPT DISPLAY
}
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

where *control-attribute* is:

```
{ ACCEPT [ = boolean ]
| CANCEL [ = boolean ]
| KEEP CURRENT ROW [ = boolean ]
| HELP = help-number
| COUNT = row-count
| UNBUFFERED [ = boolean ]
| DETAILACTION = action-name
| DOUBLECLICK = action-name
| ACCESSORYTYPE = { DETAILBUTTON | DISCLOSUREINDICATOR | CHECKMARK }
}
```

1. *array* is a static or dynamic array containing the records you want to display.
2. *screen-array* is the name of the screen array used to display data.
3. *help-number* is an integer that associates a help message number with the instruction.
4. *action-name* identifies an action that can be executed by the user.
5. *seconds* is an integer literal or variable that defines a number of seconds.
6. *row-index* identifies the program variable which holds the row index corresponding to the tree view node that has been expanded or collapsed.
7. *dnd-object* references a `ui.DragDrop` variable defined in the scope of the dialog.
8. *key-name* is an hot-key identifier (such as `F11` or `Control-z`).
9. *statement* is any instruction supported by the language.
10. *row-count* defines the total number of rows for a static array.
11. *boolean* is a boolean expression that evaluates to `TRUE` or `FALSE`.
12. *action-attributes* are dialog-specific action attributes.

DISPLAY ARRAY programming steps

Follow this procedure to use the `DISPLAY ARRAY` dialog instruction.

The following steps describe how to use the `DISPLAY ARRAY` statement:

1. Create a form specification file containing a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the rows.
2. Make sure that the program controls interruption handling with `DEFER INTERRUPT`, to manage the validation/cancellation of the interactive dialog.
3. Define an array of records with the `DEFINE` instruction. The members of the program array must correspond to the elements of the screen array, by number and data types. Static or a dynamic

arrays can be used for the full list mode, but the paged mode requires a dynamic array. For new developments, use dynamic arrays in both cases.

4. Open and display the form, using `OPEN WINDOW WITH FORM` or the `OPEN FORM` / `DISPLAY FORM` instructions.
5. If you want to use the full list mode, fill the program array with data, typically with a result set cursor, counting the number of program records being filled with retrieved data.
6. Set the `INT_FLAG` variable to `FALSE`.
7. Write the `DISPLAY ARRAY` statement block. When using a static array, specify the number of rows with the `COUNT` attribute in the `ATTRIBUTES` clause, or call the `SET_COUNT()` function before the dialog block. With dynamic arrays, the number of rows is automatically known by the dialog. Consider using the `UNBUFFERED` mode in new developments.
8. If you want to use the paged mode, define the total number of rows with the `COUNT` attribute (can be -1 for infinite number of rows), and add the `ON FILL BUFFER` clause that will contain the code to fill the dynamic array with the expected rows from `fgl_dialog_getBufferStart()` to `fgl_dialog_getBufferLength()`.
9. If multi-row selection is needed, call the `ui.Dialog.setSelectionMode()` method in `BEFORE DISPLAY` to enable this mode.
10. Inside the `DISPLAY ARRAY` block, control the behvior of the instruction with `BEFORE ROW`, `AFTER ROW` and `ON ACTION` blocks.
11. After the interaction statement block, test the `INT_FLAG` predefined variable to check if the dialog was canceled (`INT_FLAG=TRUE`) or validated (`INT_FLAG=FALSE`). If the `INT_FLAG` variable is `TRUE`, reset it to `FALSE` to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.
12. If needed, get the current row with the `ARR_CURR()` built-in function after dialog execution. During dialog execution, you can also use `DIALOG.getCurrentRow()`.

Using read-only record lists

To use read-only record lists, you must understand how they work and how to structure the code.

Variable binding in DISPLAY ARRAY

The `DISPLAY ARRAY` statement binds the members of the array of record to the screen array fields specified with the `TO` keyword. Array members and screen array fields are bound by position (i.e. not by name). The number of members in the program array must match the number of fields in the screen record (that is, in a single row of the screen array).

```
SCHEMA stock
DEFINE cust_arr DYNAMIC ARRAY OF customer.*
...
DISPLAY ARRAY cust_arr TO sr.*
        ATTRIBUTES(UNBUFFERED)
   ...
END DISPLAY
```

Keep in mind that array members are bound to screen array fields by position, so you must make sure that the members of the array are defined in the same order as the screen array fields.

Note that the array is usually defined with a flat list of members with `ARRAY OF RECORD / END RECORD`. However, the array can be structured with sub-records and still be used with a `DISPLAY ARRAY` dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the `IMAGECOLUMN` attribute):

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
                    item_data RECORD LIKE items.*,
                    it_image STRING,
```

```
                    it_count INTEGER
                END RECORD
...
DISPLAY ARRAY a_items TO sr.*
   ...
```

When using the UNBUFFERED attribute, the instruction is sensitive to program variable changes. This means that you do not have to DISPLAY the values; setting the program variable used by the dialog automatically displays the data in the corresponding form field.

```
ON ACTION change
   LET arr[arr_curr()].field1 = newValue()
```

If the program array has the same structure as a database table (this is the case when the array is defined with a DEFINE LIKE clause), you may not want to display/use some of the columns. You can achieve this by using PHANTOM fields in the screen array definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

DISPLAY ARRAY instruction configuration

This section describes the options that can be specified in the ATTRIBUTES clause of the DISPLAY ARRAY instruction. The options of the ATTRIBUTES clause override all default attributes and temporarily override any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields. With the DISPLAY ARRAY statement, the INVISIBLE attribute is ignored.

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help the DISPLAY ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

COUNT option

When using a dynamic array, the number of rows to be displayed is defined by the number of elements in the dynamic array; the COUNT attribute is ignored.

When using a static array or the paged mode, the number of rows to be displayed is defined by the COUNT attribute. You can also use the SET_COUNT( ) built-in function, but it is supported for backward compatibility only. If you don't know the total number of rows for the paged mode, you can specify -1 for the COUNT attribute (or in the SET_COUNT( ) call before the dialog block): With COUNT=-1, the dialog will ask for rows by executing ON FILL BUFFER until you provide less rows as asked, or if you reset the number of rows to a value higher as -1 with ui.Dialog.setArrayLength().

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the default accept action. Use this attribute when you want to avoid dialog validation, or if you need to write a specific validation procedure by using ACCEPT DISPLAY.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. Use this attribute when you only need a validation action (accept), or when you want to write a specific cancellation procedure by using EXIT DISPLAY.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

DOUBLECLICK option

The DOUBLICKCLICK option can be used to define the action that will be fired when the user chooses a row from the list. On front-end platforms using a mouse-device, this corresponds to a physical double-click on a row with the mouse. On mobile front-ends, this corresponds to a tap on the row with a finger. Note that this attribute can also be defined for the TABLE/TREE containers in form files; DOUBLECLICK in DISPLAY ARRAY attributes has a higher precedence as DOUBLECLICK in the form file. For more details, see Defining the action for a row choice on page 1360.

DETAILACTION option

> **Important:** This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1369.

ACCESSORTYPE option

> **Important:** This feature is only for mobile platforms.

The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on a iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or checkmark icon. For more details, see Row configuration on iOS devices on page 1369.

Default actions in DISPLAY ARRAY

When an DISPLAY ARRAY instruction executes, the runtime system creates a set of default actions.

According the invoked default action, field validation occurs and different DISPLAY ARRAY control blocks are executed.

This table lists the default actions created for this dialog:

Table 272: Default actions created for the DISPLAY ARRAY dialog

Default action	Description
accept	Validates the DISPLAY ARRAY dialog (validates current row selection) *Creation can be avoided with* ACCEPT *attribute.*
cancel	Cancels the DISPLAY ARRAY dialog (no validation, INT_FLAG is set to TRUE) *Creation can be avoided with* CANCEL *attribute.*
close	By default, cancels the DISPLAY ARRAY dialog (no validation, INT_FLAG is set to TRUE)

Default action	Description
	Default action view is hidden. See Implementing the close action on page 1337.
`help`	Shows the help topic defined by the `HELP` clause. *Only created when a* `HELP` *clause is defined.*
`nextrow`	Moves to the next row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`prevrow`	Moves to the previous row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`firstrow`	Moves to the first row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`lastrow`	Moves to the last row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`find`	Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. *Only created if the context allows built-in find.*
`findnext`	Seeks to the next row matching the value entered during the fglfind dialog. *Only created if the context allows built-in find.*

The accept and cancel default actions can be avoided with the `ACCEPT` and `CANCEL` dialog control attributes:

```
DISPLAY ARRAY arr TO sr.* ATTRIBUTES( CANCEL=FALSE, ... )
  ...
```

DISPLAY ARRAY data blocks

Data blocks are dialog triggers that are invoked when the dialog controller needs data to feed the view with values.

Such blocks are typically used when record list data is provided dynamically, with the display array paged mode of when implementing dynamic tree-views.

ON FILL BUFFER block
The `ON FILL BUFFER` block is used to fill a page of rows into the dynamic array, according to an offset and a number of rows.

This data block is used in the `DISPLAY ARRAY` blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.

ON EXPAND block
The `ON EXPAND` block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are added according to the nodes opened by the end user.

ON COLLAPSE block
The `ON COLLAPSE` block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are removed according to the nodes closed by the end user.

DISPLAY ARRAY control blocks
DISPLAY ARRAY control blocks execution order

This table shows the order in which the runtime system executes the control blocks in the `DISPLAY ARRAY` instruction, according to the user action:

Table 273: Control blocks execution order in `DISPLAY ARRAY`

Context / User action	Control Block execution order
Entering the dialog	**1.** `BEFORE DISPLAY` **2.** `BEFORE ROW`
Moving to a different row	**1.** `AFTER ROW` (the current row) **2.** `BEFORE ROW` (the new row)
Validating the dialog	**1.** `AFTER ROW` **2.** `AFTER DISPLAY`
Canceling the dialog	**1.** `AFTER ROW` **2.** `AFTER INPUT`
Firing the insert or append action for the `ON INSERT` block	**1.** `AFTER ROW` **2.** `ON INSERT` **3.** `BEFORE ROW`
Firing the delete action for the `ON DELETE` block	**1.** `AFTER ROW` **2.** `ON DELETE` **3.** `BEFORE ROW`

BEFORE DISPLAY block

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the `BEFORE DISPLAY` is only executed once when the dialog is started.

The BEFORE DISPLAY block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a DISPLAY ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE DISPLAY block is executed when a DISPLAY ARRAY list gets the focus.

BEFORE DISPLAY is executed before the BEFORE ROW block.

In this example the BEFORE DISPLAY block enables an action and displays a message:

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
       CALL DIALOG.setActionActive("print_list", TRUE)
       MESSAGE "You are now in the list of items"
```

AFTER DISPLAY block

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular DISPLAY ARRAY instruction, or when used as parallel dialog, the AFTER DISPLAY is only executed once when dialog is ended.

You typically implement dialog finalization in this block.

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       DISPLAY "Current row is: ", arr_curr()
```

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a DISPLAY ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER DISPLAY block is executed when a DISPLAY ARRAY list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER DISPLAY is executed after the AFTER ROW block.

In this example, the AFTER DISPLAY block disables an action that is specific to the current list:

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

BEFORE ROW block

BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE ROW block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, BEFORE ROW will be executed for the current row, but only if there are data rows in the array.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.

In this example, the BEFORE ROW block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
   ...
   BEFORE ROW
     MESSAGE "We are on row # ", arr_curr()
   ...
```

BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the BEFORE DISPLAY or BEFORE INPUT blocks instead.

In DISPLAY ARRAY, BEFORE ROW is executed after the BEFORE DISPLAY block. In INPUT ARRAY, BEFORE ROW is executed before the BEFORE INSERT and BEFORE FIELD blocks and after the BEFORE INPUT blocks.

When the procedural dialog starts, BEFORE ROW will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, BEFORE ROW will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular DISPLAY ARRAY or INPUT ARRAY. In singular dialogs, the BEFORE ROW block is always executed when the dialog starts (and there are rows in the array).

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.

In this example the BEFORE ROW block displays a message with the current row number:

```
   DISPLAY ARRAY p_items TO s_items.*
     BEFORE ROW
       MESSAGE "We are in items, on row #", DIALOG.getCurrentRow("s_items")
```

AFTER ROW block

AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

AFTER ROW and temporary rows in INPUT ARRAY

> **Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The AFTER ROW block will be executed for the temporary row, but ui.Dialog.getCurrentRow()/arr_curr() will be one row greater than ui.Dialog.getArrayLength()/ARR_COUNT(). In this case, you should ignore the AFTER ROW event. For example, you should not try to execute a NEXT FIELD or CONTINUE INPUT instruction, nor should you try to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.**

In this example, the AFTER ROW block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   AFTER ROW
      LET r = DIALOG.getCurrentRow("s_items")
      IF r <= DIALOG.getArrayLength("s_items") THEN
        IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
           ERROR "Item quantity is not valid"
           NEXT FIELD item_quantity'
         END IF
      END IF
```

Another way to handle the case of temporary rows in AFTER ROW is to use a flag to know if the AFTER INSERT block was executed: The AFTER INSERT block is not executed if the temporary row is automatically removed. By setting a first value in BEFORE INSERT and changing the flag in AFTER INSERT, you can detect if the row was permanently added to the list:

```
INPUT ARRAY p_items FROM s_items.*
  ...
  BEFORE INSERT
    LET op = "T"
    ...
  AFTER INSERT
    LET op = "I"
    ...
  AFTER ROW
    IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
```

```
         NEXT FIELD item_quantity
        END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
                         VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
...
```

DISPLAY ARRAY interaction blocks

ON ACTION block

The `ON ACTION` *`action-name`* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
  ON ACTION action-name
     instruction
     ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
   ON ACTION zoom
      CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
   ON ACTION zoom INFIELD cust_city
      CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
   ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (`*`key-name`*`)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *`seconds`* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

Important: The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON APPEND block

Similarly to the `ON INSERT` control block, the `ON APPEND` trigger can be used to enable row creation during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an `ON ACTION append` interaction block and the `ON APPEND` block is used, the compiler will stop with error -8408.

When the user fires the append action, the dialog first execute the user code of the `AFTER ROW` block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the `ON APPEND` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular `INPUT` statement, to let the end user enter data for the new created row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `SCR_LINE()`:

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON APPEND
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the new row is kept in the program array, and the `BEFORE ROW` block is executed for the new created row.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the new row is removed from the program array, and the `BEFORE ROW` block is executed for the row that was existing at the current position, before the new row was created.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON APPEND` block.

The append action is disabled if the maximum number of rows is reached.

If needed, the `ON APPEND` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON APPEND ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON INSERT block

Similarly to the `ON APPEND` control block, the `ON INSERT` trigger can be used to enable row creation during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an `ON ACTION insert` interaction block and the `ON INSERT` block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the `AFTER ROW` block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the `ON INSERT` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular INPUT statement, to let the end user enter data for the new created row. This is typically done with an INPUT binding explicitly array fields to the screen record fields. The new current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by scr_line():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON INSERT
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the new row is kept in the program array, and the BEFORE ROW block is executed for the new created row.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the new row is removed from the program array, and the BEFORE ROW block is executed for the row that was existing at the current position, before the new row was created.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON INSERT block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the ON INSERT handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON INSERT ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON UPDATE block

The ON UPDATE trigger can be used to enable row modification during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the TABLE container in the form by defining the DOUBLECLICK attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an ON ACTION update interaction block and the ON UPDATE block is used, the compiler will stop with error -8408.

When the user fires the *update* action, the dialog executes the user code of the ON UPDATE block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular INPUT statement, to let the end user modify the data of the current row. This is typically done with an INPUT binding explicitly array fields to the screen record fields, with the WITHOUT DEFAULTS clause. The current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by scr_line():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON UPDATE
    INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the modified values of the current row are kept in the program array.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the old values of the current row are restored in the program array.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON UPDATE block.

If needed, the ON UPDATE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON UPDATE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON DELETE block

The ON DELETE trigger can be used to enable row deletion during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an ON ACTION delete interaction block and the ON DELETE block is used, the compiler will stop with error -8408.

When the user fires the delete action, the dialog executes the user code of the ON DELETE block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with arr_curr():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON DELETE
    IF fgl_winQuestion("Delete",
          "Do you want to delete this record?",
          "yes", "no|yes", "help", 0) == "no"
    THEN
       LET int_flag = TRUE
    END IF
    ...
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the current row is deleted from the program array, and the BEFORE ROW block is executed for the next row in the list.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the current row is kept in the program array, and the BEFORE ROW block is executed again for the current row.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON DELETE block.

If needed, the ON DELETE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON DELETE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON SELECTION CHANGE block

The ON SELECTION CHANGE trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a DISPLAY ARRAY dialog. If this block is defined, multi-row selection is automatically enableb. However, the feature can be enabled/disabled with the setSelectionMode() dialog method.

ON SORT block

The `ON SORT` interfaction block can be used to detect when rows have to be sorted in a `DISPLAY ARRAY` or `INPUT ARRAY` dialog.

`ON SORT` is used in two different contexts:

1. In a regular `DISPLAY ARRAY` / `INPUT ARRAY` dialog (not using paged mode), the `ON SORT` trigger can be used to detect that a list sort was performed. In this case, the (visual) sort is already done by the runtime system and the `ON SORT` block is only used to execute post-sort tasks, such as displaying current row information, by using arrayToVisualIndex() dialog method. It is also possible to get the sort column and order with the `getSortKey()` and `getSortSelection()` dialog methods.
2. In a `DISPLAY ARRAY` using paged mode (`ON FILL BUFFER`), built-in row sorting is not available because data is provided by pages. Use the `ON SORT` trigger to detect a sort request and perform a new SQL query to re-order the rows. In this case, sort column and order is available with the `getSortKey()` and `getSortSelection()` dialog methods. See Populating a DISPLAY ARRAY on page 1372.

ON DRAG_START block

The `ON DRAG_START` block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the `ON DRAG_START` block, the program typically specifies the type of drag & drop operation by calling `ui.DragDrop.setOperation()` with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with `ui.DragDrop.addPossibleOperation()`. The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with `ui.DragDrop.setMimeType()` and `ui.DragDrop.setBuffer()` methods.

Example:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    CALL dnd.setOperation("move") -- Move is the default operation
    CALL dnd.addPossibleOperation("copy") -- User can toggle to copy if
 needed
    CALL dnd.setMimeType("text/plain")
    CALL dnd.setBuffer(arr[arr_curr()].cust_name)
    ...
END DISPLAY
```

ON DRAG_FINISHED block

Execution of the `ON DRAG_FINISHED` block notifies the dialog where the drag started that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns `NULL`. If `NULL` is returned, the `ON DRAG_FINISHED` trigger can be ignored.

In cases of successful moves to a target out of the current `DISPLAY ARRAY`, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an `ON DRAG_FINISHED` execution after the row was dropped into B, and should remove the row from the list A.

The `ON DRAG_FINISHED` interaction block is optional.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    LET last_dragged_row = arr_curr()
    ...
  ON DRAG_FINISHED (dnd)
    IF dnd.getOperation() == "move" THEN
      CALL DIALOG.deleteRow(last_dragged_row)
    END IF
    ...
END DISPLAY
```

ON DRAG_ENTER block

When the `ON DROP` control block is defined, the `ON DRAG_ENTER` block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no `ON DRAG_ENTER` block is defined. However, when `ON DROP` is defined, you should also define `ON DRAG_ENTER` to deny the drop of objects with an unsupported MIME type that come from other applications.

The program can decide to deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the `ui.DragDrop.selectMimeType()` method. This method takes the MIME type as a parameter and returns `TRUE` if the passed MIME type is used. You can call this method several times to check the availability of different MIME types.

You may also define the visual effect when flying over the target list with `ui.DragDrop.setFeedback()`.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF dnd.selectMimeType("text/plain") THEN
      CALL dnd.setOperation("copy")
      CALL dnd.setFeedback("all")
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
    ...
END DISPLAY
```

Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the `ON DRAG_OVER` trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse flies over the rows, according to the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the `ui.DragDrop.setFeedback()` method, typically called in the `ON DRAG_ENTER` block.

The values to pass to the `setFeedback()` method to get the desired visual effects described are respectively:

1. `insert` (default)
2. `select`
3. `all`

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF canDrop() THEN
      CALL dnd.setOperation(NULL)
    ELSE
      CALL dnd.setFeedback("select")
    END IF
    ...
END DISPLAY
```

ON DRAG_OVER block

When the `ON DROP` control block is defined, the `ON DRAG_OVER` block will be executed after `ON DRAG_ENTER`, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

`ON DRAG_OVER` will be called only once per row, even if the mouse cursor moves over the row.

In the `ON DRAG_OVER` block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the `ON DRAG_OVER` block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous `ON DRAG_ENTER` or `ON DRAG_OVER` events, or the operation selected by the end user, if it can toggle between copy and move. Thus, `ON DRAG_OVER` can occur even if the mouse position has not changed.

If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous `ON DRAG_OVER` event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

`ON DRAG_OVER` will not be called if drop has been disabled in `ON DRAG_ENTER` with `ui.DragDrop.setOperation(NULL)`

`ON DRAG_OVER` is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    IF arr[dnd.getLocationRow()].acceptsCopy THEN
      CALL dnd.setOperation("copy")
```

```
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
    ...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the `ON DRAG_OVER` trigger and query the `ui.DragDrop` object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the `ON DRAG_FINISHED` trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
    END CASE
    ...
  ON DROP (dnd)
    ...
END DISPLAY
```

ON DROP block

To enable drop actions on a list, you must define the `ON DROP` block; otherwise the list will not accept drop actions.

The `ON DROP` block is executed after the end user has released the mouse button to drop the dragged object. `ON DROP` will not occur if drop has been denied in the previous `ON DRAG_OVER` event or in `ON DRAG_ENTER` with a call to `ui.DragDrop.setOperation(NULL)`.

The program might also check the MIME type of the dragged object with `ui.DragDrop.getSelectedMimeType()`, and then call the `ui.DragDrop.getBuffer()` method to retrieve drag & drop data from external applications.

Ideally the drop operation should be accepted (no additional call to `ui.DragDrop.setOperation()`).

In this block, the `ui.DragDrop.getLocationRow()` method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
```

```
    ...
END DISPLAY
```

If the drag & drop operations are local to the same list or tree-view controller, you can use the `ui.DragDrop.dropInternal()` method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This `ON DROP` code example uses the `dropInternal()` method:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ...
  ...
  ON DROP (dnd)
    CALL dnd.dropInternal()
    ...
END DISPLAY
```

If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()` , the new row must be inserted before `getLocationRow()`; otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

DISPLAY ARRAY control instructions
CONTINUE DISPLAY instruction

`CONTINUE DISPLAY` skips all subsequent statements in the current control block and gives the control back to the dialog.

The `CONTINUE DISPLAY` instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not `AFTER DISPLAY`, further control blocks might be executed according to the context.

Actually, `CONTINUE DISPLAY` just instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of `GOTO end_of_control_block`). However, when executed in `AFTER DISPLAY`, the focus returns to the current row in the list, giving the user another chance to browse and select a row. In this case the `BEFORE ROW` of the current row will be invoked.

EXIT DISPLAY instruction

Use the `EXIT DISPLAY` to terminate the `DISPLAY ARRAY` instruction and resume the program execution at the instruction immediately following the `DISPLAY ARRAY` block.

ACCEPT DISPLAY instruction

The `ACCEPT DISPLAY` instruction validates the `DISPLAY ARRAY` instruction and exits the dialog block.

The `AFTER DISPLAY` control block will be executed. Statements after `ACCEPT DISPLAY` will not be executed.

Examples
Various examples using the `DISPLAY ARRAY` dialog instruction.
Example 1: DISPLAY ARRAY using full list mode

Form definition file "custlist.per":

```
SCHEMA shop

LAYOUT
TABLE
```

```
{
 Id       Name         LastName
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
}
END
END

TABLES
  customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname;
END

INSTRUCTIONS
  SCREEN RECORD srec[6] (customer.*);
END
```

Application:

```
SCHEMA shop

MAIN

  DEFINE cnt INTEGER
  DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*

  DATABASE shop

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  DECLARE c1 CURSOR FOR
    SELECT id, fname, lname FROM customer
  LET cnt = 1
  FOREACH c1 INTO arr[cnt].*
    LET cnt = cnt + 1
  END FOREACH
  CALL arr.deleteElement(cnt)

  DISPLAY ARRAY arr TO srec.*
    ON ACTION print
       DISPLAY "Print a report"
  END DISPLAY

END MAIN
```

Example 2: DISPLAY ARRAY using paged mode

Form definition file "custlist.per" (same as in Example 1)

Application:

```
SCHEMA shop
```

```
MAIN

  DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
  DEFINE cnt, ofs, len, row, i INTEGER

  DATABASE shop

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  DECLARE c1 SCROLL CURSOR FOR
         SELECT id, fname, lname FROM customer
  OPEN c1
  DISPLAY ARRAY arr TO srec.* ATTRIBUTES(COUNT=-1)
    ON FILL BUFFER
       LET ofs = fgl_dialog_getBufferStart()
       LET len = fgl_dialog_getBufferLength()
       LET row = ofs
       FOR i=1 TO len
          FETCH ABSOLUTE row c1 INTO arr[i].*
          IF SQLCA.SQLCODE!=0 THEN
            CALL DIALOG.setArrayLength("srec",row-1)
            EXIT FOR
          END IF
          LET row = row + 1
       END FOR
    AFTER DISPLAY
       IF NOT int_flag THEN
          DISPLAY "Selected customer is #"
                  || arr[arr_curr()-ofs+1].id
       END IF
  END DISPLAY
END MAIN
```

Example 3: DISPLAY ARRAY using modification triggers

Form definition file "custlist.per" (same as in Example 1)

Application:

```
SCHEMA shop

MAIN

  DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
  DEFINE cnt, ofs, len, row, i INTEGER

  DATABASE shop

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  DECLARE c1 CURSOR FOR
    SELECT id, fname, lname FROM customer
  LET cnt = 1
  FOREACH c1 INTO arr[cnt].*
    LET cnt = cnt + 1
  END FOREACH
  CALL arr.deleteElement(cnt)

  DISPLAY ARRAY arr TO srec.* ATTRIBUTES(UNBUFFERED)
        ON UPDATE
            INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM
 srec[scr_line()].* ;
```

```
        ON INSERT
            INPUT arr[arr_curr()].* FROM srec[scr_line()].* ;
        ON APPEND
            INPUT arr[arr_curr()].* FROM srec[scr_line()].* ;
        ON DELETE
            MENU "Delete" ATTRIBUTES(STYLE="dialog",
                                     COMMENT="Do you want to delete the current
 row?")
              COMMAND "Yes" LET int_flag = FALSE
              COMMAND "No"  LET int_flag = TRUE
            END MENU
  END DISPLAY

END MAIN
```

Editable record list (INPUT ARRAY)

The `INPUT ARRAY` instruction provides always-editable record list handling in an application form.

  - Example 3: INPUT ARRAY using a dynamic array on page 1125
  - Example 4: INPUT ARRAY updating the database table on page 1126

Understanding the INPUT ARRAY instruction

The `INPUT ARRAY` is a dialog instruct designed to browse and modify a list of record, binding a static or dynamic array model to a screen array of the current displayed form.

> **Important:** This feature is not supported on mobile platforms.

An `INPUT ARRAY` instruction supports additional features, built-in sort and search, multi-row selection and list modification triggers. For a detailed description of these features, see Table views on page 1345.

Use the `INPUT ARRAY` instruction to let the end user update, delete and create new records in a list, after fetching a result set from the database. The result set is produced with a database cursor executing a `SELECT` statement. The `SELECT` SQL statement is usually completed at runtime with a `WHERE` clause produced from a `CONSTRUCT` dialog.

The `INPUT ARRAY` instruction associates a program array of records with a screen-array defined in a form so that the user can update the list of records. The `INPUT ARRAY` statement activates the current form (the form that was most recently displayed or the form in the current window.)

During the `INPUT ARRAY` execution, the user can edit or delete existing rows, insert new rows, and move inside the list of records. The program controls the behavior of the instruction with control blocks such as `BEFORE DELETE`, `BEFORE INSERT`, etc.

To terminate the INPUT ARRAY execution, the user can validate (or cancel) the dialog to commit (or invalidate) the modifications made in the list of records.

When the statement completes execution, the program must test the INT_FLAG variable to check if the dialog was validated (or canceled) and then use INSERT, DELETE, or UPDATE SQL statements to modify the appropriate database tables. The database can also be updated during the execution of theINPUT ARRAY statement.

Syntax of INPUT ARRAY instruction
The INPUT ARRAY supports data entry by users into a screen array and stores the entered data in an array of records.

Syntax

```
INPUT ARRAY array
  [ WITHOUT DEFAULTS ]
  FROM screen-array.*
  [ ATTRIBUTES ( { display-attribute
                 | control-attribute
                 } [,...] ) ]
  [ HELP help-
number ]
[ dialog-control-block
   [...]
END INPUT ]
```

where *dialog-control-block* is one of:

```
{ BEFORE INPUT
| AFTER INPUT
| AFTER DELETE
| BEFORE ROW
| AFTER ROW
| BEFORE FIELD field-spec  [,...]
| AFTER FIELD field-spec  [,...]
| ON ROW CHANGE
| ON CHANGE field-spec [,...]
| ON IDLE seconds
| ON TIMER seconds
| ON ACTION action-name
             [ INFIELD field-spec ]
             [ ATTRIBUTES ( action-attributes-input-array ) ]
| ON KEY ( key-name [,...] )
| BEFORE INSERT
| AFTER INSERT
| BEFORE DELETE
}
  dialog-statement
  [...]
```

where *action-attributes-input-array* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| VALIDATE = NO
| CONTEXTMENU = { YES | NO | AUTO }
| ROWBOUND
    [,...] }
```

where *dialog-statement* is one of:

```
{ statement
| ACCEPT INPUT
| CONTINUE INPUT
| EXIT INPUT
| NEXT FIELD { CURRENT | NEXT | PREVIOUS | field-spec }
| CANCEL DELETE
| CANCEL INSERT
}
```

where *field-spec* identifies a unique field with one of:

```
{ field-name
| table-name.field-name
| screen-array.field-name
| screen-record.field-name
}
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

where *control-attribute* is:

```
{ ACCEPT [ = boolean ]
| APPEND ROW [ = boolean ]
| AUTO APPEND [ = boolean ]
| CANCEL [ = boolean ]
| COUNT = row-count
| DELETE ROW [ = boolean ]
| FIELD ORDER FORM
| HELP = help-number
| INSERT ROW [ = boolean ]
| KEEP CURRENT ROW [ = boolean ]
| MAXCOUNT = max-row-count
| UNBUFFERED [ = boolean ]
| WITHOUT DEFAULTS [ = boolean ]
}
```

1. *array* is the array of records that will be filled by the `INPUT ARRAY` statement.
2. *help-number* is an integer that allows you to associate a help message number with the instruction.
3. *field-name* is the identifier of a field of the current form.
4. *table-name* is the identifier of a database table of the current form.
5. *screen-record* is the identifier of a screen record of the current form.
6. *screen-array* is the screen array that will be used in the form.
7. *action-name* identifies an action that can be executed by the user.
8. *seconds* is an integer literal or variable that defines a number of seconds.
9. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
10. *statement* is any instruction supported by the language.
11. *row-count* defines the initial number of rows for a static array.
12. *max-row-count* is the maximum number of rows that can be created.
13. *boolean* is a boolean expression that evaluates to `TRUE` or `FALSE`.
14. *action-attributes* are dialog-specific action attributes.

INPUT ARRAY programming steps

The following steps describe how to use the INPUT ARRAY statement:

1. Create a form specification file containing a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the rows.
2. Make sure that the program controls interruption handling with DEFER INTERRUPT, to manage the validation/cancellation of the interactive dialog.
3. Define an array of records with the DEFINE instruction. The members of the program array must correspond to the elements of the screen array, by number and data types. If you want to input data from a reduced set of columns, you must define a second screen array, containing the limited list of form fields, in the form file. You can then use the second screen array in an INPUT ARRAY a FROM sa.* instruction.
4. Open and display the form, using a OPEN WINDOW WITH FORM or the OPEN FORM / DISPLAY FORM instructions.
5. If needed, fill the program array with data, for example with a result set cursor, counting the number of program records being filled with retrieved data.
6. Set the INT_FLAG variable to FALSE.
7. Write the INPUT ARRAY statement to handle data input.
8. Inside the INPUT ARRAY statement, control the behavior of the instruction with control blocks such as BEFORE INPUT, BEFORE INSERT, BEFORE DELETE, BEFORE ROW, BEFORE FIELD,AFTER INSERT,AFTER DELETE,AFTER FIELD,AFTER ROW, AFTER INPUT and ON ACTION blocks.
9. Get the new number of rows with the ARR_COUNT() built-in function or with DIALOG.getArrayLength().
10. After the interaction statement block, test the INT_FLAG predefined variable to check if the dialog was canceled (INT_FLAG=TRUE) or validated (INT_FLAG=FALSE). If the INT_FLAG variable is TRUE, you should reset it to FALSE to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

Using editable record lists

To use editable record lists, you must understand how they work and how to structure the code.

Variable binding in INPUT ARRAY

The INPUT ARRAY statement binds the members of the array of record to the screen array fields specified with the FROM keyword. Array members and screen array fields are bound by position (i.e. not by name). The number of members in the program array must match the number of fields in the screen record (that is, in a single row of the screen array).

```
SCHEMA stock
DEFINE cust_arr DYNAMIC ARRAY OF customer.*
...
INPUT ARRAY cust_arr FROM sr.*
        ATTRIBUTES(UNBUFFERED)
   ...
END INPUT
```

Keep in mind that array members are bound to screen array fields by position, so you must make sure that the members of the array are defined in the same order as the screen array fields.

Note that the array is usually defined with a flat list of members with ARRAY OF RECORD / END RECORD. However, the array can be structured with sub-records and still be used with an INPUT ARRAY dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the IMAGECOLUMN attribute):

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
```

```
                    item_data RECORD LIKE items.*,
                    it_image STRING,
                    it_count INTEGER
                END RECORD
...
INPUT ARRAY a_items FROM sr.*
   ...
```

When using a static array, the initial number of rows is defined by the COUNT attribute and the size of the array determines how many rows can be inserted. When using a dynamic array, the initial number of rows is defined by the number of elements in the dynamic array (the COUNT attribute is ignored), and the maximum rows is unlimited. For both static and dynamic arrays, the maximum number of rows the user can enter can be defined with the MAXCOUNT attribute.

The FROM clause binds the screen records in the screen array to the program records of the program array. The form can include other fields that are not part of the specified screen array, but the number of member variables in each record of the program array must equal the number of fields in each row of the screen array. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

The variables of the record array are the interface to display data or to get the user input through the INPUT ARRAY instruction. Always use the variables if you want to change some field values by program. When using the UNBUFFERED attribute, the instruction is sensitive to program variable changes. If you need to display new data during the INPUT ARRAY execution, use the UNBUFFERED attribute and assign the values to the program array row; the runtime system will automatically display the values to the screen:

```
INPUT ARRAY p_items FROM s_items.*
      ATTRIBUTES(UNBUFFERED)
  ON CHANGE code
    IF p_items[arr_curr()].code = "A34" THEN
      LET p_items[arr_curr()].desc = "Item A34"
    END IF
END INPUT
```

The runtime system adapts input and display rules to the data type of the array record members. If a member is declared with the DEFINE LIKE instruction and uses a column defined as SERIAL / SERIAL8 / BIGSERIAL, the runtime system will treat the field as if it was defined with the NOENTRY attribute in the form file. Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

The default order in which the focus moves from field to field in the screen array is determined by the declared order of the corresponding member variables, in the array of the record definition. The program OPTIONS instruction can also change the behavior of the INPUT ARRAY instruction, with the INPUT WRAP or FIELD ORDER FORM options.

By default the INPUT ARRAY instruction clears the program array when starting, unless you specify the WITHOUT DEFAULTS keywords or option. With this option, the dialog displays the program array rows in the screen fields. Unlike the INPUT dialog, the column default values defined in the form specification file with the DEFAULT attribute or in the database schema files are always used when a new row is inserted in the list.

If the program array has the same structure as a database table (this is the case when the array is defined with a DEFINE LIKE clause), you may not want to display/use some of the columns. You can achieve this by using PHANTOM fields in the screen array definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

INPUT ARRAY instruction configuration

This section describes the options that can be specified in the ATTRIBUTES clause of the INPUT ARRAY instruction. The options of the ATTRIBUTES clause override all default attributes and temporarily override

any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields. With the INPUT ARRAY statement, the INVISIBLE attribute is ignored.

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

The WITHOUT DEFAULT clause defines whether the program array elements are populated (and to be displayed) when the dialog begins. Once the dialog is started, existing rows are always handled as records to be updated in the database (i.e. WITHOUT DEFAULTS=TRUE), while newly created rows are handled as records to be inserted in the database (i.e. WITHOUT DEFAULTS=FALSE). In other words, the REQUIRED and DEFAULT attributes defined in the form are only used for new created rows.

It is unusual to implement an INPUT ARRAY with no WITHOUT DEFAULTS option, because the data of the program variables would be cleared and the list empty. So, you typically use the WITHOUT DEFAULT clause in INPUT ARRAY. In a singular INPUT ARRAY, the default is WITHOUT DEFAULTS=FALSE.

FIELD ORDER FORM option

By default, the form tabbing order is defined by the variable list in the binding specification. You can control the tabbing order by using the FIELD ORDER FORM attribute. When this attribute is used, the tabbing order is defined by the TABINDEX attribute of the form items. With FIELD ORDER FORM, if you jump from one field to a another with the mouse, the BEFORE FIELD / AFTER FIELD triggers of intermediate fields are not executed (actually, the Dialog.fieldOrder FGLPROFILE entry is ignored.)

If the form uses a TABLE container, the front-end resets the tab indexes when the user moves columns around. This way, the visual column order always corresponds to the input tabbing order. The order of the columns in an editable list can be important; you may want to freeze the table columns with the UNMOVABLECOLUMNS attribute.

UNBUFFERED option

The UNBUFFERED attribute indicates that the dialog must be sensitive to program variable changes. When using this option, you bypass the traditional "buffered" mode.

When using the traditional " buffered" mode, program variable changes are not automatically displayed to form fields; You need to execute a DISPLAY TO or DISPLAY BY NAME. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of the current field is to use GET_FLDBUF().

If the "unbuffered" mode is used, program variables and form fields are automatically synchronized. You don't need to display explicitly values with a DISPLAY TO or DISPLAY BY NAME. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. You can also use the SET_COUNT() built-in function, but it is supported for backward compatibility only. The COUNT option is ignored when using a dynamic array. If you specify the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.

MAXCOUNT option

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter, when using both static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using ACCEPT INPUT.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using EXIT INPUT.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

APPEND ROW option

The APPEND ROW attribute can be set to FALSE to avoid the append default action, and deny the user to add rows at the end of the list. If APPEND ROW =FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

INSERT ROW option

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and deny the user to insert new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and deny the user to remove rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, an new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

Default actions in INPUT ARRAY

When an INPUT ARRAY instruction executes, the runtime system creates a set of default actions.

According the invoked default action, field validation occurs and different INPUT ARRAY control blocks are executed.

This table lists the default actions created for this dialog:

Table 274: Default actions for INPUT ARRAY

Default action	Description
accept	Validates the INPUT ARRAY dialog (validates fields and leaves the dialog) *Creation can be avoided with* ACCEPT *attribute.*
cancel	Cancels the INPUT ARRAY dialog (no validation, INT_FLAG is set to TRUE) *Creation can be avoided with* CANCEL *attribute.*
close	By default, cancels the INPUT ARRAY dialog (no validation, INT_FLAG is set to TRUE) Default action view is hidden. See Implementing the close action on page 1337.
insert	Inserts a new row before current row. *Creation can be avoided with* INSERT ROW = FALSE *attribute.*
append	Appends a new row at the end of the list. *Creation can be avoided with* APPEND ROW = FALSE*attribute.*
delete	Deletes the current row. *Creation can be avoided with* DELETE ROW = FALSE*attribute.*
help	Shows the help topic defined by the HELP clause. *Only created when a* HELP*clause is defined.*
nextrow	Moves to the next row in a list displayed in one row of fields.

Default action	Description
	Only created if `DISPLAY ARRAY` *used with a screen record having only one row.*
`prevrow`	Moves to the previous row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`firstrow`	Moves to the first row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`lastrow`	Moves to the last row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *used with a screen record having only one row.*
`find`	Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. *Only created if the context allows built-in find.*
`findnext`	Seeks to the next row matching the value entered during the fglfind dialog. *Only created if the context allows built-in find.*

The insert, append, delete, accept and cancel default actions can be avoided with dialog control attributes:

```
INPUT ARRAY arr TO sr.* ATTRIBUTES( INSERT ROW=FALSE, CANCEL=FALSE, ... )
   ...
```

INPUT ARRAY control blocks
INPUT ARRAY control blocks execution order

This table shows the order in which the runtime system executes the control blocks in the `INPUT ARRAY` instruction, according to the user action:

Table 275: Control block execution order for INPUT ARRAY

Context / User action	Control Block execution order
Entering the dialog	**1.** `BEFORE INPUT` **2.** `BEFORE ROW` **3.** `BEFORE FIELD`
Moving to a different row from field A to field B	**1.** `ON CHANGE` (if value has changed for field A) **2.** `AFTER FIELD` (for field A in the row you leave) **3.** `AFTER INSERT` (if the row you leave was inserted or appended) or

Context / User action	Control Block execution order
	`ON ROW CHANGE` (if values have changed in the row you leave) **4.** `AFTER ROW` (for the row you leave) **5.** `BEFORE ROW` (the new current row) **6.** `BEFORE FIELD` (for field B in the new current row)
Moving from field A to field B in the same row	**1.** `ON CHANGE` (if value has changed for field A) **2.** `AFTER FIELD` (for field A) **3.** `BEFORE FIELD` (for field B)
Deleting a row	**1.** `BEFORE DELETE` (for the row to be deleted) **2.** `AFTER DELETE` (for the deleted row) **3.** `AFTER ROW` (for the deleted row) **4.** `BEFORE ROW` (for the new current row) **5.** `BEFORE FIELD` (field in the new current row)
Inserting a new row between rows	**1.** `ON CHANGE` (if value has changed in the field you leave) **2.** `AFTER FIELD` (for the row you leave) **3.** `AFTER INSERT` (if the row you leave was inserted or appended) or `ON ROW CHANGE` (if values have changed in the row you leave) **4.** `AFTER ROW` (for the row you leave) **5.** `BEFORE INSERT` (for the new created row) **6.** `BEFORE FIELD` (for the new created row)
Appending a new row at the end	**1.** `ON CHANGE` (if value has changed in the current field) **2.** `AFTER FIELD` (for the row you leave) **3.** `AFTER INSERT` (if the row you leave was inserted or appended) or `ON ROW CHANGE` (if values have changed in the row you leave) **4.** `AFTER ROW` (for the row you leave) **5.** `BEFORE ROW` (for the new created row) **6.** `BEFORE INSERT` (for the new created row) **7.** `BEFORE FIELD` (for the new created row)
Validating the dialog	**1.** `ON CHANGE` **2.** `AFTER FIELD` **3.** `AFTER INSERT` (if the current row was inserted or appended) or

Context / User action	Control Block execution order
	`ON ROW CHANGE` (if values have changed in the current row) **4.** `AFTER ROW` **5.** `AFTER INPUT`
Canceling the dialog	**1.** `AFTER ROW` **2.** `AFTER INPUT`

BEFORE INPUT block

BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `BEFORE INPUT` is only executed once when the dialog is started.

The `BEFORE INPUT` block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ...
   BEFORE INPUT
       MESSAGE "Input customer information"
       CALL DIALOG.setActionActive("check_info", is_super_user() )
       CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
   ...
```

The fields are initialized with the defaults values before the `BEFORE INPUT` block is executed. When the `INPUT` instruction uses the `WITHOUT DEFAULTS` option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the `DEFAULT` attributes of the form fields are used.

Use the `NEXT FIELD` control instruction in the `BEFORE INPUT` block, to jump to a specific field when the dialog starts.

BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE INPUT` block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `BEFORE INPUT` block.

`BEFORE INPUT` is executed after the `BEFORE DIALOG` block andbefore the `BEFORE ROW`, `BEFORE FIELD` blocks.

In this example, the `BEFORE INPUT` block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
   BEFORE INPUT
       CALL DIALOG.setActionActive("validate_order", TRUE)
```

AFTER INPUT block

AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER INPUT` is only executed once when dialog ends.

The AFTER INPUT block is executed after the user has validated or canceled the INPUT or INPUT ARRAY dialog with the accept or cancel default actions, or when the ACCEPT INPUT instruction is executed.

The AFTER INPUT block is not executed when the EXIT INPUT instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the NEXT FIELD instruction to force the dialog to continue. The CONTINUE INPUT instruction can be used instead of NEXT FIELD, when no particular field has to be select.

Before checking the validation rules, make sure that the INT_FLAG variable is FALSE: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
  ...

  AFTER INPUT
    IF NOT INT_FLAG THEN
       IF cust_rec.cust_address IS NOT NULL
          AND cust_rec.cust_zipcode IS NULL THEN
          ERROR "Address is incomplete, enter a zipcode."
          NEXT FIELD zipcode
       END IF
    END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER INPUT block is executed when the focus is lost by a group of fields driven by an INPUT or INPUT ARRAY sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the AFTER INPUT block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER INPUT is executed after the AFTER FIELD, AFTER ROW blocks and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER INPUT control block will keep the focus in the group of fields. Within an INPUT ARRAY sub-dialog, NEXT FIELD will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the AFTER INPUT block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
   AFTER INPUT
      IF NOT check_order_data(DIALOG) THEN
        NEXT FIELD CURRENT
      END IF
      CALL DIALOG.setFieldActive("validate_order", FALSE)
```

BEFORE ROW block

BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular `DISPLAY ARRAY`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `BEFORE ROW` block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, `BEFORE ROW` will be executed for the current row, but only if there are data rows in the array.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example, the `BEFORE ROW` block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
   ...
   BEFORE ROW
     MESSAGE "We are on row # ", arr_curr()
   ...
```

BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the `BEFORE DISPLAY` or `BEFORE INPUT` blocks instead.

In `DISPLAY ARRAY`, `BEFORE ROW` is executed after the `BEFORE DISPLAY` block. In `INPUT ARRAY`, `BEFORE ROW` is executed before the `BEFORE INSERT` and `BEFORE FIELD` blocks and after the `BEFORE INPUT` blocks.

When the procedural dialog starts, `BEFORE ROW` will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, `BEFORE ROW` will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular `DISPLAY ARRAY` or `INPUT ARRAY`. In singular dialogs, the `BEFORE ROW` block is always executed when the dialog starts (and there are rows in the array).

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example the `BEFORE ROW` block displays a message with the current row number:

```
   DISPLAY ARRAY p_items TO s_items.*
     BEFORE ROW
       MESSAGE "We are in items, on row #", DIALOG.getCurrentRow("s_items")
```

ON ROW CHANGE block

The `ON ROW CHANGE` block is executed in a list controlled by an `INPUT ARRAY`, when leaving the current row and when the row has been modified since it got the focus. This is typically used to detect row modification.

The code in ON ROW CHANGE will not be executed when leaving new rows created by the user with the default append or insert action. To detect row creation, you must use the BEFORE INSERT or AFTER INSERT control blocks.

The ON ROW CHANGE block is only executed if at least one field value in the current row has changed since the row was entered, and the modification flag of the field is set. The modified field(s) might not be the current field, and several field values can be changed. Values might have been changed by the user or by the program. The modification flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog instruction.

ON ROW CHANGE is executed after the AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row that has been changed.

You can, for example, code database modifications (UPDATE) in the ON ROW CHANGE block:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   ON ROW CHANGE
     LET r = DIALOG.getCurrentRow("s_items")
     UPDATE items SET
             items.item_code        = p_items[r].item_code,
             items.item_description = p_items[r].item_description,
             items.item_price       = p_items[r].item_price,
             items.item_updatedate  = TODAY
            WHERE items.item_num = p_items[r].item_num
```

AFTER ROW block

AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

AFTER ROW and temporary rows in INPUT ARRAY

> **Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The `AFTER ROW` block will be executed for the temporary row, but `ui.Dialog.getCurrentRow()`/`arr_curr()` will be one row greater than `ui.Dialog.getArrayLength()`/`ARR_COUNT()`. In this case, you should ignore the `AFTER ROW` event. For example, you should not try to execute a `NEXT FIELD` or `CONTINUE INPUT` instruction, nor should you try to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.**

In this example, the `AFTER ROW` block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   AFTER ROW
      LET r = DIALOG.getCurrentRow("s_items")
      IF r <= DIALOG.getArrayLength("s_items") THEN
        IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
           ERROR "Item quantity is not valid"
           NEXT FIELD item_quantity'
         END IF
      END IF
```

Another way to handle the case of temporary rows in `AFTER ROW` is to use a flag to know if the `AFTER INSERT` block was executed: The `AFTER INSERT` block is not executed if the temporary row is automatically removed. By setting a first value in `BEFORE INSERT` and changing the flag in `AFTER INSERT`, you can detect if the row was permanently added to the list:

```
INPUT ARRAY p_items FROM s_items.*
  ...
  BEFORE INSERT
    LET op = "T"
    ...
  AFTER INSERT
    LET op = "I"
    ...
  AFTER ROW
    IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity
        END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
                        VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
...
```

BEFORE INSERT block

The BEFORE INSERT block is executed when a new row ins created in an INPUT ARRAY. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing a insert action, or by executing an append action.

The BEFORE INSERT block is executed after the BEFORE ROW block and before the BEFORE FIELD block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (DIALOG.getCurrentRow("*screen-array*")) with the total number of rows (DIALOG.getArrayLength("*screen-array*")). If the current row index and the total number of rows correspond, the BEFORE INSERT concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the CANCEL INSERT instruction inside BEFORE INSERT. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with DIALOG.setActionActive().

In this example, the BEFORE INSERT block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    BEFORE INSERT
      IF NOT user_can_append THEN
         ERROR "You are not allowed to append rows"
         CANCEL INSERT
      END IF
      LET r = DIALOG.getCurrentRow("s_items")
      LET p_items[r].item_num = get_new_serial("items")
      LET p_items[r].item_name = "undefined"
```

AFTER INSERT block

The AFTER INSERT block of INPUT ARRAY is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

The AFTER INSERT block is executed afterthe AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the AFTER INSERT block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the AFTER INSERT block.

When executing a NEXT FIELD in the AFTER INSERT block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row input validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the BEFORE INSERT / AFTER INSERT triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a NEXT FIELD in the AFTER ROW block.

In this example, the AFTER INSERT block inserts a new row in the database and cancels the operation if the SQL command fails:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    AFTER INSERT
      WHENEVER ERROR CONTINUE
```

```
      INSERT INTO items VALUES
 ( p_items[DIALOG.getCurrentRow("s_items")].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<>0 THEN
         ERROR SQLERRMESSAGE
         CANCEL INSERT
      END IF
```

BEFORE DELETE block

The BEFORE DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, before the row is removed from the list.

You typically code the database table synchronization in the BEFORE DELETE block, by executing a DELETE SQL statement using the primary key of the current row. In the BEFORE DELETE block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The BEFORE DELETE block is executed before the AFTER DELETE block.

If needed, the deletion can be canceled with the CANCEL DELETE instruction.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that will be deleted.

The next example uses the BEFORE DELETE block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```
INPUT ARRAY p_items FROM s_items.*
  BEFORE DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    WHENEVER ERROR CONTINUE
    DELETE FROM items
       WHERE item_num = p_items[r].item_num
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<>0 VALUES
      ERROR SQLERRMESSAGE
      CANCEL DELETE
    END IF
...
```

AFTER DELETE block

The AFTER DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, after the row has been deleted from the list.

The AFTER DELETE block is executed after the BEFORE DELETE block and before the AFTER ROW block for the deleted row and the BEFORE ROW block of the new current row.

When an AFTER DELETE block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The arr_curr() function or the ui.Dialog.getCurrentRow() method returns the same index as in BEFORE ROW, but it is the index of the new current row. The AFTER ROW block is also executed just after the AFTER DELETE block.

> **Important: When deleting the last row of the list, AFTER DELETE is executed for the delete row, and DIALOG.getCurrentRow() / arr_curr() will be one higher as DIALOG.getArrayLength() / ARR_COUNT(). You should not access a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after ARR_COUNT().**

Here the AFTER DELETE block is used to re-number the rows with a new item line number (note that DIALOG.getArrayLength() / ARR_COUNT() may return zero):

```
INPUT ARRAY p_items FROM s_items.*
   AFTER DELETE
      LET r = DIALOG.getCurrentRow("s_items")
      FOR i=r TO DIALOG.getArrayLength("s_items")
          LET p_items[i].item_lineno = i
      END FOR
...
```

It is not possible to use the CANCEL DELETE instruction in an AFTER DELETE block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

BEFORE FIELD block

For fields controlled by an INPUT, INPUT ARRAY or by a CONSTRUCT instructions, the BEFORE FIELD block is executed every time the cursor enters into the specified field.

For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
   BEFORE FIELD cust_status
     LET p_cust.cust_comment = NULL
     MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block might be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

ON CHANGE block

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set. The ON CHANGE block can only be used for fields controlled by an INPUT or INPUT ARRAY dialog, it is not available in CONSTRUCT.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is

defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
   ON CHANGE order_checked -- Defined as CHECKBOX
      CALL setup_dialog(DIALOG)
```

If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had leaved and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This denies to do field validation in ON CHANGE blocks: you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

AFTER FIELD block

In dialog parts driven by a simple INPUT, INPUT ARRAY or by a CONSTRUCT sub-dialog, the AFTER FIELD block is executed every time the focus leaves the specified field. For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
   AFTER FIELD item_quantity
     IF p_item.item_quantity <= 0 THEN
        ERROR "Item quantity cannot be negative or zero"
        LET p_item.item_quantity = 0
        NEXT FIELD item_quantity
     END IF
```

INPUT ARRAY interaction blocks

ON ACTION block

The `ON ACTION` *`action-name`* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
  ON ACTION action-name
     instruction
     ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
   ON ACTION zoom
      CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
   ON ACTION zoom INFIELD cust_city
      CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
   ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

Important: The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable

will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (key-name)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON SORT block

The `ON SORT` interfaction block can be used to detect when rows have to be sorted in a `DISPLAY ARRAY` or `INPUT ARRAY` dialog.

`ON SORT` is used in two different contexts:

1. In a regular `DISPLAY ARRAY` / `INPUT ARRAY` dialog (not using paged mode), the `ON SORT` trigger can be used to detect that a list sort was performed. In this case, the (visual) sort is already done by the runtime system and the `ON SORT` block is only used to execute post-sort tasks, such as displaying current row information, by using arrayToVisualIndex() dialog method. It is also possible to get the sort column and order with the `getSortKey()` and `getSortSelection()` dialog methods.
2. In a `DISPLAY ARRAY` using paged mode (`ON FILL BUFFER`), built-in row sorting is not available because data is provided by pages. Use the `ON SORT` trigger to detect a sort request and perform a new SQL query to re-order the rows. In this case, sort column and order is available with the `getSortKey()` and `getSortSelection()` dialog methods. See Populating a DISPLAY ARRAY on page 1372.

ON TIMER block

The `ON TIMER seconds` clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

INPUT ARRAY control instructions

ACCEPT INPUT instruction

The `ACCEPT INPUT` instruction validates the `INPUT`instruction and exits the `INPUT ARRAY` instruction if no error is raised. The `AFTER FIELD`, `ON CHANGE`, etc. control blocks will be executed. Statements after the `ACCEPT INPUT` will not be executed.

Input field validation is a process that does several successive validation tasks, as listed here:

1. The current field value is checked, according to the program variable data type (for example, the user must input a valid date in a DATE field).
2. `NOT NULL` field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the NOT NULL constraint.
3. `INCLUDE` field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.
4. `REQUIRED` field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be "touched" by the user or by program. If the field was not edited during the dialog, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

EXIT INPUT instruction

Use the `EXIT INPUT` to terminate the `INPUT ARRAY` instruction and resume the program execution at the instruction following the `INPUT ARRAY` block.

```
ON ACTION leave_now
   EXIT INPUT
```

When leaving the `INPUT ARRAY` instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

CANCEL DELETE instruction

In a list controlled by an `INPUT ARRAY`, row deletion can be canceled by using the `CANCEL DELETE` instruction in the `BEFORE DELETE` block. Using this instruction in a different place will generate a compilation error.

When the `CANCEL DELETE` instruction is executed, the current `BEFORE DELETE` block is terminated without any other trigger execution (no `BEFORE ROW` or `BEFORE FIELD` is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```
   BEFORE DELETE
      IF user_can_delete() == FALSE THEN
```

```
         ERROR "You are not allowed to delete rows"
         CANCEL DELETE
      END IF
```

The instructions that appear after `CANCEL DELETE` will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the `DIALOG.setActionActive()` method:

```
   CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the `DELETE ROW = FALSE` option in the `ATTRIBUTE` clause.

CANCEL INSERT instruction

In a list controlled by an `INPUT ARRAY`, row creation can be canceled by the program with the `CANCEL INSERT` instruction. This instruction can only be used in the `BEFORE INSERT` and `AFTER INSERT` control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after `CANCEL INSERT` will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with `DIALOG.setActionActive()`:

```
   CALL DIALOG.setActionActive("insert", FALSE)
   CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the `INSERT ROW = FALSE` and `APPEND ROW =FALSE` options in the `ATTRIBUTE` clause of `INPUT ARRAY`, or combine with the `AUTO APPEND = FALSE` attribute.

CANCEL INSERT in BEFORE INSERT

A `CANCEL INSERT` executed inside a `BEFORE INSERT` block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The `BEFORE INSERT` block is terminated (further instructions are skipped).
3. The `BEFORE ROW` and `BEFORE FIELD` triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```
   BEFORE INSERT
      IF NOT user_can_insert THEN
         ERROR "You are not allowed to insert rows"
         CANCEL INSERT
      END IF
```

Executing `CANCEL INSERT` in `BEFORE INSERT` will also cancel a temporary row creation, except when there are no more rows in the list. In this case, `CANCEL INSERT` will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the `AUTO APPEND=FALSE` attribute. If `AUTO APPEND=FALSE` and a `CANCEL INSERT` is executed in `BEFORE INSERT` (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

CANCEL INSERT in AFTER INSERT

A `CANCEL INSERT` executed inside an `AFTER INSERT` block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The `AFTER INSERT` block is terminated (further instructions are skipped).
3. The `BEFORE ROW` and `BEFORE FIELD` triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

```
   AFTER INSERT
      WHENEVER ERROR CONTINUE
      LET r = DIALOG.getCurrentRow("s_items")
      INSERT INTO items VALUES ( p_items[r].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<>0 THEN
         ERROR SQLERRMESSAGE
         CANCEL INSERT
      END IF
```

CONTINUE INPUT instruction

`CONTINUE INPUT` skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not `AFTER INPUT`, further control blocks might be executed according to the context. Actually, `CONTINUEINPUT` just instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of `GOTO end_of_control_block`). However, when executed in `AFTER INPUT`, the focus returns to the current row and current field in the list, giving the user another chance to enter data in that field. In this case the `BEFORE ROW` and `BEFORE FIELD` triggers will be invoked.

In this example, an `ON ACTION` block gives control back to the dialog, skipping all instructions after line 04:

```
ON ACTION zoom
   IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
      ERROR "Zoom window cannot be opened."
      CONTINUE INPUT
   END IF
   IF p_cust.cust_address IS NULL THEN
      ...
```

You can also use the `NEXT FIELD` control instruction to give the focus to a specific field and force the dialog to continue. However, unlike `CONTINUE INPUT`, the `NEXT FIELD` instruction will also skip the further control blocks that are normally executed.

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The `NEXT FIELD` *`field-name`* instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in `BEFORE FIELD`, `ON CHANGE` or `AFTER FIELD` blocks, it can also force a `DISPLAY ARRAY` or `INPUT ARRAY` to stay in the current row when `NEXT FIELD` is used in the `AFTER ROW` block.

If it exists, the `BEFORE FIELD` block of the corresponding field is executed.

The purpose of the NEXT FIELD instruction is give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("*field-name*") method to register a field, for example when the name is not known at compile time. However, this method only registers the field: It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of dialog instruction (INPUT *variable-list* FROM *field-list*, INPUT BY NAME *variable-list*, CONSTRUCT BY NAME *sql* ON *column-list*,CONSTRUCT *sql* ON *column-list* FROM *field-list*, INPUT ARRAY *array-name* FROM *screen-array*.*).

The field name specification can be any of the following:

- *field-name*
- *table-name.field-name*
- *screen-record-name.field-name*
- FORMONLY.*field-name*

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog according to the field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME *variable-list*), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT *variable-list* FROM *screen-record.* / field-list-with-screen-record-prefix* or INPUT ARRAY *array-name* FROM *screen-array*.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("*field-name*", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

NEXT FIELD in procedural DIALOG blocks

In a procedural dialog block, the NEXT FIELD *field-name* instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
     IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
        ERROR "Amount of line exceeds max value."
        NEXT FIELD item_count
     END IF
  END IF
```

CLEAR instruction in dialogs

The CLEAR *field-list* and CLEAR SCREEN ARRAY *screen-array.** instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to

the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFEFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated to the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

Examples

Example 1: INPUT ARRAY with empty record list

Form definition file (custlist.per):

```
SCHEMA shop
LAYOUT
TABLE
{
 Id       First name   Last name
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
[f001    |f002        |f003        ]
}
END
END
TABLES
  customer
END
ATTRIBUTES
  f001 = customer.id ;
  f002 = customer.fname ;
  f003 = customer.lname, NOT NULL, REQUIRED ;
END
INSTRUCTIONS
  SCREEN RECORD sr_cust( customer.* );
END
```

Program source code:

```
SCHEMA shop

MAIN
  DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*

  OPEN FORM f FROM "custlist"
  DISPLAY FORM f

  INPUT ARRAY custarr WITHOUT DEFAULTS FROM sr_cust.*

END MAIN
```

Example 2: INPUT ARRAY using a static array

The form definition file is the same as in Example 1.

```
SCHEMA shop

MAIN

  DEFINE custarr ARRAY[100] OF RECORD LIKE customer.*
  DEFINE allow_insert, size INTEGER
```

```
  LET custarr[1].id = 1
  LET custarr[1].fname = "John"
  LET custarr[1].lname = "SMITH"
  LET custarr[2].id = 2
  LET custarr[2].fname = "Mike"
  LET custarr[2].lname = "STONE"
  LET size = 2
  LET allow_insert = TRUE

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  INPUT ARRAY custarr WITHOUT DEFAULTS FROM sr_cust.*
      ATTRIBUTES (COUNT=size, MAXCOUNT=50, UNBUFFERED, INSERT
 ROW=allow_insert)
      BEFORE INPUT
        MESSAGE "Editing the customer table"
      BEFORE INSERT
        IF arr_curr()=4 THEN
           CANCEL INSERT
        END IF
      BEFORE FIELD fname
        MESSAGE "Enter First Name"
      BEFORE FIELD lname
        MESSAGE "Enter Last Name"
      AFTER FIELD lname
        IF custarr[arr_curr()].lname IS NULL THEN
           LET custarr[arr_curr()].fname = NULL
        END IF
  END INPUT

END MAIN
```

Example 3: INPUT ARRAY using a dynamic array

The form definition file is the same as in .Example 1

```
SCHEMA shop

MAIN

  DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
  DEFINE counter INTEGER

  FOR counter = 1 TO 500
    LET custarr[counter].id = counter
    LET custarr[counter].fname = "ff"||counter
    LET custarr[counter].lname = "NNN"||counter
  END FOR

  OPEN FORM f FROM "custlist"
  DISPLAY FORM f

  INPUT ARRAY custarr WITHOUT DEFAULTS FROM sr_cust.*
                ATTRIBUTES ( UNBUFFERED )
      ON ROW CHANGE
        MESSAGE "Row #"||arr_curr()||" has been updated."
  END INPUT

END MAIN
```

Example 4: INPUT ARRAY updating the database table

The form definition file is the same as in Example 1.

```
SCHEMA shop

MAIN

 DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*

 DEFINE op CHAR(1)
 DEFINE i INTEGER

 DATABASE shop

 OPEN FORM f1 FROM "custlist"
 DISPLAY FORM f1

 DECLARE c1 CURSOR FOR
   SELECT id, fname, lname FROM customer ORDER BY id
 LET i = 1
 FOREACH c1 INTO custarr[i].*
    LET i = i + 1
 END FOREACH
 CALL custarr.deleteElement(custarr.getLength())

 INPUT ARRAY custarr FROM sr_cust.*
                 ATTRIBUTES(WITHOUT DEFAULTS, UNBUFFERED)

      BEFORE DELETE
        IF op == "N" THEN -- No real SQL delete for new inserted rows
           IF NOT mbox_yn("List",
                "Are you sure you want to delete this record?",
                "question") THEN
             CANCEL DELETE -- Keeps row in list
           END IF
           WHENEVER ERROR CONTINUE
           DELETE FROM customer
                  WHERE ID = custarr[arr_curr()].id
           WHENEVER ERROR STOP
           IF SQLCA.SQLCODE<0 THEN
             ERROR "Could not delete the record from database!"
             CANCEL DELETE -- Keeps row in list
           END IF
        END IF

      AFTER DELETE
        IF op == "N" THEN
           MESSAGE "Record has been deleted successfully"
        ELSE
           LET op = "N"
        END IF

      AFTER FIELD fname
        IF custarr[arr_curr()].fname MATCHES "*@#$%^&()*" THEN
           ERROR "This field contains invalid characters"
           NEXT FIELD CURRENT
        END IF

      ON ROW CHANGE
        -- Warning: ON ROW CHANGE can occur if the SQL INSERT failed...
        IF op != "I" THEN LET op = "M" END IF

      BEFORE INSERT
```

```
        LET op = "T"
        -- (not the best way to get a unique sequence number!)
        SELECT MAX(ID)+1 INTO custarr[arr_curr()].id FROM customer
        IF custarr[arr_curr()].id IS NULL THEN
          LET custarr[arr_curr()].id = 1
        END IF

      AFTER INSERT
        LET op = "I"

      BEFORE ROW
        LET op = "N"

      AFTER ROW
        IF int_flag THEN EXIT INPUT END IF
        IF op == "M" OR op == "I" THEN
          IF custarr[arr_curr()].fname IS NULL
            OR custarr[arr_curr()].lname IS NULL
            OR custarr[arr_curr()].fname ==
             custarr[arr_curr()].lname THEN
              ERROR "First name and last name are equal..."
              NEXT FIELD fname
           END IF
        END IF
        IF op == "I" THEN
          WHENEVER ERROR CONTINUE
          INSERT INTO customer (id, fname, lname)

  - Example 2: CONSTRUCT with binding by field name on page 1143

Understanding the CONSTRUCT instruction

The CONSTRUCT instruction provides database query by example. Query by example enables a user to query a database by specifying values (or ranges of values) for screen fields that correspond to the database columns. The runtime system converts the query values entered by the user into a boolean SQL condition that can be used in the WHERE clause of a prepared SELECT statement.

The CONSTRUCT statement produces an SQL condition corresponding to all search criteria that a user specifies in the fields. The instruction fills a character variable with that SQL condition, and you can use the content of this variable to create the WHERE clause of a SELECT statement. The SELECT statement must be executed with the dynamic SQL management instructions PREPARE or DECLARE FROM:

The CONSTRUCT instruction uses the data types of the form field to verify user input and to produce the SQL condition.

> **Important:** The SQL condition is generated according to the current database session, which defines the type of the database server. Therefore, the program must be connected to a database server before entering the CONSTRUCT block. The generated SQL condition is specific to the database server and may not be used with other types of database servers.

If no criteria were entered, the string '1=1' is assigned to the string variable. This is a boolean SQL expression that always evaluates to true so that all rows are returned.

The CONSTRUCT dialog activates the current form. This is the form most recently displayed or, if you are using more than one window, the form currently displayed in the current window. When the CONSTRUCT statement completes execution, the form is cleared and deactivated.

By default the screen field tabbing order is defined by the order of the field names in the FROM clause; by default this is the list of column names in the ON clause when no FROM clause is specified. If needed, change the field tabbing order with the FIELD ORDER FORM option and TABINDEX field attributes.

Syntax of CONSTRUCT instruction

The CONSTRUCT instruction provides database query by example, producing a WHERE condition for SELECT.

Syntax

```
CONSTRUCT { BY NAME variable ON column-list
```

```
          | variable ON column-list FROM field-list
          }
    [ ATTRIBUTES ( { display-attribute
                   | control-attribute }
                   [,...] ) ]
    [ HELP help-number ]
[ dialog-control-block
  [...]
END CONSTRUCT ]
```

where *column-list* defines a list of database columns as:

```
{ column-name
| table-name.*
|  table-name. column-name
} [,...]
```

where *field-list* defines a list of fields with one or more of:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

where *dialog-control-block* is one of:

```
{ BEFORE CONSTRUCT
| AFTER CONSTRUCT
| BEFORE FIELD field-spec [,...]
| AFTER FIELD field-spec [,...]
| ON IDLE seconds
| ON TIMER seconds
| ON ACTION action-name
             [ INFIELD field-spec ]
             [ ATTRIBUTES ( action-attributes-construct ) ]
| ON KEY ( key-name [,...] )
}
    dialog-statement
    [...]
```

where *action-attributes-construct* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *dialog-statement* is one of:

```
{ statement
| NEXT FIELD { NEXT | PREVIOUS | field-spec}
| CONTINUE CONSTRUCT
| EXIT CONSTRUCT
}
```

where *field-spec* identifies a unique field with one of:

```
{ field-name
| table-name.field-name
| screen-array.field-name
| screen-record.field-name
}
```

where *display-attribute* is:

```
{ BLACK | BLUE | CYAN | GREEN
| MAGENTA | RED | WHITE | YELLOW
| BOLD | DIM | INVISIBLE | NORMAL
| REVERSE | BLINK | UNDERLINE
}
```

where *control-attribute* is:

```
{ ACCEPT [ = boolean ]
| CANCEL [ = boolean ]
| FIELD ORDER FORM
| HELP = help-number
| NAME = "dialog-name"
}
```

1. *variable* is the variable that will contain the SQL condition built by the `CONSTRUCT` instruction.
2. *column-name* is the identifier of a database column of the current form.
3. *table-name* is the identifier of a database table of the current form.
4. *field-name* is the identifier of a field of the current form.
5. *screen-array* is the screen array that will be used in the current form.
6. *line* is a screen array line in the form.
7. *screen-record* is the identifier of a screen record of the current form.
8. *help-number* is an integer that allows you to associate a help message number with the instruction.
9. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
10. *dialog-name* is the identifier of the dialog.
11. *action-name* identifies an action that can be executed by the user.
12. *seconds* is an integer literal or variable that defines a number of seconds.
13. *statement* is any instruction supported by the language.
14. *action-attributes* are dialog-specific action attributes.

CONSTRUCT programming steps

The following steps describe how to implement the `CONSTRUCT` statement:

1. Declare a variable with the `DEFINE` statement, it can be `CHAR`, `VARCHAR` or `STRING`. Prefer `STRING` to avoid any size limitation.
2. Open and display the form, using an `OPEN WINDOW WITH FORM` or the `OPEN FORM` / `DISPLAY FORM` instructions.
3. Set the `INT_FLAG` variable to `FALSE`.
4. Define the `CONSTRUCT` block with the list of form fields to be used for the query by example. If needed, define dialog control blocks to implement rules for the query by example.
5. Inside the `CONSTRUCT` statement, control the behavior of the instruction with `BEFORE CONSTRUCT`, `BEFORE FIELD`, `AFTER FIELD`, `AFTER CONSTRUCT` and `ON ACTION` blocks.
6. After the interaction statement block, test the `INT_FLAG` predefined variable to check if the dialog was canceled (`INT_FLAG=TRUE`) or validated (`INT_FLAG=FALSE`).

If the INT_FLAG variable is TRUE, you should reset it to FALSE to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

7. To build the complete SQL statement, concatenate "SELECT ... WHERE" to the string variable that contains the boolean SQL expression produced by CONSTRUCT.
8. Define a database cursor with the DECLARE FROM instruction, by using the SELECT statement.
9. Execute the cursor and fetch the rows found by the database server. You can for example implement a FOREACH loop to fill a program array, to be shown by a DISPLAY ARRAY statement.

Using query by example

To use query by example, you must understand how they work and how to structure the code.

Form field specification in CONSTRUCT

In order to produce an SQL condition, the CONSTRUCT instruction uses a list of database columns that must match form fields for user input. Unlike INPUT, DISPLAY ARRAY and INPUT ARRAY, the CONSTRUCT dialog does not use a program variable for each form field: Only one string variable is required, to hold the SQL condition. Individual field criteria is available in the input buffers (GET_FLDBUF()).

The list of database columns specified in the CONSTRUCT statement will appear in the SQL condition produced.

Binding columns and fields by name

The CONSTRUCT BY NAME *variable* ON *column-list* syntax maps the field names to database column names by name. Form fields are typically defined in the form by following a database schema, specifying the column name and data type.

```
SCHEMA stock
DEFINE where_part STRING
...
CONSTRUCT BY NAME where_part ON cust_name, cust_address
  ...
END CONSTRUCT
```

Binding columns and fields by position

The CONSTRUCT *variable* ON *column-list* FROM *field-list* clause explicitly maps database columns to form fields by position. The form can include other fields that are not part of the specified column list, but the number of variables or record members must equal the number of form fields listed in the FROM clause. Each database column must be of the same (or a compatible) data type as the corresponding form field. When the user enters data, the runtime system checks the entered value against the data type of the form field.

```
DEFINE where_part STRING
...
CONSTRUCT where_part ON cust_name, cust_address
                     FROM field_02, field_04
  ...
END CONSTRUCT
```

Query operators in CONSTRUCT

The CONSTRUCT instruction supports a specific query syntax, using wildcard characters and comparison operators.

The table below lists CONSTRUCT wildcard characters that can be used during a query by example input:

Table 276: CONSTRUCT relational operators

Symbol	Meaning	Data type
value	Use value as is to filter	Any simple type
=	Is NULL	Any simple type
==	Equal to	Any simple type
>	Greater than	Any simple type
>=	Greater than or equal to	Any simple type
<	Less than	Any simple type
<=	Less than or equal to	Any simple type
<> *or* !=	Not equal to	Any simple type
!=	Not NULL	Any simple type
: *or* ..	Range of values	Any simple type
|	List of values	Any simple type
*	Wildcard for any string	Char string types
?	Single-character wildcard	Char string types
[*c1-c2*]	Range of characters	Char string types
[*c1c2...*]	Set of characters	Char string types

Queries based on character types are case sensitive, because SQL is case sensitive, except if the database server is configured to be case-insensitive.

The * (star) and ? (question mark) wildcards are specific to character string type queries, and will generate a MATCHES expression or a LIKE expression, according to the type of database used. When entering a * or ?, the pattern can also contain a character range specification with the square brackets notation [a-z] or [xyz]. A caret (^.) as the first character within the square brackets specifies the logical complement of the set, and matches any character that is not listed. For example, the search value [^AB]* specifies all strings beginning with characters other than A or B.

Some syntaxes can produce an **Error in field** dialog error if the feature is supported by the pattern matching operator of the database server. For example, not all db servers support the [a-z] character range specification in the LIKE pattern.

If you want to search for rows with values containing a * star, a ? question mark or a \ backslash, you must escape the wildcard character with a backslash. Specifying a backslash before another character will have no effect.

Table 277: CONSTRUCT input examples with matching and non matching values

QBE input example	Matching values	Non matching values
100	100	99, 101, NULL
>=100	100, 101, 200	10, 99, NULL
!=100	98, 98, 101, 102	100, NULL
!=	98, 99, 100, 101	NULL
1:100	1, 2 ... 99, 100	0, 101, NULL

QBE input example	Matching values	Non matching values
aaa:yyy	aaa, aab, ab, yy, yyy	zaa, NULL
abc	abc	bc, abcd, Abc, NULL
ABC	ABC	abc, aBC, NULL
abc*	abc, abcd, abcdef	bc, ABC, NULL
*bc	abc, bc	acd, aBC, NULL
?bc	abc, xbc, zbc	aabc, aBC, NULL
*bc?	aaaabc, abcd, bcd	abcdef, bcdef, NULL
[a-z]bc	abc, ebc, zbc	2bc, +bc, Abc, NULL
[^abc]*	deee, feee, zyx, z	azzz, byy, d, NULL
a[bxy]c	abc, axc, ayc	a2c, azc, aBc, NULL
*[xyz]	abcx, eeeez	abcd, eeee, NULL
1|2|35	1, 2, 35	4, 5, 6, NULL
aa|bb|cc	aa, bb, cc	ab, dd, NULL
\\abc*	\abc, \abcdef	abc, NULL
*bc	*bc	abc, bc, NULL
\[?\]	[a], a[b]c, xx[y]zz	a[bb]c, a[]c, NULL

CONSTRUCT instruction configuration

This section describes the options that can be specified in the `ATTRIBUTES` clause of the `CONSTRUCT` instruction. The options of the `ATTRIBUTES` clause override all default attributes and temporarily override any display attributes that the `OPTIONS` or the `OPEN WINDOW` statement specified for these fields. With the `CONSTRUCT` statement, the `INVISIBLE` attribute is ignored.

NAME option

The `NAME` attribute can be used to name the `CONSTRUCT` dialog. This is especially used to identify actions of the dialog.

The clause specifies the number of a to display if the user invokes the help the dialog. The predefined 'help' action is automatically created by the runtime system. You can bind to the 'help' action.

HELP option

`HELP`help message`CONSTRUCT`action views

The `HELP` clause overrides the `HELP` attribute.

FIELD ORDER FORM option

By default, the tabbing order is defined by the variable binding list in the instruction description. You can control the tabbing order by using the `FIELD ORDER FORM` attribute: When this attribute is used, the tabbing order is defined by the `TABINDEX` attribute of the form fields. If this attribute is used, the Dialog.fieldOrder FGLPROFILE entry is ignored.

The `OPTIONS` instruction can also change the behavior of the `INPUT` instruction, with the `INPUT WRAP` or `FIELD ORDER FORM` options.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using ACCEPT INPUT.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using `EXIT INPUT`.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an `ON ACTION close` control block to create an explicit action.

Default actions IN CONSTRUCT

When an CONSTRUCT instruction executes, the runtime system creates a set of default actions.

According the invoked default action, field validation occurs and different CONSTRUCT control blocks are executed.

This table lists the default actions created for this dialog:

Table 278: Default actions created for the CONSTRUCT dialog

Default action	Description
`accept`	Validates the CONSTRUCT dialog (validates field criteria) *Creation can be avoided with* ACCEPT *attribute.*
`cancel`	Cancels the CONSTRUCT dialog (no validation, INT_FLAG is set) *Creation can be avoided with* CANCEL *attribute.*
`close`	By default, cancels the CONSTRUCT dialog (no validation, INT_FLAG is set) Default action view is hidden. See Implementing the close action on page 1337.
`help`	Shows the help topic defined by the HELP clause. *Only created when a* HELP *clause is defined.*

The accept and cancel default actions can be avoided with the ACCEPT and CANCEL dialog control attributes:

```
CONSTRUCT BY NAME cond ON field1 ATTRIBUTES (CANCEL=FALSE)
    ...
```

CONSTRUCT control blocks

CONSTRUCT control blocks execution order

This table shows the order in which the runtime system executes the control blocks in the CONSTRUCT instruction, according to the user action:

Table 279: Control block execution order for CONSTRUCT

Context / User action	Control Block execution order
Entering the dialog	**1.** `BEFORE CONSTRUCT` **2.** `BEFORE FIELD` (first field)
Moving from field A to field B	**1.** `AFTER FIELD` (for field A) **2.** `BEFORE FIELD` (for field B)
Validating the dialog	**1.** `AFTER FIELD` **2.** `AFTER CONSTRUCT`
Canceling the dialog	**1.** `AFTER CONSTRUCT`

BEFORE CONSTRUCT block

BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `BEFORE CONSTRUCT` is only executed once when dialog is started.

The `BEFORE CONSTRUCT` block is executed once at dialog startup, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
CONSTRUCT BY NAME where_part ON ...
   BEFORE CONSTRUCT
       MESSAGE "Enter customer search filter"
       CALL DIALOG.setActionActive("clean", FALSE )
   ...
```

The fields are cleared before the `BEFORE CONSTRUCT` block is executed.

You can use the `NEXT FIELD` control instruction in the `BEFORE CONSTRUCT` block, to jump to a specific field when the dialog starts.

BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a `CONSTRUCT` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE CONSTRUCT` block is executed when the focus goes to a group of fields driven by a `CONSTRUCT` sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

`BEFORE CONSTRUCT` is executed after the `BEFORE DIALOG` block and before the `BEFORE FIELD` blocks.

In this example, the `BEFORE CONSTRUCT` block is used to display a message:

```
CONSTRUCT BY NAME sql ON customer.*
  BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
```

AFTER CONSTRUCT block

AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `AFTER CONSTRUCT` is only executed once when dialog is ended.

Use an AFTER CONSTRUCT block to execute instructions after the user has finished search criteria input.

AFTER CONSTRUCT is not executed if an EXIT CONSTRUCT is performed.

The code in AFTER CONSTRUCT can for example check if a criteria combination of different fields is required or denied, and force the end use to enter all

Before checking the content of the fields used in the CONSTRUCT, make sure that the INT_FLAG variable is FALSE: in case if the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated to the form fields, you must query the input buffers of the fields to get the values entered by the user.

```
CONSTRUCT BY NAME where_part ON ...
  ...
  AFTER CONSTRUCT
    IF NOT INT_FLAG THEN
       IF length(DIALOG.getFieldBuffer(cust_name))==0
       OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
          ERROR "Enter a search criteria for customer name and address
 fields."
          NEXT FIELD CURRENT
       END IF
    END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the AFTER CONSTRUCT block is executed when the focus is lost by a group of fields driven by a CONSTRUCT sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER CONSTRUCT is executed after the AFTER FIELD and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER CONSTRUCT control block will keep the focus in the group of fields.

In this example, the AFTER CONSTRUCT block is used to build the SELECT statement:

```
CONSTRUCT BY NAME sql ON customer.*
   AFTER CONSTRUCT
       LET sql = "SELECT * FROM customers WHERE " || sql
```

BEFORE FIELD block

For fields controlled by an INPUT, INPUT ARRAY or by a CONSTRUCT instructions, the BEFORE FIELD block is executed every time the cursor enters into the specified field.

For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
   BEFORE FIELD cust_status
     LET p_cust.cust_comment = NULL
     MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block might be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

AFTER FIELD block

In dialog parts driven by a simple INPUT, INPUT ARRAY or by a CONSTRUCT sub-dialog, the AFTER FIELD block is executed every time the focus leaves the specified field. For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
   AFTER FIELD item_quantity
     IF p_item.item_quantity <= 0 THEN
        ERROR "Item quantity cannot be negative or zero"
        LET p_item.item_quantity = 0
        NEXT FIELD item_quantity
     END IF
```

CONSTRUCT interaction blocks

ON ACTION block

The `ON ACTION` *`action-name`* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
  ON ACTION action-name
     instruction
     ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
   ON ACTION zoom
      CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
   ON ACTION zoom INFIELD cust_city
      CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
   ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

Important: The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable

will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (key-name)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

CONSTRUCT control instructions

ACCEPT CONSTRUCT instruction

The `ACCEPT CONSTRUCT` instruction validates the `CONSTRUCT` instruction and exits the dialog block if no error is raised.

The `AFTER FIELD` and `AFTER CONSTRUCT` control blocks will be executed.

The statements after the `ACCEPT CONSTRUCT` will not be executed.

```
CONSTRUCT BY NAME where_part ON ...
```

```
  ...
  ON ACTION default_query
    CALL set_default_filter()
    ACCEPT CONSTRUCT
  ...
END CONSTRUCT
```

The CONSTRUCT instruction creates the default accept action to let the user validate the dialog. The ACCEPT CONSTRUCT instruction should only be used in specific cases when the default accept action is not appropriated.

CONTINUE CONSTRUCT instruction

CONTINUE CONSTRUCT skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not AFTER CONSTRUCT, further control blocks might be executed according to the context. Actually, CONTINUE CONSTRUCT just instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of GOTO end_of_control_block). However, when executed in AFTER CONSTRUCT, the focus returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field. In this case the BEFORE FIELD of the current field will be invoked.

As alternative, use the NEXT FIELD control instruction to give the focus to a specific field and force the dialog to continue. However, unlike CONTINUE CONSTRUCT, the NEXT FIELD instruction will skip the further control blocks that are normally executed.

EXIT CONSTRUCT instruction

The EXIT CONSTRUCT instruction terminates the CONSTRUCT instruction and resumes the program execution at the instruction following the INPUT block.

Performing an EXIT CONSTRUCT instruction during a dialog is equivalent to cancel the dialog: No field validation will occur, and the AFTER FIELD or AFTER CONSTRUCT blocks will not be executed. The dialog is exited immediately. However, INT_FLAG will not be set to TRUE as when the cancel action is fired.

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The NEXT FIELD *field-name* instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

The purpose of the NEXT FIELD instruction is give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("*field-name*") method to register a field, for example when the name is not known at compile time. However, this method only registers the field: It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of

dialog instruction (`INPUT variable-list FROM field-list`, `INPUT BY NAME variable-list`, `CONSTRUCT BY NAME sql ON column-list`,`CONSTRUCT sql ON column-list FROM field-list`, `INPUT ARRAY array-name FROM screen-array.*`).

The field name specification can be any of the following:

- *field-name*
- *table-name.field-name*
- *screen-record-name.field-name*
- `FORMONLY.field-name`

Here are some examples:

- `"cust_name"`
- `"customer.cust_name"`
- `"cust_screen_record.cust_name"`
- `"item_screen_array.item_label"`
- `"formonly.total"`

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog according to the field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using `INPUT BY NAME variable-list`), the field prefix must be the database table name (or `FORMONLY`) used in the form file, or any valid screen-record using that field. When the `FROM` clause of the dialog specifies an explicit screen-record (for example, in `INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix` or `INPUT ARRAY array-name FROM screen-array.*`), the field prefix must be the screen-record name used in the `FROM` clause.

Abstract field identification is supported with the `CURRENT`, `NEXT` and `PREVIOUS` keywords. These keywords represent the current, next and previous fields respectively. When using `FIELD ORDER FORM`, the `NEXT` and `PREVIOUS` options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the `FROM` or `BY NAME` clause).

In a procedural dialog, if the focus is in the first field of an `INPUT` or `CONSTRUCT` sub-dialog, `NEXT FIELD PREVIOUS` will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an `INPUT` or `CONSTRUCT` sub-dialog, `NEXT FIELD NEXT` will jump out of the current sub-dialog and set the focus to the next sub-dialog. `NEXT FIELD NEXT` or `NEXT FIELD PREVIOUS` also jumps to another sub-dialog when the focus is in a `DISPLAY ARRAY` sub-dialog. However, when using an `INPUT ARRAY` sub-dialog, `NEXT FIELD NEXT` from within the last column will loop to the first column of the current row, and `NEXT FIELD PREVIOUS` from within the first column will jump to the last column of the current row - the focus stays in the current `INPUT ARRAY` sub-dialog. When another sub-dialog gets the focus because of a `NEXT FIELD NEXT/PREVIOUS`, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field

Non-editable fields are fields defined with the `NOENTRY` attribute, fields disabled with `ui.Dialog.setFieldActive("field-name", FALSE)`, or fields using a widget that does not allow input, such as a `LABEL`.

If a `NEXT FIELD` instruction specifies a non-editable field, the `BEFORE FIELD` block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the `AFTER FIELD` block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the `FIELD ORDER` mode used by the dialog. Doing a `NEXT FIELD` to a non-editable field can lead to infinite loops in the dialog; Use `NEXT FIELD CURRENT` instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

NEXT FIELD in procedural DIALOG blocks

In a procedural dialog block, the NEXT FIELD *field-name* instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
     IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
        ERROR "Amount of line exceeds max value."
        NEXT FIELD item_count
     END IF
  END IF
```

CLEAR instruction in dialogs

The CLEAR *field-list* and CLEAR SCREEN ARRAY *screen-array.** instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFEFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated to the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

Examples

Example 1: CONSTRUCT with binding by field position

Form definition in the *form1.per* file:

```
SCHEMA office
```

```
LAYOUT
GRID
{
  Customer id: [f001    ]
  First Name : [f002                  ]
  Last Name  : [f003                  ]
}
END
END

TABLES
  customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END
```

Program:

```
MAIN
  DEFINE condition STRING
  DATABASE office
  OPEN FORM f1 FROM "form1"
  DISPLAY FORM f1
  CONSTRUCT condition
        ON id, fname, lname
        FROM sr_cust.*
  DISPLAY condition
END MAIN
```

Example 2: CONSTRUCT with binding by field name

Form definition file "form1.per" (same as in Example 1)

Program:

```
SCHEMA office
MAIN
  DEFINE condition STRING
  DEFINE statement STRING
  DEFINE cust RECORD LIKE customer.*

  DATABASE office

  OPEN FORM f1 FROM "form1"
  DISPLAY FORM f1

  CONSTRUCT BY NAME condition ON customer.*
    BEFORE CONSTRUCT
      DISPLAY "A*" TO fname
      DISPLAY "B*" TO lname
  END CONSTRUCT

  LET statement =
    "SELECT fname, lname FROM customer WHERE " || condition
```

```
  DISPLAY "SQL: " || statement

  DECLARE c1 CURSOR FROM statement
  FOREACH c1 INTO cust.*
    DISPLAY cust.*
  END FOREACH

END MAIN
```

Multiple dialogs (DIALOG)

The procedural `DIALOG` instruction allows to combine record list, record input, query criteria input in the same application form.

Understanding multiple dialogs

The concept of *multiple dialogs* refers to the usage of a procedural `DIALOG` block, to control several elements of a form. During the execution of a procedural dialog, no other window/form can be accessed: multiple dialogs are in the category of modal dialogs.

The `DIALOG` procedural instruction handles different parts of a form simultaneously, including simple display fields, simple input fields, read-only list of records, editable list of records, query by example fields, and action views. The `DIALOG` instruction acts as a collection of singular dialogs working in parallel.

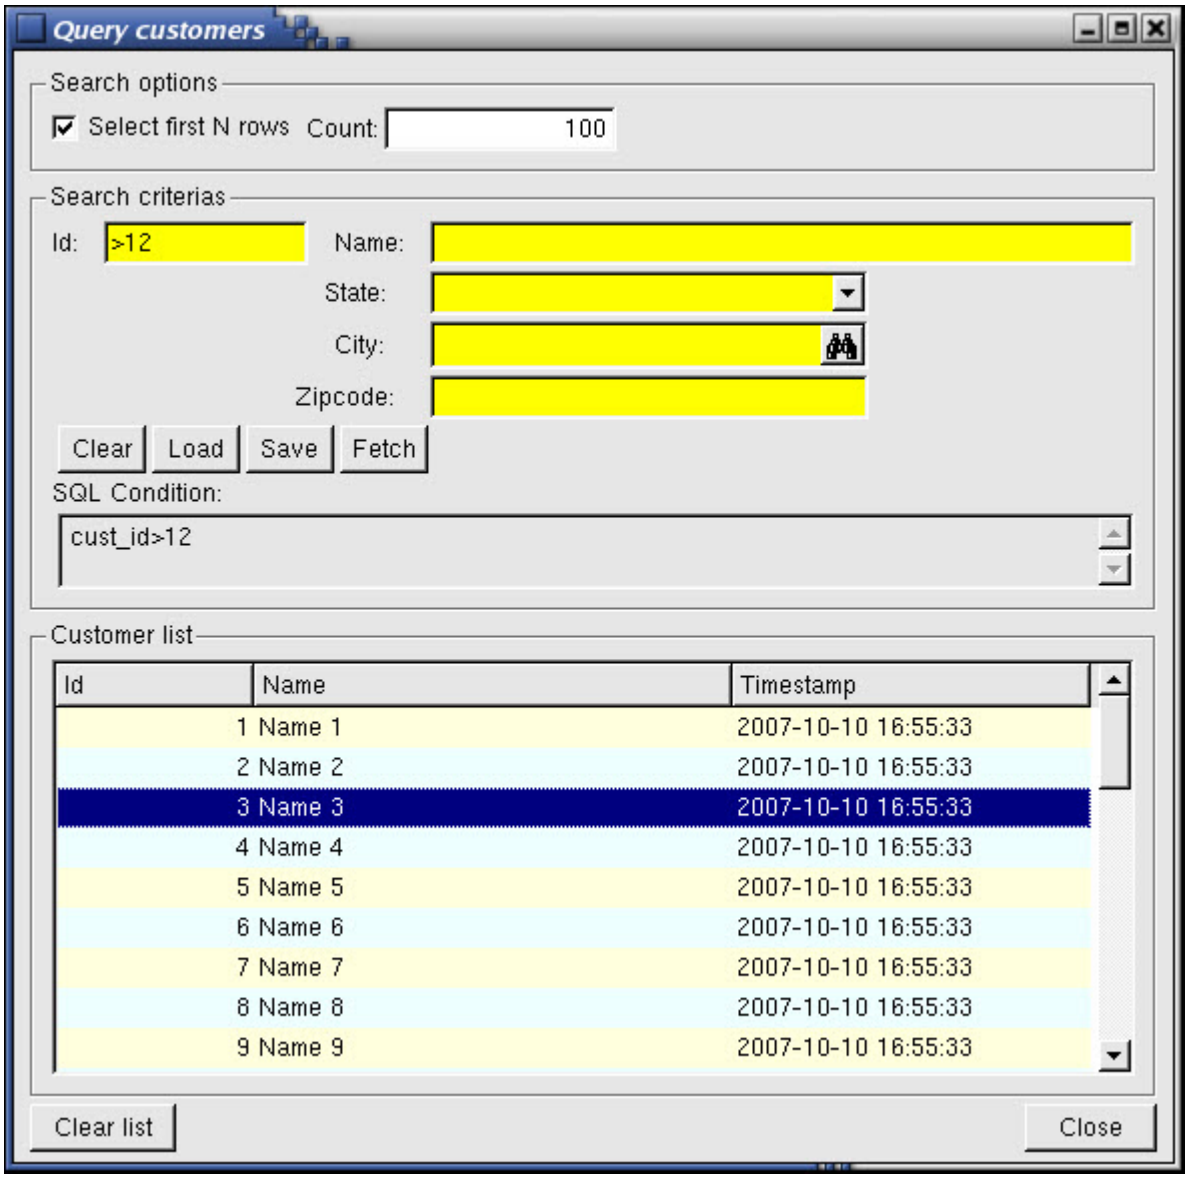

Figure 76: Query customers screenshot with multiple dialogs

"Singular interactive instructions" refer to `INPUT`, `CONSTRUCT`, `DISPLAY ARRAY` and `INPUT ARRAY` independent blocks not surrounded by the `DIALOG` / `END DIALOG` keywords. While the `DIALOG` instruction reuses some of the semantics and behaviors of singular interactive instructions, there are some differences.

Like the singular interactive instructions, `DIALOG` is an interactive instruction. You can execute a `DIALOG` instruction from one of the singular dialogs, or execute a singular dialog from a `DIALOG` block. The parent dialog will be disabled until the child dialog returns.

A `DIALOG` procedural instruction consist of several sub-dialog blocks declared inside the `DIALOG` instruction, or external dialog blocks declared in scope outside of the current function. The external dialogs are attached to the current dialog with the `SUBDIALOG` clause.

The `DIALOG` instruction binds program variables (such as simple records or arrays of records) with a screen-record or screen-array defined in a form, allowing the user to view and update application data.

When a `DIALOG` block executes, it activates the current form (the form most recently displayed or the form in the current window). When the statement completes execution, the form is deactivated.

This screen shot is from a demo program called "Query customers" that you can find in FGLDIR/demo/MultipleDialogs. This demo involves a DIALOG block that contains a simple INPUT block, a CONSTRUCT block and a DISPLAY ARRAY block:

The syntax of the DIALOG instruction is very close to singular dialogs, using common triggers such as BEFORE FIELD, ON ACTION, and so on. Despite the similarities, the behavior and semantics of DIALOG are a bit different from singular dialogs.

Understand that the DIALOG instruction is not provided to replace singular dialogs. Singular dialogs are still supported. It is recommended that you use singular dialogs if no multiple dialog is required.

Unlike singular dialogs, the DIALOG instruction does not use the INT_FLAG variable. You must implement ON ACTION accept or ON ACTION cancel to handle dialog validation or cancellation. These actions do not exist by default in DIALOG.

Unlike singular dialogs creating implicit accept and cancel actions, by default there is no way to quit the DIALOG instruction. You must implement your own action handler and execute EXIT DIALOG or ACCEPT DIALOG.

A good practice is to write a setup dialog function to centralize all field and action activations according to the context. Call that setup function at any place in the DIALOG code where the field and action activation rules may change.

While static arrays are supported by the DIALOG instruction, it is strongly recommended that you use dynamic arrays instead. With a dynamic array, the actual number of rows is automatically defined by the array variable, while static arrays need an additional step to define the total number of rows.

When needed, use the UNBUFFERED mode with multiple dialogs to force model/view synchronization, and use the FIELD ORDER FORM option to follow the TABINDEX definitions in the form file.

This example is of a DIALOG procedural instruction that includes both an INPUT and a DISPLAY ARRAY sub-dialog, plus a sub-dialog defined externally and included with the SUBDIALOG keyword:

```
SCHEMA stores
DEFINE p_customer RECORD LIKE customer.*
DEFINE p_orders DYNAMIC ARRAY OF RECORD LIKE order.*
FUNCTION customer_dialog()
  DIALOG ATTRIBUTES(UNBUFFERED, FIELD ORDER FORM)
    INPUT BY NAME p_customer.*
      AFTER FIELD cust_name
        CALL setup_dialog(DIALOG)
    END INPUT
    DISPLAY ARRAY p_orders TO s_orders.*
      BEFORE ROW
        CALL setup_dialog(DIALOG)
    END DISPLAY
    SUBDIALOG common_footer
    ON ACTION close
      EXIT DIALOG
  END DIALOG
END FUNCTION
```

All elements of the dialog are active at the same time, so you must handle tabbing order properly. By default - as in singular dialogs - the tabbing order is driven by the binding list (order of program variables). It is strongly recommended that you use the FIELD ORDER FORM option and the TABINDEX field attributes instead.

Like the singular INPUT ARRAY instruction, DIALOG creates implicit insert, append and delete actions. These actions are only active when the focus is in the list.

Syntax of the procedural DIALOG instruction

The DIALOG block is an interactive instruction that executes several sub-dialogs simultaneously.

Syntax

```
DIALOG
   [ ATTRIBUTES ( dialog-control-attribute [,...] ) ]

   { record-input-block
   | construct-block
   | display-array-block
   | input-array-block
   | SUBDIALOG dialog-name
   }
   [...]

   [
   dialog-control-block
   [...]
   ]

END DIALOG
```

where *dialog-control-attribute* is:

```
{ FIELD ORDER FORM
| UNBUFFERED [ = boolean ]
}
```

where *dialog-name* in the SUBDIALOG clause is the name of a declarative dialog block defined outside the scope of the current function.

where *dialog-control-block* is one of:

```
{ BEFORE DIALOG
| ON ACTION action-name
             [ ATTRIBUTES ( action-attributes-dialog ) ]
| ON KEY ( key-name [,...] )
| ON IDLE seconds
| ON TIMER seconds
| COMMAND option-name
        [ option-comment ]
        [ HELP help-number ]
| COMMAND KEY ( key-name  [,...] ) option-name
        [ option-comment ]
        [ HELP help-number ]
| AFTER DIALOG
}
    dialog-statement
    [...]
```

where *action-attributes-dialog* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *record-input-block* is:

```
INPUT { BY NAME { variable | record.* } [,...]
      | variable | record.* } [,...] FROM field-list
      }
   [ ATTRIBUTES ( input-control-attribute [,...] ) ]
   [ input-control-block
       [...]
   ]
END INPUT
```

where *input-control-attribute* is:

```
{ HELP = help-number
| NAME = "sub-dialog-name"
| WITHOUT DEFAULTS [ = boolean ]
}
```

where *input-control-block* is one of:

```
{ BEFORE INPUT
| BEFORE FIELD field-spec [,...]
| ON CHANGE field-spec [,...]
| AFTER FIELD field-spec [,...]
| AFTER INPUT
| ON ACTION action-name
             [ INFIELD field-spec ]
             [ ATTRIBUTES ( action-attributes-input ) ]
| ON KEY ( key-name [,...] )}
    dialog-statement
    [...]
```

where *action-attributes-input* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| VALIDATE = NO
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *construct-block* is:

```
CONSTRUCT { BY NAME variable ON column-list
          | variable ON column-list FROM field-list
          }
   [ ATTRIBUTES ( construct-control-attribute [,...] ) ]
   [ construct-control-block
       [...]
   ]
END CONSTRUCT
```

where *construct-control-attribute* is:

```
{ HELP = help-number
| NAME = "sub-dialog-name"
}
```

where *construct-control-block* is one of:

```
{ BEFORE CONSTRUCT
| BEFORE FIELD field-spec [,...]
| AFTER FIELD field-spec [,...]
| AFTER CONSTRUCT
| ON ACTION action-name
             [INFIELD field-spec]
             [ ATTRIBUTES ( action-attributes-construct ) ]
| ON KEY ( key-name [,...] )}
    dialog-statement
    [...]
```

where *action-attributes-construct* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *display-array-block* is:

```
DISPLAY ARRAY array TO screen-array.*
   [ ATTRIBUTES ( display-array-control-attribute [,...] ) ]
   [ display-array-control-block
       [...]
   ]
END DISPLAY
```

where *display-array-control-attribute* is:

```
{ HELP = help-number
| COUNT = row-count
| KEEP CURRENT ROW = [ = boolean ]
| DETAILACTION = action-name
| DOUBLECLICK = action-name
| ACCESSORYTYPE = { DETAIBUTTON | DISCLOSUREINDICATOR | CHECKMARK }
}
```

where *display-array-control-block* is one of:

```
{ BEFORE DISPLAY
| BEFORE ROW
| AFTER ROW
| AFTER DISPLAY
| ON ACTION action-name
             [ ATTRIBUTES ( action-attributes-display-array ) ]
| ON KEY ( key-name [,...] )
| ON FILL BUFFER
| ON SELECTION CHANGE
| ON SORT
| ON APPEND [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON INSERT [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON UPDATE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON DELETE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
| ON EXPAND ( row-index )
| ON COLLAPSE ( row-index )
| ON DRAG_START ( dnd-object )
| ON DRAG_FINISH ( dnd-object )
```

```
| ON DRAG_ENTER( dnd-object )
| ON DRAG_OVER ( dnd-object )
| ON DROP ( dnd-object ) }
    dialog-statement
    [...]
```

where *action-attributes-display-array* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
| ROWBOUND
    [,...] }
```

where *action-attributes-listmod-triggers* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
    [,...] }
```

where *input-array-block* is:

```
INPUT ARRAY array FROM screen-array.*
   [ ATTRIBUTES ( input-array-control-attribute [,...] ) ]
   [ input-array-control-block
       [...]
   ]
END INPUT
```

where *input-array-control-attribute* is:

```
{ APPEND ROW [ = boolean ]
| AUTO APPEND [ = boolean ]
| COUNT = row-count
| DELETE ROW [ = boolean ]
| HELP = help-number
| INSERT ROW [ = boolean ]
| KEEP CURRENT ROW [ = boolean ]
| MAXCOUNT = max-row-count
| WITHOUT DEFAULTS [ = boolean ]
}
```

where *input-array-control-block* is one of:

```
{ BEFORE INPUT
| BEFORE ROW
| BEFORE FIELD [,...]
| ON CHANGE field-spec [,...]
| AFTER FIELD field-spec [,...]
| ON ROW CHANGE
| ON SORT
| AFTER ROW
| BEFORE DELETE
| AFTER DELETE
| BEFORE INSERT
```

```
| AFTER INSERT
| AFTER INPUT
| ON ACTION action-name
             [INFIELD field-spec]
             [ ATTRIBUTES ( action-attributes-input-array ) ]
| ON KEY ( key-name [,...] ) }
    dialog-statement
    [...]
```

where *action-attributes-input-array* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| VALIDATE = NO
| CONTEXTMENU = { YES | NO | AUTO }
| ROWBOUND
    [,...] }
```

where *dialog-statement* is one of:

```
{ statement
| ACCEPT DIALOG
| CONTINUE DIALOG
| EXIT DIALOG
| NEXT FIELD
   { CURRENT
   | NEXT
   | PREVIOUS
   | field-spec
   }
}
```

where *field-list* defines a list of fields with one or more of:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

where *field-spec* identifies a unique field with one of:

```
{ field-name
| table-name.field-name
| screen-array.field-name
| screen-record.field-name
}
```

where *column-list* defines a list of database columns as:

```
{ column-name
| table-name.*
| table-name.column-name
} [,...]
```

1. *variable-definition* is a variable declaration with data type as in a regular `DEFINE` statement.
2. *array* is the array of records used by the `DIALOG` statement.
3. *help-number* is an integer that allows you to associate a help message number with the command.
4. *field-name* is the identifier of a field of the current form.
5. *option-name* is a string expression defining the label of the action and identifying the action that can be executed by the user.
6. *option-comment* is a string expression containing a description for the menu option, displayed when *option-name* is the current.
7. *column-name* is the identifier of a database column of the current form.
8. *table-name* is the identifier of a database table of the current form.
9. *variable* is a simple program variable (not a record).
10. *record* is a program record (structured variable).
11. *screen-array* is the screen array that will be used in the current form.
12. *line* is a screen array line in the form.
13. *screen-record* is the identifier of a screen record of the current form.
14. *action-name* identifies an action that can be executed by the user.
15. *seconds* is an integer literal or variable that defines a number of seconds.
16. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
17. *row-index* identifies the program variable which holds the row index corresponding to the tree node that has been expanded or collapsed.
18. *dnd-object* references a `ui.DragDrop` variable defined in the scope of the dialog.
19. *statement* is any instruction supported by the language.
20. *action-attributes* are dialog-specific action attributes for the action.

Procedural dialog programming steps

The following steps describe how to implement a procedural `DIALOG` block:

1. Create a form specification file containing screen record(s) and/or screen array(s). The screen records and screen arrays identify the presentation elements to be used by the runtime system to display the data models (i.e. the content of program variables bound to the `DIALOG` blocks).
2. With the `DEFINE` instruction, declare program variables (i.e. records and arrays) that will be used as data models. For record lists (`DISPLAY ARRAY` or `INPUT ARRAY`), the members of the program array must correspond to the elements of the screen array, by number and data types. To handle record lists, use dynamic arrays instead of static arrays.
3. Open and display the form, using the `OPEN WINDOW WITH FORM` clause or the `OPEN FORM` / `DISPLAY FORM` instructions.
4. Fill the program variables (.i.e the model) with data. For lists, you typically use a result set cursor.
5. Implement the `DIALOG` instruction block to handle interaction. Define each sub-dialog with program variables to be used as data models. The sub-dialogs will define how variables will be used (display or input).
   a) Inside each sub-dialog instruction, define the behavior with control blocks such as `BEFORE DIALOG`, `AFTER ROW`, `BEFORE FIELD`, and interaction blocks such as `ON ACTION`.
   b) To end the `DIALOG` instruction, implement an `ON ACTION close` or `ON ACTION accept` / `ON ACTION cancel` to handle dialog validation and cancellation, with the `ACCEPT DIALOG` and `EXIT DIALOG` control instructions. The `INT_FLAG` variable will not be set as in singular dialogs.

Using multiple dialogs

To use multiple dialogs, you must understand how they work and how to structure the code.

Identifying sub-dialogs in procedural DIALOG

Sub-dialogs need to be identified by a name to distinguish the different contexts.

A procedural `DIALOG` block is a collection of sub-dialogs that act as controllers for different parts of a form. In order to program a procedural `DIALOG` block, there must be a unique identifier for each sub-dialog.

For example, to set the current row of a screen array with the `DIALOG.setCurrentRow()` method, you pass the name of the screen array to specify the sub-dialog to be affected. Sub-dialog identifiers are also used as a prefix to specify actions for the sub-dialog.

The following topics describe how to specify the names of the different types of `DIALOG` sub-dialogs:

- Identifying an INPUT sub-dialog on page 1154
- Identifying a DISPLAY ARRAY sub-dialog on page 1156
- Identifying an INPUT ARRAY sub-dialog on page 1157
- Identifying a CONSTRUCT sub-dialog on page 1155
- The SUBDIALOG clause on page 1158.

Structure of a procedural DIALOG block

A procedural `DIALOG` instruction is made of several *sub-dialogs*, plus global control blocks such as `BEFORE DIALOG` and action handlers such as `ON ACTION` or `COMMAND`.

Sub-dialogs can be defined inside the `DIALOG` instruction, or can be declared externally in another module and attached to the current `DIALOG` block with the `SUBDIALOG` clause. A dialog defined in the scope of a function is know as a *procedural dialog block*, while a dialog declared in the scope of a module is named a *declarative dialog block*.

The sub-dialogs bind program variables to form fields and define the type of interaction that will take place for the data model (simple input, list input or query). The sub-dialogs implement individual control blocks which let you control the behavior of the interactive instruction. Sub-dialogs can also hold action handlers, which will define local sub-dialog actions.

The `DIALOG` procedural instruction can hold the following type of sub-dialogs:

1. Simple record input with the `INPUT` sub-dialog block.
2. Query by example input with the `CONSTRUCT` sub-dialog block.
3. Read-only record list navigation with the `DISPLAY ARRAY` sub-dialog block.
4. Editable record list handling with the `INPUT ARRAY` sub-dialog block.
5. A `SUBDIALOG` clause referencing a declarative sub-dialog by name.

The INPUT sub-dialog
The `INPUT` sub-dialog implement single record input in fields of the current form.

Program variable to form field binding

Each record member variable is bound to the corresponding field of a screen record, in order to manipulate the values that the user enters in the form fields.

The `INPUT` clause can be used in two forms:

1. `INPUT BY NAME` *`variable-list`*
2. `INPUT` *`variable-list`* `FROM` *`field-list`*

The `BY NAME` clause implicitly binds the fields to the variables that have the same identifiers as the field names. The variables must be declared with the same names as the fields from which they accept input. The runtime system ignores any record name prefix when making the match. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exceptions, and sets the `STATUS` variable to a negative value.

```
DEFINE p_cust RECORD
       cust_num INTEGER,
       cust_name VARCHAR(50),
       cust_address VARCHAR(100)
   END RECORD
   ...
DIALOG
   INPUT BY NAME p_cust.*
```

```
      BEFORE FIELD cust_name
        ...
   END INPUT
   ...
END DIALOG
```

The FROM clause explicitly binds the fields in the screen record to a list of program variables by position. The number of variables or record members must equal the number of fields listed in the FROM clause. Each variable must be of the same (or a compatible) data types as the corresponding screen field. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

```
DEFINE c_name VARCHAR(50)
       c_addr VARCHAR(100)
   ...
DIALOG
  INPUT c_name,
        c_addr
   FROM FORMONLY.field01,
        FORMONLY.field02
    BEFORE FIELD cust_name
        ...
  END INPUT
   ...
END DIALOG
```

Identifying an INPUT sub-dialog

The name of an INPUT sub-dialog can be used to qualify sub-dialog actions with a prefix.

In order to identify the INPUT sub-dialog with a specific name, you can use the ATTRIBUTES clause to set the NAME attribute:

```
INPUT BY NAME p_cust.*
      ATTRIBUTES (NAME = "cust")
  ...
```

Control blocks in INPUT

Simple record input declared with the INPUT sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- AFTER INPUT

In the singular INPUT instruction, BEFORE INPUT and AFTER INPUT blocks are typically used as initialization and finalization blocks. In an INPUT sub-dialog of a DIALOG block, BEFORE INPUT and AFTER INPUT blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

The CONSTRUCT sub-dialog

The CONSTRUCT sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL WHERE condition that can be use to execute a SELECT statement.

Defining query by example fields

The CONSTRUCT sub-dialog requires a character string variable to hold the WHERE clause, and a list of screen fields where the user can enter search criteria.

```
DEFINE sql_condition STRING
  ...
DIALOG
  CONSTRUCT BY NAME sql_condition
      ON customer.cust_name, customer.cust_address
    BEFORE FIELD cust_name
    ...
  END CONSTRUCT
  ...
END DIALOG
```

Make sure the character string variable is large enough to store all possible SQL conditions. It is better to use a STRING data type to avoid any size problems.

CONSTRUCT uses the field data types defined in the current form file to produce the SQL conditions. This is different from other interactive instructions, where the data types of the program variables define the way to handle input/display. It is *strongly* recommended (but not mandatory) that the form field data types correspond to the data types of the program variables used for input. This is implicit if both form fields and program variables are based on the database schema file.

The CONSTRUCT clause can be used in two forms:

1. `CONSTRUCT BY NAME` *`string-variable`* `ON` *`column-list`*
2. `CONSTRUCT` *`string-variable`* `ON` *`column-list`* `FROM` *`field-list`*

The BY NAME clause implicitly binds the form fields to the columns, where the form field identifiers match the column names specified in the column-list after the ON keyword. You can specify the individual column names (separated by commas) or use the `tablename.*` shortcut to include all columns defined for a table in the database schema file.

The FROM clause explicitly binds the form fields listed after the FROM keyword with the column definitions listed after the ON keyword.

In both cases, the name of the columns in *column-list* will be used to produce the SQL condition in *string-variable*.

Identifying a CONSTRUCT sub-dialog

The name of a CONSTRUCT sub-dialog can be used to qualify sub-dialog actions with a prefix. In order to identify the CONSTRUCT sub-dialog with a specific name, use the ATTRIBUTES clause to set the NAME attribute:

```
CONSTRUCT BY NAME sql_condition ON customer.*
  ATTRIBUTES (NAME = "q_cust")
  ...
```

Control blocks in CONSTRUCT

A Query By Example declared with the CONSTRUCT clause can raise the following triggers:

- BEFORE CONSTRUCT
- BEFORE FIELD

- AFTER FIELD
- AFTER CONSTRUCT

In the singular CONSTRUCT instruction, BEFORE CONSTRUCT and AFTER CONSTRUCT blocks are typically used as initialization and finalization blocks. In DIALOG block, BEFORE CONSTRUCT and AFTER CONSTRUCT blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

The DISPLAY ARRAY sub-dialog
The DISPLAY ARRAY sub-dialog is the controller to implement the navigation in a list of records, with option data modification actions.

Program array to screen array binding

The DISPLAY ARRAY sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the TO keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the DIALOG instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
       item_num INTEGER,
       item_name VARCHAR(50),
       item_price DECIMAL(6,2)
   END RECORD
   ...
DIALOG
   DISPLAY ARRAY p_items TO sa.*
      BEFORE ROW
      ...
   END DISPLAY
   ...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
   ...
DIALOG
   DISPLAY ARRAY p_names TO sa.*
      BEFORE DELETE
      ...
   END DISPLAY
   ...
END DIALOG
```

Identifying a DISPLAY ARRAY sub-dialog

The name of the screen array specified with the TO clause identifies the list. The dialog class method such as takes the name of the screen array as the parameter, identifying the list. For example, you would use `DIALOG.getCurrentRow("screen-array")` to query for the current row in the list identified by 'screen-array'. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

Control blocks in DISPLAY ARRAY

Read-only record lists declared with the DISPLAY ARRAY sub-dialog can raise the following triggers:

- BEFORE DISPLAY
- BEFORE ROW
- AFTER ROW
- AFTER DISPLAY

In the singular `DISPLAY ARRAY`instruction, `BEFORE DISPLAY` and `AFTER DISPLAY` blocks are typically used as initialization and finalization blocks. In a `DISPLAY ARRAY` sub-dialog of a `DIALOG` block, `BEFORE DISPLAY` and `AFTER DISPLAY` blocks will be executed each time the focus goes to (`BEFORE`) or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The INPUT ARRAY sub-dialog
The `INPUT ARRAY` sub-dialog is the controller to implement the navigation and edition in a list of records.

> **Important:** This feature is not supported on mobile platforms.

Program array to screen array binding

The `INPUT ARRAY` sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the `FROM` keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the `DIALOG` instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
       item_num INTEGER,
       item_name VARCHAR(50),
       item_price DECIMAL(6,2)
   END RECORD
   ...
DIALOG
   INPUT ARRAY p_items FROM sa.*
      BEFORE INSERT
      ...
   END INPUT
   ...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
   ...
DIALOG
   INPUT ARRAY p_names FROM sa.*
      BEFORE DELETE
      ...
   END INPUT
   ...
END DIALOG
```

Identifying an INPUT ARRAY sub-dialog

The name of the screen array specified with the `FROM` clause will be used to identify the list. For example, the dialog class method such as `DIALOG.getCurrentRow("screen-array")` takes the name of the screen array as the parameter, to identify the list you want to query for the current row. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

Control blocks in INPUT ARRAY

Editable record lists declared with the `INPUT ARRAY` sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE ROW
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- ON ROW CHANGE
- AFTER ROW
- BEFORE DELETE
- AFTER DELETE
- BEFORE INSERT
- AFTER INSERT
- AFTER INPUT

In the singular `INPUT ARRAY` instruction, `BEFORE INPUT` and `AFTER INPUT` blocks are typically used as initialization and finalization blocks. In the `INPUT ARRAY` sub-dialog of a `DIALOG` block, `BEFORE INPUT` and `AFTER INPUT` blocks will be executed each time the focus goes to (`BEFORE`)or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The SUBDIALOG clause

The `SUBDIALOG` clause attaches a declarative dialog to the current procedural `DIALOG` block. The declarative dialog will be implemented outside of the scope of the current dialog, at the same level as a function. The declarative dialog can be defined in a different module.

In terms of semantics, behavior and control block execution, a declarative dialog attached to a procedural dialog behaves like a sub-dialog that is defined inside the procedural `DIALOG` block. For example, the `BEFORE INPUT` control block will be executed for a declarative dialog when the focus goes to one of the fields of that sub-dialog.

Other sub-dialogs can reference the attached declarative dialog in the current scope, for example to execute a `NEXT FIELD` instruction referencing a field in another sub-dialog.

When using the `DIALOG` keyword inside a declarative dialog block to use `ui.Dialog` class methods, it references the current procedural dialog object.

Like other module elements such as functions and reports, the name specification is mandatory when defining a declarative dialog. The name of the declarative dialog will be referenced in a `SUBDIALOG` clause of a procedural dialog instruction.

Implementing a sub-dialog as a declarative dialog in a separate module can be used in conjunction with the form inclusion directive in the `LAYOUT` section of form specification files. With form inclusion and declarative dialogs, you enforce code reusability in your application sources.

Note that declarative dialog blocks can also be used to implement parallel dialogs.

Procedural DIALOG block configuration

This sections describes the `ATTRIBUTES` clause attributes that can be used to configure a procedural `DIALOG` instruction and its sub-dialogs.

The `ATTRIBUTES` clause of dialogs overrides all default attributes and temporarily override any display attributes that the `OPTIONS` or the `OPEN WINDOW` statement specified for these fields.

DIALOG ATTRIBUTES clause

FIELD ORDER FORM option

By default, the form tabbing order is defined by the variable list in the binding specification. You can control the tabbing order by using the `FIELD ORDER FORM` attribute; when this attribute is used, the tabbing order is defined by the `TABINDEX` attribute of the form items.

The field order mode can also be specified globally with the `OPTIONS FIELD ORDER` instruction.

With `FIELD ORDER FORM`, if the user changes the focus from field A to a distant field B with the mouse, the dialog does not execute the `BEFORE FIELD` / `AFTER FIELD` triggers of intermediate fields which appear in the binding specification between field A and field B. Unlike singular dialogs, if the default `FIELD ORDER CONSTRAINT` mode is used in a multiple dialog instruction, intermediate triggers are never executed (i.e. the `Dialog.fieldOrder` FGLPROFILE entry is ignored by `DIALOG`.)

See also Defining the tabbing order on page 1271.

UNBUFFERED option

The `UNBUFFERED` attribute indicates that the dialog must be sensitive to program variable changes. When using this option, you bypass the compatible "buffered" mode.

The unbuffered mode can be set globally for all `DIALOG` instructions with the `ui.Dialog.setDefaultUnbuffered()` class method:

```
CALL ui.Dialog.setDefaultUnbuffered(TRUE)
DIALOG -- Will work in UNBUFFERED mode     ...
END DIALOG
```

INPUT ATTRIBUTES clause
Attributes of the INPUT clause of a DIALOG block.

NAME option

The `NAME` attribute can be used to identify the `INPUT` sub-dialog, especially useful to qualify sub-dialog actions.

HELP option

The `HELP` attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the `INPUT` sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The `HELP` clause overrides the `HELP` attribute.

WITHOUT DEFAULTS option

By default, sub-dialogs use the default values defined in the form files. If you want to use the values stored in the program variables bound to the dialog, you must use the `WITHOUT DEFAULTS` attribute. For more details see WITHOUT DEFAULTS option.

DISPLAY ARRAY ATTRIBUTES clause
Attributes of the DISPLAY ARRAY clause of a DIALOG block.

HELP option

The `HELP` attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the `DISPLAY ARRAY` sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The `HELP` clause overrides the `HELP` attribute.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array, unless page mode is used. In this case, the COUNT attribute must be used to define the total number of rows, because the dynamic array will only hold a page of the entire row set. If the value of COUNT is negative or zero, it defines an empty list.

See also Controlling the total number of rows on page 1350.

DOUBLECLICK option

The DOUBLICKCLICK option can be used to define the action that will be fired when the user chooses a row from the list. On front-end platforms using a mouse-device, this corresponds to a physical double-click on a row with the mouse. On mobile front-ends, this corresponds to a tap on the row with a finger. Note that this attribute can also be defined for the TABLE/TREE containers in form files; DOUBLECLICK in DISPLAY ARRAY attributes has a higher precedence as DOUBLECLICK in the form file. For more details, see Defining the action for a row choice on page 1360.

ACCESSORTYPE option

Important: This feature is only for mobile platforms.

The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on a iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or checkmark icon. For more details, see Row configuration on iOS devices on page 1369.

DETAILACTION option

Important: This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1369.

INPUT ARRAY ATTRIBUTES clause
Attributes of the INPUT ARRAY clause of a DIALOG block.

INPUT ARRAY specific attributes can be defined in the ATTRIBUTE clause of the sub-dialog header:

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

You typically use the INPUT ARRAY sub-dialog with the WITHOUT DEFAULTS attribute. If this attribute is not set when using an INPUT ARRAY sub-dialog, the list is empty even if the array holds data. For more details see WITHOUT DEFAULTS option.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array. If you specify

the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.

MAXCOUNT option

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter. It can be used with static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter when using a singular INPUT ARRAY), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.

APPEND ROW option

The APPEND ROW attribute can be set to FALSE to avoid the append default action, and deny the user to add rows at the end of the list. If APPEND ROW =FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

INSERT ROW option

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and deny the user to insert new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and deny the user to remove rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, an new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

CONSTRUCT ATTRIBUTES clause
Attributes of the CONSTRUCT clause of a DIALOG block.

HELP option

The `HELP` attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the `CONSTRUCT` sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The `HELP` clause overrides the `HELP` attribute.

NAME option

The `NAME` attribute can be used to identify the `CONSTRUCT` sub-dialog; this is especially useful to qualify sub-dialog actions.

Default actions created by a DIALOG block
Default actions ease the implementation of the controller by providing expected actions.

According to the sub-dialogs defined in a (declarative or procedural) `DIALOG` block, the runtime system creates a set of default actions. These actions are provided to ease the implementation of the controller. For example, when using an `INPUT ARRAY` sub-dialog, the dialog instruction will automatically create the insert, append and delete default actions.

Table 280: Default actions created for the DIALOG block on page 1162 lists the default actions created for the `DIALOG` interactive instruction, according to the sub-dialogs defined:

Table 280: Default actions created for the DIALOG block

Default action	Control Block execution order
`help`	Shows the help topic defined by the `HELP` clause. *Only created when a* `HELP` *clause or option is defined for the sub-dialog.*
`insert`	Inserts a new row before current row. *Only created if* `INPUT ARRAY` *is used; action creation can be avoided with* `INSERT ROW = FALSE` *attribute.*
`append`	Appends a new row at the end of the list. *Only created if* `INPUT ARRAY` *is used; action creation can be avoided with* `APPEND ROW = FALSE` *attribute.*
`delete`	Deletes the current row. *Only created if* `INPUT ARRAY` *is used;* action *creation can be avoided with* `DELETE ROW = FALSE` *attribute.*
`nextrow`	Moves to the next row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*

Default action	Control Block execution order
`prevrow`	Moves to the previous row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`firstrow`	Moves to the first row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`lastrow`	Moves to the last row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`find`	Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. *Only created if the context allows built-in find.*
`findnext`	Seeks to the next row matching the value entered during the fglfind dialog. *Only created if the context allows built-in find.*

The `insert`, `append` and `delete` default actions can be avoided with dialog control attributes:

```
INPUT ARRAY arr TO sr.* ATTRIBUTES( INSERT ROW=FALSE, APPEND
 ROW=FALSE, ... )
     ...
```

DIALOG data blocks

Dialog data blocks are dialog triggers invoked when the dialog controller needs data to feed the view with values.

Such blocks are typically used when record list data is provided dynamically, with the paged mode or when implementing dynamic tree-views.

- ON FILL BUFFER block on page 1082
- ON EXPAND block on page 1082
- ON COLLAPSE block on page 1082

ON FILL BUFFER block

The `ON FILL BUFFER` block is used to fill a page of rows into the dynamic array, according to an offset and a number of rows.

This data block is used in the `DISPLAY ARRAY` blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.

ON EXPAND block
The `ON EXPAND` block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are added according to the nodes opened by the end user.

ON COLLAPSE block
The `ON COLLAPSE` block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are removed according to the nodes closed by the end user.

DIALOG control blocks
Dialog control blocks are predefined dialog triggers where you can implement specific code to control the interactive instruction.

The code could involve using `ui.Dialog` class methods or dialog specific instructions such as `NEXT FIELD` or `CONTINUE DIALOG`.

- Control block execution order in parallel dialogs on page 1220
- BEFORE FIELD block on page 1069
- AFTER FIELD block on page 1070
- ON CHANGE block on page 1069
- BEFORE INPUT block on page 1067
- AFTER INPUT block on page 1068
- BEFORE CONSTRUCT block on page 1135
- AFTER CONSTRUCT block on page 1135
- BEFORE DISPLAY block on page 1082
- AFTER DISPLAY block on page 1083
- BEFORE ROW block on page 1083
- ON ROW CHANGE block on page 1110
- AFTER ROW block on page 1084
- BEFORE INSERT block on page 1113
- AFTER INSERT block on page 1113
- BEFORE DELETE block on page 1114
- AFTER DELETE block on page 1114
- BEFORE MENU block on page 1054

Control block execution order in multiple dialogs

This table shows the order in which control blocks are executed in a procedural `DIALOG` instruction, according to the context and user action:

Table 281: Control block execution order for a procedural dialog

Context / User action	Control Block execution order
Entering the dialog	**1.** `BEFORE DIALOG` **2.** `BEFORE INPUT`, `BEFORE CONSTRUCT` or `BEFORE DISPLAY` (first sub-dialog getting focus) **3.** `BEFORE ROW` (if focus goes to a list) **4.** `BEFORE FIELD` (if focus goes to a field)
When the focus goes to an `INPUT`or to a `CONSTRUCT` from a different sub-dialog	**1.** *Triggers raised by the context of the sub-dialog you leave* **2.** `BEFORE INPUT` or `BEFORE CONSTRUCT` (new sub-dialog getting focus)

Context / User action	Control Block execution order
	3. `BEFORE FIELD`
When the focus leaves an `INPUT` or a `CONSTRUCT` to a different sub-dialog	**1.** `ON CHANGE` (if INPUT and value of current field has changed) **2.** `AFTER FIELD` (for the current field) **3.** `AFTER INPUT` or `AFTER CONSTRUCT` (current sub-dialog losing focus) **4.** *Triggers raised by the context of the sub-dialog you enter*
When the focus goes to a `DISPLAY ARRAY` list or to an `INPUT ARRAY` list from a different sub-dialog	**1.** *Triggers raised by the context of the sub-dialog you leave* **2.** `BEFORE INPUT` or `BEFORE DISPLAY` (new sub-dialog getting focus) **3.** `BEFORE ROW` (the row that was selected in the list) **4.** `BEFORE FIELD` (if it's an INPUT ARRAY)
When the focus leaves a `DISPLAY ARRAY` or `INPUT ARRAY` list to a different sub-dialog	**1.** `ON CHANGE` (if INPUT ARRAY and value of current field has changed) **2.** `AFTER FIELD` (if it's an INPUT ARRAY) **3.** `AFTER INSERT` (if INPUT ARRAY and current row was just created) or `ON ROW CHANGE` (if INPUT ARRAY and a value in the row has changed) **4.** `AFTER ROW` (the current row in the list you leave) **5.** `AFTER INPUT` or `AFTER DISPLAY` (current sub-dialog losing focus) **6.** *Triggers raised by the context of the sub-dialog you enter*
Moving from field A to field B in an `INPUT` or `CONSTRUCT` sub-dialog or in the same row of an `INPUT ARRAY` list	**1.** `ON CHANGE` (if value of current field has changed) **2.** `AFTER FIELD A` **3.** `BEFORE FIELD B`
Moving from field A of an `INPUT` or `CONSTRUCT` sub-dialog to field B in another `INPUT` or `CONSTRUCT` sub-dialog	**1.** `ON CHANGE` (if value of current field has changed) **2.** `AFTER FIELD A` **3.** `AFTER INPUT` or `AFTER CONSTRUCT` (for sub-dialog of field A) **4.** `BEFORE INPUT` or `BEFORE CONSTRUCT` (for sub-dialog of field B) **5.** `BEFORE FIELD B`
Moving to a different row in a `DISPLAY ARRAY` list	**1.** `AFTER ROW` (the row you leave) **2.** `BEFORE ROW` (the new current row)

Context / User action	**Control Block execution order**
Moving to a different row in an `INPUT ARRAY` list when current row was newly created	**1.** `ON CHANGE` (if value of current field has changed) **2.** `AFTER FIELD` (for field A in the row you leave) **3.** `AFTER INSERT` (the newly created row) **4.** `AFTER ROW` (the newly created row) **5.** `BEFORE ROW` (the new current row) **6.** `BEFORE FIELD` (field in the new current row)
Moving to a different row in an `INPUT ARRAY` list when current row was modified	**1.** `ON CHANGE` (if value of current field has changed) **2.** `AFTER FIELD` (for field A in the row you leave) **3.** `ON ROW CHANGE` (the values in current row have changed) **4.** `AFTER ROW` (for the row that was modified) **5.** `BEFORE ROW` (the new current row) **6.** `BEFORE FIELD` (field in the new current row)
Inserting or appending a new row in an `INPUT ARRAY` list	**1.** *Triggers raised by the context of the sub-dialog you leave* **2.** `BEFORE INSERT` (for the new current row) **3.** `BEFORE ROW` (the new current row) **4.** `BEFORE FIELD` (field in the new current row)
Deleting a row in an `INPUT ARRAY` list	**1.** `BEFORE DELETE` (for the current row to be deleted) **2.** `AFTER DELETE` (now the deleted row is removed) **3.** `AFTER ROW` (for the deleted row) **4.** `BEFORE ROW` (the new current row)
Firing the *insert* or *append* action for the `ON INSERT` block in a `DISPLAY ARRAY` list	**1.** `AFTER ROW` **2.** `ON INSERT` **3.** `BEFORE ROW`
Firing the *delete* action for the `ON DELETE` block in a `DISPLAY ARRAY` list	**1.** `AFTER ROW` **2.** `ON DELETE` **3.** `BEFORE ROW`
Validating the dialog with `ACCEPT DIALOG`	**1.** `ON CHANGE` (if focus is in input field and value has changed) **2.** `AFTER FIELD` (if focus is in input field) **3.** `AFTER INSERT` (if INPUT ARRAY and current row was just created) or `ON ROW CHANGE` (if INPUT ARRAY and a value in the row has changed) **4.** `AFTER ROW` (if focus is in a list) **5.** `AFTER INPUT`, `AFTER CONSTRUCT` or `AFTER CONSTRUCT` (current sub-dialog)

Context / User action	Control Block execution order
	6. AFTER DIALOG
Canceling the dialog with EXIT DIALOG	None of the control blocks will be executed; we just leave the dialog instruction.

BEFORE DIALOG block

The BEFORE DIALOG block is executed one time as the first trigger when the DIALOG instruction starts, before the runtime system gives control to the user. You can implement variable initialization and dialog configuration in this block.

In this example, the BEFORE DIALOG block performs some dialog setup and gives the focus to a specific field:

```
BEFORE DIALOG
  CALL DIALOG.setActionActive("save",FALSE)
  CALL DIALOG.setFieldActive("cust_status", is_admin())
  IF cust_is_new() THEN
     NEXT FIELD cust_name
  END IF
```

A DIALOG instruction can include no more than one BEFORE DIALOG control block.

AFTER DIALOG block

The AFTER DIALOG block is executed one time as the last trigger when the DIALOG instruction terminates, when performing an ACCEPT DIALOG instruction. Dialog finalization code can be implemented in this block.

The dialog terminates when an ACCEPT DIALOG or EXIT DIALOG control instruction is executed. However, the AFTER DIALOG block is not executed if an EXIT DIALOG is performed.

If you execute one of the following control instructions in an AFTER DIALOG block, the dialog will not terminate and it will give control back to the user:

1. NEXT FIELD
2. NEXT OPTION
3. CONTINUE DIALOG

In the next example, the AFTER DIALOG block checks whether a field value is correct and gives control back to the dialog if the value is wrong:

```
ON ACTION accept
   ACCEPT DIALOG
...
AFTER DIALOG
  IF NOT cust_is_valid_status(p_cust.cust_status) THEN
     ERROR "Customer state is not valid"
     NEXT FIELD cust_status
  END IF
```

BEFORE FIELD block

For fields controlled by an INPUT, INPUT ARRAY or by a CONSTRUCT instructions, the BEFORE FIELD block is executed every time the cursor enters into the specified field.

For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
   BEFORE FIELD cust_status
     LET p_cust.cust_comment = NULL
     MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block might be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

AFTER FIELD block

In dialog parts driven by a simple INPUT, INPUT ARRAY or by a CONSTRUCT sub-dialog, the AFTER FIELD block is executed every time the focus leaves the specified field. For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
   AFTER FIELD item_quantity
     IF p_item.item_quantity <= 0 THEN
        ERROR "Item quantity cannot be negative or zero"
        LET p_item.item_quantity = 0
        NEXT FIELD item_quantity
     END IF
```

ON CHANGE block

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set. The ON CHANGE block can only be used for fields controlled by an INPUT or INPUT ARRAY dialog, it is not available in CONSTRUCT.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
   ON CHANGE order_checked -- Defined as CHECKBOX
      CALL setup_dialog(DIALOG)
```

If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had leaved and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This denies to do field validation in ON CHANGE blocks: you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

BEFORE INPUT block

BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE INPUT is only executed once when the dialog is started.

The BEFORE INPUT block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ...
   BEFORE INPUT
       MESSAGE "Input customer information"
       CALL DIALOG.setActionActive("check_info", is_super_user() )
       CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
   ...
```

The fields are initialized with the defaults values before the BEFORE INPUT block is executed. When the INPUT instruction uses the WITHOUT DEFAULTS option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the DEFAULT attributes of the form fields are used.

Use the NEXT FIELD control instruction in the BEFORE INPUT block, to jump to a specific field when the dialog starts.

BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE INPUT` block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `BEFORE INPUT` block.

`BEFORE INPUT` is executed after the `BEFORE DIALOG` block andbefore the `BEFORE ROW`, `BEFORE FIELD` blocks.

In this example, the `BEFORE INPUT` block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
   BEFORE INPUT
       CALL DIALOG.setActionActive("validate_order", TRUE)
```

AFTER INPUT block

AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER INPUT` is only executed once when dialog ends.

The `AFTER INPUT` block is executed after the user has validated or canceled the `INPUT` or `INPUT ARRAY` dialog with the accept or cancel default actions, or when the `ACCEPT INPUT` instruction is executed.

The `AFTER INPUT` block is not executed when the `EXIT INPUT` instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the `NEXT FIELD` instruction to force the dialog to continue. The `CONTINUE INPUT` instruction can be used instead of `NEXT FIELD`, when no particular field has to be select.

Before checking the validation rules, make sure that the `INT_FLAG` variable is `FALSE`: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
  ...

  AFTER INPUT
    IF NOT INT_FLAG THEN
       IF cust_rec.cust_address IS NOT NULL
          AND cust_rec.cust_zipcode IS NULL THEN
          ERROR "Address is incomplete, enter a zipcode."
          NEXT FIELD zipcode
       END IF
    END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER INPUT` block is executed when the focus is lost by a group of fields driven by an `INPUT` or `INPUT ARRAY` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the

focus. When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the AFTER INPUT block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER INPUT is executed after the AFTER FIELD, AFTER ROW blocks and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER INPUT control block will keep the focus in the group of fields. Within an INPUT ARRAY sub-dialog, NEXT FIELD will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the AFTER INPUT block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
   AFTER INPUT
      IF NOT check_order_data(DIALOG) THEN
        NEXT FIELD CURRENT
      END IF
      CALL DIALOG.setFieldActive("validate_order", FALSE)
```

BEFORE CONSTRUCT block

BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular CONSTRUCT instruction, or when used as parallel dialog, the BEFORE CONSTRUCT is only executed once when dialog is started.

The BEFORE CONSTRUCT block is executed once at dialog startup, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
CONSTRUCT BY NAME where_part ON ...
   BEFORE CONSTRUCT
       MESSAGE "Enter customer search filter"
       CALL DIALOG.setActionActive("clean", FALSE )
   ...
```

The fields are cleared before the BEFORE CONSTRUCT block is executed.

You can use the NEXT FIELD control instruction in the BEFORE CONSTRUCT block, to jump to a specific field when the dialog starts.

BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the BEFORE CONSTRUCT block is executed when the focus goes to a group of fields driven by a CONSTRUCT sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

BEFORE CONSTRUCT is executed after the BEFORE DIALOG block and before the BEFORE FIELD blocks.

In this example, the BEFORE CONSTRUCT block is used to display a message:

```
CONSTRUCT BY NAME sql ON customer.*
  BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
```

AFTER CONSTRUCT block

AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `AFTER CONSTRUCT` is only executed once when dialog is ended.

Use an `AFTER CONSTRUCT` block to execute instructions after the user has finished search criteria input.

`AFTER CONSTRUCT` is not executed if an `EXIT CONSTRUCT` is performed.

The code in `AFTER CONSTRUCT` can for example check if a criteria combination of different fields is required or denied, and force the end use to enter all

Before checking the content of the fields used in the `CONSTRUCT`, make sure that the `INT_FLAG` variable is `FALSE`: in case if the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated to the form fields, you must query the input buffers of the fields to get the values entered by the user.

```
CONSTRUCT BY NAME where_part ON ...
  ...
  AFTER CONSTRUCT
    IF NOT INT_FLAG THEN
       IF length(DIALOG.getFieldBuffer(cust_name))==0
       OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
          ERROR "Enter a search criteria for customer name and address
 fields."
          NEXT FIELD CURRENT
       END IF
    END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a `CONSTRUCT` sub-dialog of a procedural `DIALOG` instruction, the `AFTER CONSTRUCT` block is executed when the focus is lost by a group of fields driven by a `CONSTRUCT` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER CONSTRUCT` is executed after the `AFTER FIELD` and before the `AFTER DIALOG` block.

Executing a `NEXT FIELD` in the `AFTER CONSTRUCT` control block will keep the focus in the group of fields.

In this example, the `AFTER CONSTRUCT` block is used to build the SELECT statement:

```
CONSTRUCT BY NAME sql ON customer.*
   AFTER CONSTRUCT
       LET sql = "SELECT * FROM customers WHERE " || sql
```

BEFORE DISPLAY block

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the `BEFORE DISPLAY` is only executed once when the dialog is started.

The `BEFORE DISPLAY` block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE DISPLAY` block is executed when a `DISPLAY ARRAY` list gets the focus.

`BEFORE DISPLAY` is executed before the `BEFORE ROW` block.

In this example the `BEFORE DISPLAY` block enables an action and displays a message:

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
       CALL DIALOG.setActionActive("print_list", TRUE)
       MESSAGE "You are now in the list of items"
```

AFTER DISPLAY block

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the `AFTER DISPLAY` is only executed once when dialog is ended.

You typically implement dialog finalization in this block.

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       DISPLAY "Current row is: ", arr_curr()
```

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER DISPLAY` block is executed when a `DISPLAY ARRAY` list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER DISPLAY` is executed after the `AFTER ROW` block.

In this example, the `AFTER DISPLAY` block disables an action that is specific to the current list:

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

BEFORE ROW block

BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE ROW block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, BEFORE ROW will be executed for the current row, but only if there are data rows in the array.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.

In this example, the BEFORE ROW block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
   ...
   BEFORE ROW
     MESSAGE "We are on row # ", arr_curr()
   ...
```

BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the BEFORE DISPLAY or BEFORE INPUT blocks instead.

In DISPLAY ARRAY, BEFORE ROW is executed after the BEFORE DISPLAY block. In INPUT ARRAY, BEFORE ROW is executed before the BEFORE INSERT and BEFORE FIELD blocks and after the BEFORE INPUT blocks.

When the procedural dialog starts, BEFORE ROW will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, BEFORE ROW will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular DISPLAY ARRAY or INPUT ARRAY. In singular dialogs, the BEFORE ROW block is always executed when the dialog starts (and there are rows in the array).

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.

In this example the BEFORE ROW block displays a message with the current row number:

```
   DISPLAY ARRAY p_items TO s_items.*
     BEFORE ROW
       MESSAGE "We are in items, on row #", DIALOG.getCurrentRow("s_items")
```

ON ROW CHANGE block

The ON ROW CHANGE block is executed in a list controlled by an INPUT ARRAY, when leaving the current row and when the row has been modified since it got the focus. This is typically used to detect row modification.

The code in ON ROW CHANGE will not be executed when leaving new rows created by the user with the default append or insert action. To detect row creation, you must use the BEFORE INSERT or AFTER INSERT control blocks.

The ON ROW CHANGE block is only executed if at least one field value in the current row has changed since the row was entered, and the modification flag of the field is set. The modified field(s) might not be the current field, and several field values can be changed. Values might have been changed by the user or by the program. The modification flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog instruction.

ON ROW CHANGE is executed after the AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row that has been changed.

You can, for example, code database modifications (UPDATE) in the ON ROW CHANGE block:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   ON ROW CHANGE
     LET r = DIALOG.getCurrentRow("s_items")
     UPDATE items SET
             items.item_code        = p_items[r].item_code,
             items.item_description = p_items[r].item_description,
             items.item_price       = p_items[r].item_price,
             items.item_updatedate  = TODAY
            WHERE items.item_num = p_items[r].item_num
```

AFTER ROW block

AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

AFTER ROW and temporary rows in INPUT ARRAY

> **Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The `AFTER ROW` block will be executed for the temporary row, but `ui.Dialog.getCurrentRow()`/`arr_curr()` will be one row greater than `ui.Dialog.getArrayLength()`/`ARR_COUNT()`. In this case, you should ignore the `AFTER ROW` event. For example, you should not try to execute a `NEXT FIELD` or `CONTINUE INPUT` instruction, nor should you try to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.**

In this example, the `AFTER ROW` block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   AFTER ROW
      LET r = DIALOG.getCurrentRow("s_items")
      IF r <= DIALOG.getArrayLength("s_items") THEN
        IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
           ERROR "Item quantity is not valid"
           NEXT FIELD item_quantity'
         END IF
      END IF
```

Another way to handle the case of temporary rows in `AFTER ROW` is to use a flag to know if the `AFTER INSERT` block was executed: The `AFTER INSERT` block is not executed if the temporary row is automatically removed. By setting a first value in `BEFORE INSERT` and changing the flag in `AFTER INSERT`, you can detect if the row was permanently added to the list:

```
INPUT ARRAY p_items FROM s_items.*
  ...
  BEFORE INSERT
    LET op = "T"
    ...
  AFTER INSERT
    LET op = "I"
    ...
  AFTER ROW
    IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity
        END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
                        VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
...
```

BEFORE INSERT block

The BEFORE INSERT block is executed when a new row ins created in an INPUT ARRAY. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing a insert action, or by executing an append action.

The BEFORE INSERT block is executed after the BEFORE ROW block and before the BEFORE FIELD block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (DIALOG.getCurrentRow("*screen-array*")) with the total number of rows (DIALOG.getArrayLength("*screen-array*")). If the current row index and the total number of rows correspond, the BEFORE INSERT concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the CANCEL INSERT instruction inside BEFORE INSERT. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with DIALOG.setActionActive().

In this example, the BEFORE INSERT block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    BEFORE INSERT
      IF NOT user_can_append THEN
         ERROR "You are not allowed to append rows"
         CANCEL INSERT
      END IF
      LET r = DIALOG.getCurrentRow("s_items")
      LET p_items[r].item_num = get_new_serial("items")
      LET p_items[r].item_name = "undefined"
```

AFTER INSERT block

The AFTER INSERT block of INPUT ARRAY is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

The AFTER INSERT block is executed afterthe AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the AFTER INSERT block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the AFTER INSERT block.

When executing a NEXT FIELD in the AFTER INSERT block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row input validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the BEFORE INSERT / AFTER INSERT triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a NEXT FIELD in the AFTER ROW block.

In this example, the AFTER INSERT block inserts a new row in the database and cancels the operation if the SQL command fails:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    AFTER INSERT
      WHENEVER ERROR CONTINUE
```

```
      INSERT INTO items VALUES
 ( p_items[DIALOG.getCurrentRow("s_items")].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<>0 THEN
         ERROR SQLERRMESSAGE
         CANCEL INSERT
      END IF
```

BEFORE DELETE block

The BEFORE DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, before the row is removed from the list.

You typically code the database table synchronization in the BEFORE DELETE block, by executing a DELETE SQL statement using the primary key of the current row. In the BEFORE DELETE block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The BEFORE DELETE block is executed before the AFTER DELETE block.

If needed, the deletion can be canceled with the CANCEL DELETE instruction.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that will be deleted.

The next example uses the BEFORE DELETE block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```
INPUT ARRAY p_items FROM s_items.*
  BEFORE DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    WHENEVER ERROR CONTINUE
    DELETE FROM items
       WHERE item_num = p_items[r].item_num
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<>0 VALUES
      ERROR SQLERRMESSAGE
      CANCEL DELETE
    END IF
...
```

AFTER DELETE block

The AFTER DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, after the row has been deleted from the list.

The AFTER DELETE block is executed after the BEFORE DELETE block and before the AFTER ROW block for the deleted row and the BEFORE ROW block of the new current row.

When an AFTER DELETE block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The arr_curr() function or the ui.Dialog.getCurrentRow() method returns the same index as in BEFORE ROW, but it is the index of the new current row. The AFTER ROW block is also executed just after the AFTER DELETE block.

> **Important: When deleting the last row of the list, AFTER DELETE is executed for the delete row, and DIALOG.getCurrentRow() / arr_curr() will be one higher as DIALOG.getArrayLength() / ARR_COUNT(). You should not access a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after ARR_COUNT().**

Here the AFTER DELETE block is used to re-number the rows with a new item line number (note that DIALOG.getArrayLength() / ARR_COUNT() may return zero):

```
INPUT ARRAY p_items FROM s_items.*
   AFTER DELETE
      LET r = DIALOG.getCurrentRow("s_items")
      FOR i=r TO DIALOG.getArrayLength("s_items")
          LET p_items[i].item_lineno = i
      END FOR
...
```

It is not possible to use the CANCEL DELETE instruction in an AFTER DELETE block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

DIALOG interaction blocks

Dialog interaction blocks are dialog triggers that can be used to execute specific code when the user executes an action in the dialog. For example, when pressing a button in the form, the corresponding ON ACTION interaction block will be executed.

Interaction blocks also include special handlers such as timeout event handler, drag & drop handlers, and modification triggers for DISPLAY ARRAY sub-dialogs.

- ON ACTION block on page 1056
- ON IDLE block on page 1046
- ON KEY block on page 1046
- ON APPEND block on page 1088
- ON INSERT block on page 1088
- ON UPDATE block on page 1089
- ON DELETE block on page 1090
- ON SELECTION CHANGE block on page 1090
- ON DRAG_START block on page 1091
- ON DRAG_FINISHED block on page 1091
- ON DRAG_ENTER block on page 1092
- ON DRAG_OVER block on page 1093
- ON DROP block on page 1094

ON ACTION block

The ON ACTION *action-name* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
  ON ACTION action-name
     instruction
     ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
   ON ACTION zoom
      CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```
   ON ACTION zoom INFIELD cust_city
      CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```
   ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The ON IDLE *seconds* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An ON KEY (*key-name*) block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The ON KEY block is supported for backward compatibility with TUI mode applications.

An ON KEY block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, ON KEY(F5,F6) creates two actions with the names f5 and f6. Each action object will get an ACCELERATORNAME assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for ON KEY actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, ON KEY statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs,

because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

COMMAND [KEY] block

Use `COMMAND [KEY]` blocks as global procedural `DIALOG` action handler to execute a sequence of instructions when the user clicks on a button or presses a specific key. `COMMAND` defines the text and comment decoration attributes as well as accelerator keys for a specific action. `COMMAND` is especially useful when writing TUI programs, however, it's legal to use such handler when programming new GUI dialogs, especially when the action view (`BUTTON` in form) must take the focus.

Declaring a `COMMAND` block in `DIALOG` is similar to an `ON ACTION` block, except that `COMMAND` defines an implicit text and comment decoration attribute. The name of the action will be the command text converted to lowercase letters. For example, with the following code:

```
COMMAND "Open" "Opens a new file"
```

The name of the action will be "`open`", and the default decoration text will be "`Open`" with a capital letter.

Note that if you use an ampersand (&) in the command name, some front-ends consider the letter following & as an Alt-key accelerator, and the letter will be underscored. However the ampersand forms part of the action name. For example, `COMMAND "&Save"` will create an action with the name "`&save`". It is not recommended to use & ampersand characters in action names.

Unlike `ON KEY` actions, if no explicit action view is defined in the form, the default action view will be visible for a `COMMAND` hander (i.e. the automatic button will appear for this action on the front-end).

action defaults will be applied by using the action name. For explicit action views such as a `BUTTON` in the form layout, the text/comment defined in the corresponding action default entry will overwrite the values used in the `COMMAND` handler. When no explicit action view is defined in the form, the text/comment defined in the program `COMMAND` clause take precedence over action defaults, to display the default action view (button on action frame).

Inside `DIALOG` instruction, `COMMAND` blocks can only be defined as global dialog actions; Sub-dialog specific `COMMAND` handlers cannot be defined. When binding a form `BUTTON` to a `COMMAND` handler, the

button can get the focus and will be managed in the tabbing list, using preferably the `FIELD ORDER FORM` option.

When using the optional `KEY` clause, `COMMAND` defines also an implicit accelerator key. The key name must be specified between parentheses with `COMMAND KEY`:

```
COMMAND KEY (F5) "Open" "Opens a new file"
```

The `COMMAND KEY` syntax allows multiple key names in the syntax. When using multiple keys in an `COMMAND KEY` clause, the `DIALOG` instruction will assign the specified keys as accelerators:

```
COMMAND KEY (F5, CONTROL-P, CONTROL-Z) "Open" "Opens a new file"
```

With the above code example, the action name will be "`open`" and accelerators will be F5, CONTROL-P and CONTROL-Z.

The keys defined by program will take precedence over the accelerators defined in the action default entry corresponding to the action.

The `COMMAND [KEY]` block specification can also define a help number with the `HELP` clause, to display the corresponding text of the current help file.

```
COMMAND "Open" "Opens a new file" HELP 34
```

ON APPEND block

Similarly to the `ON INSERT` control block, the `ON APPEND` trigger can be used to enable row creation during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an `ON ACTION append` interaction block and the `ON APPEND` block is used, the compiler will stop with error -8408.

When the user fires the append action, the dialog first execute the user code of the `AFTER ROW` block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the `ON APPEND` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular `INPUT` statement, to let the end user enter data for the new created row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `SCR_LINE()`:

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON APPEND
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the new row is kept in the program array, and the `BEFORE ROW` block is executed for the new created row.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the new row is removed from the program array, and the `BEFORE ROW` block is executed for the row that was existing at the current position, before the new row was created.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON APPEND` block.

The append action is disabled if the maximum number of rows is reached.

If needed, the `ON APPEND` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON APPEND ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON INSERT block

Similarly to the `ON APPEND` control block, the `ON INSERT` trigger can be used to enable row creation during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an `ON ACTION insert` interaction block and the `ON INSERT` block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the `AFTER ROW` block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the `ON INSERT` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular `INPUT` statement, to let the end user enter data for the new created row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `scr_line()`:

```
DISPLAY ARRAY arr TO sr.*
 ...
  ON INSERT
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the new row is kept in the program array, and the `BEFORE ROW` block is executed for the new created row.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the new row is removed from the program array, and the `BEFORE ROW` block is executed for the row that was existing at the current position, before the new row was created.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON INSERT` block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the `ON INSERT` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON INSERT ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON UPDATE block

The `ON UPDATE` trigger can be used to enable row modification during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the `TABLE` container in the form by defining the `DOUBLECLICK` attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an `ON ACTION update` interaction block and the `ON UPDATE` block is used, the compiler will stop with error -8408.

When the user fires the *update* action, the dialog executes the user code of the ON UPDATE block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular INPUT statement, to let the end user modify the data of the current row. This is typically done with an INPUT binding explicitly array fields to the screen record fields, with the WITHOUT DEFAULTS clause. The current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by scr_line():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON UPDATE
    INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the modified values of the current row are kept in the program array.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the old values of the current row are restored in the program array.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON UPDATE block.

If needed, the ON UPDATE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON UPDATE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON DELETE block

The ON DELETE trigger can be used to enable row deletion during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an ON ACTION delete interaction block and the ON DELETE block is used, the compiler will stop with error -8408.

When the user fires the delete action, the dialog executes the user code of the ON DELETE block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with arr_curr():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON DELETE
    IF fgl_winQuestion("Delete",
          "Do you want to delete this record?",
          "yes", "no|yes", "help", 0) == "no"
    THEN
       LET int_flag = TRUE
    END IF
    ...
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the current row is deleted from the program array, and the BEFORE ROW block is executed for the next row in the list.

- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the current row is kept in the program array, and the BEFORE ROW block is executed again for the current row.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON DELETE block.

If needed, the ON DELETE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON DELETE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON SELECTION CHANGE block

The ON SELECTION CHANGE trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a DISPLAY ARRAY dialog. If this block is defined, multi-row selection is automatically enableb. However, the feature can be enabled/disabled with the setSelectionMode() dialog method.

ON SORT block

The ON SORT interfaction block can be used to detect when rows have to be sorted in a DISPLAY ARRAY or INPUT ARRAY dialog.

ON SORT is used in two different contexts:

1. In a regular DISPLAY ARRAY / INPUT ARRAY dialog (not using paged mode), the ON SORT trigger can be used to detect that a list sort was performed. In this case, the (visual) sort is already done by the runtime system and the ON SORT block is only used to execute post-sort tasks, such as displaying current row information, by using arrayToVisualIndex() dialog method. It is also possible to get the sort column and order with the getSortKey() and getSortSelection() dialog methods.
2. In a DISPLAY ARRAY using paged mode (ON FILL BUFFER), built-in row sorting is not available because data is provided by pages. Use the ON SORT trigger to detect a sort request and perform a new SQL query to re-order the rows. In this case, sort column and order is available with the getSortKey() and getSortSelection() dialog methods. See Populating a DISPLAY ARRAY on page 1372.

ON DRAG_START block

The ON DRAG_START block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the ON DRAG_START block, the program typically specifies the type of drag & drop operation by calling ui.DragDrop.setOperation() with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with ui.DragDrop.addPossibleOperation(). The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with ui.DragDrop.setMimeType() and ui.DragDrop.setBuffer() methods.

Example:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    CALL dnd.setOperation("move") -- Move is the default operation
    CALL dnd.addPossibleOperation("copy") -- User can toggle to copy if
 needed
    CALL dnd.setMimeType("text/plain")
    CALL dnd.setBuffer(arr[arr_curr()].cust_name)
    ...
```

```
END DISPLAY
```

ON DRAG_FINISHED block

Execution of the `ON DRAG_FINISHED` block notifies the dialog where the drag started that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns `NULL`. If `NULL` is returned, the `ON DRAG_FINISHED` trigger can be ignored.

In cases of successful moves to a target out of the current `DISPLAY ARRAY`, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an `ON DRAG_FINISHED` execution after the row was dropped into B, and should remove the row from the list A.

The `ON DRAG_FINISHED` interaction block is optional.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    LET last_dragged_row = arr_curr()
    ...
  ON DRAG_FINISHED (dnd)
    IF dnd.getOperation() == "move" THEN
      CALL DIALOG.deleteRow(last_dragged_row)
    END IF
    ...
END DISPLAY
```

ON DRAG_ENTER block

When the `ON DROP` control block is defined, the `ON DRAG_ENTER` block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no `ON DRAG_ENTER` block is defined. However, when `ON DROP` is defined, you should also define `ON DRAG_ENTER` to deny the drop of objects with an unsupported MIME type that come from other applications.

The program can decide to deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the `ui.DragDrop.selectMimeType()` method. This method takes the MIME type as a parameter and returns `TRUE` if the passed MIME type is used. You can call this method several times to check the availability of different MIME types.

You may also define the visual effect when flying over the target list with `ui.DragDrop.setFeedback()`.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF dnd.selectMimeType("text/plain") THEN
      CALL dnd.setOperation("copy")
      CALL dnd.setFeedback("all")
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
```

```
    ...
END DISPLAY
```

Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the `ON DRAG_OVER` trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse flies over the rows, according to the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the `ui.DragDrop.setFeedback()` method, typically called in the `ON DRAG_ENTER` block.

The values to pass to the `setFeedback()` method to get the desired visual effects described are respectively:

1. `insert` (default)
2. `select`
3. `all`

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF canDrop() THEN
      CALL dnd.setOperation(NULL)
    ELSE
      CALL dnd.setFeedback("select")
    END IF
    ...
END DISPLAY
```

ON DRAG_OVER block

When the `ON DROP` control block is defined, the `ON DRAG_OVER` block will be executed after `ON DRAG_ENTER`, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

`ON DRAG_OVER` will be called only once per row, even if the mouse cursor moves over the row.

In the `ON DRAG_OVER` block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the `ON DRAG_OVER` block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous `ON DRAG_ENTER` or `ON DRAG_OVER` events, or the operation selected by the end user, if it can toggle between copy and move. Thus, `ON DRAG_OVER` can occur even if the mouse position has not changed.

If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous `ON DRAG_OVER` event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

`ON DRAG_OVER` will not be called if drop has been disabled in `ON DRAG_ENTER` with `ui.DragDrop.setOperation(NULL)`

`ON DRAG_OVER` is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    IF arr[dnd.getLocationRow()].acceptsCopy THEN
      CALL dnd.setOperation("copy")
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
    ...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the `ON DRAG_OVER` trigger and query the `ui.DragDrop` object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the `ON DRAG_FINISHED` trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
    END CASE
    ...
  ON DROP (dnd)
    ...
END DISPLAY
```

ON DROP block

To enable drop actions on a list, you must define the `ON DROP` block; otherwise the list will not accept drop actions.

The `ON DROP` block is executed after the end user has released the mouse button to drop the dragged object. `ON DROP` will not occur if drop has been denied in the previous `ON DRAG_OVER` event or in `ON DRAG_ENTER` with a call to `ui.DragDrop.setOperation(NULL)`.

The program might also check the MIME type of the dragged object with `ui.DragDrop.getSelectedMimeType()`, and then call the `ui.DragDrop.getBuffer()` method to retrieve drag & drop data from external applications.

Ideally the drop operation should be accepted (no additional call to `ui.DragDrop.setOperation()`).

In this block, the `ui.DragDrop.getLocationRow()` method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
    ...
END DISPLAY
```

If the drag & drop operations are local to the same list or tree-view controller, you can use the `ui.DragDrop.dropInternal()` method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This `ON DROP` code example uses the `dropInternal()` method:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ...
  ...
  ON DROP (dnd)
    CALL dnd.dropInternal()
    ...
END DISPLAY
```

If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()` , the new row must be inserted before `getLocationRow()`; otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

DIALOG control instructions

Dialog control instructions are language instructions dedicated to dialog control, to programmatically force the dialog to behave in a given way.

For example the `NEXT FIELD` instruction forces the focus to a specific form field.

- NEXT FIELD instruction on page 1121
- CLEAR instruction in dialogs on page 1073
- DISPLAY TO / BY NAME instruction on page 1192
- CONTINUE DIALOG instruction on page 1192
- EXIT DIALOG instruction on page 1193
- ACCEPT DIALOG instruction on page 1193
- CANCEL DELETE instruction on page 1119
- CANCEL INSERT instruction on page 1120

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The `NEXT FIELD` *`field-name`* instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in `BEFORE FIELD`, `ON CHANGE` or `AFTER FIELD` blocks, it can also force a `DISPLAY ARRAY` or `INPUT ARRAY` to stay in the current row when `NEXT FIELD` is used in the `AFTER ROW` block.

If it exists, the `BEFORE FIELD` block of the corresponding field is executed.

The purpose of the `NEXT FIELD` instruction is give the focus to an editable field. Make sure that the field specified in `NEXT FIELD` is active, or use `NEXT FIELD CURRENT`. Non-editable fields are fields defined with the `NOENTRY` attribute, fields disabled at runtime with `DIALOG.setFieldActive()`, or fields using a widget that does not allow input, such as a `LABEL`.

Instead of the `NEXT FIELD` instruction, you can use the `DIALOG.nextField("`*`field-name`*`")` method to register a field, for example when the name is not known at compile time. However, this method only registers the field: It does not stop code execution, like the `NEXT FIELD` instruction does. You must execute a `CONTINUE DIALOG` to get the same behavior as `NEXT FIELD`.

Form field identification with NEXT FIELD

With the `NEXT FIELD` instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of dialog instruction (`INPUT` *`variable-list`* `FROM` *`field-list`*, `INPUT BY NAME` *`variable-list`*, `CONSTRUCT BY NAME` *`sql`* `ON` *`column-list`*,`CONSTRUCT` *`sql`* `ON` *`column-list`* `FROM` *`field-list`*, `INPUT ARRAY` *`array-name`* `FROM` *`screen-array`*`.*`).

The field name specification can be any of the following:

- *field-name*
- *table-name.field-name*
- *screen-record-name.field-name*
- `FORMONLY.`*`field-name`*

Here are some examples:

- `"cust_name"`
- `"customer.cust_name"`
- `"cust_screen_record.cust_name"`
- `"item_screen_array.item_label"`
- `"formonly.total"`

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog according to the field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using `INPUT BY NAME` *`variable-list`*), the field prefix must be the database table name (or `FORMONLY`) used in the form file, or any valid screen-record using that field. When the `FROM` clause of the dialog specifies an explicit screen-record (for example, in `INPUT` *`variable-list`* `FROM` *`screen-record.* / field-list-with-screen-record-prefix`* or `INPUT ARRAY` *`array-name`* `FROM` *`screen-array`*`.*`), the field prefix must be the screen-record name used in the `FROM` clause.

Abstract field identification is supported with the `CURRENT`, `NEXT` and `PREVIOUS` keywords. These keywords represent the current, next and previous fields respectively. When using `FIELD ORDER FORM`, the `NEXT` and `PREVIOUS` options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the `FROM` or `BY NAME` clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("*field-name*", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

NEXT FIELD in procedural DIALOG blocks

In a procedural dialog block, the NEXT FIELD *field-name* instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
     IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
        ERROR "Amount of line exceeds max value."
        NEXT FIELD item_count
```

```
       END IF
    END IF
```

CLEAR instruction in dialogs

The `CLEAR` *`field-list`* and `CLEAR SCREEN ARRAY` *`screen-array.*`* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. `CLEAR` can be used outside any dialog instruction, such as the `DISPLAY BY NAME / TO` instructions.

When a dialog is configured with the `UNBUFFERED` mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with `DISPLAY` or `CLEAR` instruction in an `UNBUFFERED` dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an `UNBUFEFERED` dialog, just set to `NULL` the variables bound to the dialog. However, when using a `CONSTRUCT`, no program variables are associated to the dialog and no `UNBUFFERED` concept exits, and the `CLEAR` or `DISPLAY TO / BY NAME` instructions are the only way to modify the `CONSTRUCT` fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using `TABLE` containers, you can therefore use the `CLEAR SCREEN ARRAY` instruction to clear all rows of a list.

DISPLAY TO / BY NAME instruction

The `DISPLAY` *`variable-list`* `TO` *`field-list`* or `DISPLAY BY NAME` *`variable-list`* instruction fills the value buffers of specified form fields with the values contained in the specified program variables. The `DISPLAY` instruction changes the buffers directly in the current form, not the program variables bound to the dialog. `DISPLAY` can be used outside any dialog instruction, in the same way as the `CLEAR` instruction. `DISPLAY` also sets the modification flag of fields.

As `DIALOG` is typically used with the `UNBUFFERED` mode, there is no reason to set field buffers in a `DIALOG` block since any variable assignment will synchronize field buffers. Actually, changing the field buffers with the `DISPLAY` or `CLEAR` instruction will have no visual effect if the fields are used by a dialog working in `UNBUFFERED` mode, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. So if you want to set field values, just assign the variables and the fields will be synchronized. However, when using a `CONSTRUCT` binding, you may want to set field buffers with this `DISPLAY` instruction, as there are no program variables bound to fields (with `CONSTRUCT`, only one string variable is bound to hold the SQL condition).

Instead of using a `DISPLAY` instruction to set the modification flag of fields to simulate user input, use the `DIALOG.setFieldTouched()` method instead.

CONTINUE DIALOG instruction

The `CONTINUE DIALOG` statement continues the execution of a `DIALOG` instruction, skipping all statements appearing after this instruction.

Control returns to the dialog instruction, which executes remaining control blocks as if the program reached the end of the current control block. Then the control goes back to the user and the dialog waits for a new event.

The `CONTINUE DIALOG` statement is useful when program control is nested within multiple conditional statements, and you want to return control to the user by skipping the rest of the statements.

In the following code example, an `ON ACTION` block gives control back to the dialog, skipping all instructions below line 04:

```
ON ACTION zoom
  IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
    ERROR "Zoom window cannot be opened if no info to identify customer"
    CONTINUE DIALOG
  END IF
  IF p_cust.cust_address IS NULL THEN
     ...
```

If CONTINUE DIALOG is called in a control block that is not AFTER DIALOG, further control blocks might be executed according to the context. Actually, CONTINUE DIALOG just instructs the dialog to continue as if the code in the control block was terminated (it is a kind of GOTO end_of_control_block). However, when executed in AFTER DIALOG, the focus returns to the current field or read-only list. In this case the BEFORE ROW and BEFORE FIELD triggers will be invoked.

A CONTINUE DIALOG in AFTER FIELD, AFTER INPUT, AFTER DISPLAY or AFTER CONSTRUCT will only stop the program flow of the current block of statements; instructions after CONTINUE DIALOG will not be executed. If the user has selected a field in a different sub-dialog, this new field will get the focus and all necessary AFTER / BEFORE control blocks will be executed.

In case of input error in a field, the best practice is to use a NEXT FIELD instruction to stay in the dialog and set the focus to the field that the user has to correct.

EXIT DIALOG instruction

The EXIT DIALOG statement terminates a procedural DIALOG block without any further control block execution.

> **Note:** When used in a declarative DIALOG block, the EXIT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

Program flow resumes at the instruction following the END DIALOG keywords. Blocks such as AFTER DIALOG will not be executed.

```
   ON ACTION quit
       EXIT DIALOG
```

When leaving the DIALOG instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

ACCEPT DIALOG instruction

The ACCEPT DIALOG statement validates all input fields bound to the DIALOG instruction and leaves the block if no error is raised.

> **Note:** When used in a declarative DIALOG block, the ACCEPT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

When defined in the dialog block, ON CHANGE, AFTER FIELD, AFTER ROW, AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be executed when ACCEPT DIALOG is performed.

The statements appearing after the ACCEPT DIALOG instruction will be skipped.

You typically code an ACCEPT DIALOG in an ON ACTION accept block:

```
ON ACTION accept ACCEPT DIALOG
```

Note that any usage of ACCEPT DIALOG outside an ON ACTION accept block is not intended and its behavior is undocumented.

Input field validation is a process that does several successive validation tasks:

1. The current field value is checked, according to the program variable data type (for example, the user must input a valid date in a DATE field).
2. NOT NULL field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the NOT NULL constraint.
3. REQUIRED field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be modified by the user or by program with a DISPLAY TO / BY NAME or

`DIALOG.setFieldTouched()` call. If the field was not modified during the dialog, the `REQUIRED` constraint is not satisfied.

4. `INCLUDE` field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

After input field validation has succeeded, different types of control blocks will be executed, such as `AFTER FIELD`, `AFTER ROW`, `AFTER INPUT` and `AFTER DIALOG`.

In order to validate some parts of the dialog without leaving the block, use the `DIALOG.validate()` method.

CANCEL DELETE instruction

In a list controlled by an `INPUT ARRAY`, row deletion can be canceled by using the `CANCEL DELETE` instruction in the `BEFORE DELETE` block. Using this instruction in a different place will generate a compilation error.

When the `CANCEL DELETE` instruction is executed, the current `BEFORE DELETE` block is terminated without any other trigger execution (no `BEFORE ROW` or `BEFORE FIELD` is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```
BEFORE DELETE
   IF user_can_delete() == FALSE THEN
      ERROR "You are not allowed to delete rows"
      CANCEL DELETE
   END IF
```

The instructions that appear after `CANCEL DELETE` will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the `DIALOG.setActionActive()` method:

```
CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the `DELETE ROW = FALSE` option in the `ATTRIBUTE` clause.

CANCEL INSERT instruction

In a list controlled by an `INPUT ARRAY`, row creation can be canceled by the program with the `CANCEL INSERT` instruction. This instruction can only be used in the `BEFORE INSERT` and `AFTER INSERT` control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after `CANCEL INSERT` will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with `DIALOG.setActionActive()`:

```
CALL DIALOG.setActionActive("insert", FALSE)
CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the `INSERT ROW = FALSE` and `APPEND ROW =FALSE` options in the `ATTRIBUTE` clause of `INPUT ARRAY`, or combine with the `AUTO APPEND = FALSE` attribute.

CANCEL INSERT in BEFORE INSERT

A `CANCEL INSERT` executed inside a `BEFORE INSERT` block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The `BEFORE INSERT` block is terminated (further instructions are skipped).
3. The `BEFORE ROW` and `BEFORE FIELD` triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```
   BEFORE INSERT
      IF NOT user_can_insert THEN
         ERROR "You are not allowed to insert rows"
         CANCEL INSERT
      END IF
```

Executing `CANCEL INSERT` in `BEFORE INSERT` will also cancel a temporary row creation, except when there are no more rows in the list. In this case, `CANCEL INSERT` will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the `AUTO APPEND=FALSE` attribute. If `AUTO APPEND=FALSE` and a `CANCEL INSERT` is executed in `BEFORE INSERT` (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

CANCEL INSERT in AFTER INSERT

A `CANCEL INSERT` executed inside an `AFTER INSERT` block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The `AFTER INSERT` block is terminated (further instructions are skipped).
3. The `BEFORE ROW` and `BEFORE FIELD` triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

```
   AFTER INSERT
      WHENEVER ERROR CONTINUE
      LET r = DIALOG.getCurrentRow("s_items")
      INSERT INTO items VALUES ( p_items[r].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<>0 THEN
         ERROR SQLERRMESSAGE
         CANCEL INSERT
      END IF
```

Examples

Example 1: DIALOG controlling two lists

Form file "lists.per":

```
LAYOUT
GRID
{
<t t1              >
[f11  |f12         ]
<                  >
<t t2              >
[f21  |f22         ]
```

```
<                  >
}
END
END
ATTRIBUTES
EDIT f11 = FORMONLY.column_11;
EDIT f12 = FORMONLY.column_12;
EDIT f21 = FORMONLY.column_21;
EDIT f22 = FORMONLY.column_22;
END
INSTRUCTIONS
SCREEN RECORD sr1(FORMONLY.column_11,FORMONLY.column_12);
SCREEN RECORD sr2(FORMONLY.column_21,FORMONLY.column_22);
END
```

Program file:

```
DEFINE
   arr1 DYNAMIC ARRAY OF RECORD
        column_11 INTEGER,
        column_12 VARCHAR(10)
   END RECORD,
   arr2 DYNAMIC ARRAY OF RECORD
        column_21 INTEGER,
        column_22 VARCHAR(10)
   END RECORD

MAIN
  DEFINE i INTEGER
  FOR i = 1 TO 20
    LET arr1[i].column_11 = i
    LET arr1[i].column_12 = "aaa "||i
    LET arr2[i].column_21 = i
    LET arr2[i].column_22 = "aaa "||i
  END FOR
  OPTIONS INPUT WRAP
  OPEN FORM f FROM "lists"
  DISPLAY FORM f
  DIALOG ATTRIBUTES(UNBUFFERED)
    DISPLAY ARRAY arr1 TO sr1.*
      BEFORE DISPLAY
        MESSAGE "We are in list one"
    END DISPLAY
    DISPLAY ARRAY arr2 TO sr2.*
      BEFORE DISPLAY
        MESSAGE "We are in list two"
    END DISPLAY
    ON ACTION close
      EXIT DIALOG
  END DIALOG
END MAIN
```

Example 2: DIALOG with CONSTRUCT and DISPLAY ARRAY

Form file "form1.per":

```
LAYOUT
GRID
{
<g g1                                >
 Name:     [f1                       ]
 State:    [f2                       ]
 City:     [f3                       ]
```

```
 Zip-code: [f4                          ]
[                      :cc    :sr    ]
<                                      >
<g g2                                  >
 <t t1                                >
  Id        Name
 [c1       |c2                        ]
 [c1       |c2                        ]
 [c1       |c2                        ]
 <                                     >
<                                       >
[                             :cw    ]
}
END
END

ATTRIBUTES
GROUP g1: TEXT = "Search criteria";
EDIT f1 = FORMONLY.cust_name TYPE VARCHAR;
EDIT f2 = FORMONLY.cust_state TYPE VARCHAR;

     END CONSTRUCT

     DISPLAY ARRAY custarr TO sr.*
       BEFORE ROW
         MESSAGE SFMT("Row: %1/%2", DIALOG.getCurrentRow("sr"),
                                    DIALOG.getArrayLength("sr"))
     END DISPLAY

     ON ACTION fetch
```

```
        MESSAGE "Where:", where_clause
        -- Execute SQL query here to fill custarr ...

     ON ACTION close
        EXIT DIALOG

  END DIALOG

END MAIN
```

Example 3: DIALOG with SUBDIALOG

Form file "comment.per":

```
LAYOUT
GRID
{
[cmt                              ]
}
END
END
ATTRIBUTES
TEXTEDIT cmd = FORMONLY.the_comment, STRETCH=BOTH;
END
```

The module "comment.4gl":

```
DEFINE the_comment VARCHAR(200)

DIALOG comment_input()
    INPUT BY NAME the_comment
        ON ACTION add_sep
           LET the_comment = the_comment || "\n---"
    END INPUT
END DIALOG
```

Form file "form1.per":

```
LAYOUT
VBOX
GRID
{
Id:   [f1        ]
Name: [f2                                        ]
}
END
FORM "comment"
END
END
ATTRIBUTES
EDIT f1 = FORMONLY.cust_id TYPE INTEGER;
EDIT f2 = FORMONLY.cust_name TYPE VARCHAR;
END
```

Program file:

```
IMPORT FGL comment

MAIN
  DEFINE cust RECORD
            cust_id INTEGER,
            cust_name VARCHAR(50)
```

```
          END RECORD

  OPTIONS INPUT WRAP

  OPEN FORM f1 FROM "form1"
  DISPLAY FORM f1

  DIALOG ATTRIBUTES(FIELD ORDER FORM, UNBUFFERED)

     INPUT BY NAME cust.*

  - Example 1: Two independent record lists on page 1247

Understanding parallel dialogs

Parallel dialogs refers to the use of different declarative `DIALOG` blocks, in conjunction with the `START DIALOG` and `TERMINATE DIALOG` instructions, and an event loop using the `fgl_eventLoop()` built-in function, in order to control several forms simultaneously.

> **Important:** This feature is only for mobile platforms.

Each dialog acts independently to control several elements of a window/form. During the execution of parallel dialogs, the user can switch to a window/form that is controlled by another running declarative `DIALOG` block. For more details about categories of dialogs, see Introducing dialogs on page 1250.

The parallel dialog feature was introduced to implement mobile applications, where several forms can be accessed simultaneously, for example to get "split views" on mobile devices:

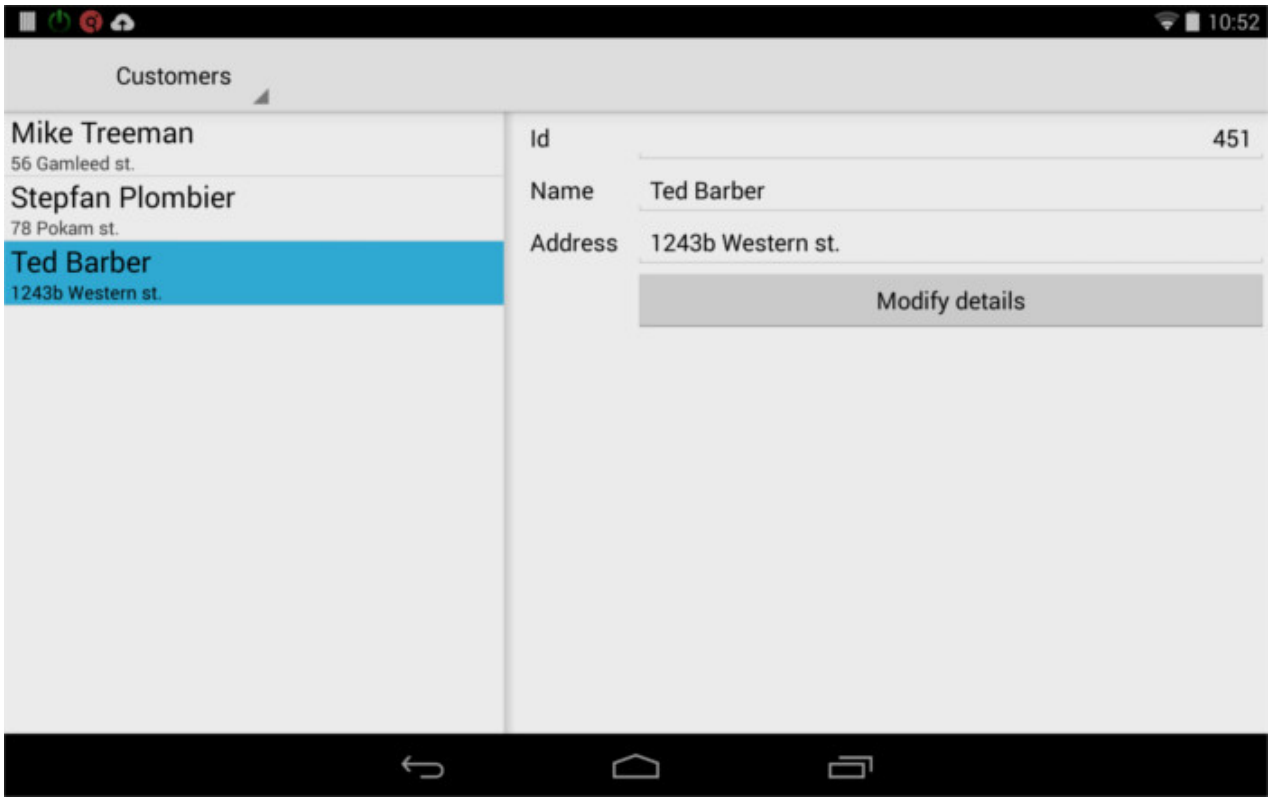

Figure 77: Form with Split View (Android™)

A *declarative dialog block* is a module element defined at the same level as a `FUNCTION` or `REPORT` routine:

```
-- Module orders.4gl
SCHEMA stock
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE orders.*
DIALOG orders_dlg()
  DEFINE x INT
  DISPLAY ARRAY arr TO sr_orders.*
     ...
  END DISPLAY
END DIALOG
```

The name of a declarative dialog is mandatory. It can be referenced by a `SUBDIALOG` clause, by a `START DIALOG` and `TERMINATE DIALOG` instruction, and can identify sub-dialog actions with a prefix. Specifically, the name of the declarative dialog will be referenced in a `START DIALOG` and `TERMINATE DIALOG` instruction to implement parallel dialogs.

In terms of semantics, behavior and control block execution, a declarative dialog started with a `START DIALOG` instruction behaves like a procedural `DIALOG` block.

> **Important:** Parallel dialogs implictly use the `UNBUFFERED` mode. It is not possible to change this mode when using parallel dialogs.

When using the `DIALOG` keyword inside a declarative dialog block to use `ui.Dialog` class methods, it references the current instance of the dialog object.

In order to execute parallel dialogs, you must implement a main interaction event loop, by using the `fgl_eventLoop()` built-in function. The minimal event loop code to implement is:

```
WHILE fgl_eventLoop()
```

```
END WHILE
```

Once the declarative dialogs and the interaction even loop are defined, it is possible to create the windows with `OPEN WINDOW`, and initiate the dialogs with the `START DIALOG` instruction.

If needed, show a given dialog window with the `CURRENT WINDOW` instruction. Additionally, (especially when implementing split views), you may want to "restart" a detail dialog, for example when selecting a new row in the main record list. To restart the detail dialog, execute `TERMINATE DIALOG`, followed by `START DIALOG` for the detail dialog. See split view programming for more details.

To finish a given dialog, execute the `TERMINATE DIALOG` instruction and close the dedicated window with `CLOSE WINDOW window-name`.

From a set of running parallel dialogs, it is possible to switch to a modal dialog by creating a dedicated window, and executing a procedural dialog instruction. When the procedural dialog is terminated, close the dedicated window, and the control will go back to the parallel dialog set.

Syntax of the declarative DIALOG block
The declarative `DIALOG` block defines an interactive instruction that can be used by a parent `DIALOG`, or as parallel dialog.

Syntax

```
[ PRIVATE | PUBLIC ] DIALOG dialog-name ()
   [ define-block ]
   { menu-block
   | record-input-block
   | construct-block
   | display-array-block
   | input-array-block
   }
END DIALOG
```

1. *dialog-name* defines the identifier for the declarative `DIALOG` block.

where *define-block* is a local variable declaration block.

where *menu-block* is:

```
MENU
   [ BEFORE MENU
       menu-statement
     [...]
   ]
   menu-option
   [...]
END MENU
```

where *menu-option* is:

```
{ COMMAND option-name
      [option-comment] [ HELP help-number ]
    menu-statement
    [...]
| COMMAND KEY ( key-name ) option-name
      [option-comment] [ HELP help-number ]
    menu-statement
    [...]
| COMMAND KEY ( key-name )
    menu-statement
    [...]
| ON ACTION action-name
```

```
              [ ATTRIBUTES ( action-attributes-menu ) ]
    menu-statement
    [...]
}
```

where *action-attributes-menu* is:

```
{ TEXT = string
| COMMENT = string
| IMAGE = string
| ACCELERATOR = string
| DEFAULTVIEW = { YES | NO | AUTO }
| CONTEXTMENU = { YES | NO | AUTO }
| DISCLOSUREINDICATOR
    [,...] }
```

where *menu-statement* is:

```
{ statement
|  NEXT OPTION option
|  SHOW OPTION { ALL | option [,...] }
|  HIDE OPTION { ALL | option [,...] }
}
```

1. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
2. *option-name* is a string expression defining the label of the menu option and identifying the action that can be executed by the user.
3. *option-comment* is a string expression containing a description for the menu option, displayed when *option-name* is the current.
4. *help-number* is an integer that allows you to associate a help message number with the menu *option*.
5. *action-name* identifies an action that can be executed by the user.
6. *idle-seconds* is an integer literal or variable that defines a number of seconds.
7. *action-name* identifies an action that can be executed by the user.
8. *action-attributes* are dialog-specific action attributes.

where *field-list* defines a list of fields with one or more of:

```
{ field-name
| table-name.*
| table-name.field-name
| screen-array[line].*
| screen-array[line].field-name
| screen-record.*
| screen-record.field-name
} [,...]
```

where *field-spec* identifies a unique field with one of:

```
{ field-name
| table-name.field-name
| screen-array.field-name
| screen-record.field-name
}
```

where *column-list* defines a list of database columns as:

```
{ column-name
| table-name.*
| table-name.column-name
} [,...]
```

1. *variable-definition* is a variable declaration with data type as in a regular `DEFINE` statement.
2. *array* is the array of records used by the `DIALOG` statement.
3. *help-number* is an integer that allows you to associate a help message number with the command.
4. *field-name* is the identifier of a field of the current form.
5. *option-name* is a string expression defining the label of the action and identifying the action that can be executed by the user.
6. *option-comment* is a string expression containing a description for the menu option, displayed when *option-name* is the current.
7. *column-name* is the identifier of a database column of the current form.
8. *table-name* is the identifier of a database table of the current form.
9. *variable* is a simple program variable (not a record).
10. *record* is a program record (structured variable).
11. *screen-array* is the screen array that will be used in the current form.
12. *line* is a screen array line in the form.
13. *screen-record* is the identifier of a screen record of the current form.
14. *action-name* identifies an action that can be executed by the user.
15. *seconds* is an integer literal or variable that defines a number of seconds.
16. *key-name* is a hot-key identifier (like `F11` or `Control-z`).
17. *row-index* identifies the program variable which holds the row index corresponding to the tree node that has been expanded or collapsed.
18. *dnd-object* references a `ui.DragDrop` variable defined in the scope of the dialog.

19.*statement* is any instruction supported by the language.
20.*action-attributes* are dialog-specific action attributes for the action.

Syntax of the START DIALOG instruction
Starts the instance of a declarative dialog.

Syntax

```
START DIALOG dialog-name
```

1. *dialog-name* is the identifier of a declarative `DIALOG` block.

Usage

The `START DIALOG` instruction starts the declarative dialog block identified by the name passed.

The current window/form will be used to attach form fields and action views to the variables and action handlers implemented in the referenced declarative dialog.

The `START DIALOG` does in fact register the specified dialog to be activated when the parallel dialog event loop executes.

The started dialog can be terminated with `TERMINATE DIALOG`.

Example

This example shows a `START DIALOG` instruction in a function that initializes a parallel dialog in a split view context:

```
FUNCTION params()
  IF ui.Window.forName("w_params") IS NULL THEN
     OPEN WINDOW w_params WITH FORM "parameters"
 ATTRIBUTES(TYPE=LEFT)
     LET params.user_name="Tom"
     LET params.auto_sync="Y"
     DISPLAY BY NAME params.*
     START DIALOG d_params_menu
  END IF
  CURRENT WINDOW IS w_params
END FUNCTION
```

Syntax of the TERMINATE DIALOG instruction
Terminates the instance of a declarative dialog.

Syntax

```
TERMINATE DIALOG dialog-name
```

1. *dialog-name* is the identifier of a declarative `DIALOG` block.

Usage

The `TERMINATE DIALOG` instruction stops a declarative dialog identified by the name passed.

If the intent is to finish the parallel dialog, the corresponding window/form bound to the dialog should be closed after `TERMINATE DIALOG`.

However, `TERMINATE DIALOG` can also be used in conjunction with `START DIALOG`, to achieve a "restart" of the parallel dialog.

Note: `TERMINATE DIALOG` will not raise an error, if the dialog was not yet started with `START DIALOG`. This is required to implement the "restart" pattern.

The next code example shows a typical restart pattern on a detail parallel dialog, when a new row is selected in the master list:

```
DIALOG d_list_view()
  DISPLAY ARRAY arr TO sr.*
                ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
      BEFORE ROW -- in BEFORE ROW, we restart the details view
        CURRENT WINDOW IS w_right
        TERMINATE DIALOG d_detail_view
        LET curr_pa = arr_curr()
        DISPLAY BY NAME arr[curr_pa].*
        DISPLAY SFMT("tapped row %1",arr_curr()) TO info
        START DIALOG d_detail_view
        CURRENT WINDOW IS w_left
   ...
```

Parallel dialog programming steps

This procedure describes how to implement parallel dialogs with a declarative `DIALOG` block.

1. Create a form specification file containing screen record(s) and/or screen array(s). The screen records and screen arrays identify the presentation elements to be used by the runtime system to display the data models (the content of program variables bound to the `DIALOG` blocks).
2. Create a dedicated .4gl module to implement the declarative `DIALOG` block.
3. With the `DEFINE` instruction, declare program variables (records and arrays) that will be used as data models. These will typically be defined as `PRIVATE` module variables. For record lists (`DISPLAY ARRAY` or `INPUT ARRAY`), the members of the program array must correspond to the elements of the screen array, by number and data types. To handle record lists, use dynamic arrays instead of static arrays.
4. Define the declarative `DIALOG` block in the module, to handle interaction. Define a sub-dialog with program variables to be used as data models. The sub-dialog will define how variables will be used (display or input).
   a) Inside the sub-dialog instruction, define the behavior with control blocks such as `BEFORE ROW`, `AFTER ROW`, `BEFORE FIELD`, and interaction blocks such as `ON ACTION`.
5. Define a `FUNCTION` to create the dialog instance.
   a) Add a test to check if the window and form combination dedicated to the dialog is already created, using `ui.Window.forName()`. If the window does not yet exist, create it by using the `OPEN WINDOW` *`window-name`* `WITH FORM` instruction. If the window exists, make it current with the `CURRENT WINDOW IS` *`window-name`* instruction.
   b) Fill the module variables (the data model) with data. For lists, you typically use a result set cursor.
   c) Start the dialog with the `START DIALOG` *`dialog-name`* instruction.
6. Define a `FUNCTION` to terminate the dialog instance.
   a) In the function, finish the dialog with `TERMINATE DIALOG` *`dialog-name`*.
   b) Close the window dedicated to the dialog with `CLOSE WINDOW` *`window-name`*.
   c) If needed, free the data model (clear large program arrays) and database cursors, to save memory.
7. If needed, add an `ON ACTION close` action handler to the declarative dialog, that calls the terminate function. This allows the end user to close the front-end window and stop the dialog.
8. In another module, implement the `WHILE` loop using the `fgl_eventLoop()` built-in function to handle interaction events for parallel dialogs. This module uses the start and terminate functions to control the individual dialog modules.

The simplest form of the user interaction event loop is:

```
WHILE fgl_eventLoop()
END WHILE
```

Using parallel dialogs

To use parallel dialogs, you must understand how they work and how to structure the code.

Structure of a declarative DIALOG block

A declarative `DIALOG` instruction is made of a single sub-dialog block, with an optional `DEFINE` clause to declare local variables.

> **Important:** Unlike procedural `DIALOG` blocks, declarative `DIALOG` blocks can only define one sub-dialog block.

The dialog instruction in the declarative DIALOG block binds program variables to form fields and define the type of interaction that will take place for the data model (simple input, list input or query). The dialog implement individual control blocks which let you control the behavior of the interactive instruction. The dialog can also hold action handlers.

The declarative `DIALOG` block can define the following dialog types:

- A list of choices controlled by a `MENU` sub-dialog block.
- Simple record input with the `INPUT` sub-dialog block.
- Query by example input with the `CONSTRUCT` sub-dialog block.
- Read-only record list navigation with the `DISPLAY ARRAY` sub-dialog block.
- Editable record list handling with the `INPUT ARRAY` sub-dialog block.

The DEFINE clause

The `DEFINE` clause can be used to define program variables with a scope that is local to the declarative dialog block.

This clause must be placed before any other sub-dialog block:

```
DIALOG ()
    DEFINE checked BOOLEAN,
           tmp STRING

    INPUT BY NAME ...
        ...
    END INPUT

END DIALOG
```

The `DEFINE` clause is only allowed in declarative dialog blocks. Variables used locally in a procedural dialog block should be defined in the scope of the function containing the procedural dialog block.

The MENU sub-dialog

The `MENU` sub-dialog implements a list of choices for the user by using action handlers.

MENU implements a list of action handlers

The following code example shows a `MENU` sub-dialog implementing a couple of action handlers with an `ON ACTION` clause or with a `COMMAND` clause (action views of `COMMAND` can get the focus):

```
DIALOG ()
   MENU
      ON ACTION customer_view
         ...
      ON ACTION order_view
         ...
   END MENU
```

```
END DIALOG
```

Control blocks in MENU

Simple record input declared with the INPUT sub-dialog can raise the following triggers:

- BEFORE MENU

In the singular MENU instruction, BEFORE MENU and AFTER MENU blocks are typically used as initialization and finalization blocks. In an MENU sub-dialog of a DIALOG block, BEFORE MENU and AFTER MENU blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the action views (buttons) controlled by this sub-dialog.

The INPUT sub-dialog
The INPUT sub-dialog implement single record input in fields of the current form.

Program variable to form field binding

Each record member variable is bound to the corresponding field of a screen record, in order to manipulate the values that the user enters in the form fields.

The INPUT clause can be used in two forms:

1. INPUT BY NAME *variable-list*
2. INPUT *variable-list* FROM *field-list*

The BY NAME clause implicitly binds the fields to the variables that have the same identifiers as the field names. The variables must be declared with the same names as the fields from which they accept input. The runtime system ignores any record name prefix when making the match. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exceptions, and sets the STATUS variable to a negative value.

```
DEFINE p_cust RECORD
       cust_num INTEGER,
       cust_name VARCHAR(50),
       cust_address VARCHAR(100)
   END RECORD
   ...
DIALOG
   INPUT BY NAME p_cust.*
      BEFORE FIELD cust_name
       ...
   END INPUT
   ...
END DIALOG
```

The FROM clause explicitly binds the fields in the screen record to a list of program variables by position. The number of variables or record members must equal the number of fields listed in the FROM clause. Each variable must be of the same (or a compatible) data types as the corresponding screen field. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

```
DEFINE c_name VARCHAR(50)
       c_addr VARCHAR(100)
   ...
DIALOG
  INPUT c_name,
        c_addr
   FROM FORMONLY.field01,
        FORMONLY.field02
    BEFORE FIELD cust_name
       ...
```

```
  END INPUT
   ...
END DIALOG
```

Identifying an INPUT sub-dialog

The name of an `INPUT` sub-dialog can be used to qualify sub-dialog actions with a prefix.

In order to identify the `INPUT` sub-dialog with a specific name, you can use the `ATTRIBUTES` clause to set the `NAME` attribute:

```
INPUT BY NAME p_cust.*
      ATTRIBUTES (NAME = "cust")
  ...
```

Control blocks in INPUT

Simple record input declared with the `INPUT` sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- AFTER INPUT

In the singular `INPUT` instruction, `BEFORE INPUT` and `AFTER INPUT` blocks are typically used as initialization and finalization blocks. In an `INPUT` sub-dialog of a `DIALOG` block, `BEFORE INPUT` and `AFTER INPUT` blocks will be executed each time the focus goes to (`BEFORE`) or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The CONSTRUCT sub-dialog
The `CONSTRUCT` sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL `WHERE` condition that can be use to execute a `SELECT` statement.

Defining query by example fields

The `CONSTRUCT` sub-dialog requires a character string variable to hold the `WHERE` clause, and a list of screen fields where the user can enter search criteria.

```
DEFINE sql_condition STRING
  ...
DIALOG
  CONSTRUCT BY NAME sql_condition
      ON customer.cust_name, customer.cust_address
    BEFORE FIELD cust_name
    ...
  END CONSTRUCT
  ...
END DIALOG
```

Make sure the character string variable is large enough to store all possible SQL conditions. It is better to use a `STRING` data type to avoid any size problems.

`CONSTRUCT` uses the field data types defined in the current form file to produce the SQL conditions. This is different from other interactive instructions, where the data types of the program variables define the way to handle input/display. It is *strongly* recommended (but not mandatory) that the form field data types correspond to the data types of the program variables used for input. This is implicit if both form fields and program variables are based on the database schema file.

The `CONSTRUCT` clause can be used in two forms:

1. `CONSTRUCT BY NAME` *`string-variable`* `ON` *`column-list`*
2. `CONSTRUCT` *`string-variable`* `ON` *`column-list`* `FROM` *`field-list`*

The `BY NAME` clause implicitly binds the form fields to the columns, where the form field identifiers match the column names specified in the column-list after the `ON` keyword. You can specify the individual column names (separated by commas) or use the `tablename.*` shortcut to include all columns defined for a table in the database schema file.

The `FROM` clause explicitly binds the form fields listed after the `FROM` keyword with the column definitions listed after the `ON` keyword.

In both cases, the name of the columns in *column-list* will be used to produce the SQL condition in *string-variable*.

Identifying a CONSTRUCT sub-dialog

The name of a `CONSTRUCT` sub-dialog can be used to qualify sub-dialog actions with a prefix. In order to identify the `CONSTRUCT` sub-dialog with a specific name, use the `ATTRIBUTES` clause to set the `NAME` attribute:

```
CONSTRUCT BY NAME sql_condition ON customer.*
  ATTRIBUTES (NAME = "q_cust")
  ...
```

Control blocks in CONSTRUCT

A Query By Example declared with the `CONSTRUCT` clause can raise the following triggers:

- BEFORE CONSTRUCT
- BEFORE FIELD
- AFTER FIELD
- AFTER CONSTRUCT

In the singular `CONSTRUCT` instruction, `BEFORE CONSTRUCT` and `AFTER CONSTRUCT` blocks are typically used as initialization and finalization blocks. In `DIALOG` block, `BEFORE CONSTRUCT` and `AFTER CONSTRUCT` blocks will be executed each time the focus goes to (`BEFORE`) or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The DISPLAY ARRAY sub-dialog
The `DISPLAY ARRAY` sub-dialog is the controller to implement the navigation in a list of records, with option data modification actions.

Program array to screen array binding

The `DISPLAY ARRAY` sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the `TO` keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the `DIALOG` instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
       item_num INTEGER,
       item_name VARCHAR(50),
       item_price DECIMAL(6,2)
   END RECORD
   ...
```

```
DIALOG
   DISPLAY ARRAY p_items TO sa.*
      BEFORE ROW
      ...
   END DISPLAY
   ...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
   ...
DIALOG
   DISPLAY ARRAY p_names TO sa.*
      BEFORE DELETE
      ...
   END DISPLAY
   ...
END DIALOG
```

Identifying a DISPLAY ARRAY sub-dialog

The name of the screen array specified with the `TO` clause identifies the list. The dialog class method such as takes the name of the screen array as the parameter, identifying the list. For example, you would use `DIALOG.getCurrentRow("screen-array")` to query for the current row in the list identified by 'screen-array'. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

Control blocks in DISPLAY ARRAY

Read-only record lists declared with the `DISPLAY ARRAY` sub-dialog can raise the following triggers:

- BEFORE DISPLAY
- BEFORE ROW
- AFTER ROW
- AFTER DISPLAY

In the singular `DISPLAY ARRAY`instruction, `BEFORE DISPLAY` and `AFTER DISPLAY` blocks are typically used as initialization and finalization blocks. In a `DISPLAY ARRAY` sub-dialog of a `DIALOG` block, `BEFORE DISPLAY` and `AFTER DISPLAY` blocks will be executed each time the focus goes to (`BEFORE`) or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The INPUT ARRAY sub-dialog
The `INPUT ARRAY` sub-dialog is the controller to implement the navigation and edition in a list of records.

> **Important:** This feature is not supported on mobile platforms.

Program array to screen array binding

The `INPUT ARRAY` sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the `FROM` keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the `DIALOG` instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
```

```
        item_num INTEGER,
        item_name VARCHAR(50),
        item_price DECIMAL(6,2)
    END RECORD
    ...
DIALOG
    INPUT ARRAY p_items FROM sa.*
       BEFORE INSERT
       ...
    END INPUT
    ...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
    ...
DIALOG
    INPUT ARRAY p_names FROM sa.*
       BEFORE DELETE
       ...
    END INPUT
    ...
END DIALOG
```

Identifying an INPUT ARRAY sub-dialog

The name of the screen array specified with the `FROM` clause will be used to identify the list. For example, the dialog class method such as `DIALOG.getCurrentRow("screen-array")` takes the name of the screen array as the parameter, to identify the list you want to query for the current row. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

Control blocks in INPUT ARRAY

Editable record lists declared with the `INPUT ARRAY` sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE ROW
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- ON ROW CHANGE
- AFTER ROW
- BEFORE DELETE
- AFTER DELETE
- BEFORE INSERT
- AFTER INSERT
- AFTER INPUT

In the singular `INPUT ARRAY` instruction, `BEFORE INPUT` and `AFTER INPUT` blocks are typically used as initialization and finalization blocks. In the `INPUT ARRAY` sub-dialog of a `DIALOG` block, `BEFORE INPUT` and `AFTER INPUT` blocks will be executed each time the focus goes to (`BEFORE`)or leaves (`AFTER`) the group of fields defined by this sub-dialog.

Declarative DIALOG block configuration

Attributes defined in the ATTRIBUTES clause of dialogs can be used to configure a declarative DIALOG block and its sub-dialogs.

The ATTRIBUTES clause of dialogs overrides all default attributes and temporarily override any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields.

- INPUT ATTRIBUTES clause on page 1159
- DISPLAY ARRAY ATTRIBUTES clause on page 1159
- INPUT ARRAY ATTRIBUTES clause on page 1160
- CONSTRUCT ATTRIBUTES clause on page 1162

INPUT ATTRIBUTES clause
Attributes of the INPUT clause of a DIALOG block.

NAME option

The NAME attribute can be used to identify the INPUT sub-dialog, especially useful to qualify sub-dialog actions.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the INPUT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

By default, sub-dialogs use the default values defined in the form files. If you want to use the values stored in the program variables bound to the dialog, you must use the WITHOUT DEFAULTS attribute. For more details see WITHOUT DEFAULTS option.

DISPLAY ARRAY ATTRIBUTES clause
Attributes of the DISPLAY ARRAY clause of a DIALOG block.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the DISPLAY ARRAY sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array, unless page mode is used. In this case, the COUNT attribute must be used to define the total number of rows, because the dynamic array will only hold a page of the entire row set. If the value of COUNT is negative or zero, it defines an empty list.

See also Controlling the total number of rows on page 1350.

DOUBLECLICK option

The DOUBLICKCLICK option can be used to define the action that will be fired when the user chooses a row from the list. On front-end platforms using a mouse-device, this corresponds to a physical double-click on a row with the mouse. On mobile front-ends, this corresponds to a tap on the row with a finger.

Note that this attribute can also be defined for the TABLE/TREE containers in form files; DOUBLECLICK in DISPLAY ARRAY attributes has a higher precedence as DOUBLECLICK in the form file. For more details, see Defining the action for a row choice on page 1360.

ACCESSORTYPE option

Important: This feature is only for mobile platforms.

The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on a iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or checkmark icon. For more details, see Row configuration on iOS devices on page 1369.

DETAILACTION option

Important: This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1369.

INPUT ARRAY ATTRIBUTES clause
Attributes of the INPUT ARRAY clause of a DIALOG block.

INPUT ARRAY specific attributes can be defined in the ATTRIBUTE clause of the sub-dialog header:

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

You typically use the INPUT ARRAY sub-dialog with the WITHOUT DEFAULTS attribute. If this attribute is not set when using an INPUT ARRAY sub-dialog, the list is empty even if the array holds data. For more details see WITHOUT DEFAULTS option.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array. If you specify the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.

MAXCOUNT option

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter. It can be used with static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter when using a singular INPUT ARRAY), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.

APPEND ROW option

The APPEND ROW attribute can be set to FALSE to avoid the append default action, and deny the user to add rows at the end of the list. If APPEND ROW =FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

INSERT ROW option

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and deny the user to insert new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and deny the user to remove rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, an new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

CONSTRUCT ATTRIBUTES clause
Attributes of the CONSTRUCT clause of a DIALOG block.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the CONSTRUCT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

NAME option

The NAME attribute can be used to identify the CONSTRUCT sub-dialog; this is especially useful to qualify sub-dialog actions.

Default actions created by a DIALOG block

Default actions ease the implementation of the controller by providing expected actions.

According to the sub-dialogs defined in a (declarative or procedural) `DIALOG` block, the runtime system creates a set of default actions. These actions are provided to ease the implementation of the controller. For example, when using an `INPUT ARRAY` sub-dialog, the dialog instruction will automatically create the insert, append and delete default actions.

Table 282: Default actions created for the DIALOG block on page 1218 lists the default actions created for the `DIALOG` interactive instruction, according to the sub-dialogs defined:

Table 282: Default actions created for the DIALOG block

Default action	Control Block execution order
`help`	Shows the help topic defined by the `HELP` clause. *Only created when a* `HELP` *clause or option is defined for the sub-dialog.*
`insert`	Inserts a new row before current row. *Only created if* `INPUT ARRAY` is *used; action creation can be avoided with* `INSERT ROW = FALSE` *attribute.*
`append`	Appends a new row at the end of the list. *Only created if* `INPUT ARRAY` is *used; action creation can be avoided with* `APPEND ROW = FALSE` *attribute.*
`delete`	Deletes the current row. *Only created if* `INPUT ARRAY` is *used;* action *creation can be avoided with* `DELETE ROW = FALSE` *attribute.*
`nextrow`	Moves to the next row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`prevrow`	Moves to the previous row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`firstrow`	Moves to the first row in a list displayed in one row of fields. *Only created if* `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`lastrow`	Moves to the last row in a list displayed in one row of fields.

Default action	Control Block execution order
	Only created if `DISPLAY ARRAY` *or* `INPUT ARRAY` *used with a screen record having only one row.*
`find`	Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. *Only created if the context allows built-in find.*
`findnext`	Seeks to the next row matching the value entered during the fglfind dialog. *Only created if the context allows built-in find.*

The `insert`, `append` and `delete` default actions can be avoided with dialog control attributes:

```
INPUT ARRAY arr TO sr.* ATTRIBUTES( INSERT ROW=FALSE, APPEND
 ROW=FALSE, ... )
     ...
```

DIALOG data blocks
Dialog data blocks are dialog triggers invoked when the dialog controller needs data to feed the view with values.

Such blocks are typically used when record list data is provided dynamically, with the paged mode or when implementing dynamic tree-views.

- ON FILL BUFFER block on page 1082
- ON EXPAND block on page 1082
- ON COLLAPSE block on page 1082

ON FILL BUFFER block
The `ON FILL BUFFER` block is used to fill a page of rows into the dynamic array, according to an offset and a number of rows.

This data block is used in the `DISPLAY ARRAY` blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.

ON EXPAND block
The `ON EXPAND` block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are added according to the nodes opened by the end user.

ON COLLAPSE block
The `ON COLLAPSE` block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are removed according to the nodes closed by the end user.

DIALOG control blocks
Dialog control blocks are predefined dialog triggers where you can implement specific code to control the interactive instruction.

The code could involve using `ui.Dialog` class methods or dialog specific instructions such as `NEXT FIELD` or `CONTINUE DIALOG`.

- Control block execution order in parallel dialogs on page 1220
- BEFORE FIELD block on page 1069

- AFTER FIELD block on page 1070
- ON CHANGE block on page 1069
- BEFORE INPUT block on page 1067
- AFTER INPUT block on page 1068
- BEFORE CONSTRUCT block on page 1135
- AFTER CONSTRUCT block on page 1135
- BEFORE DISPLAY block on page 1082
- AFTER DISPLAY block on page 1083
- BEFORE ROW block on page 1083
- ON ROW CHANGE block on page 1110
- AFTER ROW block on page 1084
- BEFORE INSERT block on page 1113
- AFTER INSERT block on page 1113
- BEFORE DELETE block on page 1114
- AFTER DELETE block on page 1114
- BEFORE MENU block on page 1054

Control block execution order in parallel dialogs

The order in which control blocks are executed in a declarative `DIALOG` used as parallel dialog is the same as when executing a singular dialog.

According to the type of dialog defined in the declarative `DIALOG`, see:

- INPUT control blocks execution order on page 1066
- DISPLAY ARRAY control blocks execution order on page 1082
- CONSTRUCT control blocks execution order on page 1134
- INPUT ARRAY control blocks execution order on page 1106

For control block execution order in the context of a procedural `DIALOG` block, see Control block execution order in multiple dialogs on page 1164.

BEFORE FIELD block

For fields controlled by an `INPUT`, `INPUT ARRAY` or by a `CONSTRUCT` instructions, the `BEFORE FIELD` block is executed every time the cursor enters into the specified field.

For editable lists driven by `INPUT ARRAY`, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The `BEFORE FIELD` block is also executed when performing a `NEXT FIELD` instruction.

The `BEFORE FIELD` keywords must be followed by a list of form field specification. The screen-record name can be omitted.

`BEFORE FIELD` is executed after `BEFORE INPUT`, `BEFORE CONSTRUCT`, `BEFORE ROW` and `BEFORE INSERT`.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
   BEFORE FIELD cust_status
     LET p_cust.cust_comment = NULL
     MESSAGE "Enter customer status"
```

When using the default `FIELD ORDER CONSTRAINT` mode, the dialog executes the `BEFORE FIELD` block of the field corresponding to the first variable of an `INPUT` or `INPUT ARRAY`, even if that field is not editable (`NOENTRY`, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of `INPUT ARRAY`. This behavior is supported for backward compatibility.

The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block might be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

AFTER FIELD block

In dialog parts driven by a simple INPUT, INPUT ARRAY or by a CONSTRUCT sub-dialog, the AFTER FIELD block is executed every time the focus leaves the specified field. For editable lists driven by INPUT ARRAY, this block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
   AFTER FIELD item_quantity
     IF p_item.item_quantity <= 0 THEN
        ERROR "Item quantity cannot be negative or zero"
        LET p_item.item_quantity = 0
        NEXT FIELD item_quantity
     END IF
```

ON CHANGE block

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set. The ON CHANGE block can only be used for fields controlled by an INPUT or INPUT ARRAY dialog, it is not available in CONSTRUCT.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in

a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
   ON CHANGE order_checked -- Defined as CHECKBOX
      CALL setup_dialog(DIALOG)
```

If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had leaved and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This denies to do field validation in ON CHANGE blocks: you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

BEFORE INPUT block

BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE INPUT is only executed once when the dialog is started.

The BEFORE INPUT block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ...
   BEFORE INPUT
       MESSAGE "Input customer information"
       CALL DIALOG.setActionActive("check_info", is_super_user() )
       CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
   ...
```

The fields are initialized with the defaults values before the BEFORE INPUT block is executed. When the INPUT instruction uses the WITHOUT DEFAULTS option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the DEFAULT attributes of the form fields are used.

Use the NEXT FIELD control instruction in the BEFORE INPUT block, to jump to a specific field when the dialog starts.

BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE INPUT block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the BEFORE INPUT block.

BEFORE INPUT is executed after the BEFORE DIALOG block andbefore the BEFORE ROW, BEFORE FIELD blocks.

In this example, the BEFORE INPUT block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
   BEFORE INPUT
       CALL DIALOG.setActionActive("validate_order", TRUE)
```

AFTER INPUT block

AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular `INPUT`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER INPUT` is only executed once when dialog ends.

The `AFTER INPUT` block is executed after the user has validated or canceled the `INPUT` or `INPUT ARRAY` dialog with the accept or cancel default actions, or when the `ACCEPT INPUT` instruction is executed.

The `AFTER INPUT` block is not executed when the `EXIT INPUT` instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the `NEXT FIELD` instruction to force the dialog to continue. The `CONTINUE INPUT` instruction can be used instead of `NEXT FIELD`, when no particular field has to be select.

Before checking the validation rules, make sure that the `INT_FLAG` variable is `FALSE`: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
  ...

  AFTER INPUT
    IF NOT INT_FLAG THEN
       IF cust_rec.cust_address IS NOT NULL
          AND cust_rec.cust_zipcode IS NULL THEN
          ERROR "Address is incomplete, enter a zipcode."
          NEXT FIELD zipcode
       END IF
    END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER INPUT` block is executed when the focus is lost by a group of fields driven by an `INPUT` or `INPUT ARRAY` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `AFTER INPUT` block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER INPUT` is executed after the `AFTER FIELD`, `AFTER ROW` blocks and before the `AFTER DIALOG` block.

Executing a `NEXT FIELD` in the `AFTER INPUT` control block will keep the focus in the group of fields. Within an `INPUT ARRAY` sub-dialog, `NEXT FIELD` will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the `AFTER INPUT` block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
   AFTER INPUT
      IF NOT check_order_data(DIALOG) THEN
```

```
        NEXT FIELD CURRENT
      END IF
      CALL DIALOG.setFieldActive("validate_order", FALSE)
```

BEFORE CONSTRUCT block

BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `BEFORE CONSTRUCT` is only executed once when dialog is started.

The `BEFORE CONSTRUCT` block is executed once at dialog startup, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
CONSTRUCT BY NAME where_part ON ...
   BEFORE CONSTRUCT
       MESSAGE "Enter customer search filter"
       CALL DIALOG.setActionActive("clean", FALSE )
   ...
```

The fields are cleared before the `BEFORE CONSTRUCT` block is executed.

You can use the `NEXT FIELD` control instruction in the `BEFORE CONSTRUCT` block, to jump to a specific field when the dialog starts.

BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a `CONSTRUCT` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE CONSTRUCT` block is executed when the focus goes to a group of fields driven by a `CONSTRUCT` sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

`BEFORE CONSTRUCT` is executed after the `BEFORE DIALOG` block and before the `BEFORE FIELD` blocks.

In this example, the `BEFORE CONSTRUCT` block is used to display a message:

```
CONSTRUCT BY NAME sql ON customer.*
  BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
```

AFTER CONSTRUCT block

AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `AFTER CONSTRUCT` is only executed once when dialog is ended.

Use an `AFTER CONSTRUCT` block to execute instructions after the user has finished search criteria input.

`AFTER CONSTRUCT` is not executed if an `EXIT CONSTRUCT` is performed.

The code in `AFTER CONSTRUCT` can for example check if a criteria combination of different fields is required or denied, and force the end use to enter all

Before checking the content of the fields used in the `CONSTRUCT`, make sure that the `INT_FLAG` variable is `FALSE`: in case if the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated to the form fields, you must query the input buffers of the fields to get the values entered by the user.

```
CONSTRUCT BY NAME where_part ON ...
  ...
```

```
  AFTER CONSTRUCT
    IF NOT INT_FLAG THEN
       IF length(DIALOG.getFieldBuffer(cust_name))==0
       OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
          ERROR "Enter a search criteria for customer name and address
 fields."
          NEXT FIELD CURRENT
       END IF
    END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a `CONSTRUCT` sub-dialog of a procedural `DIALOG` instruction, the `AFTER CONSTRUCT` block is executed when the focus is lost by a group of fields driven by a `CONSTRUCT` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER CONSTRUCT` is executed after the `AFTER FIELD` and before the `AFTER DIALOG` block.

Executing a `NEXT FIELD` in the `AFTER CONSTRUCT` control block will keep the focus in the group of fields.

In this example, the `AFTER CONSTRUCT` block is used to build the SELECT statement:

```
CONSTRUCT BY NAME sql ON customer.*
   AFTER CONSTRUCT
       LET sql = "SELECT * FROM customers WHERE " || sql
```

BEFORE DISPLAY block

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the `BEFORE DISPLAY` is only executed once when the dialog is started.

The `BEFORE DISPLAY` block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE DISPLAY` block is executed when a `DISPLAY ARRAY` list gets the focus.

`BEFORE DISPLAY` is executed before the `BEFORE ROW` block.

In this example the `BEFORE DISPLAY` block enables an action and displays a message:

```
DISPLAY ARRAY p_items TO s_items.*
   BEFORE DISPLAY
```

```
        CALL DIALOG.setActionActive("print_list", TRUE)
        MESSAGE "You are now in the list of items"
```

AFTER DISPLAY block

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the `AFTER DISPLAY` is only executed once when dialog is ended.

You typically implement dialog finalization in this block.

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       DISPLAY "Current row is: ", arr_curr()
```

AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER DISPLAY` block is executed when a `DISPLAY ARRAY` list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER DISPLAY` is executed after the `AFTER ROW` block.

In this example, the `AFTER DISPLAY` block disables an action that is specific to the current list:

```
DISPLAY ARRAY p_items TO s_items.*
   AFTER DISPLAY
       CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

BEFORE ROW block

BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular `DISPLAY ARRAY`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `BEFORE ROW` block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, `BEFORE ROW` will be executed for the current row, but only if there are data rows in the array.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example, the `BEFORE ROW` block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
   ...
   BEFORE ROW
     MESSAGE "We are on row # ", arr_curr()
   ...
```

BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list gets the focus, or when the user moves to

another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the `BEFORE DISPLAY` or `BEFORE INPUT` blocks instead.

In `DISPLAY ARRAY`, `BEFORE ROW` is executed after the `BEFORE DISPLAY` block. In `INPUT ARRAY`, `BEFORE ROW` is executed before the `BEFORE INSERT` and `BEFORE FIELD` blocks and after the `BEFORE INPUT` blocks.

When the procedural dialog starts, `BEFORE ROW` will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, `BEFORE ROW` will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular `DISPLAY ARRAY` or `INPUT ARRAY`. In singular dialogs, the `BEFORE ROW` block is always executed when the dialog starts (and there are rows in the array).

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example the `BEFORE ROW` block displays a message with the current row number:

```
DISPLAY ARRAY p_items TO s_items.*
  BEFORE ROW
    MESSAGE "We are in items, on row #", DIALOG.getCurrentRow("s_items")
```

ON ROW CHANGE block

The `ON ROW CHANGE` block is executed in a list controlled by an `INPUT ARRAY`, when leaving the current row and when the row has been modified since it got the focus. This is typically used to detect row modification.

The code in `ON ROW CHANGE` will not be executed when leaving new rows created by the user with the default append or insert action. To detect row creation, you must use the `BEFORE INSERT` or `AFTER INSERT` control blocks.

The `ON ROW CHANGE` block is only executed if at least one field value in the current row has changed since the row was entered, and the modification flag of the field is set. The modified field(s) might not be the current field, and several field values can be changed. Values might have been changed by the user or by the program. The modification flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog instruction.

`ON ROW CHANGE` is executed after the `AFTER FIELD` block and before the `AFTER ROW` block.

When called in this block, DIALOG.getCurrentRow() / `arr_curr()` return the index of the current row that has been changed.

You can, for example, code database modifications (`UPDATE`) in the `ON ROW CHANGE` block:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   ON ROW CHANGE
     LET r = DIALOG.getCurrentRow("s_items")
     UPDATE items SET
             items.item_code        = p_items[r].item_code,
             items.item_description = p_items[r].item_description,
             items.item_price       = p_items[r].item_price,
             items.item_updatedate  = TODAY
            WHERE items.item_num = p_items[r].item_num
```

AFTER ROW block

AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular `DISPLAY ARRAY`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER ROW` block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A `NEXT FIELD` instruction executed in the `AFTER ROW` control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the row that you are leaving.

AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

`AFTER ROW` is executed after the `AFTER FIELD`, `AFTER INSERT` and before `AFTER DISPLAY` or `AFTER INPUT` blocks.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the of the row that you are leaving.

For both `INPUT ARRAY` and `DISPLAY ARRAY` sub-dialogs, a `NEXT FIELD` executed in the `AFTER ROW` control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

AFTER ROW and temporary rows in INPUT ARRAY

> **Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The `AFTER ROW` block will be executed for the temporary row, but `ui.Dialog.getCurrentRow()`/`arr_curr()` will be one row greater than `ui.Dialog.getArrayLength()`/`ARR_COUNT()`. In this case, you should ignore the `AFTER ROW` event. For example, you should not try to execute a `NEXT FIELD` or `CONTINUE INPUT` instruction, nor should you try to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.**

In this example, the `AFTER ROW` block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   AFTER ROW
      LET r = DIALOG.getCurrentRow("s_items")
      IF r <= DIALOG.getArrayLength("s_items") THEN
        IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
           ERROR "Item quantity is not valid"
           NEXT FIELD item_quantity'
         END IF
      END IF
```

Another way to handle the case of temporary rows in AFTER ROW is to use a flag to know if the AFTER INSERT block was executed: The AFTER INSERT block is not executed if the temporary row is automatically removed. By setting a first value in BEFORE INSERT and changing the flag in AFTER INSERT, you can detect if the row was permanently added to the list:

```
INPUT ARRAY p_items FROM s_items.*
  ...
  BEFORE INSERT
    LET op = "T"
    ...
  AFTER INSERT
    LET op = "I"
    ...
  AFTER ROW
    IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity
        END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
                         VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
...
```

BEFORE INSERT block

The BEFORE INSERT block is executed when a new row ins created in an INPUT ARRAY. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing a insert action, or by executing an append action.

The BEFORE INSERT block is executed after the BEFORE ROW block and before the BEFORE FIELD block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (DIALOG.getCurrentRow("*screen-array*")) with the total number of rows (DIALOG.getArrayLength("*screen-array*")). If the current row index and the total number of rows correspond, the BEFORE INSERT concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the CANCEL INSERT instruction inside BEFORE INSERT. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with DIALOG.setActionActive().

In this example, the BEFORE INSERT block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    BEFORE INSERT
      IF NOT user_can_append THEN
         ERROR "You are not allowed to append rows"
         CANCEL INSERT
      END IF
```

```
      LET r = DIALOG.getCurrentRow("s_items")
      LET p_items[r].item_num = get_new_serial("items")
      LET p_items[r].item_name = "undefined"
```

AFTER INSERT block

The AFTER INSERT block of INPUT ARRAY is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

The AFTER INSERT block is executed afterthe AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the AFTER INSERT block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the AFTER INSERT block.

When executing a NEXT FIELD in the AFTER INSERT block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row input validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the BEFORE INSERT / AFTER INSERT triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a NEXT FIELD in the AFTER ROW block.

In this example, the AFTER INSERT block inserts a new row in the database and cancels the operation if the SQL command fails:

```
INPUT ARRAY p_items FROM s_items.*
    ...
    AFTER INSERT
      WHENEVER ERROR CONTINUE
      INSERT INTO items VALUES
 ( p_items[DIALOG.getCurrentRow("s_items")].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<>0 THEN
         ERROR SQLERRMESSAGE
         CANCEL INSERT
      END IF
```

BEFORE DELETE block

The BEFORE DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, before the row is removed from the list.

You typically code the database table synchronization in the BEFORE DELETE block, by executing a DELETE SQL statement using the primary key of the current row. In the BEFORE DELETE block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The BEFORE DELETE block is executed before the AFTER DELETE block.

If needed, the deletion can be canceled with the CANCEL DELETE instruction.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that will be deleted.

The next example uses the BEFORE DELETE block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```
INPUT ARRAY p_items FROM s_items.*
  BEFORE DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    WHENEVER ERROR CONTINUE
```

```
    DELETE FROM items
       WHERE item_num = p_items[r].item_num
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<>0 VALUES
      ERROR SQLERRMESSAGE
      CANCEL DELETE
    END IF
...
```

AFTER DELETE block

The AFTER DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, after the row has been deleted from the list.

The AFTER DELETE block is executed after the BEFORE DELETE block and before the AFTER ROW block for the deleted row and the BEFORE ROW block of the new current row.

When an AFTER DELETE block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The arr_curr() function or the ui.Dialog.getCurrentRow() method returns the same index as in BEFORE ROW, but it is the index of the new current row. The AFTER ROW block is also executed just after the AFTER DELETE block.

> **Important: When deleting the last row of the list, AFTER DELETE is executed for the delete row, and DIALOG.getCurrentRow() / arr_curr() will be one higher as DIALOG.getArrayLength() / ARR_COUNT(). You should not access a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after ARR_COUNT().**

Here the AFTER DELETE block is used to re-number the rows with a new item line number (note that DIALOG.getArrayLength() / ARR_COUNT() may return zero):

```
INPUT ARRAY p_items FROM s_items.*
   AFTER DELETE
      LET r = DIALOG.getCurrentRow("s_items")
      FOR i=r TO DIALOG.getArrayLength("s_items")
          LET p_items[i].item_lineno = i
      END FOR
...
```

It is not possible to use the CANCEL DELETE instruction in an AFTER DELETE block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

BEFORE MENU block

If the MENU block contains a BEFORE MENU clause, statements within this clause will be executed before the menu dialog starts.

This block is typically used to hide or disable some menu options according to the current context of the program. For example, when the current user is not allowed to create new records, the menu options can be disabled as follows:

```
MENU "Orders"
   BEFORE MENU
      CALL DIALOG.setActionActive("append", can_user_append() )
      ...
   COMMAND "Append" -- creates "append" action (lowercase)
      ...
   ...
END MENU
```

In TUI mode, the menu options can also be disabled, but they will still be displayed on the screen. The end user will see the option, but cannot select it. In this case it's more convenient to hide the option to the end user with the `DIALOG.setActionHidden()` method, instead of disabling the action.

DIALOG interaction blocks

Dialog interaction blocks are dialog triggers that can be used to execute specific code when the user executes an action in the dialog. For example, when pressing a button in the form, the corresponding `ON ACTION` interaction block will be executed.

Interaction blocks also include special handlers such as timeout event handler, drag & drop handlers, and modification triggers for `DISPLAY ARRAY` sub-dialogs.

- ON ACTION block on page 1056
- ON IDLE block on page 1046
- ON KEY block on page 1046
- ON APPEND block on page 1088
- ON INSERT block on page 1088
- ON UPDATE block on page 1089
- ON DELETE block on page 1090
- ON SELECTION CHANGE block on page 1090
- ON DRAG_START block on page 1091
- ON DRAG_FINISHED block on page 1091
- ON DRAG_ENTER block on page 1092
- ON DRAG_OVER block on page 1093
- ON DROP block on page 1094

ON ACTION block

The `ON ACTION` *`action-name`* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
   instruction
   ...
```

Action blocks will be bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

The next example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
   CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
   CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
```

```
      CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1276.

ON IDLE block

The `ON IDLE` *`seconds`* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or got a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
   IF ask_question(
      "Do you want to reload information the database?") THEN
      -- Fetch data back from the db server
   END IF
```

> **Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON KEY block

An `ON KEY (`*`key-name`*`)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action objects that will be identified by the key name in lowercase. For example, `ON KEY(F5,F6)` creates two actions with the names `f5` and `f6`. Each action object will get an `ACCELERATORNAME` assigned with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

ON TIMER block

The `ON TIMER` *`seconds`* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

> **Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you what to change the value of the timeout variable, it must be done before the dialog block.

ON APPEND block

Similarly to the ON INSERT control block, the ON APPEND trigger can be used to enable row creation during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an ON ACTION append interaction block and the ON APPEND block is used, the compiler will stop with error -8408.

When the user fires the append action, the dialog first execute the user code of the AFTER ROW block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the ON APPEND block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular INPUT statement, to let the end user enter data for the new created row. This is typically done with an INPUT binding explicitly array fields to the screen record fields. The new current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by SCR_LINE():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON APPEND
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the new row is kept in the program array, and the BEFORE ROW block is executed for the new created row.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the new row is removed from the program array, and the BEFORE ROW block is executed for the row that was existing at the current position, before the new row was created.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON APPEND block.

The append action is disabled if the maximum number of rows is reached.

If needed, the ON APPEND handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
  ON APPEND ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON INSERT block

Similarly to the `ON APPEND` control block, the `ON INSERT` trigger can be used to enable row creation during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an `ON ACTION insert` interaction block and the `ON INSERT` block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the `AFTER ROW` block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the `ON INSERT` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular `INPUT` statement, to let the end user enter data for the new created row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `scr_line()`:

```
DISPLAY ARRAY arr TO sr.*
 ...
  ON INSERT
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the new row is kept in the program array, and the `BEFORE ROW` block is executed for the new created row.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the new row is removed from the program array, and the `BEFORE ROW` block is executed for the row that was existing at the current position, before the new row was created.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON INSERT` block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the `ON INSERT` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON INSERT ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON UPDATE block

The `ON UPDATE` trigger can be used to enable row modification during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the `TABLE` container in the form by defining the `DOUBLECLICK` attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an `ON ACTION update` interaction block and the `ON UPDATE` block is used, the compiler will stop with error -8408.

When the user fires the *update* action, the dialog executes the user code of the `ON UPDATE` block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular `INPUT` statement, to let the end user modify the data of the current row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields, with the `WITHOUT DEFAULTS`

clause. The current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `scr_line()`:

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON UPDATE
    INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].* ;
    ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the modified values of the current row are kept in the program array.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the old values of the current row are restored in the program array.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON UPDATE` block.

If needed, the `ON UPDATE` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON UPDATE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON DELETE block

The `ON DELETE` trigger can be used to enable row deletion during a `DISPLAY ARRAY` dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an `ON ACTION delete` interaction block and the `ON DELETE` block is used, the compiler will stop with error -8408.

When the user fires the delete action, the dialog executes the user code of the `ON DELETE` block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with `arr_curr()`:

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON DELETE
    IF fgl_winQuestion("Delete",
          "Do you want to delete this record?",
          "yes", "no|yes", "help", 0) == "no"
    THEN
       LET int_flag = TRUE
    END IF
    ...
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the current row is deleted from the program array, and the `BEFORE ROW` block is executed for the next row in the list.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the current row is kept in the program array, and the `BEFORE ROW` block is executed again for the current row.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON DELETE` block.

If needed, the `ON DELETE` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```
  ON DELETE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

ON SELECTION CHANGE block

The `ON SELECTION CHANGE` trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a `DISPLAY ARRAY` dialog. If this block is defined, multi-row selection is automatically enableb. However, the feature can be enabled/disabled with the `setSelectionMode()` dialog method.

ON SORT block

The `ON SORT` interfaction block can be used to detect when rows have to be sorted in a `DISPLAY ARRAY` or `INPUT ARRAY` dialog.

`ON SORT` is used in two different contexts:

1. In a regular `DISPLAY ARRAY` / `INPUT ARRAY` dialog (not using paged mode), the `ON SORT` trigger can be used to detect that a list sort was performed. In this case, the (visual) sort is already done by the runtime system and the `ON SORT` block is only used to execute post-sort tasks, such as displaying current row information, by using arrayToVisualIndex() dialog method. It is also possible to get the sort column and order with the `getSortKey()` and `getSortSelection()` dialog methods.
2. In a `DISPLAY ARRAY` using paged mode (`ON FILL BUFFER`), built-in row sorting is not available because data is provided by pages. Use the `ON SORT` trigger to detect a sort request and perform a new SQL query to re-order the rows. In this case, sort column and order is available with the `getSortKey()` and `getSortSelection()` dialog methods. See Populating a DISPLAY ARRAY on page 1372.

ON DRAG_START block

The `ON DRAG_START` block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the `ON DRAG_START` block, the program typically specifies the type of drag & drop operation by calling `ui.DragDrop.setOperation()` with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with `ui.DragDrop.addPossibleOperation()`. The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with `ui.DragDrop.setMimeType()` and `ui.DragDrop.setBuffer()` methods.

Example:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    CALL dnd.setOperation("move") -- Move is the default operation
    CALL dnd.addPossibleOperation("copy") -- User can toggle to copy if
 needed
    CALL dnd.setMimeType("text/plain")
    CALL dnd.setBuffer(arr[arr_curr()].cust_name)
    ...
END DISPLAY
```

ON DRAG_FINISHED block

Execution of the `ON DRAG_FINISHED` block notifies the dialog where the drag started that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns `NULL`. If `NULL` is returned, the `ON DRAG_FINISHED` trigger can be ignored.

In cases of successful moves to a target out of the current `DISPLAY ARRAY`, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an `ON DRAG_FINISHED` execution after the row was dropped into B, and should remove the row from the list A.

The `ON DRAG_FINISHED` interaction block is optional.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_START (dnd)
    LET last_dragged_row = arr_curr()
    ...
  ON DRAG_FINISHED (dnd)
    IF dnd.getOperation() == "move" THEN
      CALL DIALOG.deleteRow(last_dragged_row)
    END IF
    ...
END DISPLAY
```

ON DRAG_ENTER block

When the `ON DROP` control block is defined, the `ON DRAG_ENTER` block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no `ON DRAG_ENTER` block is defined. However, when `ON DROP` is defined, you should also define `ON DRAG_ENTER` to deny the drop of objects with an unsupported MIME type that come from other applications.

The program can decide to deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the `ui.DragDrop.selectMimeType()` method. This method takes the MIME type as a parameter and returns `TRUE` if the passed MIME type is used. You can call this method several times to check the availability of different MIME types.

You may also define the visual effect when flying over the target list with `ui.DragDrop.setFeedback()`.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF dnd.selectMimeType("text/plain") THEN
      CALL dnd.setOperation("copy")
      CALL dnd.setFeedback("all")
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
    ...
END DISPLAY
```

Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the `ON DRAG_OVER` trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse flies over the rows, according to the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the `ui.DragDrop.setFeedback()` method, typically called in the `ON DRAG_ENTER` block.

The values to pass to the `setFeedback()` method to get the desired visual effects described are respectively:

1. `insert` (default)
2. `select`
3. `all`

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    IF canDrop() THEN
      CALL dnd.setOperation(NULL)
    ELSE
      CALL dnd.setFeedback("select")
    END IF
    ...
END DISPLAY
```

ON DRAG_OVER block

When the `ON DROP` control block is defined, the `ON DRAG_OVER` block will be executed after `ON DRAG_ENTER`, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

`ON DRAG_OVER` will be called only once per row, even if the mouse cursor moves over the row.

In the `ON DRAG_OVER` block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the `ON DRAG_OVER` block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous `ON DRAG_ENTER` or `ON DRAG_OVER` events, or the operation selected by the end user, if it can toggle between copy and move. Thus, `ON DRAG_OVER` can occur even if the mouse position has not changed.

If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous `ON DRAG_OVER` event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

`ON DRAG_OVER` will not be called if drop has been disabled in `ON DRAG_ENTER` with `ui.DragDrop.setOperation(NULL)`

`ON DRAG_OVER` is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```
DEFINE dnd ui.DragDrop
```

```
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    IF arr[dnd.getLocationRow()].acceptsCopy THEN
      CALL dnd.setOperation("copy")
    ELSE
      CALL dnd.setOperation(NULL)
    END IF
  ON DROP (dnd)
    ...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the `ON DRAG_OVER` trigger and query the `ui.DragDrop` object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the `ON DRAG_FINISHED` trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DRAG_ENTER (dnd)
    ...
  ON DRAG_OVER (dnd)
    CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
    END CASE
    ...
  ON DROP (dnd)
    ...
END DISPLAY
```

ON DROP block

To enable drop actions on a list, you must define the `ON DROP` block; otherwise the list will not accept drop actions.

The `ON DROP` block is executed after the end user has released the mouse button to drop the dragged object. `ON DROP` will not occur if drop has been denied in the previous `ON DRAG_OVER` event or in `ON DRAG_ENTER` with a call to `ui.DragDrop.setOperation(NULL)`.

The program might also check the MIME type of the dragged object with `ui.DragDrop.getSelectedMimeType()`, and then call the `ui.DragDrop.getBuffer()` method to retrieve drag & drop data from external applications.

Ideally the drop operation should be accepted (no additional call to `ui.DragDrop.setOperation()`).

In this block, the `ui.DragDrop.getLocationRow()` method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
    ...
END DISPLAY
```

If the drag & drop operations are local to the same list or tree-view controller, you can use the `ui.DragDrop.dropInternal()` method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This `ON DROP` code example uses the `dropInternal()` method:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ...
  ...
  ON DROP (dnd)
    CALL dnd.dropInternal()
    ...
END DISPLAY
```

If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()` , the new row must be inserted before `getLocationRow()`; otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

DIALOG control instructions

Dialog control instructions are language instructions dedicated to dialog control, to programmatically force the dialog to behave in a given way.

For example the `NEXT FIELD` instruction forces the focus to a specific form field.

- NEXT FIELD instruction on page 1121
- CLEAR instruction in dialogs on page 1073
- DISPLAY TO / BY NAME instruction on page 1192
- CONTINUE DIALOG instruction on page 1192
- EXIT DIALOG instruction on page 1193
- ACCEPT DIALOG instruction on page 1193
- CANCEL DELETE instruction on page 1119
- CANCEL INSERT instruction on page 1120

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The `NEXT FIELD` *`field-name`* instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

The purpose of the NEXT FIELD instruction is give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("*field-name*") method to register a field, for example when the name is not known at compile time. However, this method only registers the field: It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of dialog instruction (INPUT *variable-list* FROM *field-list*, INPUT BY NAME *variable-list*, CONSTRUCT BY NAME *sql* ON *column-list*,CONSTRUCT *sql* ON *column-list* FROM *field-list*, INPUT ARRAY *array-name* FROM *screen-array*.*).

The field name specification can be any of the following:

- *field-name*
- *table-name.field-name*
- *screen-record-name.field-name*
- FORMONLY.*field-name*

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog according to the field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME *variable-list*), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT *variable-list* FROM *screen-record.* / field-list-with-screen-record-prefix* or INPUT ARRAY *array-name* FROM *screen-array*.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first

column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("*field-name*", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

NEXT FIELD in procedural DIALOG blocks

In a procedural dialog block, the NEXT FIELD *field-name* instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
     IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
        ERROR "Amount of line exceeds max value."
        NEXT FIELD item_count
     END IF
  END IF
```

CLEAR instruction in dialogs

The CLEAR *field-list* and CLEAR SCREEN ARRAY *screen-array.** instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program

variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFEFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated to the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

DISPLAY TO / BY NAME instruction

The DISPLAY *variable-list* TO *field-list* or DISPLAY BY NAME *variable-list* instruction fills the value buffers of specified form fields with the values contained in the specified program variables. The DISPLAY instruction changes the buffers directly in the current form, not the program variables bound to the dialog. DISPLAY can be used outside any dialog instruction, in the same way as the CLEAR instruction. DISPLAY also sets the modification flag of fields.

As DIALOG is typically used with the UNBUFFERED mode, there is no reason to set field buffers in a DIALOG block since any variable assignment will synchronize field buffers. Actually, changing the field buffers with the DISPLAY or CLEAR instruction will have no visual effect if the fields are used by a dialog working in UNBUFFERED mode, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. So if you want to set field values, just assign the variables and the fields will be synchronized. However, when using a CONSTRUCT binding, you may want to set field buffers with this DISPLAY instruction, as there are no program variables bound to fields (with CONSTRUCT, only one string variable is bound to hold the SQL condition).

Instead of using a DISPLAY instruction to set the modification flag of fields to simulate user input, use the DIALOG.setFieldTouched() method instead.

CONTINUE DIALOG instruction

The CONTINUE DIALOG statement continues the execution of a DIALOG instruction, skipping all statements appearing after this instruction.

Control returns to the dialog instruction, which executes remaining control blocks as if the program reached the end of the current control block. Then the control goes back to the user and the dialog waits for a new event.

The CONTINUE DIALOG statement is useful when program control is nested within multiple conditional statements, and you want to return control to the user by skipping the rest of the statements.

In the following code example, an ON ACTION block gives control back to the dialog, skipping all instructions below line 04:

```
ON ACTION zoom
  IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
    ERROR "Zoom window cannot be opened if no info to identify customer"
    CONTINUE DIALOG
  END IF
  IF p_cust.cust_address IS NULL THEN
     ...
```

If CONTINUE DIALOG is called in a control block that is not AFTER DIALOG, further control blocks might be executed according to the context. Actually, CONTINUE DIALOG just instructs the dialog to continue as if the code in the control block was terminated (it is a kind of GOTO end_of_control_block). However, when executed in AFTER DIALOG, the focus returns to the current field or read-only list. In this case the BEFORE ROW and BEFORE FIELD triggers will be invoked.

A CONTINUE DIALOG in AFTER FIELD, AFTER INPUT, AFTER DISPLAY or AFTER CONSTRUCT will only stop the program flow of the current block of statements; instructions after CONTINUE DIALOG will not be executed. If the user has selected a field in a different sub-dialog, this new field will get the focus and all necessary AFTER / BEFORE control blocks will be executed.

In case of input error in a field, the best practice is to use a NEXT FIELD instruction to stay in the dialog and set the focus to the field that the user has to correct.

EXIT DIALOG instruction

The EXIT DIALOG statement terminates a procedural DIALOG block without any further control block execution.

> **Note:** When used in a declarative DIALOG block, the EXIT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

Program flow resumes at the instruction following the END DIALOG keywords. Blocks such as AFTER DIALOG will not be executed.

```
   ON ACTION quit
       EXIT DIALOG
```

When leaving the DIALOG instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

ACCEPT DIALOG instruction

The ACCEPT DIALOG statement validates all input fields bound to the DIALOG instruction and leaves the block if no error is raised.

> **Note:** When used in a declarative DIALOG block, the ACCEPT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

When defined in the dialog block, ON CHANGE, AFTER FIELD, AFTER ROW, AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be executed when ACCEPT DIALOG is performed.

The statements appearing after the ACCEPT DIALOG instruction will be skipped.

You typically code an ACCEPT DIALOG in an ON ACTION accept block:

```
ON ACTION accept ACCEPT DIALOG
```

Note that any usage of ACCEPT DIALOG outside an ON ACTION accept block is not intended and its behavior is undocumented.

Input field validation is a process that does several successive validation tasks:

1. The current field value is checked, according to the program variable data type (for example, the user must input a valid date in a DATE field).
2. NOT NULL field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the NOT NULL constraint.
3. REQUIRED field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be modified by the user or by program with a DISPLAY TO / BY NAME or DIALOG.setFieldTouched() call. If the field was not modified during the dialog, the REQUIRED constraint is not satisfied.
4. INCLUDE field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

After input field validation has succeeded, different types of control blocks will be executed, such as `AFTER FIELD`, `AFTER ROW`, `AFTER INPUT` and `AFTER DIALOG`.

In order to validate some parts of the dialog without leaving the block, use the `DIALOG.validate()` method.

CANCEL DELETE instruction

In a list controlled by an `INPUT ARRAY`, row deletion can be canceled by using the `CANCEL DELETE` instruction in the `BEFORE DELETE` block. Using this instruction in a different place will generate a compilation error.

When the `CANCEL DELETE` instruction is executed, the current `BEFORE DELETE` block is terminated without any other trigger execution (no `BEFORE ROW` or `BEFORE FIELD` is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```
BEFORE DELETE
   IF user_can_delete() == FALSE THEN
      ERROR "You are not allowed to delete rows"
      CANCEL DELETE
   END IF
```

The instructions that appear after `CANCEL DELETE` will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the `DIALOG.setActionActive()` method:

```
CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the `DELETE ROW = FALSE` option in the `ATTRIBUTE` clause.

CANCEL INSERT instruction

In a list controlled by an `INPUT ARRAY`, row creation can be canceled by the program with the `CANCEL INSERT` instruction. This instruction can only be used in the `BEFORE INSERT` and `AFTER INSERT` control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after `CANCEL INSERT` will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with `DIALOG.setActionActive()`:

```
CALL DIALOG.setActionActive("insert", FALSE)
CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the `INSERT ROW = FALSE` and `APPEND ROW =FALSE` options in the `ATTRIBUTE` clause of `INPUT ARRAY`, or combine with the `AUTO APPEND = FALSE` attribute.

CANCEL INSERT in BEFORE INSERT

A `CANCEL INSERT` executed inside a `BEFORE INSERT` block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The `BEFORE INSERT` block is terminated (further instructions are skipped).

3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```
BEFORE INSERT
   IF NOT user_can_insert THEN
      ERROR "You are not allowed to insert rows"
      CANCEL INSERT
   END IF
```

Executing CANCEL INSERT in BEFORE INSERT will also cancel a temporary row creation, except when there are no more rows in the list. In this case, CANCEL INSERT will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the AUTO APPEND=FALSE attribute. If AUTO APPEND=FALSE and a CANCEL INSERT is executed in BEFORE INSERT (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

CANCEL INSERT in AFTER INSERT

A CANCEL INSERT executed inside an AFTER INSERT block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The AFTER INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

```
AFTER INSERT
   WHENEVER ERROR CONTINUE
   LET r = DIALOG.getCurrentRow("s_items")
   INSERT INTO items VALUES ( p_items[r].* )
   WHENEVER ERROR STOP
   IF SQLCA.SQLCODE<>0 THEN
      ERROR SQLERRMESSAGE
      CANCEL INSERT
   END IF
```

Examples

Programming examples using parallel dialogs.

Example 1: Two independent record lists

Form file "simple_list.per":

```
LAYOUT
GRID
{
<T t1                           >
[c1  |c2                        ]
[c1  |c2                        ]
[c1  |c2                        ]
}
END
END
ATTRIBUTES
c1 = FORMONLY.col1;
c2 = FORMONLY.col2;
END
```

```
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

The module "list1.4gl":

```
DEFINE arr DYNAMIC ARRAY OF RECORD
           id INTEGER,
           name VARCHAR(50)
       END RECORD

FUNCTION start_list1()
    DEFINE i INTEGER
    IF ui.Window.forName("w_list1") IS NULL THEN
       FOR i=1 TO 10
           LET arr[i].id = i
           LET arr[i].name = "Record "||i
       END FOR
       OPEN WINDOW w_list1 WITH FORM "simple_list"
       START DIALOG control_list1
    ELSE
       CURRENT WINDOW IS w_list1
    END IF
END FUNCTION

FUNCTION terminate_list1()
    TERMINATE DIALOG control_list1
    CLOSE WINDOW w_list1
END FUNCTION

DIALOG control_list1()
    DISPLAY ARRAY arr TO sr.*
        ON ACTION add_row
           CALL DIALOG.appendRow("sr")
           LET arr[arr.getLength()].id = arr.getLength()
           LET arr[arr.getLength()].name = "[new record]"
        ON ACTION close
           CALL terminate_list1()
    END DISPLAY
END DIALOG
```

The module "list2.4gl" (quite the same code as list1.4gl):

```
DEFINE arr DYNAMIC ARRAY OF RECORD
           id INTEGER,
           name VARCHAR(50)
       END RECORD

FUNCTION start_list2()
    DEFINE i INTEGER
    IF ui.Window.forName("w_list2") IS NULL THEN
       FOR i=1 TO 10
           LET arr[i].id = i
           LET arr[i].name = "Record "||i
       END FOR
       OPEN WINDOW w_list2 WITH FORM "simple_list"
       START DIALOG control_list2
    ELSE
       CURRENT WINDOW IS w_list2
    END IF
END FUNCTION

FUNCTION terminate_list2()
```

```
    TERMINATE DIALOG control_list2
    CLOSE WINDOW w_list2
END FUNCTION

DIALOG control_list2()
    DISPLAY ARRAY arr TO sr.*
        ON ACTION clear_row
           INITIALIZE arr[arr_curr()].* TO NULL
        ON ACTION close
           CALL terminate_list2()
    END DISPLAY
END DIALOG
```

Program file:

```
IMPORT FGL list1
IMPORT FGL list2
MAIN
  OPTIONS INPUT WRAP
  CALL start_list1()
  CALL start_list2()
  WHILE fgl_eventloop()
  END WHILE
END MAIN
```

User interface programming

Describes how to program user interface and dialog instructions.

Dialog programming basics

This section describes basic dialog programming concepts.

- The model-view-controller paradigm on page 1250
- Introducing dialogs on page 1250
- Dialog configuration with FGLPROFILE on page 1251
- The DIALOG control class on page 1252
- Dialog control functions on page 1252
- User interruption handling on page 1252
- Get program control if user inactivity on page 1254
- Get program control on a regular (timed) basis on page 1255

The model-view-controller paradigm

The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

The model defines the object to be displayed (typically the application data that is stored in program variables). The view defines the decoration of the model (how the model must be displayed to the screen, this is typically the form). The controller is the interative instruction that implements the program code to handle the model.

Views are defined in the abstract user interface tree from compiled .42f forms loaded by programs. The program variables act as models, and you implement the controllers with interactive instructions, such as `DIALOG` or `INPUT`. Controllers also define action handlers that contain the program code to be executed when an action view is triggered.

Normally the controllers should not provide any decoration information, as that is the purpose of views. Because of the history of the language, however, some interactive instructions such as `MENU` define both the controller and some presentation information such as menu title, command labels, and comments. In this case, the runtime system automatically creates the view with that information; you can still associate other views to the same controller.

Introducing dialogs

Application forms are controlled by interactive instruction blocks called dialogs. These blocks perform the common tasks associated with the form, such as field input and action handling.

The *interactive instructions* allow the program to respond to user actions and data input.

Simple display (non-interactive)

The `DISPLAY BY NAME / TO` instruction allows you to display program variable data in the fields of a form and continue the program flow without giving control to the end user. This is in fact not an interactive instruction, as it just displays data to the current form, and returns immediately. However, it may be used in interactive instructions to display information to the end user. Note that when using the `UNBUFFERED` mode of a dialog, you do not need to is the DISPLAY BY NAME / TO instruction to synchronize program variables and form fields.

The `MESSAGE` and `ERROR` instructions are also simple display instructions without user interaction. These instructions are typically used to display a warning message to the end user.

The interactive dialog blocks

The singular `MENU` instruction handles a list of choices to activate a specific function of the program. No field input is possible with this instruction. The user can only select an action from the list.

The singular `INPUT` instruction is designed for simple record input. It enables the fields in a form for input, waits while the types data into the fields, and proceeds after the user accepts or cancels the dialog.

The singular `DISPLAY ARRAY` instruction is used to browse a list of records. It allows the user to view the contents of a program array of records, scrolling the record list on the screen and choosing a specific record. `DISPLAY ARRAY` implements by default a read-only list of records, but can be extended to become a modifiable list with list modification triggers such as `ON INSERT`.

The singular `INPUT ARRAY` instruction supports record list input. It allows the user to alter the contents of records of a program array, and to insert and delete records.

The singular `CONSTRUCT` instruction is designed to let the user enter search criteria for a database query. The user can enter a value or a range of values for one or several form fields, and your program looks up the database rows that satisfy the requirements.

The procedural `DIALOG` instruction (placed in the program flow) allows you to combine several `INPUT`, `DISPLAY ARRAY`, `INPUT ARRAY` and `CONSTRUCT` functionality within the same form.

The declarative `DIALOG` block (defined at the same level as a function) allows you to implement indiviual `MENU`, `INPUT`, `DISPLAY ARRAY`, `INPUT ARRAY` and `CONSTRUCT` functionality, that will perform in parallel

on sevaral forms, when used with the `START DIALOG` and `TERMINATE DIALOG` instructions. Declarative `DIALOG` blocks can also be associated to a procedural `DIALOG` instruction through the `SUBDIALOG` clause, it will then act as a procedural DIALOG sub-dialog.

Modal dialogs and parallel dialogs

Interactive instructions can be implemented as modal or parallel dialogs. *Modal dialogs* control a given window, and that window closes when the dialog is accepted or canceled. The window displays on the top of any existing windows which are not accessible while the modal dialog executes. *Parallel dialogs* allow access to several windows simultaneously; the user can switch from on window to the other.

Dialog configuration with FGLPROFILE

FGLPROFILE parameters can be used to configure dialog behavior.

By setting global parameters in FGLPROFILE, you can control the behavior of all dialogs of the program. These options are provided as global parameters to define a common pattern for all dialogs of your application. A complete description is available in the runtime configuration section.

List of FGLPROFILE entries affecting the behavior of dialogs:

1. `Dialog.fieldOrder` (only used by singular dialogs like INPUT)
2. `Dialog.currentRowVisibleAfterSort`

The Dialog.fieldOrder entry

```
Dialog.fieldOrder = {true|false}
```

The `Dialog.fieldOrder` FGLPROFILE entry defines the execution of `BEFORE FIELD` and `AFTER FIELD` triggers of intermediate fields.

When this parameter is set to **true**, as the end user moves to a new field with a mouse click, the runtime system executes the `BEFORE FIELD` and `AFTER FIELD` dialog control blocks of the input fields between the source field and the destination field. When the parameter is set to **false**, intermediate field triggers are not executed.

The `Dialog.fieldOrder` configuration parameter is ignored by the `DIALOG` multiple-dialog instruction or when using the `FIELD ORDER FORM` option in singular dialogs such as `INPUT`.

Do not use this feature for new developments: GUI applications allow users to jump from one field to any other field of the form by using the mouse. Therefore, it makes no sense to execute the `BEFORE FIELD` and `AFTER FIELD` triggers of intermediate fields in a graphical application.

> **Important:** The default setting for the runtime system is **false**; while the default setting in FGLPROFILE for `Dialog.fieldOrder` is **true**. As a result, the overall setting after installation is **true**. To modify the behavior of intermediate field trigger execution, change the setting of `Dialog.fieldOrder` in FGLPROFILE to **false**, or use the `FIELD ORDER FORM` program option.

The Dialog.currentRowVisibleAfterSort entry

```
Dialog.currentRowVisibleAfterSort = {true|false}
```

The `Dialog.currentRowVisibleAfterSort` FGLPROFILE entry controls the visibility of the current row after a sort in tables

When this parameter is set to **true**, the offset of table page is automatically adapted to show the current row after a sort. By default, the offset is not changed and current row may not be visible after sorting rows of a table. Changing this parameter has no impact on existing code, it is just an indicator to force the dialog to shift to the page of rows having the current row, as if the end-user had scrollbar. You can use this parameter to get the same behavior as well known e-mail readers.

The DIALOG control class

This topic explains the purpose of the `ui.DIALOG` class.

Inside a dialog instruction, the `DIALOG` predefined keyword represents the current dialog object. This dialog object can be used to execute methods provided by the `ui.Dialog` built-in class.

For example, you can enable or disable an action with the `setActionActive()` dialog method, or you can hide or show the default action view with the `setActionHidden()` method:

```
BEFORE INPUT
  CALL DIALOG.setActionActive("zoom",FALSE)
AFTER FIELD field1
  CALL DIALOG.setActionHidden("zoom",1)
```

The `setFieldActive()` method can be used to enable or disable a field during the dialog:

```
ON CHANGE custname
   CALL DIALOG.setFieldActive( "custaddr",
               (rec.custname IS NOT NULL) )
```

The `ui.Dialog` class provides also methods to configure the dialog, for example to enable multiple row selection:

```
BEFORE DIALOG
   CALL DIALOG.setSelectionMode( "sr1", 1 )
```

Dialog control functions

The language provides several built-in functions and operators to be used in a dialog instruction.

Use the dialog functions and operators to keep track of the relative states of the current row, the program array, and the screen array, or to access the field buffers and keystroke buffers.

Typical control functions used in dialogs are: `arr_curr()`, `arr_count()`, `fgl_set_arr_curr()`, `set_count()`, `field_touched()`, `GET_FLDBUF()`, `INFIELD()`, `fgl_dialog_getfieldname()`, `fgl_dialog_getbuffer()`.

As an alternative to functions and operators (especially for those taking hard-coded parameters such as `INFIELD()`, use the methods provided in the ui.Dialog class.

User interruption handling

Allow the end user to cancel the execution of a procedure in the program.

When do we need interruption handling?

If the program executes an interactive instruction, the GUI front end can send action events based on user actions. When the program performs a long process like a loop, a report, or a database query, the front end has no control. You might want to permit the user to stop a long-running process in the such case.

Detecting user interruptions in programs

To detect user interruptions coming from a GUI front-end, you define an action view with the name 'interrupt':

```
BUTTON sb: interrupt, TEXT="Stop";
```

When the runtime system takes control to process program code or execute a long running SQL query, the front end automatically enables the local 'interrupt' action to let the user send an asynchronous interruption request to the program.

A program (i.e. the runtime system) can also receive a SIGINT interruption signal from the operating system. The interruption request that comes from the front-end is a different source, however the runtime system handles both type of interruption events the same way.

When receiving an interrupt event from the front-end with a 'interrupt' special action, or from the system (SIGINT) the runtime system sets the INT_FLAG register to TRUE.

Consider using DEFER INTERRUPT and test the INT_FLAG register to properly handle user interruptions, and avoid immediate program termination: If the DEFER INTERRUPT instruction is not used, the program will stop immediately when an interruption event is caught. With DEFER INTERRUPT, the program continues, and can test INT_FLAG to check if an interruption event occurred. It is good practice to reset INT_FLAG to FALSE after detecting interruption:

```
WHILE ...
   IF INT_FLAG THEN
      LET INT_FLAG=FALSE
      ERROR "Procedure was interrupted by the user"
      EXIT WHILE
   END IF
   ...
END WHILE
```

SQL queries can be interrupted too, if the target database supports this feature. However, since the control is on the database server side while the SQL statement is running, it is not possible to execute program code to check INT_FLAG. In order to detect an SQL interruption, check the SQLCA.SQLCODE register after the query for SQL error -213, indicating that the last SQL statement was interrupted.

```
WHENEVER ERROR CONTINUE
-- Long running SQL statement
WHENEVER ERROR STOP
IF SQLCA.SQLCODE == -213 THEN
   ERROR "Database query interrupted by user"
   ...
END IF
```

When not using DEFER INTERRUPT, if the program enters in a long running procedure, a button with the action name 'interrupt' will become active. The user can then press that button, and the runtime system will stop the program, since DEFER INTERRUPT is not used. However, this will not happen when a dialog is active, because the 'interrupt' button will be automatically disabled in that context. Such situation can confuse the end user, expecting that the 'interrupt' button can stop the program in any context.

Note that the front end can not handle interruption requests properly if the display generates a lot of network traffic. In this case, the front end has to process a lot of user interface modifications and has no time to detect a mouse click on the 'interrupt' action view. A typical example is a program doing a loop from 1 to 10000, just displaying the value of the counter to a field and doing a refresh. This would generate hundreds of AUI tree modifications in a short period of time. In such a case, we recommended that you calculate a modulo and display steps 10 by 10 or 100 by 100.

Implementing interruption of a long running SQL query

```
-- db_busy.per
LAYOUT
 GRID
 {
  Database query in progress...
        [sb            ]
 }
 END
END
ATTRIBUTES
 BUTTON sb: interrupt, TEXT="Stop";
```

```
END
```

```
MAIN
  DEFINE oc INT
  DEFER INTERRUPT
  OPTIONS SQL INTERRUPT ON
  DATABASE stores
  OPEN FORM f FROM "db_busy"
  DISPLAY FORM f
  CALL ui.Interface.refresh()
  WHENEVER ERROR CONTINUE
  SELECT COUNT(*) INTO oc FROM orders
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE == -213 THEN
    ERROR "Database query has been interrupted..."
  END IF
END MAIN
```

Get program control if user inactivity
Execute some code after a given number of seconds, when the user does not interact with the program.

When to use the ON IDLE trigger?

If an interactive instruction has the control, the program waits for a user interaction like an action or field input. If the end user leaves the workstation, or switches to another application, the program cannot get the control and is frozen until the user comes back. You might want to execute some code, after a perio of inactivity, for example to refresh the displayed data by doing a new database query, or even after a long period, to terminate the program automatically.

Implementing the ON IDLE trigger

To detect user inactivity during a dialog, define an `ON IDLE` trigger in the dialog. This trigger is dialog specific, it is typically defined in the main dialog of the program, but it can also be defined in every dialog.

> **Important:** Consider using the `ON IDLE` interaction block in dialogs that do not handle field input, such as `DISPLAY ARRAY` and `MENU`: In input dialogs, this trigger might be executed when in the middle of a field input, and could force field value validation and raise an input error.

For example:

```
DEFINE seconds SMALLINT
LET seconds = 120
DISPLAY ARRAY ...
   ...
   ON IDLE seconds
      MESSAGE "Automatic data refresh..."
      -- Reload the array with a new database result set
...
```

Note that the parameter of the `ON IDLE` trigger can be a integer variable, but it will only be read when the dialog is started. Changing the variable during dialog execution will have no effect.

A value of zero of less of zero disables the timeout trigger.

Get program control on a regular (timed) basis

Execute some code after a given number of seconds, with or without user interaction with the program.

When to use the ON TIMER trigger?

In some cases, the application needs to execute code on a scheduled basis, for example to process a message arrived in a queue, refresh data on a dashboard, or display resources in time-based graphs.

> **Important:** Unlike the `ON IDLE` trigger which executes when there is no user activity, the `ON TIMER` trigger executes even when the user interacts with the application. Therefore, the code executed in an `ON TIMER` trigger must perform quickly, otherwise the end user will experience poor performance. As a general rule, make sure the time spent in the `ON TIMER` code is less than the timer interval. For example, if the processing time takes about 2 seconds, it doesn't make sense to have an `ON TIMER` that triggers every second.

Implementing the ON TIMER trigger

To return control to the program on regular intervals, use the `ON TIMER` *`seconds`* trigger in dialogs. This trigger is dialog specific. It is typically defined in the main dialog of the program, but it can be defined in every dialog.

> **Important:** Consider using the `ON TIMER` interaction block in dialogs that do not handle field input, such as `DISPLAY ARRAY` and `MENU`. If used in input dialogs, this trigger may execute in the middle of a field input, which can force field value validation and raise an input error.

For example:

```
DEFINE seconds SMALLINT
LET seconds = 120
DISPLAY ARRAY ...
   ...
   ON TIMER seconds
      MESSAGE "Check for messages in queue..."
      -- Query the message server for new messages.
...
```

Note that the parameter of the `ON TIMER` trigger can be a integer variable, but it will only be read when the dialog is started. Changing the variable during dialog execution will have no effect.

A value of zero or less than zero disables the timeout trigger.

Implementing dynamic dialogs

Dialogs can be created at runtime with the `ui.Dialog` class.

Dynamic dialog basics

The `ui.Dialog` class can create dialog objects at runtime, to implement generic code controlling forms that are created at runtime, when the data structure is not known at compile time.

> **Important: Dynamic dialogs are provided to resolve specific needs, like implementing a generic zoom window to select a record in a list, and control forms generated at runtime. This feature is not a replacement for regular "static" dialog instructions, used to control the forms defined in form specification files.**

The dynamic dialogs can be used in conjunction with `base.SqlHandle` objects, to get database table column information in order to build forms dynamically.

Unlike static dialog instructions, dynamic dialogs do not require a data model (i.e. program variables containing the values for fields): Dynamic dialogs hold the data model internally, and behave by default in unbuffered mode: When an action is fired and the corresponding trigger handler is executed, the field values are available.

Creating the form

Before you instanciate a new `ui.Dialog` object, you must load an existing compiled `.42f` form, or create a new form dynamically in your program.

Forms build at runtime must be created with the `ui.Window.createForm()` method, and must contain a valid definition with layout containers, form fields, and screen records.

> **Note:** See Genero BDL demos for a complete example of form creation at runtime.

The `createForm()` method will be invoked by using the current window. For the main form of the program, use directly the (empty) `SCREEN` window. For child windows, create the windows without a form by using following syntax:

```
OPEN WINDOW w1 WITH 1 ROWS, 1 COLUMNS
```

Assuming that there is a current empty window, you can then create the `ui.Form` object, to finally get the `om.DomNode` object to build your form:

```
DEFINE w ui.Window,
       f ui.Form,
       n om.DomNode
LET w = ui.Window.getCurrent()
LET f = w.createForm()
LET n = f.getNode()
...
```

Use `om` classes, to build you form dynamically. A good practice to create dynamic forms is to write first a `.per` file, that implements a static version of one of the forms you want to build at runtime. Compile the `.per` to a `.42f` and inspect the generated XML file, to understand the structure of the form file.

For more details, see:

- ui.Window.createForm on page 1770
- The om package on page 1833

Creating the dialog object

To reference the dialog object, first declare a variable with the type `ui.Dialog`:

```
DEFINE d ui.Dialog
```

The dynamic dialog creation methods take the list of field definitions as parameter, as a dynamic array with a record structure using two members to define the field name and data type.

In order to defined the fields used by the dynamic dialog, define a dynamic array with the following structure:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
           name STRING,
           type STRING
       END RECORD
```

The field definition array will identify form fields and the data types to be used to store the values. The data types are provided as strings, using the same syntax as a regular Genero type:

```
LET fields[1].name = "formonly.cust_id"
LET fields[1].type = "INTEGER"
LET fields[2].name = "formonly.cust_name"
LET fields[2].type = "VARCHAR(50)"
LET fields[3].name = "formonly.cust_modts"
```

```
LET fields[3].type = "DATETIME YEAR TO FRACTION(5)"
```

> **Note:** The type names used by the dynamic dialog API is the same as the type names returned by the `base.SqlHandle.getResultType()` method.

When the list of field definition is complete, create the dynamic dialog object.

To create a dynamic dialog handling simple record input:

```
LET d = ui.Dialog.createInputByName(fields)
```

For more details, see ui.Dialog.createInputByName on page 1789.

To create a display array dynamic dialog:

```
LET d = ui.Dialog.createDisplayArrayTo(fields, "sr_custlist")
```

> **Note:** The list handling, the `createDisplayArrayTo()` method requires the name of the screen record used to group form fields, as defined in the `INSTRUCTIONS` section of the `.per` form file.

For more details, see ui.Dialog.createDisplayArrayTo on page 1791.

To create a dynamic dialog handling query by example:

```
LET d = ui.Dialog.createConstructByName(fields)
```

For more details, see ui.Dialog.createConstructByName on page 1788.

Add user-defined triggers

Dynamic dialogs can be configured with user-defined triggers, for example to execute code when a specific action is fired.

After creating the dialog object, add user-defined triggers with the `ui.Dialog.addTrigger()` method:

```
DEFINE d ui.Dialog
...
CALL d.addTrigger("ON ACTION print")
CALL d.addTrigger("ON DELETE")
...
```

Note that some triggers must be identified with the user-defined action name, as in `"ON ACTION print"`.

User-defined triggers will then be handled in the dynamic dialog loop, when the event occurs.

For more details, see: ui.Dialog.addTrigger on page 1793.

Handling dialog events

To implement the "body" of a dynamic dynamic, mix a `WHILE` loop with the `ui.Dialog.nextEvent()` method, to handle dialog events.

The `WHILE` loop will act as the main event handler of your dynamic dialog, and will loop, waiting for dialog events until you explicitely exist the loop with an `EXIT WHILE` instruction.

```
DEFINE d ui.Dialog
...
WHILE TRUE
    CASE d.nextEvent()
       WHEN "BEFORE DISPLAY"
          ...
       WHEN "ON ACTION print"
          ...
```

```
        WHEN "ON DELETE"
           ...
        WHEN "AFTER DISPLAY"
           ...
END WHILE
```

Several implicit trigger names are supported by dynamic dialogs, such as `"BEFORE ROW"`, `"AFTER FIELD` *`field-name`*`"`. These triggers are equivalent to the static dialog control blocks, to control the behavior of your dynamic dialog.

The event handlers for the user-defined triggers that have been added with the `addTrigger()` method must also be handled in the dynamic dialog loop.

Inside the `WHILE` loop, control the behavior of the dialog with the methods provided in the `ui.Dialog` class. For example, to jump to a different field when the "jump" action is fired:

```
WHILE TRUE
    CASE d.nextEvent()
       WHEN "ON ACTION jump"
          CALL d.nextField("customer.cust_name")
    ...
```

BEFORE/AFTER FIELD handlers must be identified with the field name (without the table/formonly prefix):

```
WHILE TRUE
    CASE d.nextEvent()
       WHEN "AFTER FIELD cust_name"
          IF LENGTH(d.getFieldValue("customer.cust_name")) < 3 THEN
             ERROR "Customer name is too short"
             CALL d.nextField("customer.cust_name")
          END IF
    ...
```

For more details, see the ui.Dialog.nextEvent() method reference.

Handling field values

A dynamic dialog stores field values in internal buffers created according to the field definitions provided in the creation method. Access to these values is required, to implement the dynamic dialog. For example, to set default values before entering the dialog loop, modifying and/or querying values during the dialog loop, and to get the entered values after dialog termination when accepted by the user.

To set or get values of fields controlled by a dynamic dialog, use respectively the `ui.Dialog.setFieldValue()` and `ui.Dialog.getFieldValue()` methods.

> **Note:** These methods take a form field name as parameter, that can be provided in different notations. See Identifying fields in dialog methods on page 1818 for more details.

When implementing a display array dynamic dialog handling a record list, the set/get field value methods apply to the current row: If you want to set or get field values of a particular row, first move to the row with the `ui.Dialog.setCurrentRow()` method.

The next example copies the values from the fields in the current row of a display array dynamic dialog (`d_list`), to the field buffers of a record input dynamic dialog (`d_rec`):

```
CALL d_list.setCurrentRow("sr_custlist", index)
FOR i=1 TO fields.getLength()
    CALL d_rec.setFieldValue( fields[i].name,
                d_list.getFieldValue(fields[i].name)
          )
END FOR
```

For more details, see:

- ui.Dialog.setFieldValue on page 1813
- ui.Dialog.getFieldValue on page 1801

Get query conditions for a field

A dynamic dialog created with ui.Dialog.createConstructByName on page 1788 handles query by example input.

To generate the SQL condition from the search value entered in a construct field, use the ui.Dialog.getQueryFromField on page 1802 method, by passing the field name as parameter:

```
LET field_condition = DIALOG.getQueryFromField("customer.cust_name")
```

To build the complete `WHERE` part for the `SELECT` statement, iter through all form fields and concatenate the form field condition by separating with the `AND` or with the `OR` operator:

```
FOR i=1 TO fields.getLength()
    LET field_condition = d.getQueryFromField(fields[i].name)
    IF field_condition IS NOT NULL THEN
       IF where_clause IS NOT NULL THEN
          LET where_clause = where_clause, " AND "
       END IF
       LET where_clause = where_clause, field_condition
    END IF
END FOR
```

Implementing the accept and cancel actions

Regular static dialog instructions implement the accept and cancel actions, to respectively validate or abort the dialog.

These actions are created automatically for static dialogs, but must be created by hand for dynamic dialogs.

In the case of cancel, you can mimic the behavior of static dialogs by setting the `INT_FLAG` register to `TRUE` and then leave the `WHILE` loop with an `EXIT WHILE`.

For the accept action, call the `ui.Dialog.accept()` method to validate field input and leave the dialog, and execute an `EXIT WHILE` in the `"AFTER INPUT"` event to leave the dialog loop.

For example, to implement the accept and cancel actions for a simple record input:

```
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createInputByName(fields)
CALL d.addTrigger("ON ACTION cancel")
CALL d.addTrigger("ON ACTION accept")
...
WHILE TRUE
  CASE d.nextEvent()
    WHEN "ON ACTION cancel"
      LET int_flag = TRUE
      EXIT WHILE
    WHEN "ON ACTION accept"
      CALL d.accept()
    WHEN "AFTER INPUT"
      EXIT WHILE
  END CASE
END WHILE
```

Terminating the dialog

Some synchronization code needs to be implemented to properly destroy the dynamic dialog. A dialog needs to be destroyed by closing its corresponding window/form.

In order to terminate a dialog, assign `NULL` to the `ui.Dialog` variable referencing the dialog object. This will destroy the object, if no other variables references it, and the corresponding window can then be closed:

```
LET d = NULL
CLOSE WINDOW w1
```

Combining dynamic dialogs with dynamic cursors

To write generic code accessing a database, implement the dynamic dialog with field names and types coming from the `base.SqlHandle` cursor.

The next code example builds a list of fields according to the database table passed as first parameter. The function scans the result set column names and types of the `base.SqlHandle` cursor, to build the list of field definitions, that can then be used for the dynamic dialog creation:

```
FUNCTION build_field_list(dbtable, fields)
    DEFINE dbtable STRING,
           fields DYNAMIC ARRAY OF RECORD
               name STRING,
               type STRING
           END RECORD
    DEFINE h base.SqlHandle,
           i INT

    LET h = base.SqlHandle.create()
    CALL h.prepare("SELECT * FROM " || dbtable)
    CALL h.open()
    CALL h.fetch()
    CALL fields.clear()
    FOR i=1 TO h.getResultCount()
        LET fields[i].name = h.getResultName(i)
        LET fields[i].type = h.getResultType(i)
    END FOR

END FUNCTION
```

For more details, see The SqlHandle class on page 1725.

Input fields

Describes various concepts related to form field management in dialogs

Field input length

Field input length defines the amount of characters the user can type in a form field.

Input length basics

The *field input length* is used by interactive instructions to limit the size of the data that can be entered by the user. Additionally, when displaying a program variable to a form field with the `DISPLAY TO` or `DISPLAY BY NAME` instruction, the field input length is used to truncate the text resulting from the data conversion. For non-character values, if the resulting text does not fit into the input length, the field will show * stars to indicate an overflow.

Length semantics for character fields

When using byte length semantics (the default), the input length represents the number of bytes in the current character set. In other words, it is the number of bytes used by the character string in the character set used by the runtime system. For example, when using a Chinese BIG5 encoding, Latin characters (a,b,c) use one byte each, while Chinese ideograms use 2 bytes: If the input length is 6, the user can enter 6 Latin characters like "abcdef", or 4 Latin characters and one Chinese ideogram, or 3 Chinese ideograms.

When using character length semantics (FGL_LENGTH_SEMANTICS=CHAR environment variable), the unit for the input length is in characters. For example, in a UTF-8 character set, if the form field has a width of 6 cells, the field can hold 6 characters, from any alphabet. There is no limitation regarding the number of bytes the UTF-8 encoded string will use.

Input length control

The field input length is defined according to:

1. The type of layout (grid-based or stack-based layout)
2. The data type of the program variable bound to field by the interactive instruction.
3. In grid-based layout, the usage of the `SCROLL` attribute for `CHAR`/`VARCHAR`/`STRING` types.

Field width definition in grid-based containers

In a grid-based container, by default the input length is defined by the width of the field item tag in the `LAYOUT` section. The width of a field item tag is defined by the number of cell positions used between the square braces:

```
LAYOUT
GRID
{
  [f1 ]    -- width = 3 cells
  [f2    ] -- width = 6 cells
  ...
```

As a general rule, forms must define fields that can hold all possible values that the corresponding program variable can contain. For example, a `DATE` field must be defined with 10 cells, to hold date values in the format DD/MM/YYYY.

If the program variable is defined with a numeric data type like `INTEGER` or `DECIMAL`, the input length is defined by the width of the field defined in the form.

If the program variable is defined with character data type such as `CHAR`, `VARCHAR` or `STRING`, by default, the input length is defined by the width of the field defined in the form. The `SCROLL` attribute can be used to bypass this limit and force the input length to be as large as the program variable. For example, when using a `CHAR(20)` variable with a form field defined with width of 3 characters, the input length will be 20 characters instead of 3.

> **Note:** Using the `SCROLL` attribute must be an exception: Form fields should be large enough to hold all possible characters that fit in the corresponding program variable. Note also that for specific item types like `TEXTEDIT`, the `SCROLL` attribute behavior is implicit when the element is stretchable or allows scrollbars.

If the program variable is defined with a `DATE`, `DATETIME` or `INTERVAL` data type, the input length is defined by the data type. For example. a `DATE` field will allow 10 characters.

Field width definition in stack-based containers

In a stack-based layout, the input length is defined by the data type of the program variable.

In the next example, the `cust_id` field will allow numeric input length in the range of the `INTEGER` data type, and the `cust_name` field will allow up to 50 characters:

```
-- Form file
LAYOUT
 STACK
   EDIT customer.cust_id;
   EDIT customer.cust_name;
 ...

-- Program
MAIN
   DEFINE cust_rec RECORD
              cust_id INTEGER,
              cust_name VARCHAR(50)
          END RECORD
   ...
   INPUT BY NAME cust_rec.*
      ...
```

If the program variable is defined with a numeric data type like `INTEGER` or `DECIMAL` or a character data type such as `CHAR`, `VARCHAR` or `STRING`, the input length is defined by the value range of the program variable. For numeric values, you can use the `INCLUDE` attribute to define the range of possible values.

If the program variable is defined with a `DATE`, `DATETIME` or `INTERVAL` data type, the input length is defined by the data type. For example. a `DATE` field will allow 10 characters.

The buffered and unbuffered modes
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Data model / view / controller paradigm

When bound to an interactive instruction (i.e. dialog), program variables act as a data model to display data or to get user input. To change the values of form fields by program, the corresponding variables must be set and displayed.

Synchronization of program variables with the form fields depends on the buffer mode used by the dialog. Use the unbuffered mode to get automatic data model / form field synchronization.

Configuring the buffer mode

By default, singular dialogs (`INPUT`, `DISPLAY ARRAY`) and procedural `DIALOG` blocks are using the buffered mode, while parallel dialogs are using the unbuffered mode by default.

The unbuffered mode can be set per (modal) dialog instruction, with the `UNBUFFERED` dialog attribute:

```
INPUT BY NAME p_site.* ATTRIBUTES(UNBUFFERED)
   ...
END INPUT
```

When using a procedural DIALOG block, all subdialogs defined locally or included with the SUBDIALOG clause inherit the buffer mode of the parent procedural dialog block:

```
DIALOG ATTRIBUTES(UNBUFFERED)
  INPUT BY NAME p_site.* -- unbuffered
     ...
  END INPUT
  DISPLAY ARRAY a_events TO sr_events.* -- unbuffered
     ...
  END DISPLAY
  SUBDIALOG d_comments -- unbuffered
```

```
END DIALOG
```

The unbuffered mode can also be set globally with the ui.Dialog.setDefaultUnbuffered() method, for singular and procedural dialogs:

```
CALL ui.Dialog.setDefaultUnbuffered(TRUE)
...
INPUT BY NAME rec_cust.* WITHOUT DEFAULTS -- uses unbuffered mode
   ...
END INPUT
```

In contrast with modal dialogs described above, when implementing parallel dialogs, all started dialogs are implicitly using the unbuffered mode, and it is not possible to use the buffered mode:

```
DIALOG d_customers()
  INPUT BY NAME r_cust.*
     ...
  END INPUT
END DIALOG
...
START DIALOG d_customers  -- will be unbufferd by default
...
```

The buffered mode

When you use the default "buffered" mode, program variable changes are not automatically displayed to form fields; you need to execute `DISPLAY TO` or `DISPLAY BY NAME`. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of a field is to use GET_FLDBUF() or DIALOG.getFieldBuffer(). These functions return the current text, which might not be a valid representation of a value of the field data type:

```
INPUT BY NAME p_item.*
   ON ACTION zoom
      CALL select_item()
           RETURNING p_item.code, p_item.desc
         DISPLAY BY NAME p_item.code, p_item.desc
      END IF
   ...
END INPUT
```

The unbuffered mode

With the unbuffered mode, program variables and form fields are automatically synchronized, and the dialog instruction is sensitive to program variable changes: You don't need to display values explicitly with `DISPLAY TO` or `DISPLAY BY NAME`. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable. If you need to display new data during the dialog execution, just assign the values to the program variables; the runtime system will automatically display the values to the screen after user code of the current control or interaction block has been executed:

```
INPUT BY NAME p_site.* ATTRIBUTES(UNBUFFERED)
   ON ACTION zoom
      CALL select_item()
           RETURNING p_item.code, p_item.desc
         -- no need to display desc.
      END IF
   ...
END INPUT
```

Actions configuration for field validation

During data input, values entered by the user in form fields are automatically validated and copied into the program variables. Actually the value entered in form fields is first available in the form field buffer. This buffer can be queried with built-in functions or dialog class methods. With the unbuffered mode, the field buffer is used to synchronize program variables each time control returns to the runtime system - for example, when the user clicks on a button to execute an action.

With the unbuffered mode, data validation must be prevented for some actions such as cancel or close . To avoid field validation for a given action, set the `validate` action default attribute to "no", in the `.4ad` file or in the `ACTION DEFAULTS` section of the form file:

```
ACTION DEFAULTS
   ACTION undo (TEXT = "Undo", VALIDATE = NO)
   ...
END
```

Some predefined actions are already configured with `validate=no` in the `default.4ad` file.

If field validation is disabled for an action, the code executed in the `ON ACTION` block acts as if the dialog was in buffered mode: The program variable is not set; however, the input buffer of the current field is updated. When returning from the user code, the dialog will not synchronize the form fields with program variables, and the current field will display the input buffer content. Therefore, if you change the value of the program variable during an `ON ACTION` block where validation is disabled, you must explicitly display the values to the fields with `DISPLAY TO / BY NAME`.

To illustrate this case, imagine that you want to implement an undo action to allow the modifications done by the user to be reverted (before these have been saved to the database of course). You typically copy the current record into a clone variable when the dialog starts, and copy these old values back to the input record when the undo action is invoked. An undo action is a good candidate to avoid field validation, since you want to ignore current values. If you don't re-display the values, the input buffer of the current field will remain when returning from the `ON ACTION` block:

```
DIALOG ATTRIBUTES(UNBUFFERED)
 INPUT BY NAME p_cust.*
   BEFORE INPUT
     LET p_cust_copy.* = p_cust.*
   ON ACTION undo -- Defined with VALIDATE=NO
     LET p_cust.* = p_cust_copy.*
     DISPLAY BY NAME p_cust.*
 END INPUT
END DIALOG
```

For more details, see Data validation at action invocation on page 1331.

Binding variables to form fields

Some dialogs need program variables to store form field values.

Dialogs handling data fields input or display (`INPUT`, `INPUT ARRAY`, `DISPLAY ARRAY`) need program variables to store the information displayed in form fields during the dialog execution. The exception is `CONSTRUCT`, which needs only one string variable that holds the SQL condition produced.

When declaring a dialog handling form fields, you specify what program variables must be bound to the form fields:

```
   INPUT BY NAME custrec.* ...
      ...
   END INPUT
```

There are different ways to bind program variables to screen record fields. Basically program variables can be bound to form fields by name or by position, according to the binding clause used in the dialog definition.

When binding program variables with a screen record followed by a `.*` (dotstar), program variables are bound to screen record fields by position, so you must make sure that the program variables are defined (or listed) in the same order as the screen array fields. This is true for `INPUT`, `DISPLAY ARRAY` and `INPUT ARRAY`.

The program variables can be of any simple data type supported by the dialogs; the runtime system will adapt input and display rules to the variable type. When the user enters data for an `INPUT` or `INPUT ARRAY` instruction, the runtime system checks the entered value against the data type of the variable, not the data type of the form field. For example, if you want to use a `DATE` variable, the dialog will check for a valid date value when the user enters a value in the corresponding form field.

With `CONSTRUCT`, no program variable is used for fields: Only one string variable is bound to that type of dialog, to hold the generated SQL condition. Note that the `CONSTRUCT` dialog uses the field data types defined in the form file.

Program variables are typically declared with a `DEFINE LIKE` clause to get the data type of a column as defined in the database schema file. When the form fields are also defined like a column of the database schema, this ensure that the program variable and form field data type matches the underlying database column type. If a variable is declared `LIKE` a SERIAL / SERIAL8 / BIGSERIAL column, the runtime system will treat the field as if it was defined as `NOENTRY` in the form file: Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

Program variables (simple records and arrays) used in dialogs can have a flat definition, or structured definition with sub-records.

Data format for input and display of numeric (`DECIMAL`, `INTEGER`) and `DATE` fields can be defined with the `FORMAT` attribute. A default data format can be defined with environment variables (DBDATE, DBFORMAT, etc)

Some data validation rules can be defined at the form level, such as `NOT NULL`, `REQUIRED` and `INCLUDE` attributes. Data validation constraints are checked when leaving a field, or when the dialog is validated (for example, with the `ACCEPT DIALOG` instruction inside a `DIALOG` multiple dialog block).

If the program record or array has the same structure as a database table (this is the case when the variable is defined with a `DEFINE LIKE` clause), you may not want to display / use some of the columns. You can achieve this by used `PHANTOM` fields in the screen array definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

Form field initialization

Form field initialization can be controlled by the `WITHOUT DEFAULTS` dialog option.

The `INPUT` and `INPUT ARRAY` dialogs provide the `WITHOUT DEFAULTS` option to use program variable values when the dialog starts, or to apply the `DEFAULT` attribute defined in forms. The semantics of this options is slightly different in `INPUT` and `INPUT ARRAY` dialogs. The `WITHOUT DEFAULTS` clause should always be used in `INPUT ARRAY`.

The `WITHOUT DEFAULTS` option can be used in the binding clause or as an `ATTRIBUTES`. When used in the binding clause, the option is defined statically at compile time as `TRUE`. When used as an `ATTRIBUTES` option, it can be specified with an integer expression that is evaluated when the `DIALOG` interactive instruction starts:

```
INPUT BY NAME p_cust.* ATTRIBUTES (WITHOUT DEFAULTS = NOT new)
   ...
END INPUT
```

The WITHOUT DEFAULTS clause in INPUT

In the default mode, an INPUT clears the program variables and assigns the values defined by the DEFAULT attribute in the form file (or indirectly, the default value defined in the database schema files). This mode is typically used to input and INSERT a new record in the database. The REQUIRED field attributes are checked to make sure that the user has entered all data that is mandatory. Note that REQUIRED only forces the user to enter the field, and can leave the value NULL unless the NOT NULL attribute is used. Therefore, if you have an AFTER FIELD or ON CHANGE control block with validation rules, you can use the REQUIRED attribute to force the user to enter the field and trigger that block.

In contrast, the WITHOUT DEFAULTS option starts the INPUT dialog with the existing values of program variables. This mode is typically used in order to UPDATE an existing database row. Existing values are considered valid, thus the REQUIRED attributes are ignored when this option is used.

The NOT NULL field attribute is always checked at dialog validation, even if the WITHOUT DEFAULTS option is set.

The WITHOUT DEFAULTS clause in INPUT ARRAY

With an INPUT ARRAY, the WITHOUT DEFAULT option defines whether the program array is populated when the dialog begins. Once the dialog is started, existing rows are always handled as records to be updated in the database (i.e. WITHOUT DEFAULTS=TRUE), while newly created rows are handled as records to be inserted in the database (i.e. WITHOUT DEFAULTS=FALSE). In other words, column default values defined in the form specification file or the database schema files are only used for new created rows.

It is unusual to implement an INPUT ARRAY with no WITHOUT DEFAULTS option, because the program array would be cleared and the list would appear empty.

> **Important:** The default in INPUT ARRAY used inside DIALOG is WITHOUT DEFAULTS=TRUE, but in a singular INPUT ARRAY dialog, the default is WITHOUT DEFAULTS=FALSE.

Input field modification flag

Each input field controlled by a dialog instruction has a modification flag.

The modification flag is used to execute form-level validation rules and trigger ON CHANGE blocks. The flag can also be queried to detect if a field was touched/changed during the DIALOG instruction, for example with the FIELD_TOUCHED() operator or with ui.Dialog.getFieldTouched().

Both FIELD_TOUCHED() and ui.Dialog.getFieldTouched() accept a list of fields and/or the *screen-record.** notation in order to check the modification flag of multiple fields in a unique function call. You can also pass a simple * star as parameter, to reference all fields used by the dialog.

The modification flag is set to TRUE when the user enters data in a field, or when the program executes a DISPLAY TO / DISPLAY BY NAME instruction. The flag can also be set by program to TRUE or reset to FALSE with the ui.Dialog.setFieldTouched() method, to emulate user input by program or to reset the modification flags after data was saved in the database.

The modification flags of all fields are automatically reset to FALSE by the interactive instruction in the following cases:

- When the dialog instruction starts.
- In a DIALOG block, when entering a group of fields controlled by an INPUT or a CONSTRUCT sub-dialog .
- When moving to (or creating) a new row in an INPUT ARRAY.
- Withing a DISPLAY ARRAY, the modification flags are always TRUE for all fields.

When using a DISPLAY ARRAY, the modification flags are set to TRUE for all fields. This behavior exists because of backward compatibility. Since values cannot be modified by the user, the modification flags are not relevant in this dialog. However, you must pay attention when implementing nested dialogs, because DISPLAY ARRAY will set the modification flags of the fields driven by the parent dialog, for example when executing a DISPLAY ARRAY from an INPUT ARRAY.

Query the modification flags with the `ui.Dialog.getFieldTouched()` method, typically in the context of `AFTER INPUT`, `AFTER CONSTRUCT`, `AFTER INSERT` or `AFTER ROW` control blocks.

When using a list driven by an `INPUT ARRAY` binding, a temporary row added at the end of the list will be automatically removed if all fields have the modification flag is set to `FALSE`.

For typical `EDIT` fields, the modification flag is set when leaving the field. If you want to detect data modification earlier, you should use the dialogtouched predefined action. However, this event is only an indicator that the user started to modify a field, the value will not be available in the program variables.

Reacting to field value changes
This section describes the purpose of the `ON CHANGE` interaction block.

The `ON CHANGE` interaction block can be used in different ways:

- With form fields allowing only entire value input such as `CHECKBOX`, or using an additional widget such as a calendar in a `DATEEDIT`: `ON CHANGE` can be used to detect an immediate value change, or the selection of a value in the additional widget, without leaving the field.
- With text fields like `EDIT` (allowing incomplete values), defined with the `COMPLETER` attribute to implement autocompletion: In this case the `ON CHANGE` trigger is fired without leaving the field, when the user types characters in (after a short delay).
- With text fields like `EDIT` (allowing incomplete values): `ON CHANGE` can be used to detect a value change, when the field is left.

A typically usage of `ON CHANGE` is for example with a `CHECKBOX`, to enable/disable other form elements according to the value of the checkbox field:

```
INPUT BY NAME rec.* ...
    ...
    ON CHANGE input_details -- can be TRUE or FALSE
       CALL DIALOG.setFieldActive("address1", rec.input_details)
       CALL DIALOG.setFieldActive("address2", rec.input_details)
    ...
END INPUT
```

The `dialogtouched` predefined action can also be used to detect field changes immediately, but with this action you can't get the data in the target variables; this special action should only be used to detect that the user has started to modify data in the current dialog.

Immediate detection of user changes
This section describes the purpose of the predefined `dialogtouched` action.

The *dialogtouched* special predefined action can be used to detect user changes immediately and execute code in the program.

Singular interactive instruction are typically ended with an accept or cancel action. For example, a singular `INPUT` statement allows the end user to enter a database record, and validate or cancel the input for that record. The `INPUT` statement is then re-executed to input another record. Unlike singular dialogs, the `DIALOG` instruction can be used continuously for several data operations, such as navigation, creation, or modification. Typically, default is the navigation mode, and as soon as the user starts to modify a field, it switches to edit mode, to modify a record, or create a new record. In such case, the dialog must be notified when the user starts to modify the current record, for example to enable a save action. This is achieved with the `dialogtouched` predefined action.

The dialogtouched action works for any field controlled by the current interactive instruction, and with any type of form field: Every time the user modifies the value of a field (without leaving the field), the `ON ACTION dialogtouched` block will be executed; This can be triggered by typing characters in a text editor field, clicking a checkbox / radiogroup, or modifying a slider. When a `ON ACTION dialogtouched` action handler is defined, the front-end knows that it must send this action when the end-user modifies the current field (without leaving that field), just by a simple keystroke.

> **Important: The dialogtouched action must be enabled/disabled in accordance with the status of the dialog: If this action is enabled, the `ON ACTION dialogtouched` block will be invoked each time the user types characters (or modifies the value with copy/paste) in the current field; This can generate a lot of network traffic and is not the goal of this action: The dialogtouched action must be disabled as soon as it is detected, and the DIALOG can then enter in modification/edit mode. When user input is validated and saved in the database, the dialogtouched action can be enabled again.**

Use `ON ACTION dialogtouched` to detect the beginning of a record modification in a `DIALOG` block, to enable a "save" action for example. To prevent further dialogtouched action events, disable the action with a `DIALOG.setActionActive()` method. When the dialogtouched action is enabled, the `ON ACTION` block will be invoked each time the user types characters in an editable field. This programming pattern is illustrated by the next code example:

```
DIALOG
   ...
   ON ACTION dialogtouched
      CALL setup_dialog(DIALOG,TRUE)
   ...
   ON ACTION save
      CALL save_record()
      CALL setup_dialog(DIALOG,FALSE)
   ...
END DIALOG

FUNCTION setup_dialog(d,editing)
   DEFINE d ui.Dialog, editing BOOLEAN
    CALL DIALOG.setActionActive("dialogtouched", NOT editing)
    CALL DIALOG.setActionActive("save", editing)
    CALL DIALOG.setActionActive("query", NOT editing)
END FUNCTION
```

When a dialogtouched action occurs, the current field may contain some text that does not represent a valid value of the underlying field data type. For example, a form field bound to a `DATE` variable may contain only a part of a valid date string, such as `[12/24/ ]`. For this reason, the target variable cannot hold the current text displayed on the screen when the `ON ACTION dialogtouched` code is executed, even when using the `UNBUFFERED` mode.

To avoid data validation on action code execution, the dialogtouched action is defined with `validate="no"` attribute in the `FGLDIR/lib/default.4ad` action defaults file. This is mandatory when using the `UNBUFFERED` mode; otherwise the runtime would try to copy the input buffer into the program variable when a dialogtouched action is invoked. Since the text of the current field will in most cases contain only a part of a valid data value, using `validate="yes"` would always result in a conversion error.

In order to detect field input changes, you can use the `ON CHANGE` trigger, when the form item type allows to detect value changes immediately, for example in `COMBOBOX`, `CHECKBOX` or `DATEEDIT` fields.

Form-level validation rules

Form-level validation rules can be defined for each field controlled by a dialog.

Form-level validation can be specified at the form field level with attributes such as `NOT NULL`, `REQUIRED` and `INCLUDE`. These attributes are part of the business rules of the application and must be checked before saving data into the database.

Implicit validation rule checking

An `INPUT` or `INPUT ARRAY` block automatically executes form-level validation rules in the following cases:

- The `NOT NULL` attribute is satisfied if a value is in the field. `NOT NULL` is checked:

    - when the user moves to a different row in a list controlled by an `INPUT ARRAY`; However, if the row is temporary and none of the fields is touched, the attribute is ignored.
    - in a `DIALOG` block, when focus leaves the sub-dialog controlling the field;
    - in a `DIALOG` block, when `NEXT FIELD` gives the focus to a field in a different sub-dialog than the current sub-dialog.
    - when the dialog instruction is ended, for example when a procedural `DIALOG` is ended with `ACCEPT DIALOG`, or when an singular `INPUT` is ended with `ACCEPT INPUT` or with the implicit accept action.
- The `REQUIRED` attribute is satisfied if the field modification flag is true, if a `DEFAULT` value is defined, or if the `WITHOUT DEFAULTS` option is used. `REQUIRED` is checked:
    - when the user moves to a different row in a list controlled by an `INPUT ARRAY`; However, if the row is temporary and none of the fields is touched, the attribute is ignored.
    - in a `DIALOG` block, when focus leaves the sub-dialog controlling the field;
    - in a `DIALOG` block, when `NEXT FIELD` gives the focus to a field in a different sub-dialog than the current sub-dialog.
    - when the dialog instruction is ended, for example when a procedural `DIALOG` is ended with `ACCEPT DIALOG`, or when an singular `INPUT` is ended with `ACCEPT INPUT` or with the implicit accept action.
- The `INCLUDE` attribute is satisfied if the value is in the list defined by the attribute. `INCLUDE` is checked when the target program variable must be assigned. This happens:
    - when `UNBUFFERED` mode is used, focus is in the field, and an action is invoked;
    - when the focus leaves the field;
    - when the user moves to a different row in a list controlled by an `INPUT ARRAY`; However, if the row is temporary and none of the fields is touched, the attribute is ignored.
    - in a `DIALOG` block, when focus leaves the sub-dialog controlling the field;
    - in a `DIALOG` block, when `NEXT FIELD` gives the focus to a field in a different sub-dialog than the current sub-dialog.
    - when the dialog instruction is ended, for example when a procedural `DIALOG` is ended with `ACCEPT DIALOG`, or when an singular `INPUT` is ended with `ACCEPT INPUT` or with the implicit accept action.

Performing validation rules explicitly

Singular input dialogs (`INPUT` / `INPUT ARRAY`) create default accept / cancel actions. The form-level validation rules are typically performed when the implicit accept action is triggered.

The `DIALOG` procedural instruction can be used as in singular interactive instructions, with the typical OK / Cancel buttons (i.e. accept / cancel actions) to finish the instruction. The accept/cancel action handlers would respectively execute the `ACCEPT DIALOG` and `EXIT DIALOG` instructions. This solution lets the user input or modify one record at a time, and the program flow must reenter the`DIALOG` instruction to edit or create another record. Alternatively, the`DIALOG` instruction can let the user input / modify multiple records without leaving the dialog. In this case, you need a way to execute the form-level validation rules defined for each field, before saving the data to the database.

To validate a subset of fields controlled by the `DIALOG` instruction, use the `ui.Dialog.validate("field-list")` method, as shown in this example:

```
   ON ACTION save
      IF DIALOG.validate("cust.*") < 0 THEN
         CONTINUE DIALOG
      END IF
      CALL customer_save()
```

This method automatically displays an error message and registers the next field in case of error. It is mandatory to execute a `CONTINUE DIALOG` instruction if the function returns an error.

Within singular input dialogs, form-level validation rules can also be explicitly performed with the ACCEPT INPUT instruction, or with the DIALOG.validate("*") API call, followed by a CONTINUE INPUT in case of error.

Form field deactivation

The form fields bound to a dialog are by default active (i.e. they can get the focus). When needed, disable the fields that do not require user input, and reactivate them later during the dialog execution. For example, imagine a form containing an "Industry" COMBOBOX field , with the options *Healthcare*, *Education*, *Government*, *Manufacturing*, and *Other* . If the user selects "Other", an secondary EDIT field should be activated automatically, to let the user input the specific description of the industry. But if one of the predefined values is selected, there is no need for the additional field, so secondary field can be left disabled.

This can be achieved by enabling/disabling fields with the ui.Dialog.setFieldActive() method according to the context. The "Industry" field case described can be implemented as follows:

```
DIALOG ATTRIBUTES(UNBUFFERED)
   INPUT BY NAME rec.*
      ON CHANGE industry
         -- A value of 99 corresponds to the "Other" item
         CALL DIALOG.setFieldActive( "cust.industry", (rec.industry!=99) )
     ...
   END INPUT
   BEFORE DIALOG
     CALL DIALOG.setFieldActive( "cust.industry", FALSE )
     ...
END DIALOG
```

Consider centralizing field activation / deactivation in a setup function specific to the dialog, passing the DIALOG object as parameter.

Do not disable all fields of a dialog, otherwise the dialog execution stops (at least one field must get the focus during a dialog execution).

It is also possible to hide fields with the ui.Form.setFieldHidden() method of the form objects. The dialog considers hidden fields as disabled (i.e. there is no need to disable fields that are already hidden). But hiding form elements changes the space used in the window layout and the form may be displayed in unexpected way, except when hiding elements in containers prepared to that, such as tables.

Identifying sub-dialogs in procedural DIALOG

Sub-dialogs need to be identified by a name to distinguish the different contexts.

A procedural DIALOG block is a collection of sub-dialogs that act as controllers for different parts of a form. In order to program a procedural DIALOG block, there must be a unique identifier for each sub-dialog.

For example, to set the current row of a screen array with the DIALOG.setCurrentRow() method, you pass the name of the screen array to specify the sub-dialog to be affected. Sub-dialog identifiers are also used as a prefix to specify actions for the sub-dialog.

The following topics describe how to specify the names of the different types of DIALOG sub-dialogs:

- Identifying an INPUT sub-dialog on page 1154
- Identifying a DISPLAY ARRAY sub-dialog on page 1156
- Identifying an INPUT ARRAY sub-dialog on page 1157
- Identifying a CONSTRUCT sub-dialog on page 1155
- The SUBDIALOG clause on page 1158.

Defining the tabbing order

Control the order of tabbing trough the fields with the TABINDEX attribute.

When a dialog is executing, the end-user can jump from field to field with the keyboard by using the Tab and Shift-Tab keys.

> **Note:** One can tab out of an INPUT ARRAY sub-dialog with Ctrl-Tab and Shift-Ctrl-Tab accelerators (in INPUT ARRAY, Tab and Shift-Tab loop in the fields of the current row).

The order in which the fields can be visited with the Tab key can be controlled with a program option and the TABINDEX form field attribute.

The FIELD ORDER dialog attribute defines the way tabbing order works. Tabbing order can be based on the dialog binding list (FIELD ORDER CONSTRAINED, the default) or it can be based on the form tabbing order (FIELD ORDER FORM). It is recommended that you use the FIELD ORDER FORM option, to use the tabbing order specified in the form file.

The TABINDEX field attribute allows tabbing order in the form to be defined for each form item. By default, the form compiler assigns a tabbing index for each form item according to the position of the item in the layout.

Form elements that can get the focus are:

- Simple form fields controlled by INPUT or CONSTRUCT,
- Read-only lists controlled by DISPLAY ARRAY,
- Editable list cells controlled by INPUT ARRAY,
- Simple buttons controlled by a COMMAND interaction block.

If you use the keyboard to tab into a form element, the focus will go to the next (or previous) element that is visible and activated . In other words, if a form item is hidden or disabled, it is removed from the tabbing list.

The tabbing position of a read-only list driven by a DISPLAY ARRAY binding is defined by the TABINDEX of the first field .

When TABINDEX is set to zero, the form item is excluded from the tabbing list. However, the item with TABINDEX=0 can still get the focus with the mouse (or when you tap on it on a mobile device).

The NEXT FIELD instruction can also use the tabbing order, when executing NEXT FIELD NEXT and NEXT FIELD PREVIOUS.

If the form uses a TABLE container, the front-end resets the tab indexes when the user moves columns around. This way, the visual column order always corresponds to the input tabbing order. If the order of the columns in an editable list shouldn't be changed, you can freeze the table columns with the UNMOVABLECOLUMNS attribute.

Which form item has the focus?

Identify what element of the current form has the focus.

Sometimes it is important to know what form element has currently the focus. This is especially important when implementing a DIALOG block, that can control several parts of a form. For example, when several lists are driven by multiple DISPLAY ARRAY sub-dialogs, you may need to know what is the current list.

To get the name of the current form item, use the DIALOG.getCurrentItem() method. This method is the replacement of the former fgl_dialog_getfieldname() built-in function. It has been extended to return identifiers for fields, lists or actions identifiers.

```
DIALOG ATTRIBUTES(UNBUFFERED)
   DISPLAY ARRAY p_orders TO orders.*
     ...
   END DISPLAY
   DISPLAY ARRAY p_items TO items.*
     ...
   END DISPLAY
```

```
   ...
      IF DIALOG.getCurrentItem() == "items" THEN
         ...
      END IF
   ...
END DIALOG
```

It is also possible to detect when the focus enters or leaves a field or a group of fields by using control blocks such as `BEFORE INPUT/DISPLAY` or `AFTER INPUT/DISPLAY`.

Giving the focus to a form element
How to force the focus by program, to move or stay in a specific form element.

Use the `NEXT FIELD` instruction to force the focus to a specific field or screen record (list). The `NEXT FIELD` instruction expects a form field name.

In a `DIALOG` block, when the specified field is the first column identifier of a sub-dialog driven by a `DISPLAY ARRAY` block, the read-only list gets the focus. If the field name is not known at compile time, you can alternatively use the `ui.Dialog.nextfield()` method.

```
DIALOG ATTRIBUTES(UNBUFFERED)
   INPUT BY NAME p_cust ATTRIBUTES(NAME="cust")
     ...
   END DISPLAY
   DISPLAY ARRAY p_orders TO orders.*
     ...
   END DISPLAY
   ON ACTION go_to_header
      NEXT FIELD cust_num
   ON ACTION go_to_detail
      NEXT FIELD order_lineno
   ...
END DIALOG
```

When a `BUTTON` exist in the form layout, it can get the focus if the `DIALOG` block defines a `COMMAND` clause as action handler. Currently there is no way to give the focus to a `BUTTON` by program.

```
DIALOG ATTRIBUTES(UNBUFFERED)
   ...
   COMMAND "print"
      CALL print_order()
   ...
END DIALOG
```

In some seldom cases (especially when using folder tabs), it may be need to show a part of the form that is not controlled by the dialog (i.e. there is no active field or button that can get the focus in that form part, thus the above techniques cannot work). To show temporary a given part of the form that cannot get the focus, use the `ui.Form.ensureFieldVisible()` or `ui.Form.ensurelementVisible()` methods.

```
DEFINE form ui.Form
...
DIALOG ATTRIBUTES(UNBUFFERED)
   ...
   BEFORE DIALOG
      LET form = DIALOG.getForm()
   ...
   ON ACTION show_image1
      CALL form.ensureElementVisible("image1")
   ...
END DIALOG
```

Detection of focus changes

Describes how to detect when the focus goes from field to field or to a read-only list.

Detecting focus changes in a singular INPUT or CONSTRUCT

An singular `INPUT` or `CONSTRUCT` controls several fields that can get the focus and become current. In order to execute some code when a field gets (or loses) the focus, use the following control blocks:

- `BEFORE FIELD` (a specific field (or group of fields) gets the focus)
- `AFTER FIELD` (the field (or group of fields) loses focus)

Detecting focus changes in a singular DISPLAY ARRAY

An singular `DISPLAY ARRAY` controls rows of a list, that can get the focus and become current. In order to execute some code when a row gets (or loses) the focus, use the following control blocks:

- `BEFORE ROW` (a new row gets the focus inside a `DISPLAY ARRAY` or `INPUT ARRAY` list)
- `AFTER ROW` (a row inside a `DISPLAY ARRAY` or `INPUT ARRAY` list loses focus)

Detecting focus changes in a singular INPUT ARRAY

An singular `INPUT ARRAY` controls several fields and rows of a list, that can get the focus and become current. In order to execute some code when a field or a row gets (or loses) the focus, use the following control blocks:

- `BEFORE ROW` (a new row gets the focus inside a `DISPLAY ARRAY` or `INPUT ARRAY` list)
- `BEFORE FIELD` (a specific field (or group of fields) gets the focus)
- `AFTER FIELD` (the field (or group of fields) loses focus)
- `AFTER ROW` (a row inside a `DISPLAY ARRAY` or `INPUT ARRAY` list loses focus)

Detecting focus changes in a DIALOG

A `DIALOG` interaction block can handle different parts of a form simultaneously. In order to execute some code when a part of the form gets (or loses) the focus, use the following control blocks:

- `BEFORE INPUT` (a field of this `INPUT` or `INPUT ARRAY` sub-dialog gets the focus and none of its fields had focus before)
- `BEFORE CONSTRUCT` (a field of this `CONSTRUCT` sub-dialog gets the focus and none of its fields had focus before)
- `BEFORE DISPLAY` (this `DISPLAY ARRAY` sub-dialog gets the focus and none of its fields had focus before)
- `BEFORE ROW` (a new row gets the focus inside a `DISPLAY ARRAY` or `INPUT ARRAY` list)
- `BEFORE FIELD` (a specific field (or group of fields) gets the focus)
- `AFTER FIELD` (the field (or group of fields) loses focus)
- `AFTER ROW` (a row inside a `DISPLAY ARRAY` or `INPUT ARRAY` list loses focus)
- `AFTER DISPLAY` (this `DISPLAY ARRAY` sub-dialog loses the focus = focus goes to another sub-dialog)
- `AFTER CONSTRUCT` (this `CONSTRUCT` sub-dialog loses the focus = focus goes to another sub-dialog)
- `AFTER INPUT` (this `INPUT` or `INPUT ARRAY` sub-dialog loses focus = focus goes to another sub-dialog)

These triggers are also executed by `NEXT FIELD`.

Enabling autocompletion

Autocompletion allows to display a list of proposals while the user is typing text into a field.

Introduction to autocompletion

Text input fields (like `EDIT` and `BUTTONEDIT`) can be defined with autocompletion feature, by combining the `COMPLETER` form field attribute with program code providing the list of proposals in a dynamic array of strings, with the `DIALOG.setCompleterItems()` method, when the `ON CHANGE` trigger is fired for the autocompletion field.

Defining a form field for autocompletion

In order to enable autocompletion in a text form field, you must define the `COMPLETER` attribute:

```
EDIT f1 = FORMONLY.firstname, COMPLETER;
```

The `COMPLETER` attribute can be used for `EDIT` and `BUTTONEDIT` fields.

Providing the front-end with a list of proposals

The `DIALOG.setCompleterItems()` method must be used to provide the list of proposal during dialog execution:

```
DEFINE items DYNAMIC ARRAY OF STRING
-- fill the array with items
LET items[1] = "Ann"
LET items[2] = "Anna"
LET items[3] = "Annabel"
CALL DIALOG.setCompleterItems(items)
```

> **Important:** Consider the execution time of the code creating the proposal list. For example, avoid long complex SQL queries that can take more than a few milliseconds to complete.

The `setCompleterItems()` method will raise error -8114 if the list of items contains more than 50 elements. The purpose of autocompletion is to provide a short list of proposals to the user. Note that this error is not trappable with exception handlers like `TRY/CATCH`, the code must avoid to reach the limit.

Detecting user input

When implementing autocompletion, you must detect when the user modifies the field value, to adapt the list of items with the `setCompleterItems()` method.

In order to detect user input, define the `ON CHANGE` dialog control block, and call a custom function by passing the `DIALOG` object, and the value of the current field as paramter, to filter the proposal list accordingly:

```
INPUT BY NAME rec.firstname
   ...
   ON CHANGE firstname
      CALL fill_proposals_firstname(DIALOG, rec.firstname)
```

For text fields defined with the `COMPLETER` attribute, the `ON CHANGE` trigger will be fired without leaving the field, each time the user types characters in. The event is fired after a short delay, to not overload the UI exchanges between the front-end and the runtime system.

> **Note:** The item list for a field implementing autocompletion is not permanent: The program must re-define the autocompletion item list with `setCompleterItems()`, on every `ON CHANGE` event.

Example

The example below implements form field with autocompletion: Each time the `ON CHANGE` trigger is fired, the set of proposals is adapted to the current field value, to match names that start with the same characters typed by the user.

Form file (`compl.per`):

```
LAYOUT
GRID
{
[f1                             ]
[f2                             ]
}
END
END
ATTRIBUTES
EDIT f1 = FORMONLY.field1, COMPLETER;
EDIT f2 = FORMONLY.field2;
END
```

Program file (`compl.4gl`):

```
DEFINE all_names DYNAMIC ARRAY OF STRING

MAIN
  DEFINE rec RECORD
              field1 STRING,
              field2 STRING
         END RECORD
  CALL fill_names()
  OPEN FORM f FROM "compl"
  DISPLAY FORM f
  OPTIONS INPUT WRAP
  INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
      ON CHANGE field1
         CALL fill_proposals(DIALOG, rec.field1)
  END INPUT
END MAIN

FUNCTION fill_names()
  DEFINE i INTEGER
  LET i=0
  LET all_names[i:=i+1] = "Amanda"
  LET all_names[i:=i+1] = "Ann"
  LET all_names[i:=i+1] = "Anna"
  LET all_names[i:=i+1] = "Annabelle"
  LET all_names[i:=i+1] = "Barbara"
  LET all_names[i:=i+1] = "Barry"
  LET all_names[i:=i+1] = "Brice"
END FUNCTION

FUNCTION fill_proposals(dlg, curr_val)
  DEFINE dlg ui.Dialog, curr_val STRING
  DEFINE curr_set DYNAMIC ARRAY OF STRING,
         i, x INTEGER
  LET x=0
  FOR i=1 TO all_names.getLength()
      IF upshift(all_names[i]) MATCHES upshift(curr_val)||"*"
 THEN
         LET curr_set[x:=x+1] = all_names[i]
      END IF
  END FOR
```

```
  CALL dlg.setCompleterItems(curr_set)
END FUNCTION
```

Dialog actions

Describes how to program action handling when the end user triggers an action on the front-end.

Action handling basics

This topic describes the basics of action views, action events and action handlers.

In the user interface of the application, *action views* can produce *action events*, that will execute user code in the corresponding *action handler* defined in the current interactive instruction of the program.

Actions views are for example `BUTTON` form items.

Action handlers are `ON ACTION` or `COMMAND` dialog blocks that execute user code, in the current interactive dialog.

Action views are bound to action handlers by name.

If no action view is explicitly defined in the current form, the front end will create a "*default action view*" for the action. This is typically a button that appears in a specific area, located and decorated according to the front end platform standards.

Actions can be configured with *action attributes*. These can be defined explicitly at the action view level (button in form), as dialog-specific action configuration (`ON ACTION` *name* `ATTRIBUTES(...)`), or with *action defaults*.

Special actions are supported, such as the `interrupt` action to the user cancel a running application procedure.

Defining action views in forms

How to define action views that will fire action events.

Actions views are form items that can be activated to fire an action event. The action event triggers user code in an `ON ACTION` block.

We distinguish action views defined explicitly in form files from default action views. A default action view will automatically appear when an action handler is implemented in the current dialog (if no explicit action view with the same name exists in the form). Default action view creation can be controlled with the `DEFAULTVIEW` action attribute.

To fire user code, action views are bound to action handlers by name.

Action view decoration attributes (`IMAGE` for icons, `TEXT` for label, `COMMENT` for hint) can be centralized in action defaults.

Action views can be items of form elements dedicated to action execution, such as `TOOLBAR` items (i.e. toolbar buttons) or `TOPMENU` options:

```
TOOLBAR
   ITEM accept
   ITEM cancel
   ...
END
```

Action views can be typical `BUTTON` items defined in the form `LAYOUT`:

```
LAYOUT
GRID
{
   [b1     ]
   ...
```

```
}
...
ATTRIBUTES
BUTTON b1 : print, IMAGE="printer";
...
```

Action views can be sub-elements of other elements, as when defining a `BUTTONEDIT` with an `ACTION` attribute:

```
LAYOUT
GRID
{
   [f1             ]
   ...
}
...
ATTRIBUTES
BUTTONEDIT f1 = customer.cust_city, ACTION=choose_city, IMAGE="zoom";
...
```

Action views can also be simple `IMAGE` items, when the `ACTION` attribute is specified:

```
LAYOUT
GRID
{
   [i1             ]
   ...
}
...
ATTRIBUTES
IMAGE i1: image1, ACTION=show_details, IMAGE="mylogo";
...
```

Note that `IMAGE` fields can be defined as `TABLE` columns and define the `ACTION` attribute to trigger user code:

```
LAYOUT
GRID
{
<TABLE t1          >
[c1  |c2       |c3 ]
[c1  |c2       |c3 ]
[c1  |c2       |c3 ]
...
}
...
ATTRIBUTES
...
IMAGE c3: FORMONLY.image, ACTION=delete;
...
```

For more details about image column actions see Defining actions on list columns with images on page 1355.

The row selection in a `TABLE` (or `TREE`) will be considered an action view when defining the `DOUBLECLICK` attribute:

```
DISPLAY ARRAY arr TO sr.*
        ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select)
  ...
END DISPLAY
```

Action views can also be graphical elements that are standard action triggers on the front-end platform, such as the [x] cross button of desktop windows, that will automatically bind to a "close" action, or the FAB button of Android, which can be configured to trigger a specific action.

Implementing dialog action handlers
How to execute user code in ON ACTION blocks when an action is fired.

Actions handlers are typically defined in dialog instructions with the `ON ACTION` interaction block. You must specify the name of the action after the `ON ACTION` keywords:

```
INPUT BY NAME ...
   ...
   ON ACTION print
      -- user code
   ...
```

Action handlers can also be defined with the `COMMAND` syntax in `MENU` and `DIALOG` instructions:

```
MENU ...
   ...
   COMMAND "Print" "Print the current record"
      -- user code
   ...
```

`ON ACTION` blocks provide better abstraction than `COMMAND` blocks by using simple action identifiers and leaving the decoration in the form files or action defaults files. The `ON ACTION` block defines an action handler with a simple action name. The `COMMAND` block defines an action handler with an action name, but it also defines decoration attributes, such as the label and comment. Keyboard accelerators and help topic numbers can also be defined.

> **Note:** Action views controlled by `ON ACTION` handlers cannot get the focus. When using the `COMMAND` action handler, action views such as a `BUTTON` defined in the form layout can get the focus and are part of the tabbing item list.

Action handlers are bound to action views by name.

Binding action views to action handlers
How are action views of the forms bound to action handlers in the program code?

Action views (such as buttons) are bound to action handlers by the `name` attribute. Action handlers are defined in interactive instructions with an `ON ACTION` clause or `COMMAND` / `ON KEY` clauses.

For example, in the `ATTRIBUTES` section of the form, a button may be defined as follows:

```
BUTTON b1: show_help, TEXT="Show Help";
```

The corresponding action handler (code) in the program will use the "`show_help`" action name:

```
ON ACTION show_help
   CALL ShowHelp()
```

The `COMMAND` / `ON KEY` clauses are typically used to write text mode programs. Such clauses define the name of the action and the decoration label. It is recommended that you use `ON ACTION` clauses instead, because they identify user actions with an abstract name. However, if required, you can use a `COMMAND` clause in a non-menu dialog to include the corresponding action view in the focus-able form items.

In the `ON ACTION` *`action-name`* clause, the name of the action must be a valid identifier, preferably written in lowercase letters. In the abstract user interface tree (where the action views are defined), action names are case-sensitive (as they are standard DOM attribute values). However, identifiers are not case-

sensitive in the language. The fglcomp compiler always converts the action identifiers of `ON ACTION` clauses to lowercase:

```
ON ACTION PrintRecord   -- will be compiled as "printrecord"
```

To avoid confusion, always use lower-case names for action names (for example, `print_record` instead of `PrintRecord`).

Default action views
A default action view is created to render an action handler when no explicit action view exists for it.

If no explicit action view is defined, such as a toolbar button, a topmenu item or a simple button in the form layout, the front end creates a *default action view* for each `COMMAND` or `ON ACTION` action handler, or implicit action such as insert/delete in `INPUT ARRAY`, in the current interactive instruction.

The rendering of default action views depends from the platform. On a desktop front-end, the default action views appear as buttons in the action frame in the right-hand side of the current window. On a mobile device, the default action views will follow the mobile user interface standards, which can be vendor specific. For more details about default action views on mobile, see Rendering default action views on mobile on page 1279.

When creating action handlers with `ON KEY` (or `COMMAND KEY` without a command name in a `MENU`), the default action view is invisible. If you define a `text` attribute in the action defaults, the default action view is made visible.

Control the default action view visibility by using the `DEFAULTVIEW` action attribute.

If one or more action views are defined explicitly for a given action, the front end considers that the default view is not needed. Typically, if you define in the form a `BUTTONEDIT` field, a `BUTTON`, or a `TOOLBAR` item that triggers the action, you do not need an additional button in the action frame.

The presentation of the default action views can be controlled with presentations style attributes for the `Window` AUI tree nodes.

Rendering default action views on mobile
Default action views are rendered according to the mobile specific standards.

Default action view rendering on mobile

The top and/or bottom part of the app screen is dedicated to displaying default action views to the user.

Key functions of these areas:

- Make important actions prominent and accessible in a predictable way (such as **New** or **Search**).
- Support consistent navigation and view switching within apps.
- Reduce clutter by providing an action overflow for less-used actions.
- Provide a dedicated space for giving your app an identity with text and/or an image.

How actions are rendered on the mobile device depends on:

- the order of the `ON ACTION` statements in the current dialog of the running app.
- The type of platform (Android™/iOS).
- The type (phone/tablet) and orientation of the device.

Actions are mapped to the Android or iOS platform in a specific way, following the platform standard.

Actions can be programmatically enabled and disabled, and hidden and shown. The text, image and other properties of the action can be controlled with action attributes.

GUI elements to trigger actions on mobile devices

Each mobile platform provides its own standard to display action triggers.

GMA and GMI follow respectively the Android and iOS standards:

- Navigation controller on iOS devices on page 1280
- Action bar on Android devices on page 1285
- Floating action button on Android devices on page 1286

Decorating action views on mobile

Actions are typically decorated using the `IMAGE` or the `TEXT` action attribute. If these attributes are not defined or if the specified image resource is not available, the mobile front-end uses a default decoration. For some actions, the front-end always uses the platform-specific decoration. For example, on iOS devices, the "refresh" action always renders as a typical circular arrow icon.

Well-known actions use a default icon or text corresponding to the mobile platform GUI guidelines. As these follow the mobile OS standards, do not define your own text or icons for common actions such as "accept" or "cancel".

For a complete list of predefined action decorations, see:

- Default action views decoration on iOS devices on page 1284
- Default action views decoration on Android devices on page 1288

Rendering close/cancel/accept actions on Android devices

The physical back button on an Android device is considered a default action view for the "close", "cancel", or "accept" action in the current dialog:

- If a close action is defined, it is assigned to the back button.
- If the close action is not defined, but the cancel action is defined, it is assigned to the back button.
- If neither close nor cancel actions are defined, but the accept action is defined, it is assigned to the back button.

If accept or cancel cannot be assigned to the back button, a default action view appears in the action panel. For example, if all three actions (close, cancel and accept) exist and are active, the action panel shows a check mark for the accept action and a cross icon for the cancel action, while the back button fires the close action.

Navigation controller on iOS devices
On iOS devices, apps display a **navigation controller** on the top of the screen.

The iOS **navigation controller** is made of a **navigation bar** on the left side and a **common action pane** on the right side.

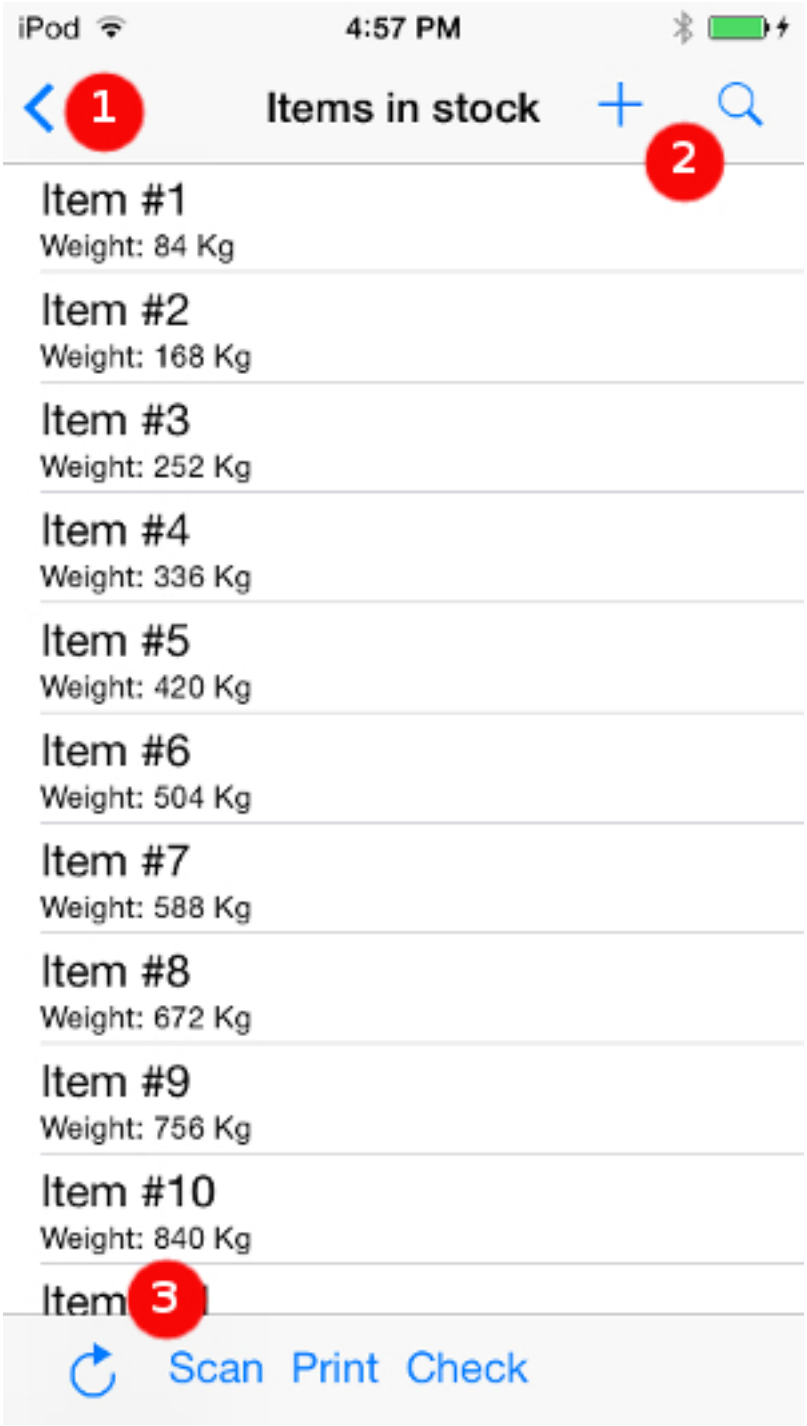

Figure 78: iOS app interface

Navigation bar (1)

The left side navigation bar provides a linear path through various screens. The `accept`, `cancel` or `close` action is rendered as back button, respectively in the order of precedence given here. If there is a previous form or window, then this button shows the title of the previous page. If there is not a form to return to, the "back" navigation button is shown.

Common action pane (2)	The right-hand side is the common action pane. Default action views are displayed here, in the order of the current dialog's `ON ACTION` statements of the current dialog.
Toolbar pane (3)	When default action views are displayed, if there is not enough room in the common action pane (2), the remaining actions are displayed in the toolbar pane at the bottom of the screen. If there is not enough space to display all action views in the toolbar pane, an overflow icon appears on the right. Tap on the overflow icon to show the remaining action views. Use a TOOLBAR in your form, to have full control on the toolbar pane. An action displayed as a TOOLBAR item in the toolbar pane will no longer display as default action view in the common action pane (2).

In this screen shot, the device is oriented in landscape mode. The app is the same, yet since there is enough space in the navigation bar, all default action views display in the common action pane.

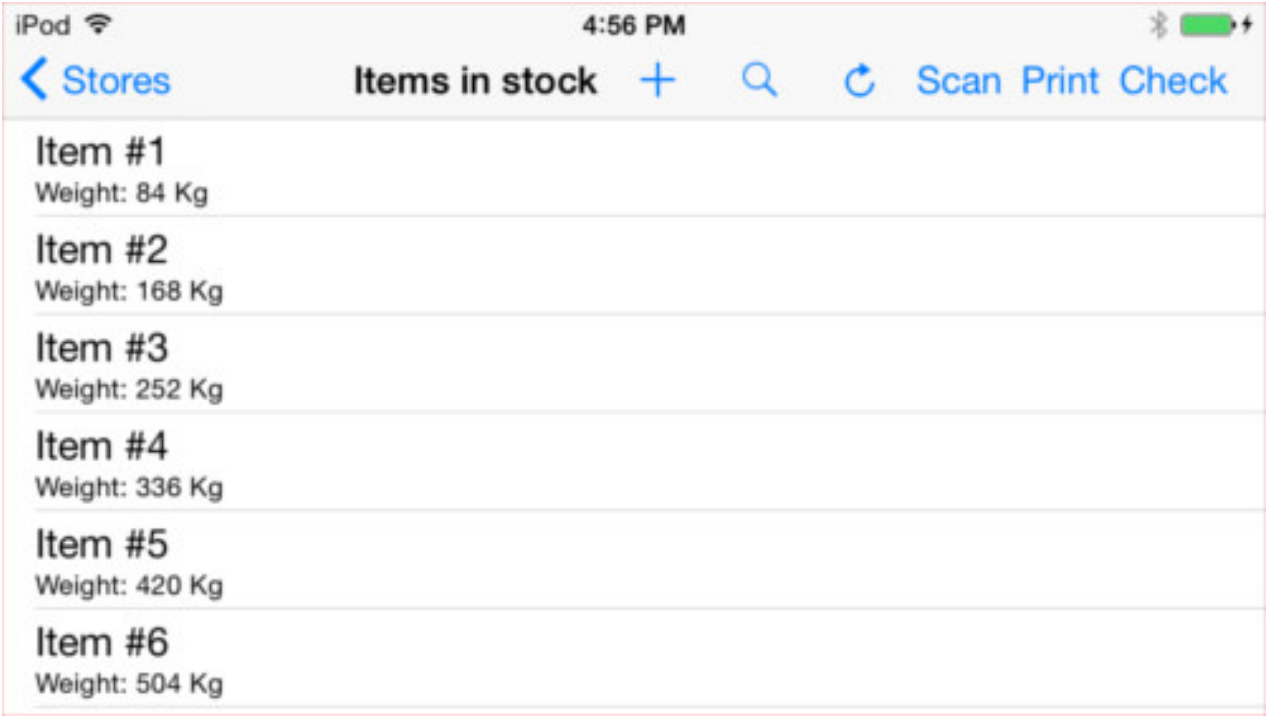

Figure 79: iOS app interface in landscape mode

To customize the application, define the colors of the iOS navigation bar and toolbar with the following Window-class style attributes:

- `iosTintColor`, for items in (1), (2) and (3) (and for other form items)
- `iosNavigationBarTintColor`, for (1) and (2).
- `iosToolBarTintColor`, for (3).

For example, by setting the following style attributes, the navigation bar will render as shown in the screen shot:

```
<Style name="Window">
```

```
  <StyleAttribute name="iosTintColor"                value="darkRed" />
  <StyleAttribute name="iosNavigationBarTintColor" value="orange"  />
  <StyleAttribute name="iosToolBarTintColor"        value="orange"  />
  <StyleAttribute name="iosTabBarTintColor"         value="orange"  />
</Style>
```

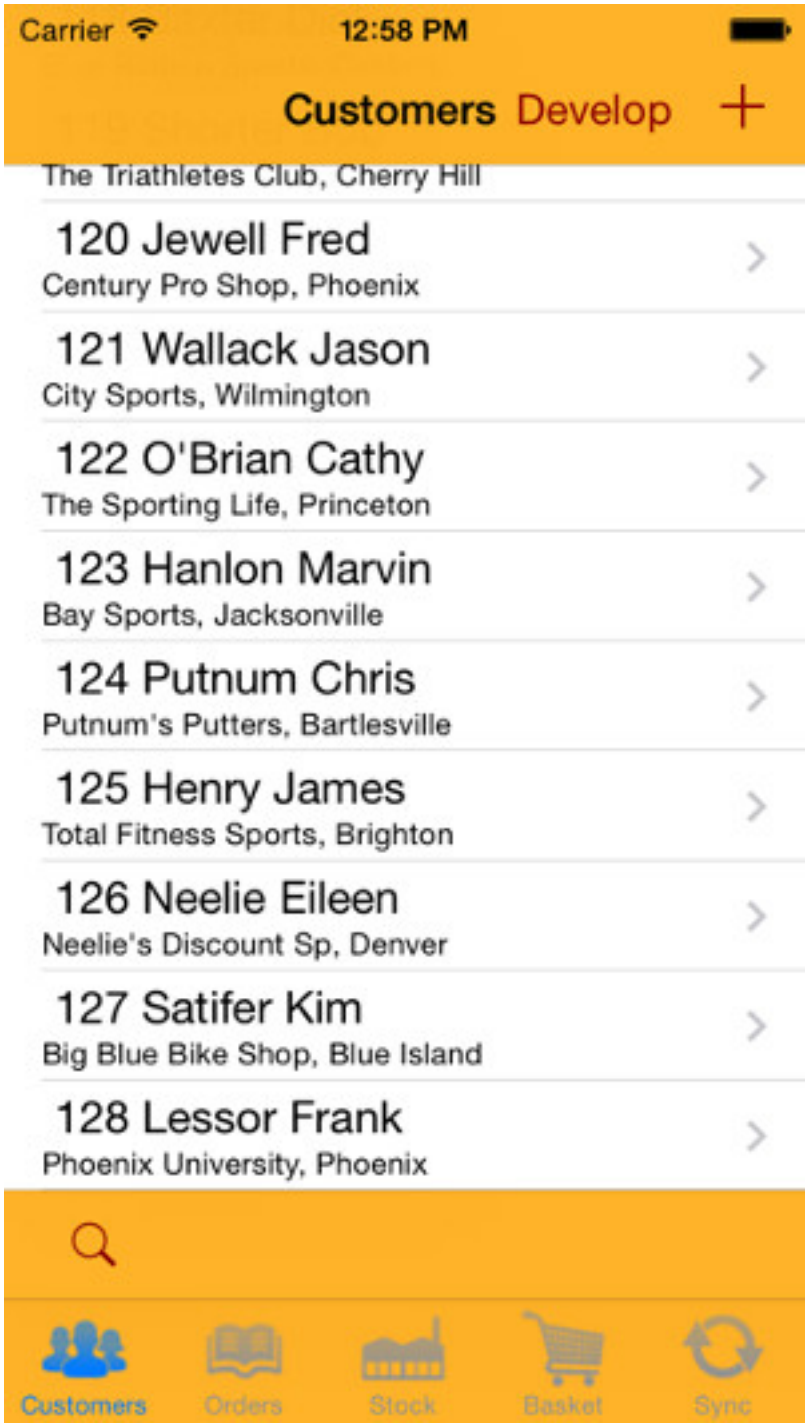

Figure 80: iOS (7) colored navigation bar

Default action views decoration on iOS devices
Common default action views get a decoration implicitly, following iOS standards.

On iOS devices, the decoration for well known actions can be a symbol or a text. When a text is used, it is internationalized. For example, the "accept" action translates to "Done" when the mobile language is English, "Fertig" in German and "OK" in French.

For the default action views of the common actions, the decoration will always follow the iOS standards, even if an attribute is explicitly specified for the action. For example, if you implement an `ON ACTION save` action handler with `ATTRIBUTES(TEXT="Write",IMAGE="disk")`, the action view renders with the "Save" text on an iOS device configured for the English language.

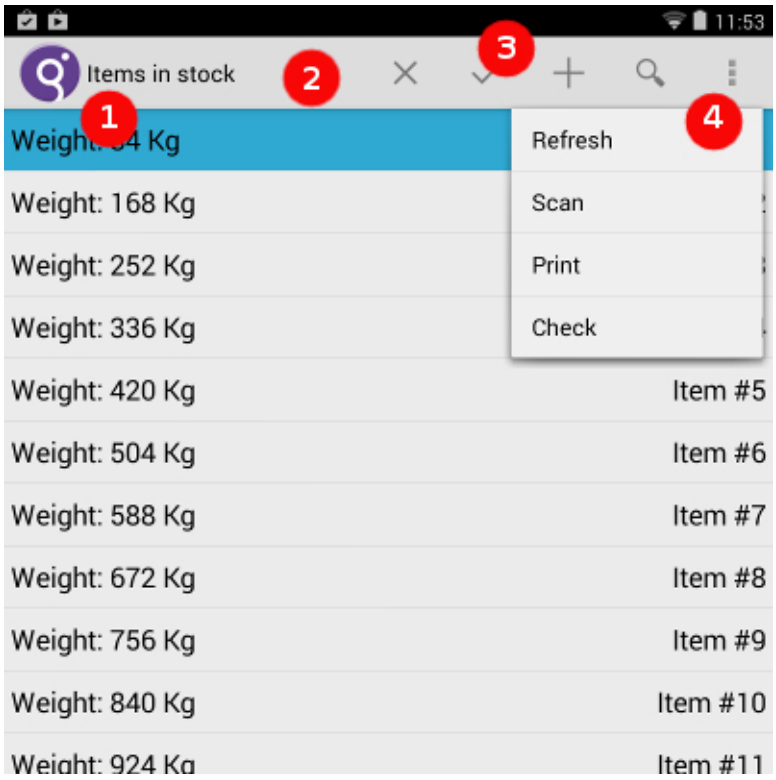
Table 283: Default rendering for common actions on iOS

Action name	iOS default rendering	Symbol
`accept`	Internationalized text (English: Done)	N/A
`cancel`	Internationalized text (English: Cancel)	N/A
`refresh`	Typical circular symbol	
`insert`	Typical plus sign symbol	
`append`	Typical plus sign symbol	
`delete`	Typical trash symbol	
`find`	Typical magnifier symbol	

Action name	iOS default rendering	Symbol
		
`search`	Typical magnifier symbol	
`edit`	Internationalized text (English: Edit)	N/A
`save`	Internationalized text (English: Save)	N/A

Action bar on Android™ devices
On Android devices, apps show an **action bar**.

The Android **action bar** displays in the top of the screen, with several elements having a specific purpose:



The app icon (1)

The app icon and the title of the current form display in the upper left corner.

The application title is defined by the TEXT attribute of the main window displayed by the application.

The icon that appears is either the icon set for the app in the packaging, or it is the image specified by the `ui.Interface.setImage` method. The application icons must be included in the deployment package (.apk) and follow the Android standards (several icon sizes are required).

The view control (2)

If your app implements different views controlled by a top-level navigator, this segment allows users to switch between views. For more details, see Navigator pane on page 1399. In an application handling multiple views in parallel, the view control item displays as a text button.

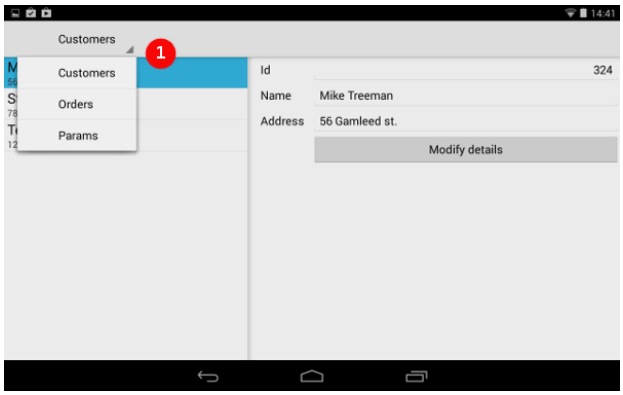


Figure 81: Android View Control

Action buttons (3) and Action overflow (4)

The right-hand side of the action bar shows the actions. The action buttons (3) show the most important actions of your app. Actions that do not fit in the action bar are moved to the action overflow, and an overflow icon appears on the right. Tap on the overflow icon to display the list of remaining action views. If the device has a physical Menu button, the overflow actions are accessible by pressing the physical Menu button and not from an action overflow icon.

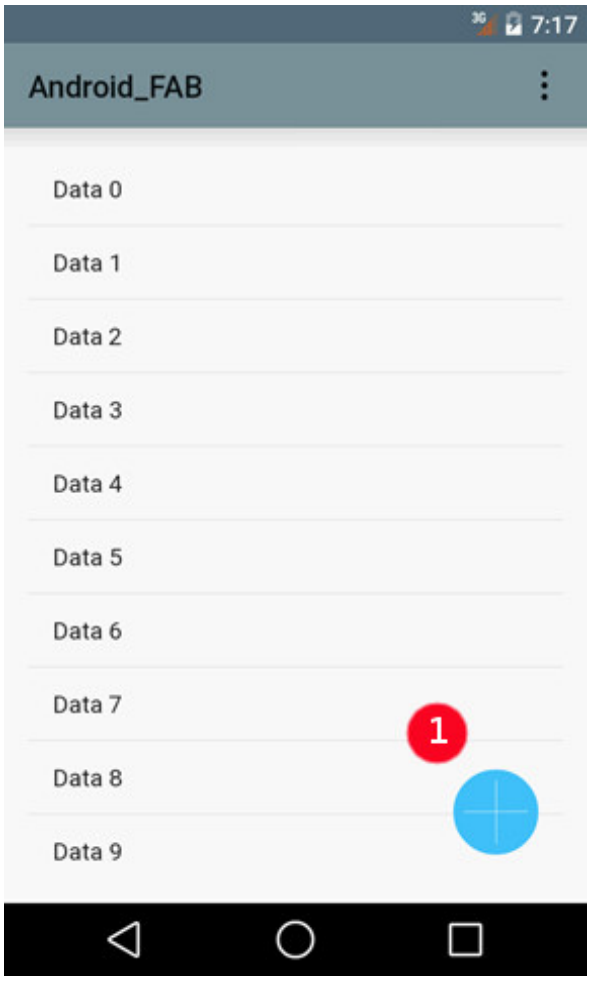
Actions display in the order of the `ON ACTION` statements of the current dialog. If a toolbar is defined, the actions defined in the toolbar take priority and list prior to other actions, in the order they are defined in the toolbar.

If an image is available, it is displayed, otherwise the action text is shown. Depending on the space available (space used by the app icon, screen size, orientation, and so on), the number of actions and the device type, Android displays either the icon or the icon and the text of the action.

Floating action button on Android™ devices

On Android devices, apps using material design show a **Floating Action Button (FAB)**.

The Android **floating action button** displays on the bottom right of the screen, and can be tapped to fire a specific action:



The floating action button (1)

The material design guidelines include the concept of promoted actions, that can be triggered with the floating action button.

Define the list of actions that can be fired from the FAB button with FAB configuration style attributes:

```
<Style name="Window">
    <StyleAttribute
 "materialFABActionList="accept,select,detail"
</Style>
```

The order of the actions define which action is triggered when the FAB button is tapped, and several matching actions are active. With the above example, if the "accept" action is disabled, and the "select" and "detail" actions are active, a tap on the FAB button fires the "select" action.

The icon of the FAB button is defined by the `IMAGE` attribute of the corresponding action. If no `IMAGE` attribute is defined for the action, a default icon is selected from the built-in icons, according to the name of the action. See Default action views decoration on Android devices on page 1288 for

more details about action names to default Android built-in icon mapping.

Default action views decoration on Android™ devices
Common default action views get a decoration implicitly, following Android standards.

On Android devices, when the `IMAGE` and the `TEXT` action attributes are not defined for an action, the default action view gets an implicit decoration.

The default icon is selected according to the name of the action: The symbol is picked from a built-in images (i.e. Android material design icons), if it has the same name as the action. If no icon corresponds, the default action view will get no icon.

The text defaults to the name of the action, converted to uppercase. The text displays only if the Android system considers that the screen is large enough to display the texts. Typically, texts are shown on tablets, but not on smartphones with small/medium screens.

For example, when implementing a `ON ACTION refresh` handler, GMA will implicitly use the default icon with the name "refresh" (the typical circular refresh symbol), and, if there is enough room, display the text "REFRESH" on the right of the icon.

Position and rendering of default action views can be controlled with Android specific style attributes. For more details, see Default action view style attributes on page 825.

Not also that some actions can be rendering as the Floating Action Button of material design, as described in Floating action button on Android devices on page 1286.

Default actions views displayed in the top control bar and in the overflow button will get a text but no icons, while the FAB material design button will get an icon but no text.

The next table shows the default icons that will be selected for common Genero BDL action names.

> **Note:** This table does not list all possible built-in icons: More images are available from the Android material design icon library, and the GMA will select the icon according to the action name. For example, an action with the name "audio" will get the Android music symbol icon:

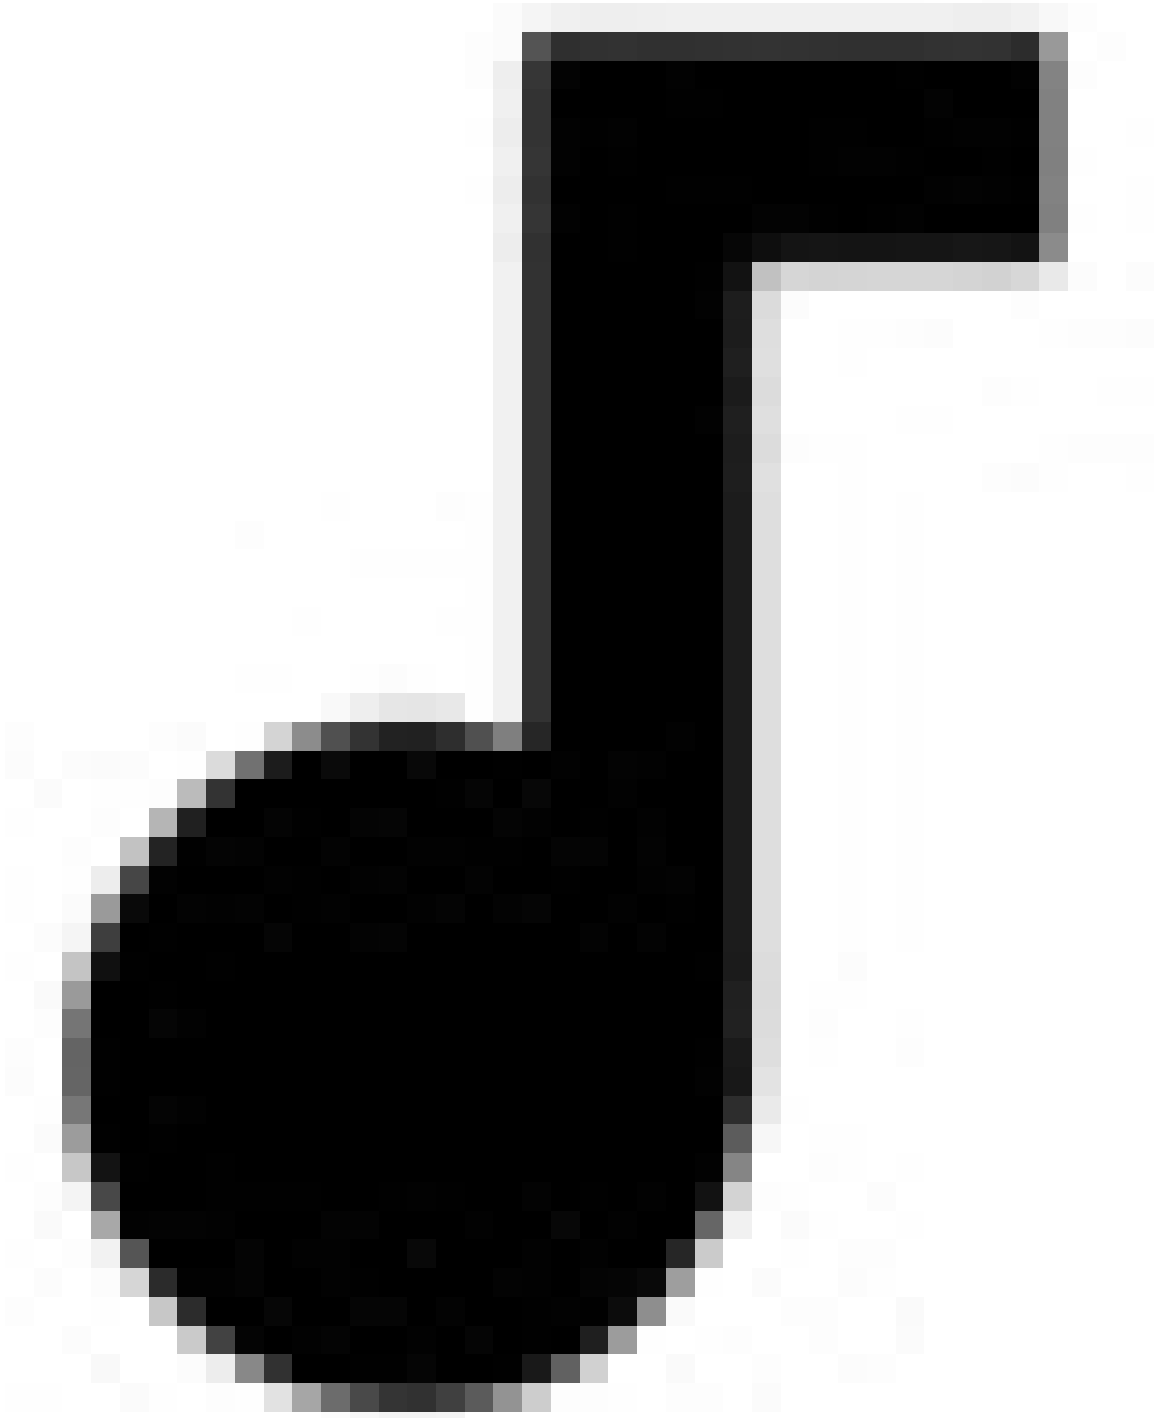


Table 284: Default icons for common actions on Android

Action name	Icon
`about`	
`accept`	
`append`	

Action name	Icon
	`attention`	

Action name	Icon
	
`bell`	`calendar`	

Action name	Icon
	`camera`	
`cancel`	

Action name	Icon
	copy	

Action name	Icon
	`cut`	
`delete`	

Action name	Icon
	`diropen`	

Action name	Icon
	edit	
editcopy	

Action name	Icon
	editcut	
editpaste	

Action name	Icon
	exit	
file	

Action name	Icon
	`filenew`	

Action name	Icon
	`filter`	

Action name	Icon
	`find`	
`findnext`	

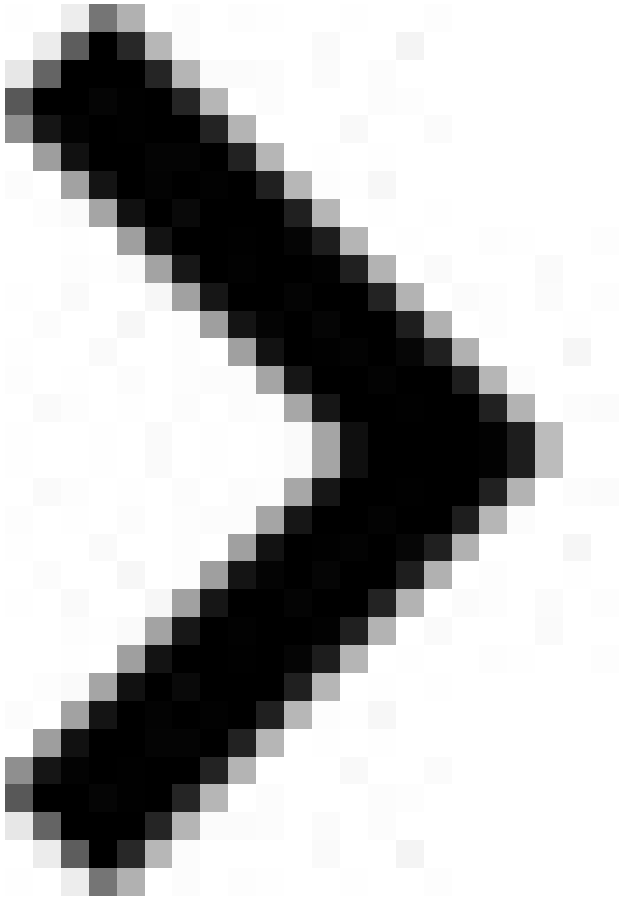
Action name	Icon
	`first`	

Action name	Icon
`firstrow`	

Action name	Icon
forwind	

Action name	Icon
	help	
hint	

Action name	Icon
	`insert`	

Action name	Icon
	


Action name	Icon

Action name	Icon
previous	prevrow	

Action name	Icon
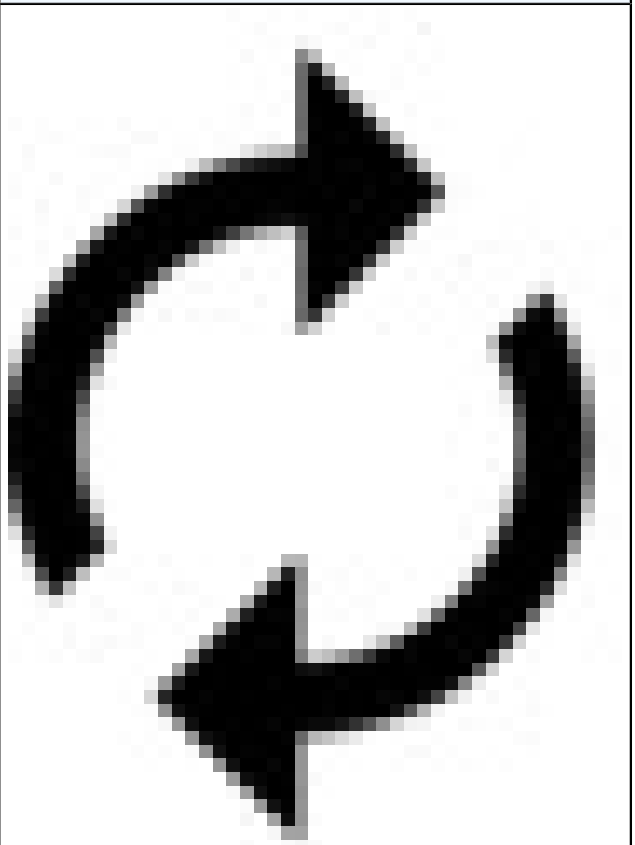
	`query`	
`rewind`	

Action name	Icon
	`update`	

Action name	Icon
	


Configuring actions
Action attributes related to decoration, keyboard shortcuts and behavior can be defined with *action attributes*.

Action attributes define attributes for actions, including decoration such as text, icon, comment, as well as keyboard accelerator (ctrl-?, function keys), and also semantics such as current field validation control when an action is fired.

The action attributes can be defined at different levels, through action defaults, form item attributes and action handler attributes:

1. Common action attributes can be centralized in a global action defaults file with the `.4ad` extension,
2. Form-specific action attributes can be defined in the `ACTION DEFAULTS` section of a form definition file,
3. Dialog-specific action attributes can be defined in programs with the `ATTRIBUTES()` clause of `ON ACTION` handlers.
4. Form-item specific action view attributes (decoration only) can be defined directly at the item level (labels, icons, comments).

Action attributes do not only define action view decoration: It is possible to define the semantics of an action, for example by using the `VALIDATE` action default attribute. Functional attributes take effect for a given action when the dialog implementing the action handler becomes active.

Action attributes are particularly important to render the default action view (when there is no explicit action view defined in the form). This is typically the case when not form is associated to the dialog.

Action attributes can be defined with action defaults: Common action defaults are defined in a global action defaults (`.4ad`) file, while form specific actions are define withing the `ACTION DEFAULTS` section of form files.

If a dialog is not attached to a specific form such as an independent `MENU`, define the action attributes with the `ATTRIBUTES` clause on `ON ACTION` handlers, to render the default view and configure the action semantics. Attributes defined by `ON ACTION` *`action-name`* `ATTRIBUTES()` will only be applied to the default action view: The elements in the forms do not get decoration attributes defined by dialog action handlers.

The final decoration and functional attribute values are set in this order of precedence:

1. The attribute defined in the action view element definition itself (local form element decoration).
2. The attribute defined in the `ATTRIBUTES` clause of an `ON ACTION` handler.
3. The attribute defined for the action in the `ACTION DEFAULTS` section of the current form.
4. The attribute defined for the action in the global action defaults file (`.4ad`).

Note that the syntax to define action attributes depends on the context where the action attributes are defined:

- In the `.4ad` file, the syntax follows XML standards, as defined in Action default attributes reference (.4ad) on page 797.
- In the `.per` files, the syntax follows the form specification file attributes, as defined in ACTION DEFAULTS section on page 903.
- In the `.4gl` files (in dialog action handlers), the syntax follows the language syntax, as defined in ON ACTION block on page 1056.

Example

Consider the following parts of code related to the same action definition, namely "print":

1. A `BUTTON` item defined in the form specification file:

```
ATTRIBUTES
 BUTTON b1: print, TEXT="Print item";
END
```

2. A dialog instruction with code defining the `ON ACTION` handler with an `ATTRIBUTES` clause:

```
DIALOG ...
   ...
   ON ACTION print
      ATTRIBUTES( ROWBOUND, IMAGE = "printer_2" )
      ...
```

3. The form `ACTION DEFAULTS` section defining:

```
form.per:
ACTION DEFAULTS
  ACTION print (IMAGE="printer_1",
                COMMENT="Print the order",
                ACCELERATORNAME=Control-P,
                CONTEXTMENU=NO)
END
```

4. A global .4ad action defaults file defining:

```
<ActionDefaultList>
  <ActionDefault name="print" text="Print" image="smiley" />
</ActionDefaultList>
```

When the dialog executes, the "print" action will get the following functional attributes:

- `acceleratorName = "control-p"` - from the form `ACTION DEFAULTS` section
- `rowBound = "yes"` - from the dialog `ON ACTION` handler
- `contextMenu = "no"` - from the form `ACTION DEFAULTS` section

The form button (i.e. the action view) will get the following decoration attribute values:

- `text = "Print item"` - from the `BUTTON` form item
- `image = "printer_2"` - from the dialog `ON ACTION` handler
- `comment = "Print the order"` - from the form `ACTION DEFAULTS` section

Action attributes context usage

Action attributes are used to configure functional and decoration properties of actions. The table below lists the possible action atttributes and indicates in what context they can be defined.

Table 285: Action attributes definitions

Attribute	Context			
	Form action view	**Dialog action handler**	**Form action defaults section**	**Global action defaults file (.4ad)**
`ACCELERATOR` See ACCELERATOR action attribute on page 1323.	No	Yes	Yes	Yes
`ACCELERATOR2` See ACCELERATOR2 action attribute on page 1324.	No	No	Yes	Yes
`ACCELERATOR3` See ACCELERATOR3 action attribute on page 1325.	No	No	Yes	Yes
`ACCELERATOR4` See ACCELERATOR4 action attribute on page 1325.	No	No	Yes	Yes
`COMMENT` See COMMENT action attribute on page 1325.	Yes	Yes	Yes	Yes
`CONTEXTMENU` See CONTEXTMENU action attribute on page 1326.	No	Yes	Yes	Yes
`DEFAULTVIEW` See DEFAULTVIEW action attribute on page 1327.	No	Yes	Yes	Yes
`DISCLOSUREINDICATOR`	No	Yes (only for `MENU`)	No	No

Attribute	Context			
	Form action view	**Dialog action handler**	**Form action defaults section**	**Global action defaults file (.4ad)**
See DISCLOSUREINDICATOR action attribute on page 1328.				
`IMAGE` See IMAGE action attribute on page 1328.	Yes	Yes	Yes	Yes
`ROWBOUND` See ROWBOUND action attribute on page 1329.	No	Yes (only for list dialogs)	No	No
`TEXT` See TEXT action attribute on page 1330.	Yes	Yes	Yes	Yes
`VALIDATE` See VALIDATE action attribute on page 1331.	No	Yes (only for input dialogs)	Yes	Yes

Using attributes of action defaults

Purpose of action defaults

Action defaults allow to define default attributes for common action. These defaults can be overwritten with form item attributes, or with dialog action handler attributes (only for default action views).

Centralize action attributes with action defaults, to avoid specifying them in all the source files that define the same action view and action handler. For example, you can specify the default text, image and keyboard accelerator for elements like push buttons, toolbar items, topmenu options.

Common action defaults are typically defined in a global action defaults (`.4ad`) file, while form specific actions are configured with form action defaults in the `ACTION DEFAULTS` section of the `.per` form specification file.

Global action defaults file

Global action defaults are defined in an XML file with the `4ad` extension. By default, the runtime system searches for a file named `default.4ad` in the current directory. If the file does not exist, it searches in the directories defined by the FGLRESOURCEPATH (or DBPATH) environment variable. If no file was found using the environment variable(s), standard action default settings are loaded from the `FGLDIR/lib/default.4ad` file.

> **Important: Global action defaults must be defined in a unique file; you cannot combine several 4ad files.**

If needed, override the default search by loading a specific global action defaults file with the `ui.Interface.loadActionDefaults()` method.

It is possible to use localized strings in action default attributes such as `TEXT` and `COMMENT`, by using `LStr` XML elements:

```
<ActionDefaultList>
```

```
  <ActionDefault name="yes" text="Yes">
     <LStr text="common.yes"/>
  </ActionDefault>
  ...
```

Form specific action defaults

Action defaults can be defined at the form level in the `ACTION DEFAULTS` section. When action defaults are defined in the form file, action views get the attributes defined locally for this form:

```
ACTION DEFAULTS
  ACTION print (TEXT="Print",
                IMAGE="printer",
                COMMENT="Print the current record",
                ACCELERATOR=CONTROL-P)
END
```

Form action defaults can also be defined in a `.4ad` file to be loaded dynamically with the `ui.Form.loadActionDefaults()` method. This method is typically used in form initializers to decorate several application forms without defining an `ACTION DEFAULTS` section in each `.per` file.

It is possible to use localized strings in action default attributes such as `TEXT` and `COMMENT`:

```
ACTION print (TEXT=%"common.print")
```

Action defaults are applied only once

Decoration attributes (like `TEXT`, `IMAGE`) of an action view will automatically be set with the value defined in the action defaults to all new action views of a new created form, if there is no explicitly value specified in the element definition for that attribute. Decoration action default attributes are applied only once, to newly created form elements: Dynamic changes are not reapplied to action views. For example, if you first load a toolbar, then you load a global action defaults file, the attributes of the toolbar items will not be updated with the last loaded action defaults. If you dynamically create action views (like `TopMenu` or `ToolBar`), the action defaults are not applied, so you must set all decoration attributes by hand.

Action defaults and sub-dialog actions

The action default attributes to be applied are selected according to name of the action. In some situations, the action view can be bound to an action handler by specifying a sub-dialog and/or field name prefix. For those views, the action defaults defined with the corresponding action name will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an action view is defined with the name `custlist.append`, it will get the action defaults defined for the `append` action.

Functional attributes

Functional attributes (like `VALIDATE`, `ACCELERATOR`) can only be defined in action defaults, or in `ON ACTION` dialog action handlers with the `ATTRIBUTES` clause. Functional attributes take effect for a given action when the dialog becomes active.

Dialog action handler attributes

Action attributes can be specified at the dialog instruction level for default action views. These action attributes will overwrite the attributes defined in action defaults.

To define dialog-level action attributes for an action, add the `ATTRIBUTES()` clause to `ON ACTION`, with a comma-separated list of action default attributes:

```
ON ACTION print
   ATTRIBUTES (TEXT = "Print",
               COMMENT = "Print the current record",
```

```
                IMAGE = "printer",
                VALIDATE = NO)
```

It is possible to use localized strings in action attributes such as TEXT and COMMENT:

```
ON ACTION print
   ATTRIBUTES (TEXT = %"common.print.label",
               COMMENT = %"common.print.comment",
               ... )
```

Dialog-level action attributes are typically used when the dialog is not related to a specific form, for example with independent MENU dialogs.

If the current form defines explicit action views (buttons in layout, toolbar buttons, topmenu items) with the same name as the ON ACTION handler defining action attributes with the ATTRIBUTES( ) clause, the explicit action views will not get the action attributes defined by the ON ACTION.

Text attribute shows default action view

When creating actions with ON KEY (or COMMAND KEY without a command name in a MENU), the default action view (i.e. button in action frame) is invisible. However, if you define a text action attribute for the corresponding key action, the default action view is made visible.

You can also control the visibility of the default action view with the DEFAULTVIEW action attribute.

Note that it is also possible to set key labels with form attributes (KEY) or with function calls (FGL_SET_KEYLABEL( )), this feature is supported for backward compatibility. Use action default text attributes in new developments.

Defining keyboard accelerators

When using the ON ACTION clause in a dialog instruction, action defaults accelerators are applied in both GUI and TUI mode. For backward compatibility, this is not done in TUI mode when using the ON KEY clause.

The traditional ON KEY clause in a dialog like INPUT implicitly defines the acceleratorName attribute for the action, and the corresponding action default accelerator will be ignored. For example, when you define an ON KEY(F10) block, the first accelerator will be "F10", even if an action default defines an accelerator "F5" for the action "F10". However, you can set other accelerators with the acceleratorName2, acceleratorName3 and acceleratorName4 attributes in action defaults.

> **Important: In TUI mode, actions created with ON KEY do not get accelerators of action defaults; Only actions defined with ON ACTION will get accelerators of Action Defaults.**

In menus, the behavior is a bit different, see the COMMAND and COMMAND KEY clause in MENU.

If no accelerator is specified in action defaults for a predefined action, the runtime system sets one or more default accelerators according to the user interface mode. For example, the accept action will get the Return and Enter keys in GUI mode, but in TUI mode, the Escape key would be used.

If you want to force an action to have no accelerator, you can use none as the accelerator name.

Action attributes list
ACCELERATOR action attribute
The ACCELERATOR is an action attribute defining the primary accelerator key for an action.

Syntax

Syntax 1 (Dialog action handlers)

```
ACCELERATOR = "key"
```

Syntax 2 (`ACTION DEFAULTS` section in form files)

```
ACCELERATOR = key
```

Syntax 3 (Global .4ad action defaults file)

```
acceleratorName = "key"
```

1. *key* defines the accelerator key.

Usage

The `ACCELERATOR` attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

Note that in dialog-specific action attributes, the `ACCELERATOR` must be specified as a string expression.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global `.4ad` file, in the `ACTION DEFAULTS` section of form files, or as dialog action attribute.

Example

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(ACCELERATOR="control-p")

-- As action default
ACTION DEFAULTS
  ACTION print (ACCELERATOR=control-p)
END

-- In a global action defaults file
<ActionDefault name="print" acceleratorName="control-p" ... />
```

ACCELERATOR2 action attribute

The `ACCELERATOR2` is an action attribute defining the secondary accelerator key for an action.

Syntax

Syntax 1 (Dialog action handlers): N/A

Syntax 2 (`ACTION DEFAULTS` section in form files)

```
ACCELERATOR2 = key
```

Syntax 3 (Global .4ad action defaults file)

```
acceleratorName2 = "key"
```

1. *key* defines the accelerator key.

Usage

The `ACCELERATOR2` attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

> **Important:** This attribute is provided for specific cases, consider using only one accelerator per action.

ACCELERATOR3 action attribute
The ACCELERATOR3 is an action attribute defining the third accelerator key for an action.

Syntax

Syntax 1 (Dialog action handlers): N/A

Syntax 2 (ACTION DEFAULTS section in form files)

```
ACCELERATOR3 = key
```

Syntax 3 (Global .4ad action defaults file)

```
acceleratorName3 = "key"
```

1. *key* defines the accelerator key.

Usage

The ACCELERATOR3 attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

> **Important:** This attribute is provided for specific cases, consider using only one accelerator per action.

ACCELERATOR4 action attribute
The ACCELERATOR4 is an action attribute defining the fourth accelerator key for an action.

Syntax

Syntax 1 (Dialog action handlers): N/A

Syntax 2 (ACTION DEFAULTS section in form files)

```
ACCELERATOR4 = key
```

Syntax 3 (Global .4ad action defaults file)

```
acceleratorName4 = "key"
```

1. *key* defines the accelerator key.

Usage

The ACCELERATOR4 attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

> **Important:** This attribute is provided for specific cases, consider using only one accelerator per action.

COMMENT action attribute
The COMMENT attribute defines hint for the user about the action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
COMMENT = [%]"string"
```

Syntax 2 (Global .4ad action defaults file)

```
comment = "string"
(with optional LStr node for localized strings)
```

1. *string* is the text to display, with the % prefix it is a localized string.

Usage

Use the COMMENT attribute to define a description for the action. This text will typically be displayed as a hint for the corresponding action view.

Consider using localized strings with the %"*string-id*" syntax, if you plan to internationalize your application.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

Example

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(COMMENT="Prints current record")

-- As action default
ACTION DEFAULTS
  ACTION print (COMMENT="Print current order information")
END

-- In a form buttom, using a localized string id
BUTTON b1: print, COMMENT=%"actions.print.comment";

-- In a global action defaults file with a localized string id
<ActionDefault name="zoom" comment="Opens a zoom window" ... >
   <LStr comment="actions.zoom.comment" />
</ActionDefault>
```

CONTEXTMENU action attribute

The CONTEXTMENU attribute defines whether a context menu option must be displayed for an action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
CONTEXTMENU = [ AUTO | YES | NO ]
```

Syntax 2 (Global .4ad action defaults file)

```
contextMenu = [ "yes" | "no" | "auto" ]
```

Usage

CONTEXTMENU is an action attribute defining whether the context menu option must be displayed for an action.

1. NO indicates that no context menu option must be displayed for this action.
2. YES indicates that a context menu option must always be displayed for this action, if the action is visible.
3. AUTO means that the context menu option is displayed if no explicit action view is used for that action and the action is visible.

The default is YES.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

Example

```
-- As action handler attribute
ON ACTION zoom ATTRIBUTES(CONTEXTMENU=YES)

-- As action default
ACTION DEFAULTS
  ACTION zoom (CONTEXTMENU=YES)
END

-- In a global action defaults file
<ActionDefault name="zoom" contextMenu="yes" ... />
```

DEFAULTVIEW action attribute

The DEFAULTVIEW attribute defines if a default view (a button) must be displayed for a given action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
DEFAULTVIEW = [ AUTO | YES | NO ]
```

Syntax 2 (Global .4ad action defaults file)

```
defaultView = [ "yes" | "no" | "auto" ]
```

Usage

DEFAULTVIEW is an action attribute defining whether the default action view (a button) must be displayed for an action.

- NO indicates that no default action view must be displayed for this action.
- YES indicates that a default action view must always be displayed for this action, if the action is visible.
- AUTO means that a default action view is displayed if no explicit action view is used for that action and the action is visible.

The default is AUTO.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

Example

```
-- As action handler attribute
ON ACTION zoom ATTRIBUTES(DEFAULTVIEW=YES)

-- As action default
ACTION DEFAULTS
  ACTION zoom (DEFAULTVIEW=YES)
END

-- In a global action defaults file
```

```
<ActionDefault name="zoom" defaultView="yes" ... />
```

DISCLOSUREINDICATOR action attribute
The DISCLOSUREINDICATOR attribute a drill-down decoration to an action.

Syntax

(only in MENU action handlers)

```
DISCLOSUREINDICATOR
```

Usage

DISCLOSUREINDICATOR is an action attribute defining whether a disclosure indicator must be shown for the default view (a button) of an action.

> **Important:** This feature is only for mobile platforms.

A disclosure indicator gives a visual hint to the user, to show that the selection of the action will drill down in the application screens.

The DISCLOSUREINDICATOR attribute is typically used in a MENU instruction, for options that open a sub-menu.

The rendering of a disclosure indicator depends from the front-end platform standards. On iOS devices, buttons will show a typical > icon on the right.

This attribute can only be specified in a MENU dialog, as action attribute in the ATTRIBUTES( ) clause of ON ACTION handlers, and applies to the actions defined by the current dialog in the current window.

Note however, that form buttons can get a DISCLOSUREINDICATOR attribute, as an action view decoration.

Example

```
MENU ...
   ...
   ON ACTION details ATTRIBUTES(DISCLOSUREINDICATOR)
      CALL show_customer_details(cust_rec.cust_no)
   ...
```

IMAGE action attribute
The IMAGE attribute defines the image resource to be displayed for the action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
IMAGE = "resource"
```

Syntax 2 (Global .4ad action defaults file)

```
image = "resource"
```

1. *resource* defines the file name, path or URL to the image source.

Usage:

The IMAGE attribute is used to define the image resource for the action view such a BUTTON , BUTTONEDIT or a TOOLBAR button.

For more details about image resource specification, see Providing the image resource on page 784.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

Example

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(IMAGE="printer")

-- As action default
ACTION DEFAULTS
  ACTION print (IMAGE="printer")
END

-- In a form buttonedit or button
BUTTONEDIT f001 = FORMONLY.field01, IMAGE = "zoom";
BUTTON b01: open_file, IMAGE = "buttons/fileopen";
BUTTON b02: accept, IMAGE = "http://myserver/images/accept.png";
```

ROWBOUND action attribute

The ROWBOUND attribute defines if the action is related to the row context of a record list.

Syntax

(only in action handlers of record list dialog)

```
ROWBOUND
```

Usage

The ROWBOUND is typically used in a DISPLAY ARRAY or INPUT ARRAY dialog action handler, when the action depends from the row context. The actions marked with this attribute will be automatically enabled/disabled according the current row existence, and rendered in a special way according to the front-end platform standards.

Important: This feature is only for mobile platforms.

The ROWBOUND attribute was mainly introduced for mobile applications, when using a TABLE container to get a list view: Actions marked with this attribute will be rendered in a native manner on the mobile device.

If a default action view is displayed for the action, it will be automatically hidden when no current row context is available.

This attribute can only be specified in a list handling dialog, as action attribute in the ATTRIBUTES( ) clause of ON ACTION handlers, and applies to the actions defined by the current dialog in the current window.

Default actions such as the delete action when using an ON DELETE modification trigger will automatically get the ROWBOUND attribute, to be available only when at least one row exists in the list. Therefore, the ROWBOUND attribute cannot be specified for such DISPLAY ARRAY modification triggers.

Example

```
DISPLAY ARRAY ...
   ...
```

```
   ON ACTION print ATTRIBUTES(ROWBOUND)
      CALL print_customer_info(arr_curr())
   ...
```

TEXT action attribute
The TEXT attribute defines the label associated to the action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
TEXT = [%]"string"
```

Syntax 2 (Global .4ad action defaults file)

```
text = "string"
(with optional LStr node for localized strings)
```

1. *string* defines the label for the action, with the % prefix it is a localized string.

Usage

The TEXT attribute is used to define the label associated to an action, for example for a CHECKBOX form field or a BUTTON action view.

Consider using localized strings with the %"*string-id*" syntax, if you plan to internationalize your application.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

Example

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(TEXT="Print")

-- As form action default
ACTION DEFAULTS
  ACTION print (TEXT="Print")
END

-- As a CHECKBOX label
CHECKBOX cb01 = FORMONLY.checkbox01,
                TEXT="OK" ... ;

-- As a BUTTON label, using a localized string id
BUTTON b1: print, TEXT=%"actions.print.label";

-- In a global action defaults file with a localized string id
<ActionDefault name="zoom" text="Zoom" ... >
   <LStr text="actions.zoom.label" />
</ActionDefault>
```

VALIDATE action attribute
The VALIDATE action attribute defines the data validation level for a given action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
VALIDATE = NO
```

Syntax 2 (Global .4ad action defaults file)

```
validate = "no"
```

Usage

When the VALIDATE action attribute is set to NO, it indicates that no data validation must occur for this action. However, current input buffer contains the text modified by the user before triggering the action.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

Example

```
-- As action handler attribute
ON ACTION undo ATTRIBUTES(VALIDATE=NO)

-- As action default
ACTION DEFAULTS
  ACTION undo (VALIDATE=NO)
END

-- In a global action defaults file
<ActionDefault name="undo" validate="nos" ... />
```

Data validation at action invocation
The validate action default attribute controls field validation when an action is fired.

When using the UNBUFFERED mode of interactive instructions such asINPUT or DIALOG, if the user triggers an action, the current field data is checked and loaded in the target variable bound to the form field. For example, if the user types a wrong date (or only a part of a date) in a field using a DATE variable and then clicks on a button to invoke an action, the runtime system will display an invalid input error and will not execute the ON ACTION block corresponding to the button.

To prevent data validation for some actions, use the validate action default attribute. This attribute instructs the runtime not to copy the input buffer text into the program variable (requiring input buffer text to match the target data type).

```
ACTION DEFAULTS
   ...
   ACTION zoom ( ... VALIDATE = NO ... )
   ...
END
```

This is especially needed in DIALOG instructions; in singular dialogs like INPUT, predefined actions like cancel do not validate the current field value when UNBUFFERED mode is used.

The validate action default attribute can be set in the global action default file, or at the form level, with the VALIDATE attribute in a line of the ACTION DEFAULTS section.

Enabling and disabling actions

By default, dialog actions are enabled, however an action should be disabled when not allowed in the current context.

Dialog actions are enabled to let the user invoke the action handler (`ON ACTION`/`COMMAND`) by clicking on the corresponding action view (button) or by pressing its accelerator key. In most situations, actions remain active during the whole dialog execution. However, to follow GUI standards, actions must be disabled when not allowed in the current context. For example, a print action should be disabled if no record is currently shown in the form. After a database query, when the form is filled with a given record, the print action can be activated.

Depending on the front-end ergonomics, the visual result of disabling an action can be different. On desktop front-ends, the action views (buttons) are typically grayed, indicating that the action is there but cannot be triggered. On other front-ends such as some mobile devices, the action view might be hidden, for layout reasons (there is not much space on a mobile device screen).

During a dialog instruction, enable or disable an action with the `setActionActive()` method of the `ui.Dialog` built-in class. This method takes the name of the action (in lowercase letters) and a boolean expression (`0` or `FALSE`, `1` or `TRUE`) as arguments.

```
  BEFORE INPUT
    CALL DIALOG.setActionActive( "zoom", FALSE )
```

Consider centralizing action activation / deactivation in a setup function specific to the dialog, passing the `DIALOG` object as the parameter. Centralizing the action activation defines the rules in a single location:

```
FUNCTION cust_dialog_setup(d)
  DEFINE d ui.Dialog
  DEFINE can_modify BOOLEAN
  LET can_modify = (cust_rec.is_new OR user_info.is_admin)
  CALL d.setActionActive("update", can_modify)
  CALL d.setActionActive("delete", can_modify)
  ...
END FUNCTION
```

Some predefined dialog actions such as insert / append / delete of `INPUT ARRAY` are automatically enabled/disabled according to the context. For example, if the maximum number of rows (`MAXCOUNT`) is reached in an `INPUT ARRAY`, insert and append actions are disabled.

When the action activation depends on the focus being in a specific field, consider using the `INFIELD` clause of `ON ACTION` to automatically disable an action if the focus leaves the specified field.

Inside a `DIALOG` block, actions can be defined a different levels, and may need to be identified with the sub-dialog prefix, when you invoke the `ui.Dialog.setActionActive()` method outside of the context of the sub-dialog. In the next example, the `check_row` action must be prefixed by the `s_ord` sub-dialog name, because `setActionActive()` is called from the `INPUT BY NAME` sub-dialog context, to disable an action from the `DISPLAY ARRAY` sub-dialog:

```
DIALOG ATTRIBUTES(UNBUFFERED)
   DISPLAY ARRAY a_ord TO s_ord.*
      -- sub-dialog-level action
      ON ACTION check_row
         ...
   END DISPLAY
   ...
   INPUT BY NAME rec.* ...
      ON CHANGE consolidation
          -- Must use sub-dialog name to identify the check_row action:
          CALL DIALOG.setActionActive( "s_ord.check_row", FALSE )
      ...
   END INPUT
```

```
END DIALOG
```

Hiding and showing default action views
If needed, default action views can be hidden or shown.

When an action is rendered with a default action view (for example, by a button on the action frame of a destop front-end, or in the top action panel on a mobile front-end), it is sometimes required to hide the action button when the operation is not possible and there is not much space on the screen.

> **Important:** Hiding an action will only make the default action view invisible, if there is a keyboard accelerator associated to the action, it can still fire the action. Consider disabling the action completely with `setActionActive()`.

During a dialog instruction, shown or hide an action with the `setActionHidden()` method of the `ui.Dialog` built-in class. This method takes the name of the action (in lowercase letters) and an integer boolean expression (`0` or `FALSE`, `1` or `TRUE`) as arguments.

```
  BEFORE INPUT
    CALL DIALOG.setActionHidden( "zoom", 1 )
```

Consider centralizing action visibility control in a setup function specific to the dialog, passing the `DIALOG` object as the parameter. Centralizing the action activation defines the rules in a single location:

```
FUNCTION cust_dialog_setup(d)
  DEFINE d ui.Dialog
  DEFINE can_modify BOOLEAN
  LET can_modify = (cust_rec.is_new OR user_info.is_admin)
  CALL d.setActionActive("update", can_modify)
  CALL d.setActionHidden("update", IIF(can_modify,0,1))
  CALL d.setActionActive("delete", can_modify)
  CALL d.setActionHidden("delete", IIF(can_modify,0,1))
  ...
END FUNCTION
```

Pay attention to multi-level action definitions inside a `DIALOG` block: Inside a `DIALOG` block, actions must be hidden/shown with the `ui.Dialog.setActionHidden()` method by specifying a simple action name:

```
DIALOG ATTRIBUTES(UNBUFFERED)
     ...
   BEFORE DIALOG
     CALL DIALOG.setActionHidden( "print", 1 )
     ...
   ON ACTION query
     -- query the database and fill the record
     ...
     CALL DIALOG.setActionHidden( "print", (cust_id IS NULL) )
     ...
END DIALOG
```

Sub-dialog actions in procedural DIALOG blocks
This topic describes how action are differentiated with handlers defined in a procedural DIALOG block.

We distinguish *dialog actions* from *sub-dialog actions*: When the `ON ACTION` handler is defined at the same level as a `BEFORE DIALOG` control block, it is a dialog action, and the action name is a simple identifier as in singular interactive instructions:

```
action-name
```

When the `ON ACTION` handler is defined inside a sub-dialog, or if the action is an implicit action such as `insert` in `INPUT ARRAY`, it is a sub-dialog action, and the action name gets the name of the sub-dialog as the prefix to identify the sub-dialog action with a unique name:

```
sub-dialog-name.action-name
```

The `INPUT ARRAY` and `DISPLAY ARRAY` sub-dialogs are implicitly identified with the screen-record name defined in the form. For `INPUT` and `CONSTRUCT` sub-dialogs, the sub-dialog identifier can be specified with the `NAME` attribute.

The next example defines two 'check' action in different sub-dialog contexts, and a 'close' action at the dialog level:

```
DIALOG
  INPUT BY NAME ... ATTRIBUTES (NAME = "cust")
    ON ACTION check                   -- sub-dialog action "cust.check"
    ...
  END INPUT
  DISPLAY ARRAY arr_orders TO sr_ord.*
    ...
    ON ACTION check                   -- sub-dialog action "sr_ord.check"
    ...
  END DISPLAY
  BEFORE DIALOG
    ...
  ON ACTION close                      -- dialog action "close"
    ...
END DIALOG
```

By using the sub-dialog identifier in form definition files, you can bind action views to specific sub-dialog actions. Action views bound to sub-dialog actions with qualified sub-dialog action names will always be active, even if the focus is not in the sub-dialog of the action. You typically use fully-qualified sub-dialog actions names for buttons in the form body or in topmenu options. However, it does not make much sense to use this technique for toolbar buttons, where buttons must be enabled/disabled according to the context.

```
TOOLBAR
   ...
   ITEM append
   ...
END

TOPMENU
   ...
   GROUP orders (TEXT="Orders")
     COMMAND sr_ord.append
   ...
END

LAYOUT
GRID
{
   ...
   [b002  ]
}
END
END

ATTRIBUTES
BUTTON b002: sr_ord.append;
END
```

If you bind an action view with a simple action name (without the sub-dialog prefix), the action view will be attached to any sub-dialog action with the matching name. This is especially useful for common actions such as the implicit insert / append / delete actions created by `INPUT ARRAY`, when the dialog handles multiple editable lists. Bind toolbar buttons to these actions without the sub-dialog prefix; the buttons will apply to the current list that has the focus. The action views bound to sub-dialog actions without the sub-dialog qualifier will automatically be enabled or disabled when entering or leaving the group of fields controlled by the sub-dialog (i.e. typical navigation buttons in the toolbar will be disabled if the focus is not in a list).

If a sub-dialog action is invoked when the focus is not in the sub-dialog of the action, the focus will automatically be given to the first field of the sub-dialog, before executing the user code defined in the `ON ACTION` clause. This will trigger the same validation rules and control blocks as if the user had selected the first field of the sub-dialog by hand.

When using `DIALOG.setActionActive()` (or any method that takes an action name as parameter), you can specify the action name with or without a sub-dialog identifier. If you qualify the action with the sub-dialog identifier, the sub-dialog action is clearly identified. If you don't specify a sub-dialog prefix, the action will be identified based on the focus context - when the focus is in the sub-dialog of the action, non-qualified action names identify the local sub-dialog action; otherwise, they identify a dialog action if one exists with the same name. Disabling an action by the program with `setActionActive()`, will take precedence over the built-in activation rules (i.e. if the action is disabled by the program, the action will not be activated when entering the sub-dialog).

For action views bound to sub-dialog actions with qualifiers, the action defaults defined with the corresponding action name will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an action view is defined with the name "`custlist.append`", it will get the action defaults defined for the "`append`" action.

Field-specific actions (INFIELD clause)
Using the `INFIELD` clause of `ON ACTION` provides automatic action activation when a field gets the focus.

The `ON ACTION` interaction block of `INPUT`, `CONSTRUCT` and `INPUT ARRAY` (as singular dialogs or sub-dialogs in `DIALOG` instruction), can be specified with the `INFIELD` *`field-name`* clause. With this clause, the action will only be active when the focus is in one of the fields. The same action name can be used for several fields.

```
INPUT ARRAY custarr WITHOUT DEFAULTS FROM sr_cust.*
  ON ACTION zoom INFIELD cust_city
    LET custarr[arr_curr()].cust_city = zoom_city()
  ON ACTION zoom INFIELD cust_state
    LET custarr[arr_curr()].cust_state = zoom_state()
END INPUT
```

Actions defined with the `INFIELD` *`field-name`* clause can be identified with the field name as prefix:

```
field-name.action-name
```

Bind action views with field name prefix to identify the action specifically to a field, or use the action name only. Without the field name prefix, the action view is enabled and disabled automatically according to the current field. When binding the action view with the fully-qualified name including the field name prefix, the action view will always be active, and the focus will jump to the field if the action is fired.

Actions defined in sub-dialogs of the `DIALOG` instruction get the name of the sub-dialog as prefix. If `ON ACTION` *`action-name`* `INFIELD` *`field-name`* is used in a sub-dialog, the action object name is prefixed with the name of the sub-dialog, followed by the name of the field. The fully-qualified action name will be:

```
sub-dialog-name.field-name.action-name
```

When the field-specific action is invoked (for example by a button of the toolbar bound with the fully-qualified action name) and if the field does not have the focus, the runtime system first selects that field before executing the code of the `ON ACTION INFIELD` block. The field selection forces data validation and `AFTER FIELD` of the current field, followed by `BEFORE FIELD` of the target field associated to the action.

It's still possible to enable and disable field-specific action objects by the program using the `DIALOG.setActionActive()` method. When specifying a fully-qualified action name with the field name prefix, that field-specific action will be enabled or disabled. When disabled by the `setActionActive()` method, the corresponding action views will always be disabled, even if the field has the focus. If you do not specify a fully-qualified name in the method call, and if several actions are defined with the same action name in different sub-dialogs and/or using the `INFIELD` clause, the method will identify the action according to the current focus context. For example, if you define `ON ACTION zoom INFIELD cust_city` and `ON ACTION zoom INFIELD cust_addr`, when the focus is in `cust_city`, a call to `DIALOG.setActionActive("zoom", FALSE)` will disable the action specific to the `cust_city` field.

Fields can be enabled or disabled dynamically with the `DIALOG.setFieldActive()` method. If an `ON ACTION INFIELD` is declared on a field and if you enable/disable the field dynamically, then the field-specific action (and corresponding action views in the form) will be enabled or disabled accordingly.

For action views bound to field actions with qualifiers, the action defaults defined with the corresponding action name will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an action view is defined with the name "`cust_addr.check`", it will get the action defaults defined for the "`check`" action.

Multilevel action conflicts

Actions can be defined at two levels in a singular dialog, and three levels in the context of a `DIALOG` block:

1. Dialog level
2. Sub-dialog level (procedural `DIALOG` only)
3. Field level (`ON ACTION` with `INFIELD` clause)

It is not good practice to use the same action name at different levels of a dialog: This makes action view bindings and action handling (i.e. enabling / disabling) very complex, because there are many possible combinations. Therefore, when using the same action name at different dialog levels, the fglcomp compiler will raise a warning -8409. However, it is legal to use the same action name for a given level of action handlers in a sub-dialogs or for field-actions. For example, using the "zoom" action name for multiple `ON ACTION INFIELD` handlers is a common practice.

When binding action views with full qualified names, the `ON ACTION` handler is clearly identified, and the corresponding user code will be executed. However, when you do not specify the complete prefix of a sub-dialog or field action, the runtime system searches for the best `ON ACTION` handler to be executed, according to the current focus context.

Take for example a `DIALOG` instruction defining three `ON ACTION print` handlers at the dialog, sub-dialog and field level:

```
DIALOG
  INPUT BY NAME ... ATTRIBUTES (NAME = "cust")
    ...
    ON ACTION print INFIELD cust_name -- field-level action (1)
      ...
    ON ACTION print                   -- sub-dialog-level action (2)
      ...
  END INPUT
  ...
  ON ACTION print                     -- dialog-level action (3)
    ...
END DIALOG
```

The action views of the form will behave as follows:

- Action views bound with the name "`print`" will always be active, and invoke the `ON ACTION print` handler corresponding to the current focus context:
  - (1) is invoked if the focus is in the `cust_name` field.
  - (2) is invoked if the focus is in the `cust` sub-dialog, but not in `cust_name` field.
  - (3) is invoked if the focus is in another sub-dialog as `cust` sub-dialog.
- Action views bound with the name "`cust.print`" will always be active, even if the focus is not the `cust` sub-dialog, and invoke the `ON ACTION print` handler according to the current focus context:
  - (1) is invoked if the focus is in the `cust_name` field.
  - (2) is invoked if the focus is in the `cust` sub-dialog, but not in `cust_name` field.
- Action views bound with the name "`cust.cust_name.print`" will always be active, and invoke the `ON ACTION print INFIELD cust_name` handler after giving the focus to the `cust_name` field.

If the first field of a sub-dialog defines an `ON ACTION INFIELD` with the same action name as a sub-dialog action, and the focus is not in that sub-dialog when the user selects an action view bound with the name *sub-dialog-name.action-name*, the runtime system gives the focus to the first field of the sub-dialog. This field becomes the current field, and the runtime system executes the field-specific action handler instead of the sub-dialog action handler.

To avoid mistakes and complex combinations, you should use specific action names for each dialog level.

Action display in the contextual menu

The `CONTEXTMENU` action default attribute allows to control action visibility in the contextual menu.

Some front-ends can display a *contextual menu*, with all the active actions that are possible in the current form. Displaying all actions might not be adapted to your needs. To control if an action must be displayed in the context menu, set the `CONTEXTMENU` attribute in action defaults. Values for `CONTEXTMENU` can be `YES`, `NO` and `AUTO`.

```
ACTION DEFAULTS
   ...
   ACTION insert ( ... CONTEXTMENU = YES ... )
   ACTION append ( ... CONTEXTMENU = YES ... )
   ACTION delete ( ... CONTEXTMENU = YES ... )
   ...
   ACTION validate_order ( ... CONTEXTMENU = NO ... )
   ...
END
```

Implementing the close action

The close action is a predefined action dedicated to close graphical windows (for example, with the X cross button).

In graphical applications, windows can be closed by the user, for example by pressing Alt+F4 or by clicking the cross button in the upper-left corner of the window. A predefined action is dedicated to this specific event, named "close".

When the end user closes a graphical window, the program gets a close action.

Note that the default action view (i.e. button in the action frame) of the close action is hidden.

The close action in DIALOG dialogs

When executing a `DIALOG` instruction, the close action executes the `ON ACTION close` block, if defined. Otherwise, the close action is mapped to the cancel action if an `ON ACTION cancel` handler is defined.

If neither `ON ACTION close`, nor `ON ACTION cancel` are defined, nothing will happen if the user tries to close the window with the X cross button or an `ALT+F4` keystroke.

The INT_FLAG register will not be set in the context of DIALOG.

The close action in form input singular dialogs

When an ON ACTION close handler is defined in an INPUT, INPUT ARRAY, CONSTRUCT, DISPLAY ARRAY or PROMPT interactive instruction, the handler code will be executed if the close action is fired.

If no explicit ON ACTION close handler is defined, the close action acts the same as the cancel predefined action. So by default when the user clicks the X cross button in a window, the interactive instruction stops and INT_FLAG is set to 1.

If there is an explicit ON ACTION cancel block defined, INT_FLAG is set to 1 and the user code under ON ACTION cancel will be executed.

If the CANCEL=FALSE option is set, no cancel and no close action will be created, and you must write an ON ACTION close handler to proceed with the close action. In this case, the INT_FLAG register will not be set when the close action is invoked.

The close action in MENU dialogs

When an ON ACTION close handler is defined in a MENU statement, the handler code will be executed if the close action is fired.

If no explicit ON ACTION close action handler is defined, the code of the COMMAND KEY(INTERRUPT) or ON ACTION cancel will be executed, if defined. if neither COMMAND KEY(INTERRUPT) nor ON ACTION cancel are defined, nothing happens and the program stays in the MENU instruction. Regarding the close action, the value of INT_FLAG is undefined in a MENU instruction.

The close action on mobile devices

When displaying on a mobile device, the close action is rendered differently according to the type of mobile platform:

- On Android™, the close action is mapped to the [Back] button (it is not rendered in the action panel)
- On iOS, there is no [Back] button concept and the close action is rendered as a regular action.

For more details, see Rendering default action views on mobile on page 1279.

Example

You typically implement a close action handler to open a confirmation dialog box as in following example:

```
INPUT BY NAME cust_rec.*
  ...
  ON ACTION close
    IF msg_box_yn("Are you sure you want to close this window?")
 == "y" THEN
      EXIT INPUT
    END IF
  ...
END INPUT
```

Predefined actions

Genero predefines some action names for common operations of interactive instructions.

Predefined actions are different from user-defined action, in the sense that the name of a predefined action is reserved, and the action may has an ON ACTION handler, while user-defined actions have a specific name, and must be implemented with an ON ACTION handler.

There are three types of predefined actions:

- *Automatic actions*: actions that are automatically created and handled by the program dialog, like `accept`, `cancel`, `insert`.
- *Special actions*: actions with a special usage, that can be invoked asynchronously or automatically by the front-end, like `interrupt`, `dialogtouched`.
- *Local actions*: actions that are handled on the front end side, without program interaction, such as `editcopy`.

Default decoration attributes and keyboard shortcuts are defined with action defaults, like for user-defined actions.

Automatic and local actions with same name

Some predefined actions exist as both automatic actions and as local actions (for example, editcopy). The automatic actions are created according to the dialog context. If an automatic action has to be defined and if a local action exists with the same name, the automatic action takes precedence over the local action.

For example, if the dialog context requires a editcopy runtime action, the local editcopy action will not be handled by the front end. Identical action names are used for automatic and local action to bind with the same action view. For example, the same toolbar button created with the editcopy name will trigger the automatic action or the local action, according to the context.

Overwriting predefined actions with ON ACTION

If you define your own `ON ACTION` handler with the name of a predefined action, the default action processing is bypassed and the program code is executed instead.

The next code example defines an `ON ACTION` clause with the `accept` predefined action name:

```
INPUT BY NAME customer.*
  ON ACTION accept
    ...
END INPUT
```

In this case, the default behavior of the automatic accept action is not performed; the user code is executed instead.

Local actions can be overwritten in the same manner, however, this is not recommended (use your own action names).

Predefined actions enabled according to context

Some predefined actions (such as insert, append and delete in `INPUT ARRAY`) are enabled and disabled automatically by the dialog according to the context (for example, when a static array used by the `INPUT ARRAY` is full, the insert and append actions get disabled).

Even when overwriting such actions with your own action handler, the runtime system will continue to enable and disabled the actions automatically.

You should not overwrite predefined actions.

Binding action views to predefined actions

As for user-defined actions, if you design forms with action views using predefined action names, they will automatically attach themselves to the actions of the interactive instructions.

It is also possible to define default images, texts, comments and accelerator keys in the action defaults resource file for the predefined actions.

List of predefined actions

Table 286: Automatic actions (automatically created by dialogs)

Action Name	Description	ON ACTION block is required	Context
`accept`	Validates the current interactive instruction (singular dialogs only)	can overwrite	(1)
`cancel`	Cancels the current interactive instruction (singular dialogs only)	can overwrite	(1)
`close`	Triggers a cancel key in the current interactive instruction (by default)	can overwrite	(7)
`insert`	Inserts a new row before current row	can overwrite	(2)
`append`	Appends a new row at the end of the list	can overwrite	(2)
`delete`	Deletes the current row	can overwrite	(2)
`find`	Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value	can overwrite	(4)
`findnext`	Seeks to the next row matching the value entered during the fglfind dialog	can overwrite	(4)
`nextrow`	Moves to the next row (only if list using one flat screen record)	can overwrite	(8)
`prevrow`	Moves to the previous row (only if list using one flat screen record)	can overwrite	(8)
`firstrow`	Moves to the first row (only if list using one flat screen record)	can overwrite	(8)
`lastrow`	Moves to the last row (only if list using one flat screen record)	can overwrite	(8)
`help`	Shows the help topic defined by the `HELP` clause	can overwrite	(1)
`editcopy`	Copy selected rows (or current row if MRS is off) to the clipboard	can overwrite	(9)

Table 287: Special actions (special behavior)

Special Action Name	Description	ON ACTION block is required	Context
`browser_back`	Sent when the user hits the back button in a web browser (web front-end only).	yes	(7)
`browser_forward`	Sent when the user hits the forward button in a web browser (web front-end only).	yes	(7)
`dialogtouched`	Sent by the front end each time the user modifies the value of a field. For more details, see Immediate detection of user changes on page 1267.	yes	(7)
`interrupt`	Sends an interruption request to the program when processing. For more details, see User interruption handling on page 1252.	no	(5)
`windowresized`	On Mobile devices, this action is sent when changing the orientation of the device. On other front-ends, it is sent when the current active window is resized. For more details, see Adapting to viewport changes on page 1003.	yes	(6)
`notificationpushed`	On Mobile devices, this action is fired when receiving a push notification message. See getRemoteNotifications on page 1930	yes	(6)

Table 288: Local actions (handled by the front end)

Local Action Name	Description	ON ACTION block is required	Context
`editcopy`	Copies the current selected text to the clipboard	can overwrite	(7)

Local Action Name	Description	ON ACTION block is required	Context
`editcut`	Copies the current selected text to the clipboard and removes the text from the current input widget	can overwrite	(7)
`editpaste`	Pastes the clipboard content to the current input widget	can overwrite	(7)
`nextfield`	Moves to the next field in the form	can overwrite	(3)
`prevfield`	Moves to the previous field in the form	can overwrite	(3)
`nextrow`	Moves to the next row in the list	can overwrite	(4)
`prevrow`	Moves to the previous row in the list	can overwrite	(4)
`firstrow`	Moves to the first row in the list	can overwrite	(4)
`lastrow`	Moves to the last row in the list	can overwrite	(4)
`nextpage`	Moves to the next page in the list	can overwrite	(4)
`prevpage`	Moves to the previous page in the list	can overwrite	(4)
`nexttab`	Moves to the next page in the folder	can overwrite	(6)
`prevtab`	Moves to the previous page in the folder	can overwrite	(6)

Context column descriptions

1. `CONSTRUCT`, `INPUT`, `PROMPT`, `INPUT ARRAY` and `DISPLAY ARRAY`.
2. `INPUT ARRAY` only.
3. `CONSTRUCT`, `INPUT` and `INPUT ARRAY`.
4. `INPUT ARRAY` and `DISPLAY ARRAY`.
5. Only possible when no interactive instruction is active.
6. Possible in any kind of interactive instruction (`MENU` included).
7. `DIALOG`, `CONSTRUCT`, `INPUT`, `PROMPT`, `INPUT ARRAY` and `DISPLAY ARRAY`.
8. `INPUT ARRAY` and `DISPLAY ARRAY` on flat screen-record.
9. `DISPLAY ARRAY` only.

Keyboard accelerator names

Virtual keys

Virtual keys are the key names that can be used in program instructions such as `ON KEY` and `COMMAND KEY`.

An `ON KEY` block defines one to four different action objects that will be identified by the key name in lowercase (`ON KEY(F5,F6) = creates Action f5 + Action f6`). Each action object will get an `acceleratorName` attribute assigned. In GUI mode, Action defaults are applied for `ON KEY` actions by using the name of the key. You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the `ON KEY CONTROL-?` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with `ESC`, `TAB`, `UP`, `DOWN`, `LEFT`, `RIGHT`, `HELP`, `NEXT`, `PREVIOUS`, `INSERT`, `CONTROL-M`, `CONTROL-X`, `CONTROL-V`, `CONTROL-C` and `CONTROL-A` should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the Action Defaults.

By default, `ON KEY` actions are not decorated with a default button in the action frame (i.e. default action view). You can show the default button by configuring a `text` attribute with the action defaults.

Table 289: Names of keys to be referenced in programs

Key Name	Description
`ACCEPT`	The validation key.
`INTERRUPT`	The interruption key.
`ESC` or `ESCAPE`	The ESC key (not recommended, use `ACCEPT` instead).
`TAB`	The TAB key (not recommended).
`Control-`*`char`*	A control key where *char* can be any character except A, D, H, I, J, K, L, M, R, or X.
`F1` through `F255`	A function key.
`DELETE`	The key used to delete a new row in an array.
`INSERT`	The key used to insert a new row in an array.
`HELP`	The help key.
`LEFT`	The left arrow key.
`RIGHT`	The right arrow key.
`DOWN`	The down arrow key.
`UP`	The up arrow key.
`PREVIOUS` or `PREVPAGE`	The previous page key.
`NEXT` or `NEXTPAGE`	The next page key.

Accelerator keys

Accelerators keys are attributes defining the keyboard shortcuts for actions.

Keyboard accelerators can be defined at several level in the form files or in action defaults. You can define up to four accelerator keys for the same action in action defaults, by setting the `acceleratorName`, `acceleratorName2`, `acceleratorName3` and `acceleratorName4` attributes.

If no accelerators are defined in the action defaults, the runtime system sets default accelerators for predefined actions, according to the user interface mode. For example, the accept action will get the `Return` and `Enter` keys in GUI mode, but gets the `Escape` key in TUI mode.

Accelerators can also be defined in on the program in the attribute list of the `ON ACTION` interaction block.

If one of the user-defined actions uses an accelerator that would normally be used for a predefined action, the runtime system does not set that accelerator for the predefined action. For example (in GUI mode), if you define an `ON ACTION quit` with an action default using the accelerator "`Escape`", the "cancel" predefined action will not get the "`Escape`" default accelerator. In this case, user settings take precedence over defaults.

Text edition and navigation accelerators such as `Home` and `End` are usually local to the widget. According to the context, such accelerators might be eaten by the graphical widget and will not invoke the action bound to the corresponding accelerator defined in the action defaults. For example, even if the action defaults for the "firstrow" action defines the `Home` accelerator, when using an `INPUT ARRAY`, the Home key will jump to the beginning of the edit field, not the first row of the list.

If you want to force an action to have no accelerator, specify "`none`" as the accelerator name.

This table lists all the keyboard accelerator names:

Table 290: Keyboard accelerator names

Accelerator Name	Description
`none`	Special name indicating the runtime system must not set any default accelerator for the action.
`0-9`	Decimal digits from 0 to 9
`A-Z`	Letters from A to Z
`F1-F35`	The functions keys
`BackSpace`	The BACKSPACE key (do not confuse with DELETE key)
`Delete`	The DELETE key (navigation keyboard group)
`Down`	The DOWN key (arrow keyboard group)
`End`	The END key (navigation keyboard group)
`Enter`	The ENTER key (numeric keypad, see Note)
`Escape`	The ESCAPE key
`Home`	The HOME key (navigation keyboard group)
`Insert`	The INSERT key (navigation keyboard group)
`Left`	The LEFT key (arrow keyboard group)
`Minus`	The MINUS sign key (-)
`Next`	The NEXT PAGE key (navigation keyboard group)
`Prior`	The PRIOR PAGE key (navigation keyboard group)
`Return`	The RETURN key (alphanumeric keypad, see Note)
`Right`	The RIGHT key (arrow keyboard group)
`Space`	The SPACEBAR key

Accelerator Name	Description
`Tab`	The TABULATION Key
`Up`	The UP key (arrow keyboard group)

> **Note:** The "`Enter`" key represents the ENTER key available on the numeric keypad of standard keyboards, while "`Return`" represents the RETURN key of the alphanumeric keyboard. By default, the "accept" validation action is configured to accept both "`Enter`" and "`Return`" keys.

Accelerator key modifiers

All of the key names listed in the previous table can be combined with modifiers representing the Ctrl, Shift and Alt keys.

The names to be used for the key modifiers are "`Control-`", "`Shift-`", and "`Alt-`", to be added as prefix in accelerator name.

For example:

```
Control-P
Shift-Alt-F12
Control-Shift-Alt-Z
```

Table views

Describes how to program dialogs controlling record lists.

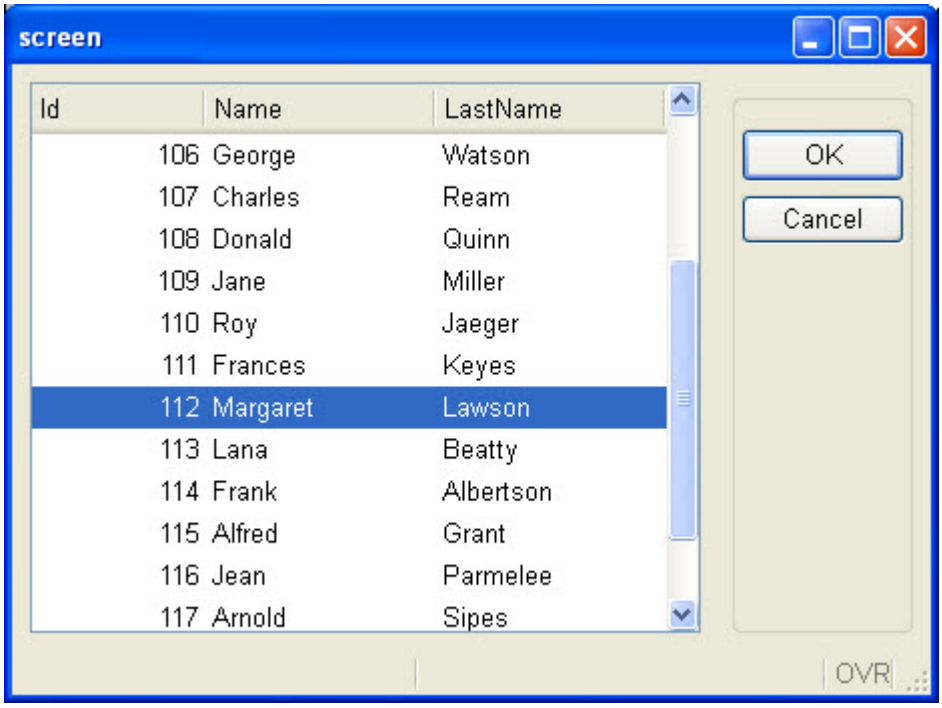
Understanding tables views

Table views define the graphical element to display a list of records.

The end user can navigate in the list to select a row or edit rows, according to the dialog controlling the table.

If the front-end platform standards allow it, the user can resize the table, sort rows, move/resize/hide columns, make multiple-row selections, search rows by criterion, and more.

Figure 82: Form with Table View (desktop front-end)



Tables views are controlled by a `DISPLAY ARRAY` or `INPUT ARRAY` instruction using a form screen-array bound to a `TABLE` container.

You can customize the rendering and the behavior of table views with form attributes in the TABLE container, and in the program using the dialog implementation.

Defining tables in the layout

Define table views in the `LAYOUT` section of the form definition file.

Desiging table views

When using a grid-based layout, the table rows and columns are defined within an area delimited by curly braces. Columns are defined with item tags and form fields. Every column tag must be properly aligned. You typically use a pipe character to separate the column tags.

A table definition using the `TABLE` layout item:

```
TABLE
{
[c1     |c2              |c3              ]
[c1     |c2              |c3              ]
[c1     |c2              |c3              ]
}
END
```

Alternatively, you can define a `<TABLE >` layout tags inside a `GRID` container, beside other layout tags:

```
GRID
{
<GROUP g1                                 >
```

```
[f1            ]
[f2                                    ]
[                                      ]
<                                      >
<TABLE t1                              >
[c1     |c2             |c3            ]
[c1     |c2             |c3            ]
[c1     |c2             |c3            ]
<                                      >
}
END
```

> **Important:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters are replaced with 8 blanks at compilation with `fglform`.

The position of the item tags is detected by the form compiler to build the table. Column item types (widget to be used) and behavior are defined with form items in the `ATTRIBUTES` section:

```
ATTRIBUTES
EDIT c1 = customer.cust_id;
EDIT c2 = customer.cust_name;
EDIT c3 = customer.cust_address;
END
```

When using a stack-based layout, table views are defined with the `TABLE` stack item inside a `STACK` container. In this case, position/size and behavior are defined at a single place:

```
LAYOUT
  STACK
    TABLE t1(UNMOVABLECOLUMNS)
      EDIT customer.cust_id;
      EDIT customer.cust_name;
      EDIT customer.cust_address;
    END
  END
END
```

Controlling the size of the table

In a grid-based container, the default width and height of a table are defined by the columns and the number of lines used in the table layout respectively. In a stack-based container,

You can overwrite the default table by specifying the `WIDTH` and `HEIGHT` attributes.

```
TABLE t1 ( WIDTH = 5 COLUMNS, HEIGHT = 10 LINES )
```

Defining column titles

The `TABLE` layout item definition can contain column titles as well as the tag identifiers for each column's form fields. The `fglform` form compiler can associate column titles in the table layout with the form field columns if they are aligned properly.

> **Note:** At least two spaces are required between column titles.

```
TABLE
{
 Title1  Title2           Title3
[c1     |c2             |c3            ]
[c1     |c2             |c3            ]
[c1     |c2             |c3            ]
```

```
}
END
```

Alternatively, you can set the column titles of a table container by using the `TITLE` attribute in the definition of the form fields. This allows you to use localized strings for the column titles.

```
TABLE
{
[c1  |c2          |c3         ]
[c1  |c2          |c3         ]
[c1  |c2          |c3         ]
}
END
...
ATTRIBUTES
EDIT c1 = customer.cust_id, TITLE=%"label.cust_id";
EDIT c2 = customer.cust_name, TITLE=%"label.cust_name";
EDIT c3 = customer.cust_address, TITLE=%"label.cust_address";
END
```

Similarly, in a stack item `TABLE` container, columns can get a `TITLE` attribute:

```
LAYOUT
  STACK
    TABLE t1(UNMOVABLECOLUMNS)
      EDIT customer.cust_id, TITLE=%"label.cust_id";
      EDIT customer.cust_name, TITLE=%"label.cust_name";
      EDIT customer.cust_address, TITLE=%"label.cust_address";
    END
  END
END
```

Height of table rows

The height of table rows can be defined with a grid-based layout by adding empty tags underneath column tags (this makes sense only when using widgets that can get a height such as `TEXTEDIT` or `IMAGE`).

```
LAYOUT
TABLE
{
[c1  |c2                    ]
[    |                      ]
[    |                      ]
}
END
END
ATTRIBUTES
EDIT c1=FORMONLY.key;
TEXTEDIT c2=FORMONLY.thetext;
END
...
```

In the above example, the second column is defined as a `TEXTEDIT` item type, that can get a height as a number of grid cells. The height is defined by the number of item tags of the table row in the layout section (height=3 in our example)

Binding tables to arrays in dialogs

Identifying list views in program dialogs

In list dialogs such as the `INPUT ARRAY` or `DISPLAY ARRAY`, the screen array identifies the record list element in the current form to be bound to the program array used by the dialog.

In the next example, the `INPUT ARRAY` uses the `custlist` screen array of the form, and binds the `custarr` program ARRAY with:

```
INPUT ARRAY custarr FROM custlist.*
```

The screen array members will be associated to the program array record members by position. The order and number of the screen array elements matters, because these are bound by position to the members the program array. The position of the `TABLE` columns, however, can differ from the members of the screen array and program array.

To omit columns in the `TABLE` layout, yet include them in the definition of the screen array, and define the columns as `PHANTOM` fields in the form definition file.

The program array can be defined from the database table definition with the `DEFINE LIKE` instruction:

```
DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
```

Note that the array is usually defined with a flat list of members with `ARRAY OF RECORD / END RECORD`. However, the array can be structured with sub-records and still be used with a list dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the `IMAGECOLUMN` attribute):

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
                   item_data RECORD LIKE items.*,
                   it_image STRING,
                   it_count INTEGER
               END RECORD
...
DISPLAY ARRAY a_items TO sr.*
   ...
```

Defining screen arrays in grid-based layout TABLEs

When using a grid-based layout, the `TABLE` container is bound to a screen array defined in the `INSTRUCTION` section, by the name of the form fields used in the screen array definition.

The column data type and additional column properties are defined in the `ATTRIBUTES` section as form fields:

```
LAYOUT
...
TABLE
{
[c1    |c2     |c3             ]
[c1    |c2     |c3             ]
[c1    |c2     |c3             ]
[c1    |c2     |c3             ]
}
END
...

ATTRIBUTES
```

```
EDIT c1 = customer.cust_num;
EDIT c2 = customer.cust_name,
EDIT c3 = customer.cust_cdate;
...
```

Each form field of the table must be grouped in the `INSTRUCTIONS` section in a `SCREEN RECORD` definition.

```
SCREEN RECORD custlist( cust_num, cust_name, cust_cdate );
```

Defining screen arrays in stack-based layout TABLEs

When using a stack-based layout, the `TABLE` stack item gets a identifier, which defines the screen array to be used in programs:

```
LAYOUT
  STACK
    TABLE custlist (STYLE="regular")
       EDIT customer.cust_num;
       EDIT customer.cust_name,
       EDIT customer.cust_cdate;
    END
  END
END
```

This identified is mandatory for `TABLE` stack items.

Controlling table rendering

Table rendering can be controlled by the use of presentation styles and table attributes.

Current row rendering

By default, the current row in a `TABLE` is highlighted in display mode (`DISPLAY ARRAY`) but not in input mode (`INPUT ARRAY`, `CONSTRUCT`). You can set decoration attributes of a table with a presentation style of the `Table` class.

Table resize control

By default, tables can be resized in height. Use the `WANTFIXEDPAGESIZE` form file attribute to deny table resizing.

Current row visibility after dialog execution

When the dialog controlling the table has finished, the current row may be deselected, depending on the `KEEP CURRENT ROW` dialog attribute.

Controlling the total number of rows

Methods are provided to set and get the number of rows in a read-only or editable list of records.

> **Note:** The `DISPLAY ARRAY` and `INPUT ARRAY` dialogs can use dynamic or static arrays. Static arrays are supported for backward compatibility, consider using dynamic arrays for new development.

Set the number of rows when using a static array

When using a static array in DISPLAY ARRAY or INPUT ARRAY, you must specify the actual number of rows with the SET_COUNT() built-in function or with the COUNT dialog attribute. Both of them are only taken into account when the interactive instruction starts.

```
DEFINE arr ARRAY[100] OF ...
... (fill the array with x rows)
CALL set_count(x)
DISPLAY ARRAY arr TO sa.*
   ...
END DISPLAY
```

When using multiple list subdialogs in a DIALOG block, the SET_COUNT() built-in function is unusable, as it defines the total number of rows for all lists. The only way to define the number of rows when using a static array in multiple dialogs is to use the COUNT attribute.

Consider using dynamic arrays instead of static arrays.

Set the number of rows when using a dynamic array

When using a dynamic array in DISPLAY ARRAY or INPUT ARRAY, the total number of rows is automatically defined by the array variable (array.getLength()).

```
DEFINE arr DYNAMIC ARRAY OF ...
... (fill the array with x rows)
DISPLAY ARRAY arr TO sa.*
   ...
END DISPLAY
```

However, special consideration has to be taken when using the paged mode of DISPLAY ARRAY. In this mode, the dynamic array only holds a page of the complete row set shown to the user: In paged mode, you must specify the total number of rows with the ui.Dialog.setArrayLength() method.

Get the number of rows in a list

To get the current number of rows in a DISPLAY ARRAY or INPUT ARRAY, use either the ui.Dialog.getArrayLength() or the ARR_COUNT() function.

The getArrayLength() method can be used inside or outside the context of the list dialog, as it takes the screen array as parameter to identify the list dialog. For example, when implementing a DIALOG block with two DISPLAY ARRAY subdialogs, you can query the number of rows of a list in the code block of another list controller:

```
DIALOG ...
   DISPLAY ARRAY arr1 TO sa1.*
      ON ACTION check
         IF DIALOG.getArrayLength("sa2")] > 1 THEN
            ...
         END IF
   END DISPLAY
   DISPLAY ARRAY arr2 TO sa2.*
   END DISPLAY
END DIALOG
```

The ARR_COUNT() function must be used in the context of the DISPLAY ARRAY or INPUT ARRAY dialog, or just after executing such dialog. For example, it can be used just after an INPUT ARRAY dialog, to get the number of rows left in the list:

```
INPUT ARRAY arr FROM sa.*
   ...
```

```
END INPUT
IF NOT int_flag THEN
   FOR i=1 TO arr_count()
     ...
   END FOR
END IF
```

The ARR_COUNT( ) function returns the number of rows for the last executed dialog, until a new list dialog is started.

Handling the current row
Query and control the current row in a read-only or editable list of records.

Get the current row

To query the current row of a list, use either the ui.Dialog.getCurrentRow( ) method or the ARR_CURR( ) built-in function, according to the context.

The getCurrentRow( ) method can be used inside or outside the context of the DISPLAY ARRAY or INPUT ARRAY dialog. The method takes the name of the screen array as the argument to identify the list. For example, when implementing a DIALOG block with two DISPLAY ARRAY subdialogs, you can query the current row of a list in the code block of the other list controller:

```
DIALOG ...
   DISPLAY ARRAY arr1 TO sa1.*
      ON ACTION check
         IF arr2[DIALOG.getCurrentRow("sa2")].value > 0 THEN
            ...
         END IF
   END DISPLAY
   DISPLAY ARRAY arr2 TO sa2.*
   END DISPLAY
END DIALOG
```

The ARR_CURR( ) function must be used in the context of the current DISPLAY ARRAY or INPUT ARRAY dialog, or just after executing such a dialog. For example, when implementing modification triggers in a DISPLAY ARRAY dialog, the current row and the current screen line can be queried respectively with the ARR_CURR( ) and SCR_LINE( ) functions:

```
DISPLAY ARRAY arr TO sa.*
    ON UPDATE
       INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sa[scr_line()].* ;
END DISPLAY
```

The ARR_CURR( ) function returns the current row index for the last executed dialog, until a new list dialog is started.

Set the current row

To set the current row in a list controlled by a DISPLAY ARRAY or INPUT ARRAY, use the ui.Dialog.setCurrentRow( ) method. This method takes the name of the screen array and the new row index as parameters:

```
DISPLAY ARRAY p_items TO sa.*
   ...
   ON ACTION next_empty
      LET row = findEmptyRow(p_items)
      CALL DIALOG.setCurrentRow("sa", row)
   ...
END DISPLAY
```

Calling the `DIALOG.setCurrentRow()` method will not execute control blocks such as `BEFORE ROW` and `AFTER ROW`, and will not set the focus. If you want to set the focus to the list, you must use the `NEXT FIELD` instruction. This works with `DISPLAY ARRAY` as well as with `INPUT ARRAY`.

> **Tip:** Use this method with care. Let the dialog handle normal navigation automatically, and jump to a specific row only in the context of an `ON ACTION` block.

The `FGL_SET_ARR_CURR()` function can also be used. This function must be called in the context of the current list having the focus.

> **Note:** `FGL_SET_ARR_CURR()` triggers control blocks such as `BEFORE ROW`, while `DIALOG.setCurrentRow()` does not trigger any control blocks.

Converting visual index to/from program array index

When the end user sorts rows in a table, the program array index (`arr_curr()`) may differ from the visual row index (the row position as seen by the user).

The `ui.Dialog` class provides methods to convert between these contexts:

The ui.Dialog.arrayToVisualIndex on page 1796 method converts a program array index to a visual index. It can be used, for example, to display a typical list position message (Row: *current-row* / *total-rows*). The current row (*arr_curr()*/*getCurrentRow()*) is a program array index that must be converted to a visual index. Note that you need to display such messages in the `BEFORE ROW` trigger and `ON SORT` trigger:

```
FUNCTION disp_row(d,n)
   DEFINE d ui.DIALOG, n STRING
   MESSAGE SFMT("Row: %1/%2",
                d.arrayToVisualIndex(n,d.getCurrentRow(n)),
                d.getArrayLength(n))
END FUNCTION
...
   DISPLAY ARRAY arr TO sr.*
       ...
       BEFORE ROW
           CALL disp_row(DIALOG,"sr")
       ON SORT
           CALL disp_row(DIALOG,"sr")
       ...
   END DISPLAY
```

The ui.Dialog.visualToArrayIndex on page 1815 method converts a visual index to a program array index. It can be used for example to ask the user for a row position (visual index), and make that row current by using `DIALOG.setCurrentRow()` after converting to the program array index:

```
DEFINE i INTEGER
...
DISPLAY ARRAY arr TO sr.*
   ...
   ON ACTION move_to
      PROMPT "Enter row index:" FOR i
      CALL DIALOG.setCurrentRow( "sr", DIALOG.visualToArrayIndex("sr", i))
   ...
END DISPLAY
```

Displaying column images

You can use PHANTOM fields and the IMAGECOLUMN attribute to display images in a column, to the left of the column value.

To display an image on the left of the column value in table views, define a PHANTOM field to hold the image name, and bind it to a parent column with the IMAGECOLUMN attribute.

```
LAYOUT
TABLE
{
[c1            |c2          ]
[c1            |c2          ]
[c1            |c2          ]
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.file_icon;
EDIT c1 = FORMONLY.file_name, IMAGECOLUMN=file_icon;
EDIT c2 = FORMONLY.file_size;
...
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

The program code can then display the specified image with each row.

```
DEFINE arr DYNAMIC ARRAY OF RECORD
     file_icon STRING,
     file_name STRING,
     file_size INTEGER
  END RECORD
...
FOR x=1 TO max_files
    CASE file_type(arr[x].file_name)
    WHEN "file" LET arr[x].file_icon = "file"
    WHEN "dir"  LET arr[x].file_icon = "folder"
    END CASE
END FOR
...
DISPLAY ARRAY arr TO sr.*
   ...
END DISPLAY
```

When images come from the database, these are typically fetched into BYTE variables. If the BYTE variable is located in a file (LOCATE IN FILE), it can be bound to the IMAGECOLUMN field: The runtime system will automatically display the image data. Note however that each BYTE element of the array must be located in a distinct file. This can be done as follows:

```
DEFINE arr DYNAMIC ARRAY OF RECORD
           pic_num INTEGER,
           pic_data BYTE,
           pic_when DATETIME YEAR TO SECOND
       END RECORD
...
DECLARE c1 CURSOR FOR SELECT * FROM mypics
LET i=1
LOCATE arr[i].pic_data IN FILE
FOREACH c1 INTO arr[i].*
    LOCATE arr[i:=i+1].pic_data IN FILE
END FOREACH
```

```
CALL arr.deleteElement(i)
...
```

Defining actions on list columns with images
Columns in tables displaying images can trigger action events, when the user selects the image.

TABLE and TREE containers can define columns as IMAGE field, to display pictures or icons. By default, these table cells are not clickable. When you define an ACTION attribute for a table column defined as IMAGE, the action event will fire when the image is selected (with a mouse click, for example). Note that this note apply to the IMAGECOLUMN concept, which is rather a column decoration.

> **Important:** When selecting an image, the current row may change as when selecting a new row in the table.

The following example defines a TABLE with two IMAGE columns, and attaches the update and delete actions:

```
LAYOUT
TABLE
{
[c1   |c2                |i1|i2]
[c1   |c2                |i1|i2]
[c1   |c2                |i1|i2]
}
END
END
ATTRIBUTES
EDIT c1 = FORMONLY.id, TITLE="Id", NOENTRY;
EDIT c2 = FORMONLY.name, TITLE="Name";
IMAGE i1 = FORMONLY.i_modify, ACTION=update;
IMAGE i2 = FORMONLY.i_delete, ACTION=delete;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

In the program code, use a dialog instruction to implement the action handlers for the image actions. For example, you can define a DISPLAY ARRAY with ON UPDATE and ON DELETE list modification triggers that will respectively create the update and delete actions:

```
DISPLAY ARRAY arr TO sr.*
    ON UPDATE
       -- user code
    ON DELETE
       -- use code
END DISPLAY
```

Built-in table features
Several implicit list handling features are provided by table views.
Columns layout
By default, a user can position, hide, show, and resize columns in TABLE and TREE containers.

> **Important:** This feature is not supported on mobile platforms.

Resizing columns

By default, columns can be resized. On desktop front-ends, the user can drag the right edge of a column header to increase or decrease the width of the column.

To deny column resizing for all columns in a table, add the UNSIZABLECOLUMNS attribute to the TABLE or TREE container.

To deny column resizing for an individual column, add the UNSIZABLE attribute to the form field definition for that column.

Hiding/showing columns

By default, the user can control the visibility of columns. On desktop front-ends, a user right-clicks on a column header to get a contextual menu that allows to show/hide columns.

To deny the column visibility option for all columns in a table, add the UNHIDABLECOLUMNS attribute to the TABLE or TREE container.

To deny the column visibility option for an individual column, add the UNHIDABLE attribute to the form field definition for that column.

To hide a column initially but allow column visibility, set the HIDDEN attribute with the value USER in the form field definition for that column. This hides the column by default, and lets the user show the column if needed.

Changing column positions

By default, columns can be moved around. On desktop front-ends, a user can rearrange columns by dragging the column header to a different position.

To deny this option, add the UNMOVABLECOLUMNS attribute to the TABLE or TREE container.

To deny this option for an individual column, add the UNMOVABLE attribute to the form field definition for that column.

List ordering

List controllers implement a built-in sort. This feature can be disabled if not required.

When a DISPLAY ARRAY or INPUT ARRAY block is combined with a TABLE container, the row sorting feature is implicitly available. Row sorting is supported on TREE containers with DISPLAY ARRAY dialogs only.

> **Important:** This feature is not supported on mobile platforms.

To sort rows in a list, the user must click on a column header of the table. Clicking on a table column header triggers a GUI event that instructs the runtime system to reorder the rows displayed in the list container.

In fact, the rows are only sorted from a visual point of view; the data rows in the program array (the model) are left untouched. Therefore, when rows are sorted, the visual position of the current row might be different from the current row index in the program array.

To sort rows, the runtime system uses the standard collation order of the system, following the current locale settings. As result, the rows might be ordered a bit differently than when using the database server to sort rows (with an ORDER BY clause of the SELECT statement), since database servers can define their own collation sequences to sort character data.

The built-in sort is enabled by default. To prevent sorting in a TABLE or TREE containers, defined the UNSORTABLECOLUNMS attribute at the list container level, or set the UNSORTABLE attribute at the column/field level. As rows can be created and modified during an INPUT ARRAY instruction, you may want to use the UNSORTABLECOLUMNS attribute for tables controlled by INPUT ARRAY.

To execute code after a sort was performed, use the ON SORT interaction block in the dialog, for example to display the current row position with ui.Dialog.arrayToVisualIndex on page 1796.

The sorting feature is disabled when using the paged mode of DISPLAY ARRAY, because not all result set rows are known by the runtime system in this mode. However, it is possible to detect a sort request from the user with the ON SORT trigger. You can then re-execute the SQL query with a new sort order. For more details, see Populating a DISPLAY ARRAY on page 1372.

When an application window is closed, the selected sort column and order is stored by the front-end in the user settings database of the system (for example, on Windows™ platforms it's the registry database). The sort will be automatically re-applied the next time the window is created. This way, the rows will appear sorted when the program restarts. The saved sort column and order is specific to each list container.

Find function
List controllers implement a built-in find. This feature can be disabled if not required.

The `DISPLAY ARRAY` and `INPUT ARRAY` block blocks support the built-in find feature by default.

> **Important:** This feature is not supported on mobile platforms.

This feature works with any list container (`TABLE`, `TREE`, `SCROLLGRID`).

The built-in find creates the implicit "find" and "findnext" actions. These actions can be decorated, enabled and disabled as regular actions.

When the user triggers the "find" action (default accelerator is Ctrl-F), the dialog opens a popup window to let the user enter a search value. On validation with the OK button, the dialog starts to search a row where a field value matches the value entered in the find dialog. The "find" action starts the search from the current row. After a first search, the user can trigger the "findnext" action (default accelerator is Ctrl-G), in order to continue the search in the rest of the record list, without opening the find dialog again (the current search value will be reused).

By default, any table column is scanned, but the user can select a specific column in the find dialog box, as long as a column title is available. Case-sensitive or insensitive search as well as wraparound options are also available.

The value entered in the find dialog is compared to all fields of visible columns, except columns of the type `TEXT` or `BYTE`. The comparison is based on the formatted value. For example, a `MONEY` column will display values formatted with the currency symbol. To match values in that column, the user must enter exactly the same value (i.e. with the currency symbol and the correct decimal separator). When using `COMBOBOX` fields, the find searches in the visible values of combobox items.

Only text widgets displaying values are searched. Columns using widgets such as images, radio-groups, checkboxes are not searched. Further, the find function ignores `PHANTOM` fields, hidden fields and fields defined with the `INVISIBLE` attribute.

Only rows in memory can be searched. When using the paged-mode (`ON FILL BUFFER`), the built-in search is disabled. When implementing dynamic tree views , the built-in find will only search the tree nodes available in the program array.

If the dialog defines an explicit `ON ACTION find` or `ON ACTION findnext`, the default built-in find is disabled.

Keyboard seek
The keyboard seek feature allows a user to find a row in a read-only list, by typing characters.

During a `DISPLAY ARRAY`, when the user types alphabetic characters on the keyboard, the runtime system will automatically seek to the next row having a character field that contains a value starting with the typed characters. The seek search restarts from the current row when the user types a new characters on the keyboard.

> **Important:** This feature is not supported on mobile platforms.

This feature works with any list container (`TABLE`, `TREE`, `SCROLLGRID`).

Numeric, date/time and large data (`TEXT`/`BYTE`) columns are ignored. Only character columns are searched, fields using widgets like image, radio-group or checkbox are ignored. Further, the seek function ignores `PHANTOM` fields, hidden fields and fields defined with the `INVISIBLE` attribute.

The user can rapidly type several characters on the keyboard, to search for a value that starts with the typed characters. After a given timeout (less than a second), the seek buffer is cleared and a new search filter can be taken into account.

The seek search is case-insensitive.

If no row could be found from the typed characters, the [Not found] error -8105 will be displayed automatically.

If an alphabetic character is used as action accelerator, the built-in seek feature is disabled, because the accelerator must fire the corresponding action.

Only rows in memory can be searched. When using page-mode (`ON FILL BUFFER`), the built-in seek is disabled. When implementing dynamic tree views, the built-in seek will only search the tree nodes available in the program array.

By default, any character column of the list is scanned. But if the list gets sorted, the runtime system considers that the sort column is the most important and searches only in that column.

Reduce filter
The reduce filter allows a user to reduce the row set in a read-only list according to a filter.

When using a `DISPLAY ARRAY` with a `TABLE` container, and if the front-end supports filter search facility, the user can enter a criterion in that search field, to show only the rows matching the content of the filter.

> **Important:** This feature is only for mobile platforms.

The filter search is case-insensitive.

The value entered in the filter field is compared to all fields of visible columns, except columns of the type `TEXT` or `BYTE`. The comparison is based on the formatted value. For example, a `MONEY` column will display values formatted with the currency symbol. To match values in that column, the user must enter exactly the same value (i.e. with the currency symbol and the correct decimal separator). When using `COMBOBOX` fields, the find searches in the visible values of combobox items.

Only text widgets displaying values are searched. Columns using widgets such as images, radio-groups or checkboxes are not searched. The filter function ignores `PHANTOM` fields, hidden fields and fields defined with the `INVISIBLE` attribute.

Only rows in memory can be searched. When using page-mode (`ON FILL BUFFER`), the built-in filter is disabled. When implementing dynamic tree views, the built-in filter will only search the tree nodes available in the program array.

If the rows are filtered (i.e. some value is present in the search field), any non-rowbound action is disabled. On iOS, the action bar is replaced by the search bar.

The list filter is typically used on mobile devices for full-screen list views.

Figure 83: iOS list view with filter field

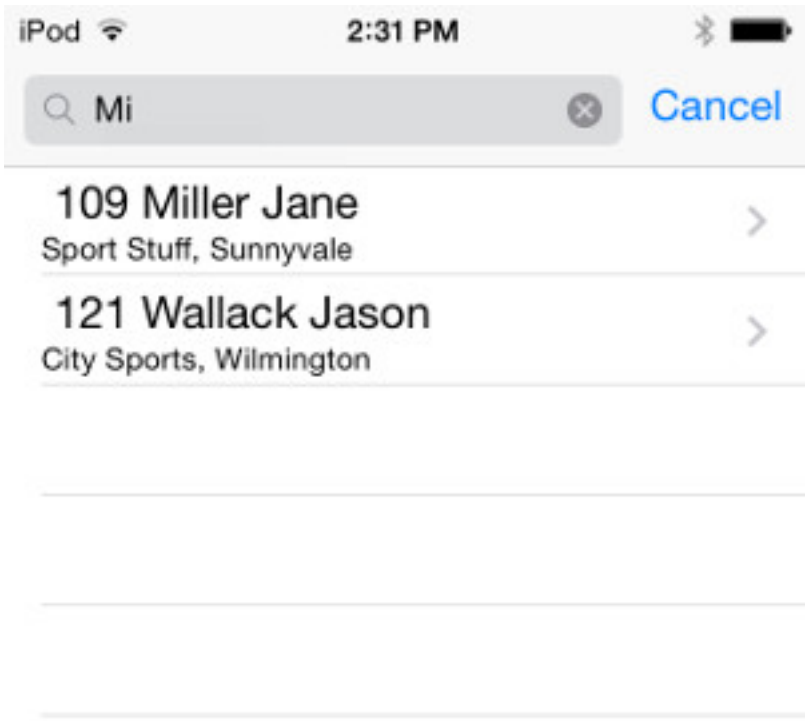


Figure 84: Android™ list view with filter field

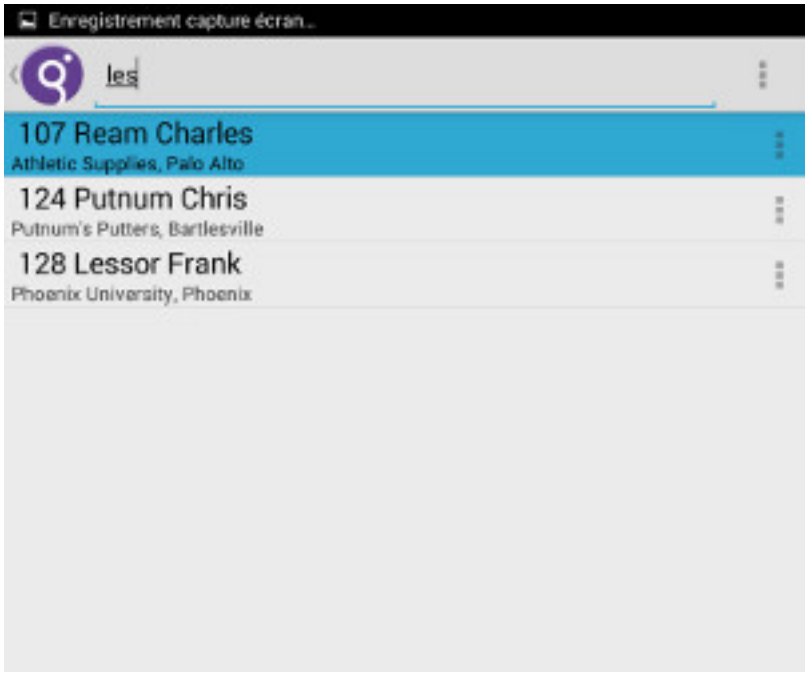


Summary lines in tables

Table views can display a summary line, to show aggregate values for columns.

To get a summary line in a table, define AGGREGATE fields at the bottom of the TABLE container, with the corresponding form item definition in the INSTRUCTION section.

> **Important:** This feature is not supported on mobile platforms.

Define the type of the aggregate field with the AGGREGATETYPE attribute: The aggregate value can be automatically computed, or set by program.

To get a global label for the summary line, specify the AGGREGATETEXT attribute at the TABLE level. This aggregate label will appear on the left in the summary line, if no aggregate text is defined at the aggregate field level.

To decorate the summary line, use presentation style attributes such as summaryLineAlwaysAtBottom.

The next example defines a "total" aggregate field for the third column of the table:

```
TABLE (AGGREGATETEXT="Total")
{
 [c1  |c2          |c3         ]
 [c1  |c2          |c3         ]
                   [total      ]
}
END
...
ATTRIBUTES
...
AGGREGATE total = FORMONLY.total, AGGREGATETYPE=PROGRAM;
...
```

For details, see AGGREGATE item definition on page 933.

Defining the action for a row choice

The row choice in the DISPLAY ARRAY dialog can be associated with a dedicated action.

When using a DISPLAY ARRAY dialog to control a table view with a graphical front-end, by default, a double-click on a row (for a desktop client), or a tap on a row (for mobile clients) has the following behavior:

- On a desktop front-end, by default, a mouse double-click changes the current row, and fires the "accept" action if available. If the default accept action is fired, the dialog will end, except if the accept action has been disabled or was over-written by a ON ACTION accept handler. This default behavior fits most of the record list of a desktop application, where the main purpose is to let the user choose a row from the list.
- On a mobile devices, by default, a tap on a row changes the current row only. This corresponds to a single mouse click on a desktop front-end, and therefore does not fire the "accept" action by default. If a tap must fire the accept action, define the DOUBLECLICK attribute.

In order to detect the physical event when the user chooses a row with a double-click on desktop clients and tap on mobile clients, define the DOUBLECLICK attribute of DISPLAY ARRAY dialogs to fire an action handler block (ON ACTION *double-click-action-name*):

```
DISPLAY ARRAY arr TO sr.*
        ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select)
   ON ACTION select
      MESSAGE "myselect:", arr_curr()
END DISPLAY
```

If the DOUBLECLICK attribute is defined, it will only configure the action for the double-click or tap physical event: By default, the accept action is still available, and the [Ok] button or the [Return] key will still fire

the accept action and leave the dialog. To avoid the default accept action, add ACCEPT=FALSE to the DISPLAY ARRAY attribute list:

```
DISPLAY ARRAY arr TO sr.*
        ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select, ACCEPT=FALSE)
   ON ACTION select
      MESSAGE "myselect:", arr_curr()
END DISPLAY
```

Note that if the selected row is not the current row, any defined AFTER ROW and BEFORE ROW control blocks execute before the ON ACTION block. The code blocks execute in the following order:

1. AFTER ROW (for the previous current row)
2. BEFORE ROW (for the new current row)
3. ON ACTION *double-click-action*

When defining a DOUBLECLICK action, you declare an explicit action view, and no default action view will be displayed for this action (except if you explicitely force it with DEFAULTVIEW=YES).

The double-click action can also be defined as TABLE/TREE attribute in form files. DOUBLECLICK in DISPLAY ARRAY attributes has a higher precedence as DOUBLECLICK in the form file. For more details, see DOUBLECLICK attribute on page 962.

Actions bound to the current row

Actions can be configured with the ROWBOUND attribute to depend from the current row.

When using a DISPLAY ARRAY or INPUT ARRAY dialog to control a table view, actions can get the ROWBOUND attribute in order to make the action only available when there is a current row in the list.

> **Important:** This feature is only for mobile platforms.

The ROWBOUND attribute must only be used with TABLE and TREE containers (it does not make sense for SCROLLGRID and static lists in GRID containers).

This attribute is generally used in mobile applications, when a list view requires actions to be decorated in a row-specific way. For example, on Android™ devices, the actions with the ROWBOUND attribute will be available by selecting the three-dot button on the right of each list view cell.

In the next example, the DISPLAY ARRAY dialog implements three actions:

- The "refresh" action is not "rowbound", and will always be available (i.e. active/visible), even if the list is empty.
- The "check" action is rowbound, and will only be available if there is a (current) row in the list.
- The "delete" action created by the ON DELETE modification trigger is implicitely "rowbounded".

```
DISPLAY ARRAY a_orders TO sr.* ATTRIBUTES(UNBUFFERED)
   ...
   ON ACTION refresh -- not rowbound
      CALL fetch_orders()
   ON ACTION check ATTRIBUTES(ROWBOUND)
      CALL check_order(arr_curr())
   ON DELETE -- implicitly rowbound
      CALL delete_order(arr_curr())
   ...
END DISPLAY
```

Using tables on mobile devices
Table views render in a specific way on mobile devices, in order to take advantage of mobile device ergonomics.
Unsupported table features
Some table / list view features are not supported on mobile devices.

The list view features not supported on mobile devices include:

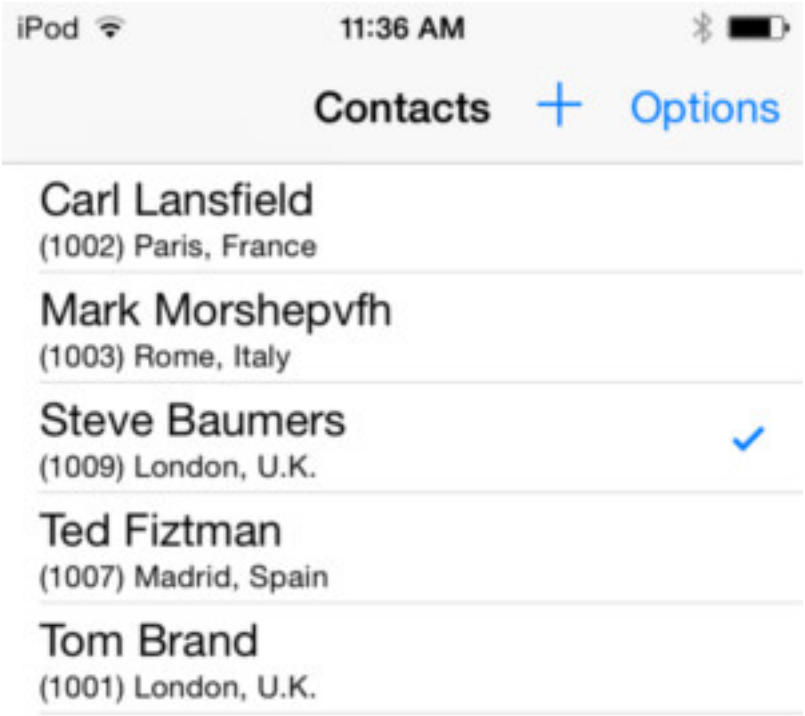
- Multiple row selection on page 1381
- Summary lines in tables on page 1360
- List ordering on page 1356
- Find function on page 1357
- Keyboard seek on page 1357
- Columns layout on page 1355
- Drag & drop on page 1411

Note also that there are no column headers/titles in mobile list views.

Two-column display
On mobile devices, a TABLE container displays as a list view with the first two columns' content.

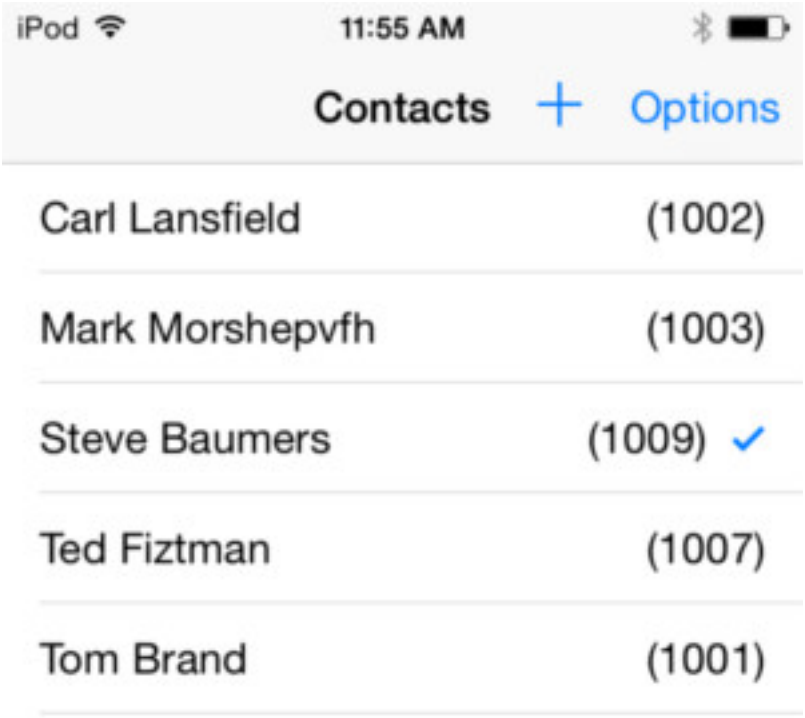
While a TABLE container and the corresponding list controller (DISPLAY ARRAY) can define multiple columns, only the first two columns are rendered on a mobile device. The first column defines the main information to be shown for the row (such as a customer name), while the second column contains additional information (such as a comment, date, address or phone number).

Figure 85: iOS list view with two-column default rendering



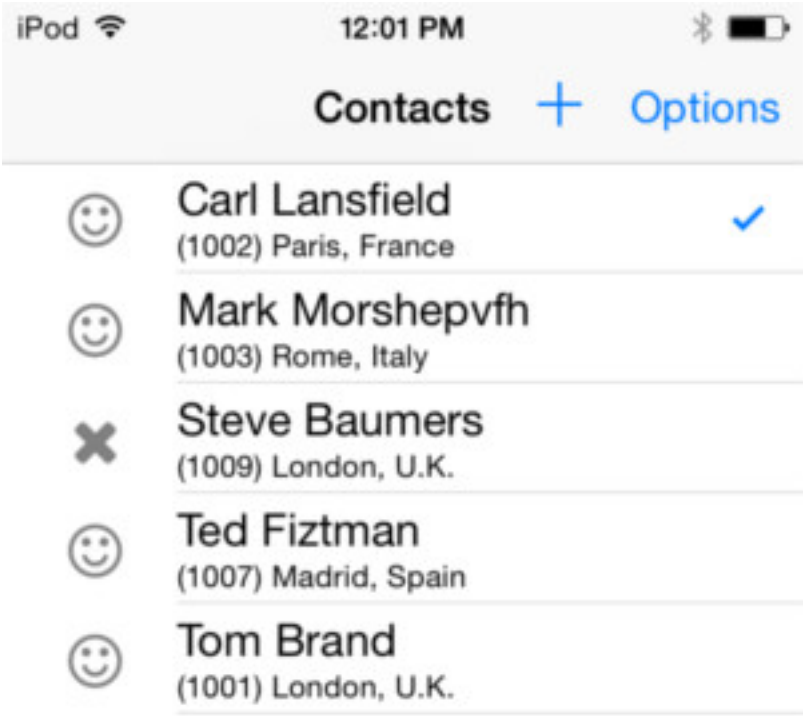
If the second column contains numeric data or has the `JUSTIFY=RIGHT` attribute, both columns display on a single line with the first column left-aligned and the second column right-aligned.

Figure 86: iOS list view with side-by-side rendering



A list view on a mobile device can include an image for each row. To display an image, associate a `PHANTOM` column to the `IMAGECOLUMN` attribute of the first column definition. For more details about images in lists, see Displaying column images on page 1354.

Figure 87: iOS list view with row images



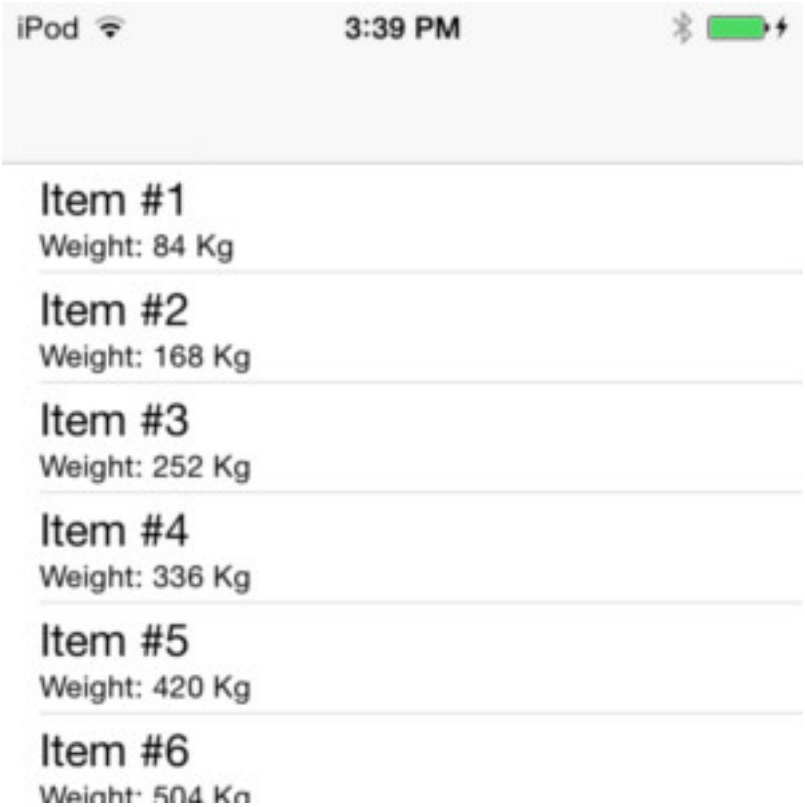
Full and Embedded list views
On mobile devices, table views are displayed as either full screen lists or embedded lists, according to the layout definition.

Full list view

A *full list view* displays when the table is the only element in a form.

```
LAYOUT
TABLE
{
[c1   |c2        ]
}
END
END
```

Figure 88: iOS full list view rendering



Embedded list view

An *embedded list view* displays when the table is mixed with other form elements. All rows of the table are shown. Scrolling is not possible.

> **Tip:** With an embedded list view, consider limiting the number of rows in the program array.

In this example, the table is inside a `GRID` container:

```
LAYOUT
GRID
{
<GROUP g1             >
 Id:   [f1           ]
 Name: [f2           ]
<                     >
<GROUP g2             >
 <TABLE t1          >
 [c1    |c2         ]
 [c1    |c2         ]
 [c1    |c2         ]
 <                  >
<                     >
}
END
END
```

Figure 89: iOS embedded list view rendering

The DOUBLECLICK (tap) action
On mobile devices, the `DOUBLECLICK` attribute defines the action to fire when a row is tapped.

By default, no action is fired on mobile devices when the user taps on a row. To fire a dedicated action, add the `DOUBLECLICK` attribute to the `DISPLAY ARRAY` dialog and define an `ON ACTION` action handler.

```
DISPLAY ARRAY arr TO sr.*
        ATTRIBUTES( DOUBLECLICK=row_select )
   ON ACTION row_select
      CALL process_row(arr_curr())
...
```

Alternatively, you can add a `DOUBLECLICK` attribute to your `TABLE` definition in your form file.

> **Tip:** We recommend you specify the `DOUBLECLICK` attribute with the `DISPLAY ARRAY` dialog, as it is strongly related to the `DISPLAY ARRAY` dialog.
>
> **Note:**
>
> - On Android™ devices, a long tap on a row only selects the row. The `DOUBLECLICK` action is not fired.
> - For iOS devices, consider using list view decoration options, as described in Row configuration on iOS devices on page 1369.

Rowbound actions

A rowbound action specifies an action to apply to the selected row. Rowbound actions get specific rendering and behavior on mobile devices.

Rowbound actions are action defined with the `ROWBOUND` action attribute in `ON ACTION` handlers. Rowbound actions can also be default actions that are implicitly related to the current row, such as the "delete" action.

```
DISPLAY ARRAY arr TO sr.*
   ...
   ON ACTION clear_list -- not rowbound
      ...
   ON ACTION copy_row ATTRIBUTES(ROWBOUND, TEXT="Copy row")
      ...
   ON ACTION check_row ATTRIBUTES(ROWBOUND, TEXT="Check row")
      ...
   ON DELETE -- implicitly rowbound
      ...
```

Genero Mobile for Android™ (GMA)

On Android 4 devices, when rowbound actions are defined, each row of a list view shows the three-dot indicator. Tap this icon to bring up a row context menu with options to execute the corresponding rowbound actions. Swipe the row from the right to the left to fire the delete action, it defined.

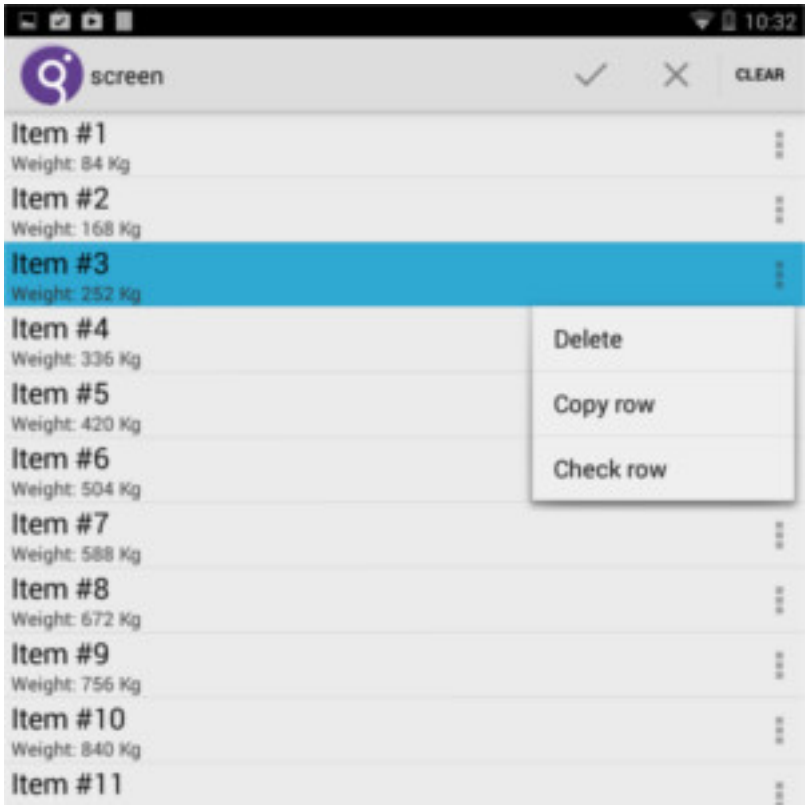


Figure 90: Android list view with rowbound actions

Genero Mobile for iOS (GMI)

On iOS 7 devices, when you swipe your finger from right to left, **More…** and/or **Delete** icons show up in the row. Tap **More...** to bring up a list of rowbound actions to execute. Tap **Delete** to fire the corresponding delete action code.

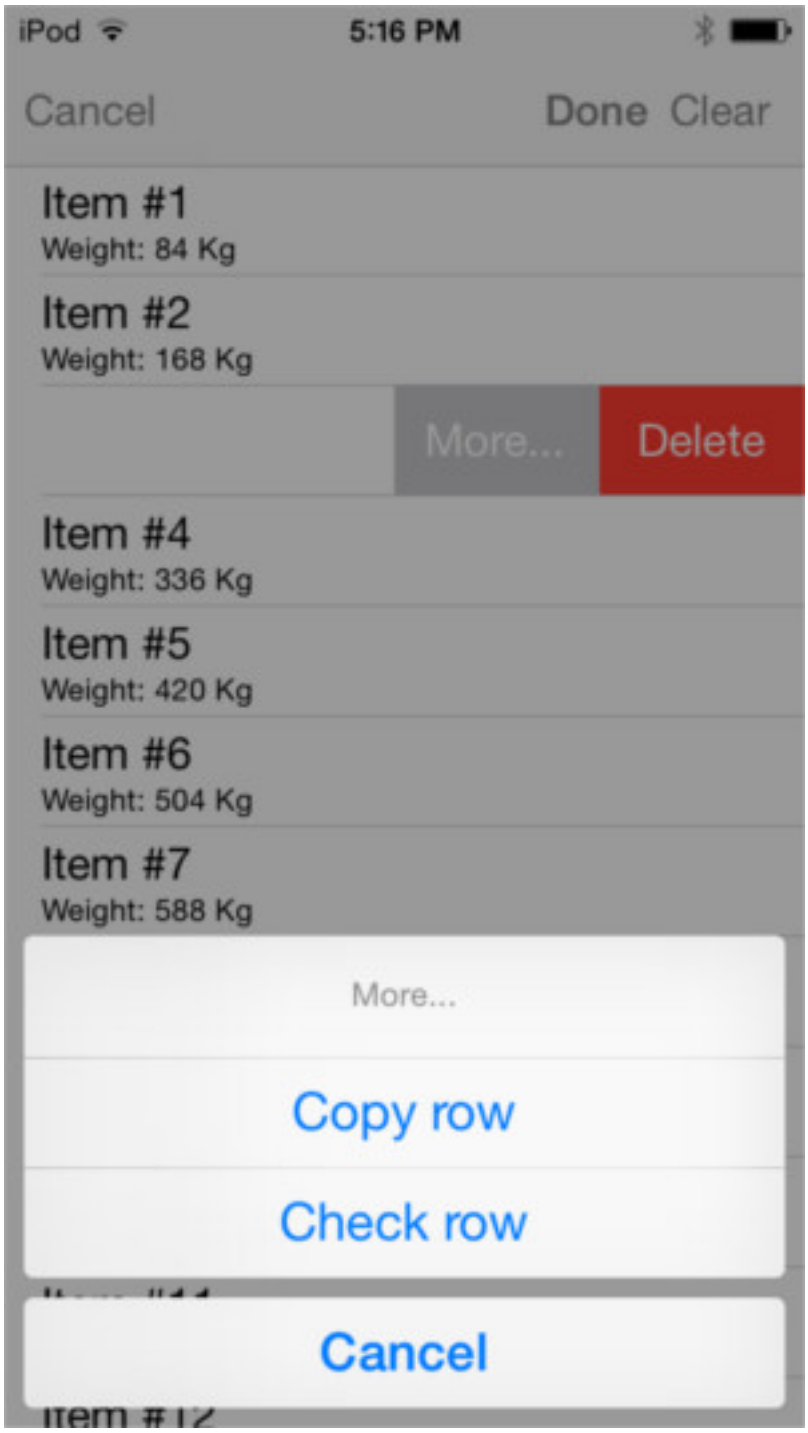

Figure 91: iOS list view with rowbound actions

Close, accept and cancel actions
The default rendering of the close, accept and cancel actions with a list view depends on the mobile device.

A `DISPLAY ARRAY` dialog implements the "close", "accept", and "cancel" actions by default. When using a full list view, these actions are default action views. The rendering of these actions vary according to the type of mobile device. The accept and cancel buttons typically show up on the top of the list view.

For more details, see Rendering default action views on mobile on page 1279.

Row configuration on iOS devices

On iOS devices, table views can be configured to use specific row decorations.

> **Note:** The features described in this topic are provided for iOS devices. The decoration attributes are ignored by Genero Mobile for Android™ (GMA)

The ACCESSORYTYPE attribute

On iOS devices, the `ACCESSORYTYPE` attribute used in the `DISPLAY ARRAY` dialog `ATTRIBUTES` clause defines the type of icon that appears at the right side of each row.

Possible values for the `ACCESSORYTYPE` attribute are:

- `CHECKMARK`
- `DETAILBUTTON`
- `DISCLOSUREINDICATOR`

For more details about the `ATTRIBUTES` syntax, see Syntax of DISPLAY ARRAY instruction on page 1076.

Checkmark

When using `ACCESSORYTYPE=CHECKMARK`, the current row gets a check mark icon on the right hand side.

This decoration is typically used to get a visual indicator for the current row, so the user knows what row will be selected when the `DISPLAY ARRAY` dialog is validated with an accept (Done) action:

```
DISPLAY ARRAY arr TO sr.*
      ATTRIBUTES( ACCESSORYTYPE=CHECKMARK )
    ...
```

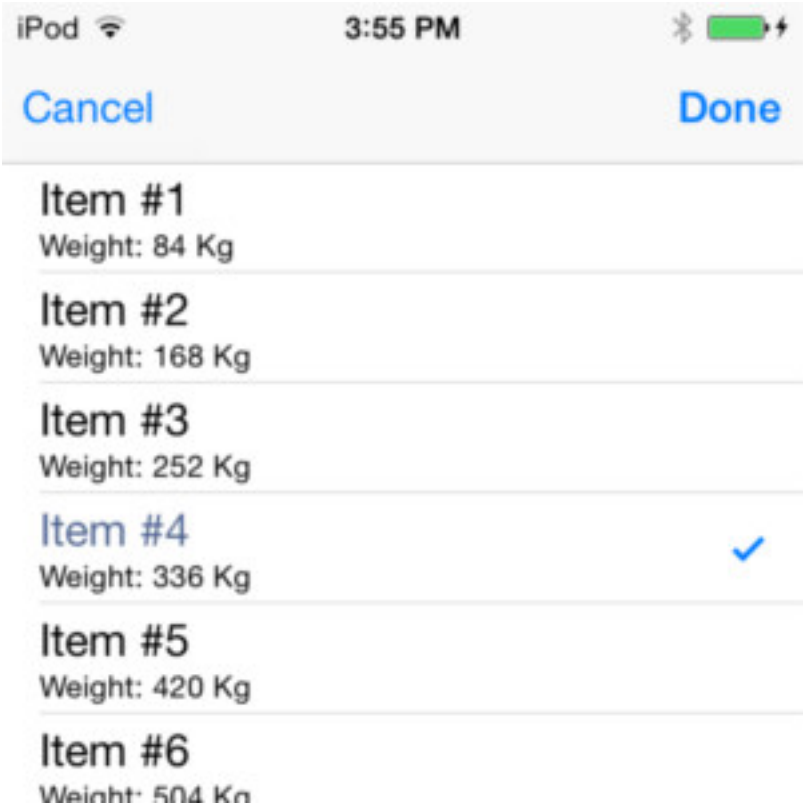

Figure 92: iOS list view with checkmark

To customize the application, define the color of the checkmark with the `iosTintColor` Window-class style attribute.

Detail button

When using `ACCESSORYTYPE=DETAILBUTTON`, each row gets a `(i)` icon on the right-hand side.

To specify what action must be fired when the user taps on the `(i)` icon, define the `DETAILACTION` in the `DISPLAY ARRAY` attributes, and its corresponding `ON ACTION` handler.

By opening a new window when in the detail action code, a tap on the icon shifts the current window from right to left, to show the new screen.

When tapping on another part of a row, by default, the row becomes then new current row. To follow typical iOS standards, you should also define a `DOUBLECLICK` with its corresponding `ON ACTION` handler, to handle current row selection with a dedicated action. If tapping on any part of a row should open a detail form, use the `DISCLOSUREINDICATOR` solution instead of `DETAILBUTTON`.

When selecting a different row, the `AFTER ROW` / `BEFORE ROW` control blocks are executed before the detail action or double-click action.

```
DISPLAY ARRAY arr TO sr.*
      ATTRIBUTES( ACCESSORYTYPE=DETAILBUTTON,
                  DETAILACTION=edit_details,
                  DOUBLECLICK=select_row )
   ...
   ON ACTION edit_details
      OPEN WINDOW w_details WITH FORM "details"
      INPUT BY NAME arr[i].*
        ...
      END INPUT
      CLOSE WINDOW w_details
   ON ACTION select_row
      ...
```

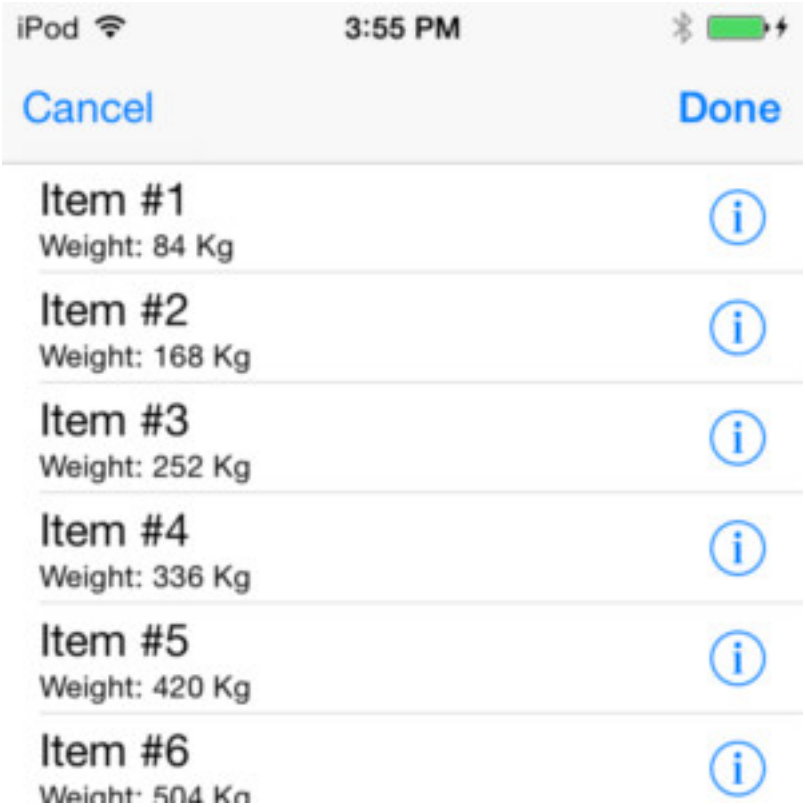

Figure 93: iOS list view with detail button

To customize the application, define the color of the disclosure indicator with the `iosTintColor` Window-class style attribute.

Disclosure indicator

When using `ACCESSORYTYPE=DISCLOSUREINDICATOR`, each row gets a > gray chevron at the right of each row. This decoration is typically used when tapping the button brings up a list of more choices related to the current row, or to open a detail form to modify the list element.

To execute code when a tapping on a row, define the `DOUBLECLICK` attribute and its corresponding `ON ACTION` handler.

By opening a new window when in the detail action code, a tap on a row shifts the current window from right to left, to show the new screen.

When selecting a different row, the `AFTER ROW` / `BEFORE ROW` control blocks are executed before the double-click action.

```
DISPLAY ARRAY arr TO sr.*
      ATTRIBUTES( ACCESSORYTYPE=DISCLOSUREINDICATOR,
                  DOUBLECLICK=row_select )
   ...
   ON ACTION row_select
      MENU "Options" ATTRIBUTES(STYLE="dialog")
         COMMAND "Refresh"
            ...
         COMMAND "Duplicate"
            ...
         COMMAND "Compress"
            ...
         COMMAND "Refresh"
            ...
```

```
        COMMAND "Synchronize"
           ...
     END MENU
...
```

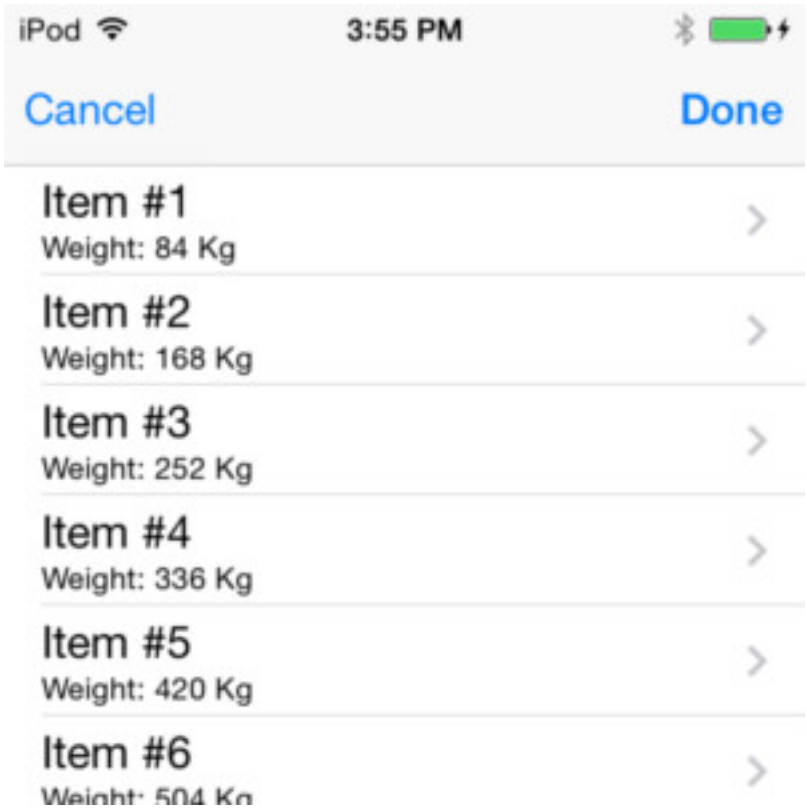

Figure 94: iOS list view with disclosure indicator

Populating a DISPLAY ARRAY
The program array must be filled with rows to populate the `DISPLAY ARRAY` dialog.

With `DISPLAY ARRAY`, either full list mode or paged mode is used to fill the form array. Consider using full list mode for short/medium result sets, and use paged mode for very large result sets.

Full list mode of DISPLAY ARRAY
In order to handle short/medium result sets, use the full list mode of `DISPLAY ARRAY`.

Understanding the full list mode

In *full list mode*, `DISPLAY ARRAY` uses a complete copy of the result set to be displayed in the form array. The full list mode is typically used for a short or medium row set (10 - 100 rows).

In full list mode, the `DISPLAY ARRAY` instruction uses a static or dynamic program array defined with a record structure corresponding to (or to a part of) a screen-array in the current form.

The program array is filled with data rows before `DISPLAY ARRAY` is executed, typically with a `FOREACH` loop when rows come from the database.

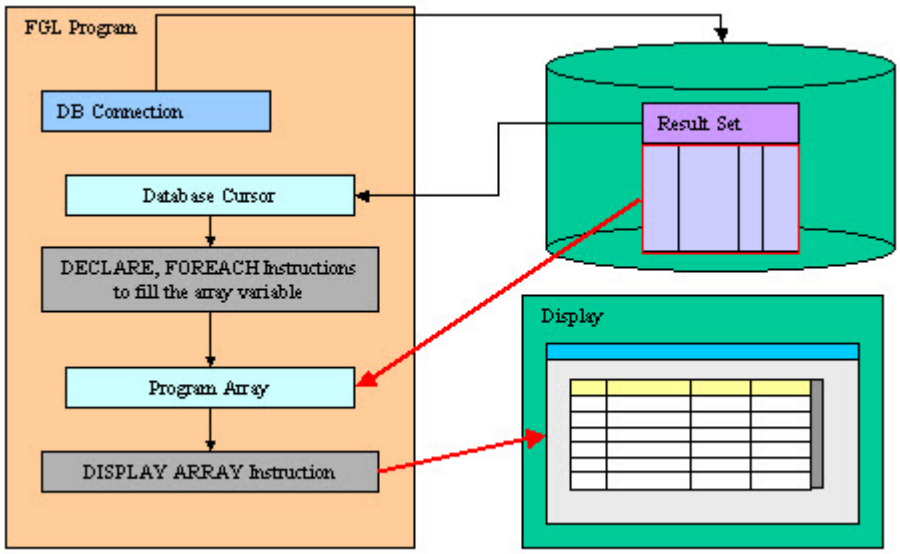

Figure 95: Full list mode in DISPLAY ARRAY diagram

Consider using a dynamic array instead of a static array: By using a dynamic array the program will only use the required memory resources, and the dialog will automatically detect the number of rows from the dynamic array (`array.getLength()`)

Full list mode example

The following example implements a `DISPLAY ARRAY` in its simpler form: A dynamic array is filled with database rows and contains the whole result set to be displayed in the table:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
             id INTEGER,
             fname CHAR(30),
             lname CHAR(30)
         END RECORD
  DEFINE i INTEGER

  DATABASE stores

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  DECLARE c1 CURSOR FOR
          SELECT customer_num, fname, lname FROM customer
  LET i=1
  FOREACH c1 INTO arr[i].*
      LET i = i+1
  END FOREACH
  CALL arr.deleteElement(i)

  DISPLAY ARRAY arr TO sa.* ATTRIBUTES(UNBUFFERED)
      BEFORE ROW
        MESSAGE "Moved to row ", arr_curr()
  END DISPLAY

END MAIN
```

Paged mode of DISPLAY ARRAY

In order to handle very large result sets, use the paged mode of DISPLAY ARRAY.

Understanding the paged mode

The *paged mode* of DISPLAY ARRAY allows the program to display a very large number of rows, without copying all database rows into the program array.

This mode uses the ON FILL BUFFER data block to let the program populate the array with the current visible page of rows. This is a subset of the database query result set (SELECT), typically controlled by a scrollable cursor.

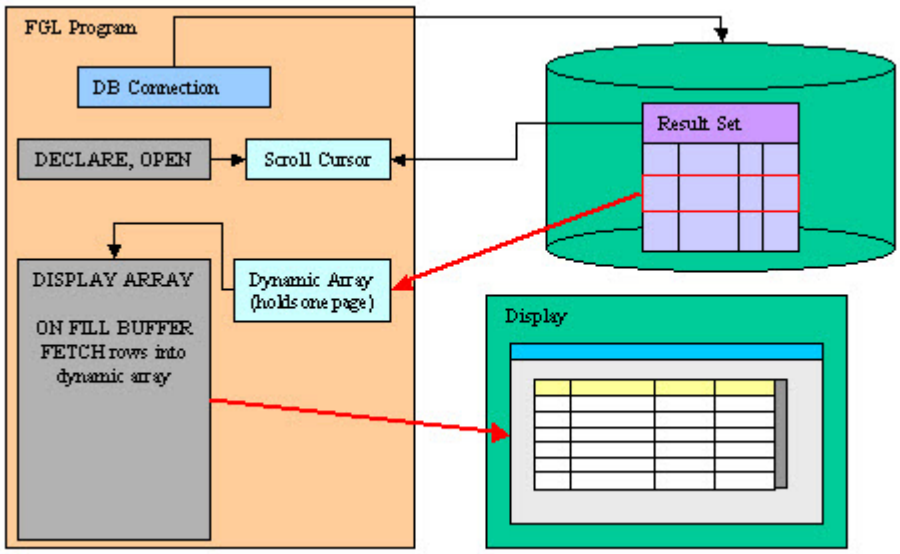

Figure 96: Paged mode diagram

> **Note:** DISPLAY ARRAY has following contraints when using the paged mode:
>
> - By default, row sorting is not allowed: Implement an ON SORT trigger to handle list sorting,
> - Multi-range selection is not supported, if the paged mode uses an undefined number of rows (COUNT=-1),
> - To fill a tree view dynamically, use the ON EXPAND / ON COLLAPSE data blocks.

Paged mode programming details

In paged mode, the dynamic array holds a page of rows, not all rows of the result set. The data rows are provided throught the ON FILL BUFFER block, by filling a dynamic array with the rows of the current page.

The ON FILL BUFFER clause is used to fill a page of rows in the dynamic array, according to a row offset and the number of rows required in the page. The row offset is defined by the FGL_DIALOG_GETBUFFERSTART() built-in function, and the number of rows to provide is defined by the FGL_DIALOG_GETBUFFERLENGTH() built-in function.

> **Note:** The ON FILL BUFFER is triggered when all the user code is executed and the dialog gets the control back, this means that the fill clause is not immediately fired when calling DIALOG.setArrayLength().

If known, specify the total number of rows with the COUNT attribute in the ATTRIBUTES clause of DISPLAY ARRAY. The total number of rows can be changed during dialog execution with the ui.Dialog.setArrayLength() method. In singular DISPLAY ARRAY instructions, you define the total number of rows of a paged mode with the SET_COUNT() built-in function or the COUNT attribute. But

these are only taken into account when the dialog starts. If the total number of rows changes during the execution of the dialog, the only way to specify the number of rows is `DIALOG.setArrayLength()`.

If the total number of rows is not known before starting the `DISPLAY ARRAY` dialog, set `COUNT=-1`. The dialog will then query for rows until the end of the result set is reached. The end of the result set is detect when the number of rows provided in `ON FILL BUFFER` are less then the number of rows asked by the dialog, or if you reset the total number of rows to a value higher value as -1 with the `ui.Dialog.setArrayLength()` method. Note that the dialog cannot support multi-row selection when the total number of rows is undefined.

It is not possible to use treeview decoration when the dialog uses the paged mode: For treeviews, the dialog needs the complete set of open nodes with parent/child relations to handle the tree view display. With the paged mode only a short window of the dataset is known by the dialog. If you use a tree view with a paged mode `DISPLAY ARRAY`, the program will raise an error at runtime.

A typical paged `DISPLAY ARRAY` implementation consists of a scroll cursor providing the list of records to be displayed. Scroll cursors use a static result set. If you want to display fresh data, you can implement an advanced paged mode by using a scroll cursor that provides the primary keys of the referenced result set, plus a prepared cursor to fetch rows on demand in the `ON FILL BUFFER` clause. In this case you may need to check whether a row still exists when fetching a record with the second cursor.

Paged mode basic example

The following example shows a `DISPLAY ARRAY` implementation using a scroll cursor to fill pages of records in `ON FILL BUFFER`, specifying an undefined number of rows (`COUNT=-1`).

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
             id INTEGER,
             fname CHAR(30),
             lname CHAR(30)
         END RECORD
  DEFINE cnt, ofs, len, row, i INTEGER

  DATABASE stores

  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1

  DECLARE c1 SCROLL CURSOR FOR
          SELECT customer_num, fname, lname FROM customer
  OPEN c1

  DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=-1)
    ON FILL BUFFER
       CALL arr.clear()
       LET ofs = fgl_dialog_getBufferStart()
       LET len = fgl_dialog_getBufferLength()
       LET row = ofs
       FOR i=1 TO len
          FETCH ABSOLUTE row c1 INTO arr[i].*
          IF SQLCA.SQLCODE!=0 THEN
            CALL DIALOG.setArrayLength("sa",row-1)
            EXIT FOR
          END IF
          LET row = row + 1
       END FOR
    ON ACTION ten_first_rows_only
       CALL DIALOG.setArrayLength("sa", 10)
  END DISPLAY

END MAIN
```

Paged mode with sorting feature

To implement row sorting in a `DISPLAY ARRAY` using paged mode, use the `ON SORT` trigger to detect a sort request, get the sort information with the ui.Dialog.getSortKey on page 1802 / ui.Dialog.getSortReverse on page 1802 methods, and re-execute the SQL query to sort rows accordingly with an `ORDER BY` clause. The `ON SORT` trigger will be fired before the `ON FILL BUFFER` trigger:

```
MAIN
  DATABASE test1
  OPEN FORM f1 FROM "custlist"
  DISPLAY FORM f1
  CALL show_list()
END MAIN

FUNCTION execute_sql(order_by)
  DEFINE order_by STRING
  DEFINE sql STRING
  IF order_by IS NULL THEN
     LET order_by = "ORDER BY fname"
  END IF
  LET sql = "SELECT customer_num, fname, lname FROM customer ", order_by
  DECLARE c1 SCROLL CURSOR FROM sql
  OPEN c1
END FUNCTION

FUNCTION show_list()
  DEFINE arr DYNAMIC ARRAY OF RECORD
             id INTEGER,
             fname VARCHAR(30),
             lname VARCHAR(30)
         END RECORD
  DEFINE cnt, ofs, len, row, i INTEGER,
         key STRING, rev BOOLEAN

  CALL execute_sql(NULL)
  DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=-1)
    ON SORT
       LET key = DIALOG.getSortKey("sa")
       LET rev = DIALOG.isSortReverse("sa")
       IF key IS NULL THEN
          CALL execute_sql( NULL )
       ELSE
          -- Assuming that form field names match table column names
          CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," ") )
       END IF
    ON FILL BUFFER
       CALL arr.clear()
       LET ofs = fgl_dialog_getBufferStart()
       LET len = fgl_dialog_getBufferLength()
       LET row = ofs
       FOR i=1 TO len
          FETCH ABSOLUTE row c1 INTO arr[i].*
          IF SQLCA.SQLCODE!=0 THEN
            CALL DIALOG.setArrayLength("sa",row-1)
            EXIT FOR
          END IF
          LET row = row + 1
       END FOR
  END DISPLAY

END FUNCTION
```

Note that with the above example, the current row remains at the same position: When the table is sorted, the set of rows provided in the `ON FILL BUFFER` may not include the database row that was the current row before the sort.

To track the current row, store the primary key value of the current row before re-executing the query. After query execution, scan the cursor result set and perform a `DIALOG.setCurrentRow()` when the primary key of the current row is found. The current row might be outside the row set provided in `ON FILL BUFFER`. In order to make setCurrentRow() work properly, you have to count the total number of rows before the `DISPLAY ARRAY`:

```
...
DEFINE cnt, ofs, len, row, i INTEGER,
       key STRING, rev BOOLEAN,
       row_count, curr_id, last_id INTEGER

...

SELECT COUNT(*) INTO row_count FROM customer

CALL execute_sql(NULL)
DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=row_count)
  ON SORT
     LET row = DIALOG.getCurrentRow("sa")
     FETCH ABSOLUTE row c1 INTO last_id
     LET key = DIALOG.getSortKey("sa")
     LET rev = DIALOG.isSortReverse("sa")
     IF key IS NULL THEN
        CALL execute_sql( NULL )
     ELSE
        -- Assuming that form field names match table column names
        CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," ") )
     END IF
     LET row=1
     WHILE TRUE
         FETCH c1 INTO curr_id
         IF SQLCA.SQLCODE==100 THEN
            ERROR "Last current row disappeared from result set!"
            EXIT PROGRAM 1
         END IF
         IF curr_id == last_id THEN
            CALL DIALOG.setCurrentRow("sa",row)
            EXIT WHILE
         END IF
         LET row = row+1
     END WHILE
  ON FILL BUFFER
     ...
```

INPUT ARRAY row modifications
Controlling row creation and deletion in an editable record list.

The `INPUT ARRAY` instruction handles record list edition. This controller allows the user to directly edit existing rows and to create or remove rows with implicit actions.

The following implicit actions are created by default by the `INPUT ARRAY` dialog:

- `insert`: creates a new row before the current row. If there are no rows in the list, the action adds a new row.
- `append`: creates a new row after the last row of the list.
- `delete`: deletes the current row.

To prevent INPUT ARRAY to create the implicit "insert", "append" and "delete" actions, set respectively the INSERT ROW, APPEND ROW, or DELETE ROW control attributes to FALSE. To fully deny row addition, set also the AUTO APPEND attribute to FALSE.

```
...
  INPUT ARRAY p_items FROM sa.*
    -- Allow only row append and delete implicit actions.
    ATTRIBUTES(AUTO APPEND=FALSE,
               INSERT ROW=FALSE)
      ...
  END INPUT
...
```

Specific control blocks are available to take control when a row is created or deleted:

- BEFORE INSERT and AFTER INSERT control blocks can be used to control row creation. Cancel a row creation with CANCEL INSERT in BEFORE INSERT or AFTER INSERT blocks.
- BEFORE DELETE and AFTER DELETE control blocks can be used to control row deletion. Cancel row deletion with the CANCEL DELETE instruction in BEFORE DELETE.

Dynamic arrays and the ui.Dialog class provide methods such as array.deleteElement() or ui.Dialog.appendRow() to modify the list. When using these methods, the predefined triggers such as BEFORE DELETE or BEFORE INSERT are not executed. While it is safe to use these methods within a DISPLAY ARRAY, you must take care when using an INPUT ARRAY. For example, you should not call such methods in triggers like BEFORE ROW, AFTER INSERT, BEFORE DELETE.

Users can append temporary rows by moving to the end of the list, or when executing the append action. Appending temporary rows is a different from inserting a row; an appended row is considered temporary until the user modifies a field while an inserted row remains in the list even if the user does not modify a field.

By default, when the last row is removed by a delete action, the INPUT ARRAY instruction will automatically create a new temporary row at the same position. The visual effect of this behavior can be misinterpreted - if no data was entered in the last row, you can't see any difference. However, the last row is really deleted and a new row is created, and the BEFORE DELETE / AFTER DELETE / AFTER ROW / BEFORE ROW / BEFORE INSERT control block sequence is executed. In order to deny to avoid the creation of a new temporary row when the last row is deleted, set AUTO APPEND = FALSE attribute.

The insert, append or delete actions will be automatically disabled according to the context: If the INPUT ARRAY is using a static array that becomes full, or if the MAXCOUNT attribute is reached, both insert and append actions will be disabled. The delete action is automatically disabled when AUTO APPEND = FALSE and there are no more rows in the array.

INPUT ARRAY temporary rows
Temporary rows can be created at the end of an editable record list.

In record list controlled by an INPUT ARRAY, the user can create a new *temporary row* at the end of the list: The new row is called "temporary" because it will be automatically removed if the user leaves the row without entering data. If data is entered by the user or by program (setting the touched flag), the temporary row becomes permanent.

A temporary row is promoted to a permanent row under certain conditions described in this topic. We distinguish also *explicit* temporary row creation from *automatic* temporary row creation.

Temporary row creation is different from adding new rows with the DIALOG.appendRow() method; When appending a row by program, the row is considered permanent and remains in the list even if the user did not enter data in fields.

Conditions to make a temporary row permanent

The temporary row is made permanent, when moving down to the next new temporary row, or if the modification flag of one of the fields is set. The modification flag of a field is typically set when the user enters data in the form field and tabs to another field (or validates the dialog), but this modification flag can also be set by program, with a `DISPLAY TO / BY NAME` instruction or with the `DIALOG.setFieldTouched()` method. When the modification is set by program, `NOENTRY` fields are ignored, however, fields dynamically disabled by `DIALOG.setFieldActive()` are taken into account.

Explicit temporary row creation

Explicit temporary row creation takes place when the user decided to append a new row explicitly with the append action. If the list is empty, an insert action will have the same effect as an append action (i.e. a temporary row will be created at position 1).

Automatic temporary row creation

By default, automatic temporary row creation takes place when:

- The user tries to move below the last row, with a Down keystroke or with the mouse.
- The user presses the Tab key when in the last field of the last row.
- The list has the focus and the last row of the list is deleted by an implicit delete action.
- The list has the focus and the last row of the list is deleted by program with `DIALOG.deleteRow()` or `DIALOG.deleteAllRows()`.
- When the `INPUT ARRAY` is in a `DIALOG` block, the list has no rows and gets the focus (A new temporary row is created to let the user enter data immediately)

Avoiding temporary row creation

Temporary row creation is useful because, in most cases, `INPUT ARRAY` is used to edit existing rows and append new rows at the end of the list. However, you might want to deny row addition or at least avoid the automatic temporary row creation when the last row is deleted or when an empty list gets the focus.

To avoid explicit temporary row creation, prevent `INPUT ARRAY` to defined the implicit append action by setting the `APPEND ROW` attribute to `FALSE` in the `ATTRIBUTE` clause:

```
...
   INPUT ARRAY p_items FROM sa.* ATTRIBUTES(APPEND ROW=FALSE)
   ...
   END INPUT
...
```

Even if `APPEND ROW` /`INSERT ROW` attributes are set to `FALSE`, automatic temporary row can still occur when the user deletes the last row of the list or if the list is empty when the `INPUT ARRAY` is entered. Without automatic temporary row creation, an `INPUT ARRAY` instruction would have no rows to edit if the array is empty. To avoid automatic temporary row creation is such cases, set the `AUTO APPEND` attribute to `FALSE`:

```
...
   INPUT ARRAY p_items FROM sa.* ATTRIBUTES(AUTO APPEND=FALSE)
   ...
   END INPUT
...
```

To fully deny row addition, set both `APPEND ROW` and `AUTO APPEND` to `FALSE`.

If both `APPEND ROW` and `INSERT ROW` attributes are set to `FALSE`, the dialog will deny explicit temporary row creation but also automatic temporary row creation, as if `AUTO APPEND = FALSE` would be used.

Row creation control blocks for temporary rows

In order to control row creation, use the `BEFORE INSERT` and `AFTER INSERT` control blocks. The `BEFORE INSERT` trigger is invoked after a new row was inserted or appended, just before the user gets control to enter data in fields. Regarding temporary rows, the `AFTER INSERT` block is invoked if data has been entered and you leave the new row (for example, when the focus moves to another row or leaves the current list), or if the dialog is validated, for example with `ACCEPT DIALOG` in case of `DIALOG` (or `ACCEPT INPUT` in case of singular `INPUT ARRAY`). No `AFTER INSERT` block is invoked if the user did not enter data: The temporary row is automatically deleted.

In the `BEFORE INSERT` control block, you can tell if a row is a temporary appended one by comparing the current row (`DIALOG.getCurrentRow()` or `ARR_CURR()`) with the total number of rows (`DIALOG.getArrayLength()` or `ARR_COUNT()`). If the current row index equals the row count, you are in a temporary row.

AFTER ROW and temporary rows

When a temporary row as automatically removed, the `AFTER ROW` block will be executed for the temporary row, but `ui.Dialog.getCurrentRow()` / `ARR_CURR()` will be one row greater than `DIALOG.getArrayLength()` / `ARR_COUNT()`. In this case, ignore the `AFTER ROW` event.

DISPLAY ARRAY modification triggers

Using dedicated interaction blocks to allow the user to modify a read-only record list.

The `DISPLAY ARRAY` block implements by default a read-only list of records. The end user can navigate in the list, but cannot modify the rows.

The traditional way to implement an editable list of record is to use `INPUT ARRAY`. However, `INPUT ARRAY` uses ergonomics that may not correspond to the end user expectations. Basically, a list controlled by an `INPUT ARRAY` is always in "edit mode": the focus is in a field and the user can modify the current field. When moving up or down in the list, the edit cursor jumps to the upper or lower cell.

Other GUI applications use a different pattern, with read-only lists that can switch to edit mode when a specific action is fired. To implement such ergonomics, use the `ON INSERT`, `ON APPEND`, `ON UPDATE`, `ON DELETE` modification triggers to control row insertion, appending, modification and deletion in a `DISPLAY ARRAY` block.

Cell color attributes

List controllers can display every cell in a specific color.

When using the `DISPLAY ARRAY` or `INPUT ARRAY`, you can assign specific colors to cells of a `TABLE` or `TREE` rows with the `DIALOG.setArrayAttributes()` or `DIALOG.setCellAttributes()` method.

Call the method in the dialog initialization clause, for example, in `BEFORE DISPLAY` for a singular `DISPLAY ARRAY` dialog.

The method takes an array as parameter. This array must have the same structure as the data array, but each element of the record must be a string. Attributes can be set for individual cells by using the TTY attributes (see method reference for possible values).

If cell attribute values are changed in during the dialog execution, use the `UNBUFFERED` mode to get automatic form synchronization. The unbuffered mode is not required if the cell attributes are defined before executing the dialog, and leave unchanged until the dialog ends.

Example

This is the `list.per` form file defining the table view:

```
LAYOUT
TABLE
{
[c1         |c2             ]
```

```
}
END
END
ATTRIBUTES
c1 = FORMONLY.key;
c2 = FORMONLY.name;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

This is the program code (main.4gl):

```
MAIN
    DEFINE arr DYNAMIC ARRAY OF RECORD
                key INTEGER,
                name VARCHAR(100)
            END RECORD
    DEFINE att DYNAMIC ARRAY OF RECORD
                key STRING,
                name STRING
            END RECORD
    DEFINE I INT

    FOR i=1 TO 10
        LET arr[i].key = i
        LET arr[i].name = "Item "||i
        LET att[i].key = "red reverse"
        LET att[i].name = IIF(i MOD 2,"blue","green")
    END FOR

    OPEN FORM f1 FROM "list"
    DISPLAY FORM f1

    DISPLAY ARRAY arr TO sr.* ATTRIBUTES(UNBUFFERED)
        BEFORE DISPLAY
           CALL DIALOG.setCellAttributes(att)
       ON ACTION att_modify_cell
         LET att[2].key = "red reverse"
       ON ACTION att_clear_cell
         LET att[2].key = NULL
    END DISPLAY

END MAIN
```

Multiple row selection

Multiple row selection allows the end user to select several rows in a list of records.

The `DISPLAY ARRAY` controller supports multiple row selection when the `ON SELECTION CHANGE` block is defined, or by enabling the feature with the `ui.Dialog.setSelectionMode()` method when the dialog starts. The `setSelectionMode()` method can also be used to enable or disable the multi-row selection during the dialog execution.

> **Important:** This feature is not supported on mobile platforms.

When multi-row selection is enabled, the end user can select one or several rows with the standard keyboard and mouse click combinations. When the end user selects or de-selects rows, the `ON SELECTION CHANGE` block is fired, if defined. The program can then query the `DIALOG.isRowSelected()` method to check for selected rows.

```
DISPLAY ARRAY arr TO sr.*
```

```
  ...
  ON SELECTION CHANGE
     FOR i=1 TO DIALOG.getArrayLength("sr")
         DISPLAY SFMT("Row: %1 s=%2", i, DIALOG.isRowSelected("sr", i) )
     END FOR
  ON ACTION enable_mrs
     CALL DIALOG.setSelectionMode( "sr", 1 )
  ON ACTION disable_mrs
     CALL DIALOG.setSelectionMode( "sr", 0 )
  ...
END DISPLAY
```

Multiple row selection is GUI-specific and therefore can't be used in TUI mode.

With multiple row selection, you must distinguish between two concepts: *row selection* and *current row*. In GUI mode, a selected row usually has a blue background, while the current row has a dotted focus rectangle. The current row may not be selected, or a selected row may not be the current row. When the default single-row selection is used, the current row is always selected automatically.

If the `ON SELECTION CHANGE` block is not required, use the `ui.Dialog.setSelectionMode()` method to enable multi-row selection for the dialog:

```
DISPLAY ARRAY arr TO sr.*
  BEFORE DISPLAY
     CALL DIALOG.setSelectionMode( "sr", 1 )
  ...
END DISPLAY
```

Note however that without the `ON SELECTION CHANGE` trigger, it is not possible to detect row selection change when staying on the current row, since no `BEFORE ROW` / `AFTER ROW` trigger is fired in this case.

Row selection flags can be changed by program for a range of rows with the `DIALOG.setSelectionRange()` method.

The `DISPLAY ARRAY` dialog implements an implicit row-copy feature: The selected rows can be dragged to another dialog or external program, or the end-user can do an "editcopy" predefined action (Ctrl-C shortcut), to copy the selected rows to the front-end clipboard. The row-copy feature works also when multiple row selection is disabled, but only the current row will be dragged or copied to the front-end clipboard.

If you delete, insert or append rows in the program array with methods such as `array.deleteElement()`, selection information is not synchronized: To sync the selection flags with the data rows, use dialog methods like `DIALOG.insertRow()` (or `DIALOG.insertNode()` for tree-views), .

Behavior of ui.Dialog class methods with multiple row selection

Table 291: Effect of ui.Dialog class on selection flags when multi-range selection is enabled

Dialog class method	Effect on multiple row selection
`appendRow()`	Selection flags of existing rows are unchanged. New row is appended at the end of the list with selection flag set to zero.
`appendNode()`	Selection flags of existing rows are unchanged. New node is appended at the end of the tree with selection flag set to zero.
`deleteAllRows()`	Selection flags of all rows are cleared.

Dialog class method	Effect on multiple row selection
deleteRow()	Selection flags of existing rows are unchanged. Selection information is synchronized (i.e., shifted up) for all rows after the deleted row.
deleteNode()	Selection flags of existing rows are unchanged. Selection information is synchronized (i.e., shifted up) for all nodes after the deleted node.
insertRow()	Selection flags of existing rows are unchanged. Selection information is synchronized (i.e., shifted down) for all rows after the new inserted row.
insertNode()	Selection flags of existing rows are unchanged. Selection information is synchronized (i.e., shifted down) for all nodes after the new inserted node.
setArrayLength()	Selection flags of existing rows are unchanged. If the new array length is larger than the previous length, selection flags of new rows are not initialized to zero.
setCurrentRow()	Selection flags of all rows are reset, and the new current row gets selected.
setSelectionMode()	When you switch off multiple row selection, the selection flags of existing rows are cleared.

Examples
Example 1: Simple list view

The form file `table.per` (grid-based layout):

```
LAYOUT
TABLE (DOUBLECLICK=myselect)
{
[c1         |c2             ]
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.key;
c1 = FORMONLY.name, IMAGECOLUMN=image;
PHANTOM FORMONLY.image;
c2 = FORMONLY.detail;
END
INSTRUCTIONS
SCREEN RECORD list1(FORMONLY.*);
END
```

The form file `table.per` (stack-based layout):

```
LAYOUT
STACK
 TABLE list1(DOUBLECLICK=myselect)
```

```
   PHANTOM FORMONLY.key;
   EDIT FORMONLY.name,
        IMAGECOLUMN=image, TITLE="Name";
   PHANTOM FORMONLY.image;
   EDIT FORMONLY.detail, TITLE="Detail";
 END
END
END
```

The program `main.4gl`:

```
MAIN
    DEFINE arr DYNAMIC ARRAY OF RECORD
                key INTEGER,
                name STRING,
                image STRING,
                detail STRING
            END RECORD,
            i INTEGER
    FOR i=1 TO 60
        LET arr[i].key = i
        LET arr[i].name = SFMT("Item %1", i)
        IF i MOD 2 THEN
           LET arr[i].image = "file"
        ELSE
           LET arr[i].image = "smiley"
        END IF
        LET arr[i].detail = SFMT("This is item %1", i)
    END FOR
    OPEN FORM f1 FROM "table"
    DISPLAY FORM f1
    DISPLAY ARRAY arr TO list1.* ATTRIBUTES(UNBUFFERED)
        ON ACTION myselect
           MESSAGE "myselect:", arr_curr()
    END DISPLAY
END MAIN
```

Tree views

Describes tree view programming in the language.

  - Example 2: Dynamic tree view (filled on demand) on page 1393

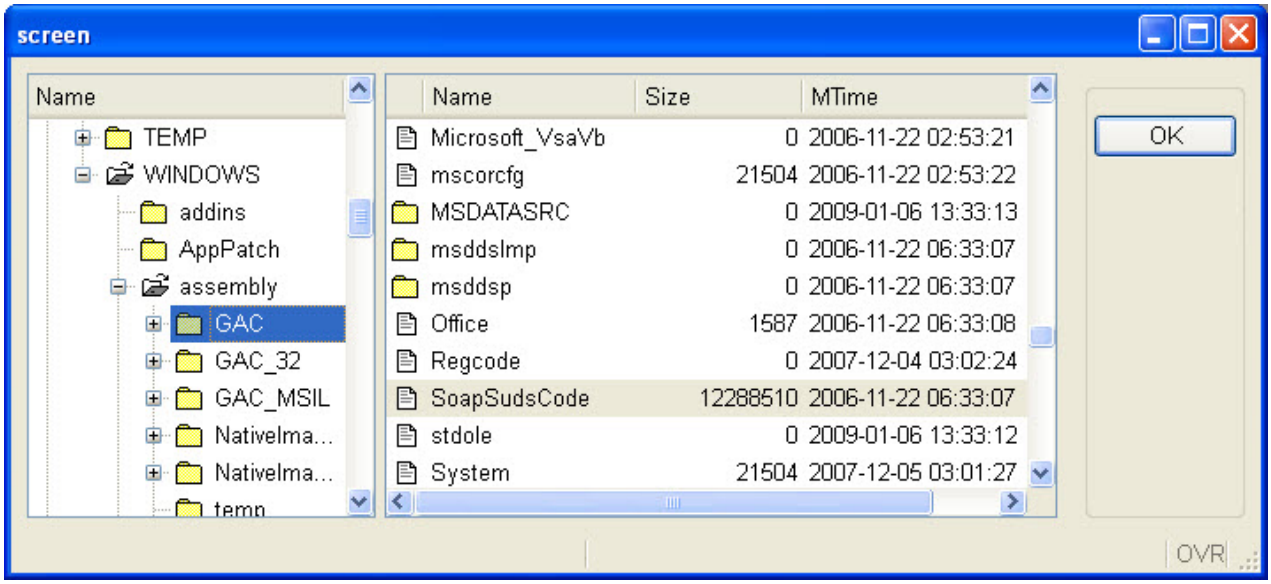
Understanding tree-views

Tree-views can be implemented with a `DISPLAY ARRAY` instruction using a form screen-array bound to a `TREE` container with tree-view specific attributes. `TREE` containers are very similar to `TABLE` containers, except that the first columns are used to display a tree of nodes on the right of the widget.

> **Important:** This feature is not supported on mobile platforms.

The next screen-shot shows a typical file browser using a tree-view. This example implements a `DIALOG` instruction with two `DISPLAY ARRAY` sub-dialogs. The first `DISPLAY ARRAY` sub-dialog controls the tree-view while the second one controls the file list on the right side.

Figure 97: Form with Tree View



The data used to display tree-view nodes must be provided in a program array and controlled by a `DISPLAY ARRAY`. It is possible to control a tree view table with a singular `DISPLAY ARRAY` or with a `DISPLAY ARRAY` sub-dialog within a `DIALOG` instruction.

A tree view model is implemented with a flat program array (i.e. a list of rows), where each row defines parent/child node identifiers to describe the structure of the tree; so, the order of the rows matters:

```
Tree structure          parent-id        child-id
Node 1                  NULL              1
     Node 1.1            1                1.1
     Node 1.2            1                1.2
         Node 1.2.1      1.2              1.2.1
         Node 1.2.2      1.2              1.2.2
         Node 1.2.3      1.2              1.2.3
     Node 1.3            1                1.3
         Node 1.3.1      1.3              1.3.1
  ...                    ...              ....
```

Depending on your need, you can fill the program array with all rows of the tree before dialog execution, or you can fill or reduce the list of nodes dynamically upon expand / collapse action events. In the second case, you must provide additional information for each row of the program array, to indicate whether the node has children. A dynamic build of the tree view allows you to implement programs displaying very large trees, for example in a bill of materials application, where thousands of elements can be assembled together.

Tree-views can display additional columns for each node, to show specific row data as in a regular table.

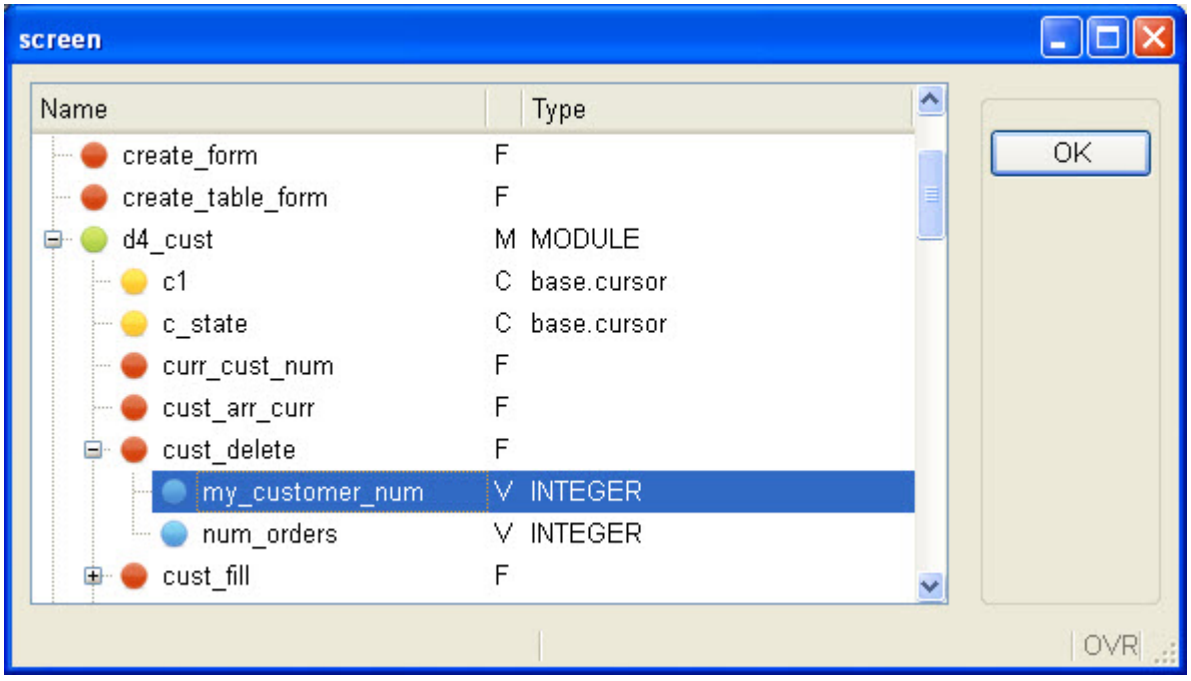


Figure 98: Tree-view with additional columns

Defining a TREE container

Create a form specification file containing a TREE container bound to a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the tree-view and the additional columns.

A TREE container must be present in the LAYOUT section of the form, defining the columns of the tree-view list. The TREE container must hold at least one column defining the node texts (or names). This column will be used on the front-end side to display the tree-view widget. Additional columns can be added in the TREE container to display node information. The TREE container attributes must be declared in the ATTRIBUTES section of the form.

Secondary form fields have to be used to hold tree node information such as icon image, parent node id, current node id, expanded flag and parent flag. While these secondary fields can be defined as regular form fields and displayed in the tree-view list, we recommend that you use PHANTOM fields instead: Phantom fields can be listed in the screen-array but do not need to be part of the LAYOUT section. Phantom fields will only be used by the runtime system to build the tree of nodes.

Example of tree-view definition using a TREE container:

```
LAYOUT
TREE mytree ( PARENTIDCOLUMN=parentid, IDCOLUMN=id,
              EXPANDEDCOLUMN=expanded, ISNODECOLUMN=isnode )
{
 Tree
[name                       |desc     ]
[name                       |desc     ]
[name                       |desc     ]
[name                       |desc     ]
[name                       |desc     ]
}
END
END
ATTRIBUTES
EDIT name = FORMONLY.name, IMAGECOLUMN=image;
```

```
PHANTOM FORMONLY.image;
PHANTOM FORMONLY.parentid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.expanded;
PHANTOM FORMONLY.isnode;
EDIT desc = FORMONLY.description;
END
INSTRUCTIONS
SCREEN RECORD sr( FORMONLY.* );
END
```

Example of tree-view definition using the <Tree> layout tag inside a `GRID` container, with a `TREE` form element to define attributes in the `ATTRIBUTES` section:

```
LAYOUT
GRID
{
<Tree tv                            >
 Tree
[name                      |desc     ]
[name                      |desc     ]
[name                      |desc     ]
[name                      |desc     ]
[name                      |desc     ]
<                                   >
}
END
END
ATTRIBUTES
TREE tv: mytree,
     PARENTIDCOLUMN=parentid, IDCOLUMN=id,
     EXPANDEDCOLUMN=expanded, ISNODECOLUMN=isnode;
EDIT name = FORMONLY.name, IMAGECOLUMN=image;
PHANTOM FORMONLY.image;
PHANTOM FORMONLY.parentid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.expanded;
PHANTOM FORMONLY.isnode;
EDIT desc = FORMONLY.description;
END
INSTRUCTIONS
SCREEN RECORD sr( FORMONLY.* );
END
```

The first visual column ("name" in example) must be the field defining the node names, and the widget must be an `EDIT` or `LABEL`.

Several attributes are used to configure a `TREE` form element:

- The `PARENTIDCOLUMN` and `IDCOLUMN` attributes are respectively used to identify the form field containing the identifiers of the parent and child nodes, defining the structure of the tree. You must specify form field column names, not item tag identifiers (used to reference a form item in the layout section). If these attributes are not specified, the parent node id and node id field names default respectively to "*parentid*" and "*id*".
- The `EXPANDEDCOLUMN` attribute can be used to define the form field holding the flag indicating that a node is expanded (i.e. opened).
- If the `ISNODECOLUMN` attribute is used, it defines the form field indicating that a node has children, even if the program array does not contain child nodes for that parent node. This attribute must be used to implement dynamic filling of tree-views.

- The IMAGEEXPANDED, IMAGECOLLAPSED and the IMAGELEAF attributes are optional attributes defining global images for expanded, collapsed and leaf nodes. You should use these attributes if you want to display the same icons for all nodes.
- The IMAGEEXPANDED and IMAGECOLLAPSED instruct the runtime system to set a specific icon when a node gets expanded or collapsed. The IMAGELEAF attribute defines the global icon for leaf nodes. This saves the programmer from writing code to display common node images.

Tree-view definition must be completed with form fields declaration. These must be defined in the ATTRIBUTES section. The fields not used for display are declared as PHANTOM fields. The tree-view form fields must be grouped in a screen-array declared in the INSTRUCTIONS section.

The form fields required to declare a tree-view table are the following.

Table 292: Form fields required to declare a tree-view table

Description	Field type	Tree attribute to define the field	Mandatory	Default name
Text to be displayed for the node	EDIT	N/A	yes	N/A
Id of the node	PHANTOM	IDCOLUMN	yes	id
Id of the parent node	PHANTOM	PARENTIDCOLUMN	yes	parentid
Icon image for a node	PHANTOM	IMAGECOLUMN	no	N/A
Node expansion indicator	PHANTOM	EXPANDEDCOLUMN	no	no
Parent node indicator	PHANTOM	ISNODECOLUMN	no	no

The first three fields (node text, parent id and node id) are mandatory, and that the first visual (non-phantom) field listed in the screen array will be implicitly used to hold the text of tree-view nodes.

Additional fields (like the *desc* field in this example) can be defined to display details for each node in regular columns, that will appear on the right of the tree widget.

The order of the fields in the screen array of the tree-view does not matter, but it must of course match the order of the corresponding variables in the record-array of the program.

If you need to display node-specific images, define a phantom field to hold node images and attach it to the tree-view definition by using the IMAGECOLUMN attribute. Alternatively you can globally define images for all nodes with the IMAGEEXPANDED, IMAGECOLLAPSED and the IMAGELEAF attributes of the TREE form element.

Defining the program array for tree-views

In the program code, define a dynamic array of records with the DEFINE instruction. The DISPLAY ARRAY dialog will use that program array as the model for the tree-view list. A tree of nodes will be automatically built according to the data found in the program array. The front-end can then render the tree of nodes in a tree-view widget.

The members of the program array must correspond to the elements of the screen-array bound to the TREE container, by number and data types.

The name of the array members does not matter; the purpose of each member is defined by the name of the corresponding screen-array members declared in the form file. Program array members and screen-array members are bound by position.

The next code example defines a program array with a member structure corresponding to the screen-array defined in the form example of the previous section.

```
DEFINE tree_arr DYNAMIC ARRAY OF RECORD
       name STRING,       -- text to be displayed for the node
       pid STRING,        -- id of the parent node
       id STRING,         -- id of the current node
       image STRING,      -- name of the image file for the node (can be
 null)
       expanded BOOLEAN,  -- node expansion flag (TRUE/FALSE) (optional)
       isnode BOOLEAN,    -- children indicator flag (TRUE/FALSE) (optional)
       description STRING -- user field describing the node
END RECORD
```

The *name*, *pid*, *id* members are mandatory. These hold respectively the node text, parent and current node identifiers that define the structure of the tree.

The *image* member will hold the name of the little icon to be displayed for each node and leaf. You can omit this member, if you do not want to display images, or when then tree defines default images with the `IMAGEEXPANDED`, `IMAGECOLLAPSED` and the `IMAGELEAF` attributes.

The *expanded* member can be used to handle node expansion by program. You can query this member to check whether a node is expanded, or set the value to expand a specific node.

The *isnode* member can be used to indicate whether a given node has children, without filling the array with rows defining the child nodes. This information will be used by front-ends to decorate a node as a parent, even if no children are present. The program should then fill the array with child nodes when an expand action is invoked, to implement dynamic tree-views).

The program array can hold more columns (like the *description* field), which can be displayed in regular table columns as part of a node's data.

Remember the order of the program array members must match the screen-array members in the form file, but this order can be different from the column order used in the layout, with the exception of the first column defining the text of nodes (i.e. *name* field in example).

Filling the program array with rows

Once the program array is defined according to the screen-array of the tree-view table, fill the array with the tree-view definition.

You can directly fill the program array before the dialog execution. Once the dialog has started, you must use the methods `DIALOG.insertNode()`, `DIALOG.appendNode()` and `DIALOG.deleteNode()`, if you want to modify the tree, otherwise information like multi-range selection flags and cell attributes will not be synchronized.

Fill the rows in the correct order defining the structure of the tree, to reflect the parent/child relationship of the tree nodes. If a row defines a tree-view node with a parent identifier that does not exist, or if the child row is inserted under the wrong parent row, the orphan row will become a new node at the root of the tree.

In order to fill the program array with database rows defining the tree structure, you will need to write a recursive function, keeping track of the current level of the nodes to be created for a given parent.

The next example shows how to fill the array with data coming from a database table having the following structure:

```
CREATE TABLE dbtree (
     id SERIAL NOT NULL,
     parentid INTEGER NOT NULL,
     name VARCHAR(20) NOT NULL
   )
```

The difficulty with fetching a tree from a database table is in the cursor management, which can not be used recursively. A workaround for this problem is to fetch all the children of a given node at once, then call the function recursively for each of the fetched nodes:

```
TYPE tree_t RECORD
       id INTEGER,
       parentid INTEGER,
       name VARCHAR(20)
    END RECORD

DEFINE tree_arr tree_t

FUNCTION fetch_tree(pid)
    DEFINE pid, i, j, n INTEGER
    DEFINE a DYNAMIC ARRAY OF tree_t
    DEFINE t tree_t

    DECLARE cu1 CURSOR FOR SELECT * FROM dbtree WHERE parentid = pid
    LET n = 0
    FOREACH cu1 INTO t.*
       LET n = n + 1
       LET a[n].* = t.*
    END FOREACH

    FOR i = 1 TO n
        LET j = tree_arr.getLength() + 1
        LET tree_arr[j].name = a[i].name
        LET tree_arr[j].id = a[i].id
        LET tree_arr[j].parentid = a[i].parentid
        CALL fetch_tree(a[i].id)
    END FOR

END FUNCTION
```

Controlling a tree-view with DISPLAY ARRAY

After the program array has been filled, you must execute a `DISPLAY ARRAY` dialog.

The next code example implements a `DISPLAY ARRAY` binding the program array called *tree_arr* to the *sr* screen-array, attaching the dialog to the tree table defined in the form:

```
CALL fill_tree(tree_arr)
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  BEFORE ROW
    DISPLAY "Current row is: ", DIALOG.getCurrentRow("sr")
END DISPLAY
```

It is not possible to use the `DISPLAY ARRAY` paged mode (`ON FILL BUFFER`) when the decoration is a tree view list. The dialog needs the complete set of open nodes with parent/child relation to handle the tree view display, with the paged mode only a given window of the dataset is known by the dialog. If you use a the paged mode in `DISPLAY ARRAY` with a tree view as decoration, the program will raise an error at runtime.

However, tree-views can be filled dynamically with `ON EXPAND` / `ON COLLAPSE` triggers.

Modifying the tree during dialog execution

During the `DISPLAY ARRAY` execution, it is possible to modify the content of the tree model (i.e. the program array), by inserting, adding or removing nodes by program. However, you should not directly modify the program array: You must use the dialog class methods `DIALOG.insertNode()`, `DIALOG.appendNode()` and `DIALOG.deleteNode()` to modify the tree model. By using these methods, the dialog can synchronize internal data, otherwise the tree display would be corrupted.

It is recommended to be in UNBUFFERED mode to get a front-end synchronization of the tree-view content.

Using regular DISPLAY ARRAY control blocks

If needed, you can implement traditional DISPLAY ARRAY control blocks like BEFORE ROW or AFTER ROW:

```
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  BEFORE ROW
    DISPLAY "BEFORE ROW - Current row is: ", DIALOG.getCurrentRow("sr")
  AFTER ROW
    DISPLAY "AFTER ROW  - Current row is: ", DIALOG.getCurrentRow("sr")
END DISPLAY
```

Dynamic filling of very large trees

When a huge tree needs to be displayed, tree data filling can be optimized by creating the nodes on demand. There is no need to fill the complete program array with all possible nodes (down to the last leaf), when only the first levels/branches of the tree are displayed on the screen.

To implement a dynamically filled tree, first define an additional column in the TREE container, to indicate whether a given node has children. That field will be used to render a node with a [+] button, and let the end user click on the node to expand it, even if no child nodes are created yet.

In the DISPLAY ARRAY code, if a node is expanded (or collapsed), the dialog will invoke the ON EXPAND or ON COLLAPSE triggers, to let the program add (or remove) rows in the array, to adapt the tree data dynamically according to navigation events.

```
DEFINE row_index INTEGER
...
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  ON EXPAND (row_index)
    DISPLAY "EXPAND   - Expanded row is: ", row_index
    -- Fill with children nodes for tree_arr[row_index]
  ON COLLAPSE (row_index)
    DISPLAY "COLLAPSE - Collapsed row is: ", row_index
    -- Remove children nodes of tree_arr[row_index]
END DISPLAY
```

The program array can be filled directly before the dialog execution, but once the dialog has started, use dialog methods such as DIALOG.insertNode() to modify the tree, otherwise information like multi-range selection flags and cell attributes will not be synchronized. This is typically the case when implementing a dynamically-filled tree with ON EXPAND/ ON COLLAPSE triggers.

Built-in sort and tree-views

By default, the built-in sort is enabled in a TREE container; when the end user clicks on column headers, the runtime system sorts the visual representation of the program array. Tree nodes are ordered by levels; the children nodes are ordered inside a given parent node.

This is a powerful built-in feature. However, in some cases, the tree structure must be static (i.e. the order of the nodes must not change) and you don't want the end user to sort the rows. To prevent the built-in sort, use the UNSORTABLECOLUMNS attribute for the TREE container definition:

```
LAYOUT
...
END
ATTRIBUTES
TREE tv: mytree, UNSORTABLECOLUMNS, ...
...
```

Multi-row selection and tree-views

Multi-row selection can be used with a `DISPLAY ARRAY` controlling a `TREE` container. However, because of the tree-view ergonomic differences with simple tables, the selection of tree nodes follows some specific rules:

1. When selecting a range of nodes, only visible nodes will get the selection flag. For example, if you select all nodes with Ctrl-A, and if the root node is collapsed, only the root node will be selected. This applies also when selecting nodes by program with the `DIALOG.setSelectionRange()`.
2. Collapsing a node will de-select all child nodes.

Drag and drop in tree-views

Drag and drop can be implemented within a `DISPLAY ARRAY` controlling a `TREE` container, with the `ON DRAG*` and `ON DROP` interactive blocks.

The nodes can be moved around in the same tree, can be dropped outside the tree or can be inserted in the tree from external sources.

Examples

Example 1: Static tree view (filled before dialog starts)

Form file "form1.per":

```
LAYOUT
GRID
{
<Tree t1                        >
 Name                    Index
[c1                      |c2    ]
[c1                      |c2    ]
[c1                      |c2    ]
[c1                      |c2    ]
}
END
END

ATTRIBUTES
LABEL c1 = FORMONLY.name;
LABEL c2 = FORMONLY.idx;
PHANTOM FORMONLY.pid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.exp;
TREE t1: tree1
    IMAGEEXPANDED  = "open",
    IMAGECOLLAPSED = "folder",
    IMAGELEAF = "file",
    PARENTIDCOLUMN = pid,
    IDCOLUMN = id,
    EXPANDEDCOLUMN = exp;
END

INSTRUCTIONS
SCREEN RECORD sr_tree(name, pid, id, idx, exp);
END
```

Static tree `DISPLAY ARRAY`:

```
DEFINE tree DYNAMIC ARRAY OF RECORD
    name STRING,
    pid STRING,
    id STRING,
    idx INTEGER,
```

```
    expanded BOOLEAN
END RECORD

MAIN
    OPEN FORM f FROM "form1"
    DISPLAY FORM f
    CALL fill(4)
    DISPLAY ARRAY tree TO sr_tree.* ATTRIBUTES(UNBUFFERED)
    BEFORE ROW
        DISPLAY "Current row: ", arr_curr()
    END DISPLAY
END MAIN

FUNCTION fill(max_level)
    DEFINE max_level, p INTEGER
    CALL tree.clear()
    LET p = fill_tree(max_level, 1, 0, NULL)
END FUNCTION

FUNCTION fill_tree(max_level, level, p, pid)
    DEFINE max_level, level INTEGER
    DEFINE p INTEGER
    DEFINE i INTEGER
    DEFINE id, pid STRING
    DEFINE name STRING
    IF level < max_level THEN
        LET name = "Node "
    ELSE
        LET name = "Leaf "
    END IF
    FOR i = 1 TO level
        LET p = p + 1
        IF pid IS NULL THEN
            LET id = i
        ELSE
            LET id = pid || "." || i
        END IF
        LET tree[p].id = id
        LET tree[p].pid = pid
        LET tree[p].idx = p
        LET tree[p].expanded = FALSE
        LET tree[p].name = name || level || '.' || i
        IF level < max_level THEN
            LET p = fill_tree(max_level, level + 1, p, id)
        END IF
    END FOR
    RETURN p
END FUNCTION
```

Example 2: Dynamic tree view (filled on demand)

Form file "form1.per":

```
LAYOUT
GRID
{
<Tree t1                        >
 Name             Description
[c1              |c2           ]
[c1              |c2           ]
[c1              |c2           ]
[c1              |c2           ]
}
```

```
END
END

ATTRIBUTES
LABEL c1 = FORMONLY.name;
PHANTOM FORMONLY.pid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.hasChildren;
LABEL c2 = FORMONLY.descr;
TREE t1: tree1
    IMAGEEXPANDED  = "open",
    IMAGECOLLAPSED = "folder",
    IMAGELEAF = "file",
    PARENTIDCOLUMN = pid,
    IDCOLUMN = id,
    ISNODECOLUMN = hasChildren;
END

INSTRUCTIONS
SCREEN RECORD sr_tree(FORMONLY.*);
END
```

Dynamic tree `DISPLAY ARRAY`:

```
DEFINE tree DYNAMIC ARRAY OF RECORD
    name STRING,
    pid STRING,
    id STRING,
    hasChildren BOOLEAN,
    description STRING
END RECORD

MAIN
    DEFINE id INTEGER

    OPEN FORM f FROM "form1"
    DISPLAY FORM f

    LET tree[1].pid = 0
    LET tree[1].id = 1
    LET tree[1].name = "Root"
    LET tree[1].hasChildren = TRUE
    DISPLAY ARRAY tree TO sr_tree.* ATTRIBUTES(UNBUFFERED)
    BEFORE DISPLAY
        CALL DIALOG.setSelectionMode("sr_tree",1)
    ON EXPAND(id)
        CALL expand(DIALOG,id)
    ON COLLAPSE(id)
        CALL collapse(DIALOG,id)
    END DISPLAY
END MAIN

FUNCTION collapse(d,p)
    DEFINE d ui.Dialog
    DEFINE p INTEGER
    WHILE p < tree.getLength()
        IF tree[p + 1].pid != tree[p].id THEN EXIT WHILE END IF
        CALL d.deleteNode("sr_tree", p + 1)
    END WHILE
END FUNCTION

FUNCTION expand(d,p)
    DEFINE d ui.Dialog
```

```
    DEFINE p INTEGER
    DEFINE id STRING
    DEFINE i, x INTEGER
    FOR i = 1 TO 4
        LET x = d.appendNode("sr_tree", p)
        LET id = tree[p].id || "." || i
        LET tree[x].id = id
        -- tree[x].pid is implicitly set by the appendNode() method...
        LET tree[x].name = "Node " || id
        IF i MOD 2 THEN
            LET tree[x].hasChildren = TRUE
        ELSE
            LET tree[x].hasChildren = FALSE
        END IF
        LET tree[x].description = "This is node " || tree[x].name
    END FOR
END FUNCTION
```

Split views

These topics describe split view programming in the language.

  - Example 2: Multiple split views with navigation bar on page 1405
  - Example 3: Split view using an HBox on page 1409

Understanding split views

Split views refer to the ability to access two forms side by side on a mobile device. This feature is mainly provided for tablet devices, as most phones can only display one window/form at a time.

A split view is composed by a "*left pane*" and and "*right pane*". In the programs, the panes are implemented with window objects displaying forms, which are controlled by parallel dialogs.

> **Important:** This feature is only for mobile platforms.

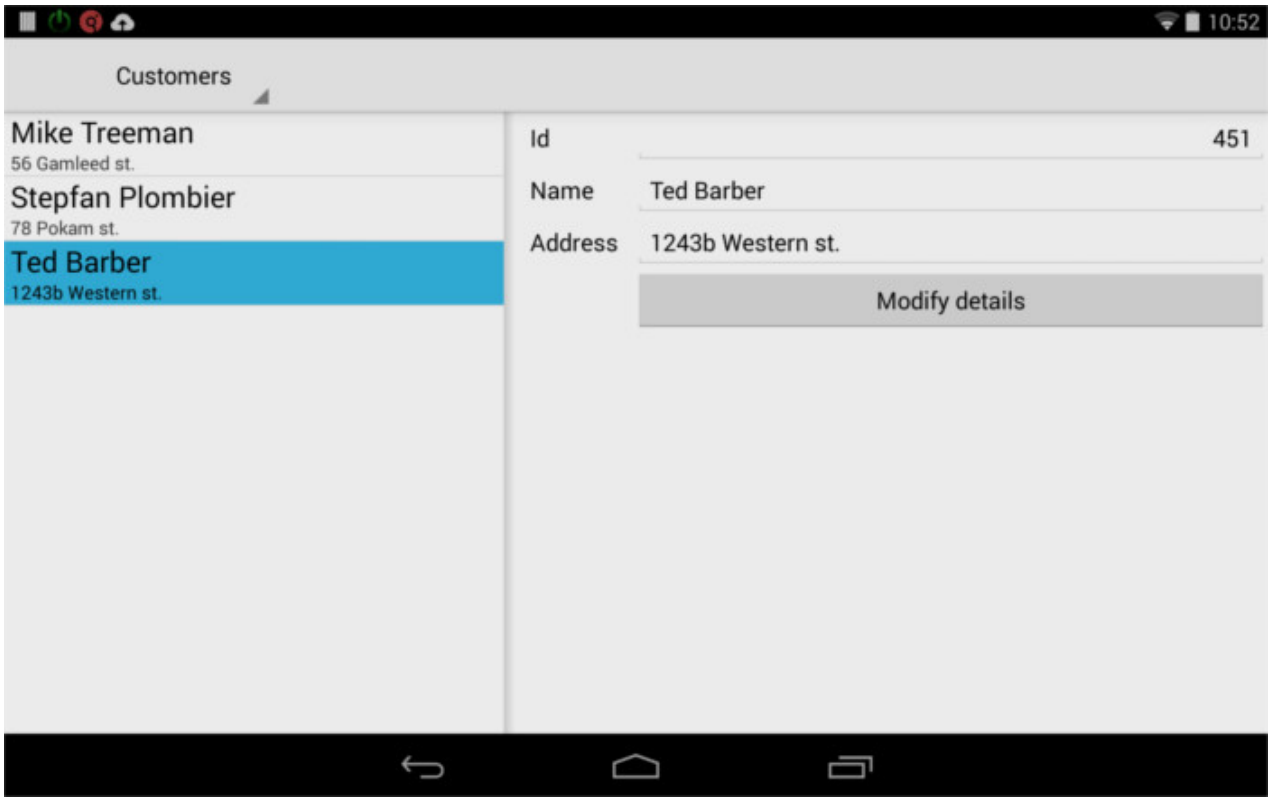

Figure 99: Form with Split View (Android™)

Split views (controlled by parallel dialogs) are typically used to browse in the application data, while modal dialogs are used for data input in a single form. An application based on split views will start with parallel dialogs, and switch to a simple modal dialog when the user chooses to edit application data. Parallel dialog handling is suspended by the runtime system, when a modal dialog executes. For details about parallel dialogs compared to modal dialogs, see Introducing dialogs on page 1250.

If the application displays several split views simultaneously, implement a navigator pane, to let the end user switch between the different split views.

Creating split view windows

The application specifies which window opens in which pane by using the `STYLE` attribute in the `OPEN WINDOW` instruction.

Specify either `LEFT` or `RIGHT` for the `TYPE` attribute, to define a left-hand side pane and a right-hand side pane of the split view respectively.

> **Important:** Both left (`TYPE=LEFT`) and right (`TYPE=RIGHT`) splitview windows need to be created.

This example specifies that the window `w_left` (with the form `customer_list`) display in the left pane, and the window `w_right` (with the form `customer_detail`) display in the right pane:

```
OPEN WINDOW w_left WITH FORM "customer_list" ATTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
```

The window content of both panels will be controlled by parallel dialogs.

> **Important:**
>
> Split-view windows must be the root window (after closing the default `SCREEN` window), or direct children of the `NAVIGATOR` window, if it is used. If regular windows are created before split views, these must be closed:

Case 1: Close regular windows created before the split-views:

```
CLOSE WINDOW screen
OPEN WINDOW w1 WITH FORM "form1"
...
CLOSE WINDOW w1
...
OPEN WINDOW w_left WITH FORM "customer_list" ATTTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
...
```

Case 2: Create split-views as direct NAVIGATOR children

```
CLOSE WINDOW screen
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)
...
OPEN WINDOW w_left WITH FORM "customer_list" ATTTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
...
```

When using a navigator window, the names of the split view windows must match the action names created in the parallel dialog controlling the options of the navigator pane. For more details, see Navigator pane on page 1399.

Parallel dialogs for split views
In order to control the left-hand and right-hand split view content, you must implement two parallel dialogs, each dedicated to a pane.

Create each window and start the parallel dialog for that window. Repeat for each window. When all windows have been created and all dialogs started, run the event loop to activate them.

```
OPEN WINDOW w_left WITH FORM "customer_list"
       ATTRIBUTES(TYPE=LEFT)
START DIALOG d_list_view

OPEN WINDOW w_right WITH FORM "customer_detail"
       ATTRIBUTES(TYPE=RIGHT)
START DIALOG d_detail_view

WHILE fgl_eventLoop()
END WHILE
```

The parallel dialogs must be implemented with a declarative dialog block. See Parallel dialogs (START DIALOG) on page 1199 for more details.

For small iOS devices (not tablets), consider using the `ACCESSORYTYPE=DISCLOSUREINDICATOR` in the `DISPLAY ARRAY` dialog, for left-pane controllers.

Refreshing a parallel dialog
To restart a parallel dialog, use `TERMINATE DIALOG` + `START DIALOG`.

Once the split view parallel dialogs are started, the typically programming pattern to refresh the detail view of the right pane is to restart the detail dialog by executing a `TERMINATE DIALOG` followed by a `START DIALOG`.

The next example shows the case of a list view master (`d_list_view` dialog) displayed on the left pane, which is bound to a detail view of the right pane (`d_detail_view` dialog). The detail information must be refreshed when moving to a new row (BEFORE ROW control block):

```
DIALOG d_list_view()
  DISPLAY ARRAY arr TO sr.*
                ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
```

```
      BEFORE ROW -- in BEFORE ROW, we restart the details view
        CURRENT WINDOW IS w_right
        TERMINATE DIALOG d_detail_view
        LET curr_pa = arr_curr()
        DISPLAY BY NAME arr[curr_pa].*
        DISPLAY SFMT("tapped row %1",arr_curr()) TO info
        START DIALOG d_detail_view
        CURRENT WINDOW IS w_left
  END DISPLAY
END DIALOG
```

One or two panes
The same application displays as a split view application with two panes on some devices, yet displays as a single pane on other devices. What controls this?

With split views, you open two windows, assigning one to the left pane and one to the right pane of the split view. Not all mobile devices, however, can display multiple panes on the same screen. While the application code is the same, the mobile client displays either one pane (typical for phones) or two panes (typical for tablets).

If the device only allows a single pane to display, the window in the left pane is the first window displayed.

The rules for single-pane or two-pane display differ according to the mobile platform:

- On Android™ devices, the two-pane mode is activated if the width of the screen is more than 900 dp (density-independent pixels). The width of the screen depends on the orientation; you may notice that you have two panes when the tablet is held in landscape mode (width greater than height), yet only one pane when the tablet is held in portrait mode (height greater than width).

  Note: A density-independent pixel (dp) is an abstract unit that is based on the physical density of the screen. The unit is relative to a 160 dpi screen, so one dp is one pixel on a 160 dpi screen. The ratio of dp-to-pixel will change with the screen density, but not necessarily in direct proportion.
- On iOS devices:
  - With the iPad, the two-pane mode is activated, regardless of the orientation of the tablet.
  - With the iPhone or iTouch devices, only a single pane displays.

Switching between panes
How to switch between the left and right panes of a split view depends on the mobile platform and the ergonomic standards of that platform.

Switching between panes by program

After creating the split view windows and starting the parallel dialogs to control them, the application program can switch between the left and right panes of a split view by selecting the corresponding window with the `CURRENT WINDOW IS` instruction.

```
CURRENT WINDOW IS w_customers
```

Switching between panes on phone devices

On a mobile device (such as phones) that only displays one split view pane at the time, switching from the left pane to the right pane is handled automatically by the front-end.

Note: The ergonomics and rendering depend on the device's operating system.

When starting the application, the left-pane is displayed first. This pane typically uses a table view controlled by a `DISPLAY ARRAY` dialog.

On an iOS phone, consider using the ACCESSORYTYPE=DISCLOSUREINDICATOR in the DISPLAY ARRAY dialog of left-pane controllers.

If the end user taps on a row in the list of the left pane, the right pane is automatically shown. To avoid this implicit switch from the left to the right pane, define a DOUBLECLICK = *action-name* attribute in the DISPLAY ARRAY dialog, and bind this action to an ON ACTION handler which does not change the current window.

Once the right pane is displayed, the user can switch to the left pane:

- On an Android™ phone, press the physical back button.
- On an iOS phone, press the back arrow on the top left of the window.

> **Important:** This automatic "back to left panel" option is only possible if the dialog on the right side does not have a `close`, `cancel` or `accept` action defined. If one of these actions are defined, it will be attached to the back button, and that action will be executed when pressed.

Navigator pane
A *navigator pane* enables access to several views in an application from a main panel.

For many mobile applications, you will want to provide a view that allows you to show different forms and views that are active at the same time, to expose different functional areas for your application. This can be achieved by providing a top-level navigator with several views, controlled by parallel dialogs.

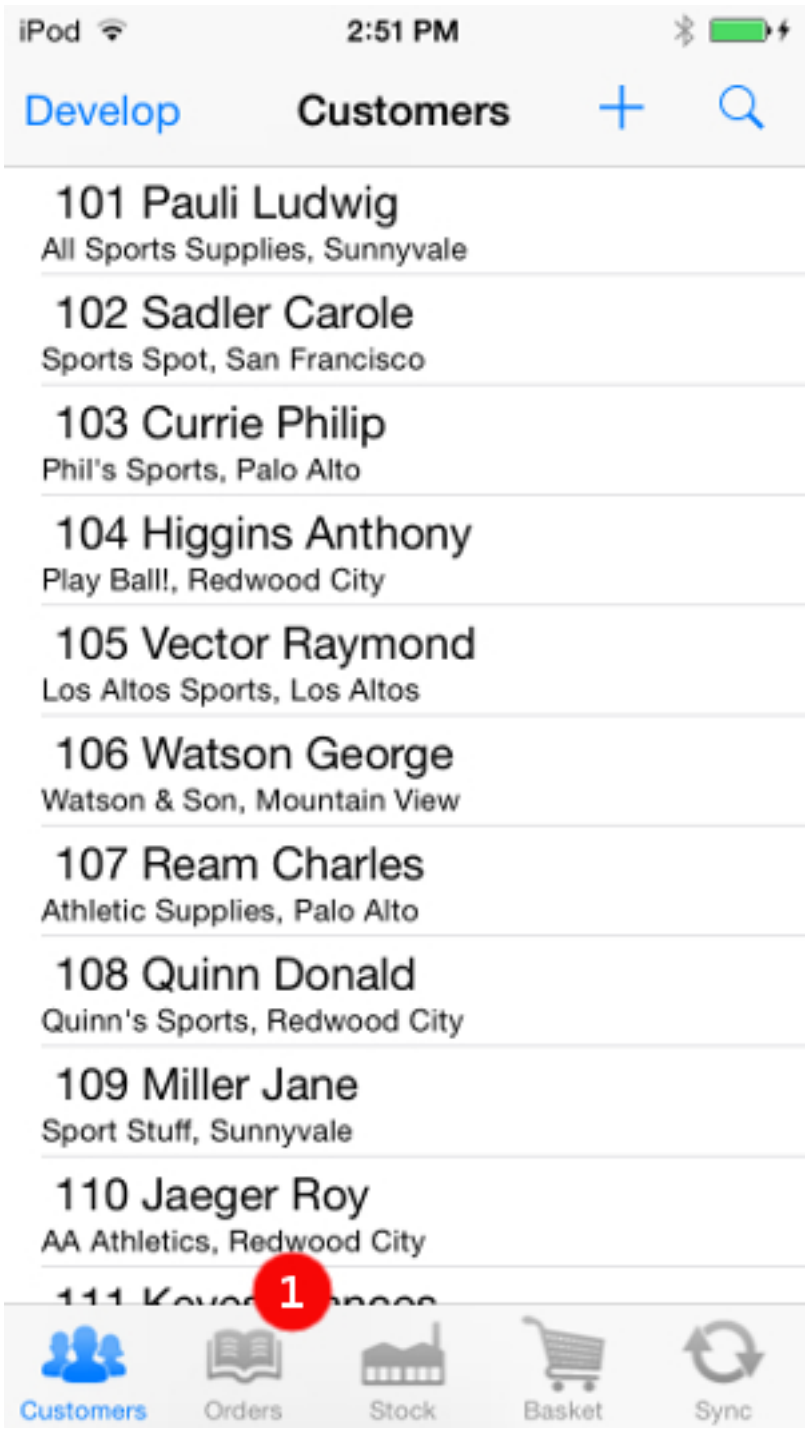
In order to implement a *top-level navigator*, create a window with the TYPE=NAVIGATOR attribute and without a form (i.e. using the x ROWS y COLUMNS clause). This window will only be used to display a set of actions views, to let the user switch between views. A view can be implemented as a split view by using a left and right typed window.

> **Important:** The navigator window must be the root window (after closing the default SCREEN window). If regular windows are created before the navigator window, these must be closed:

```
-- Case 1: Screen window is closed, navigator is the root window
CLOSE WINDOW screen
...
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)

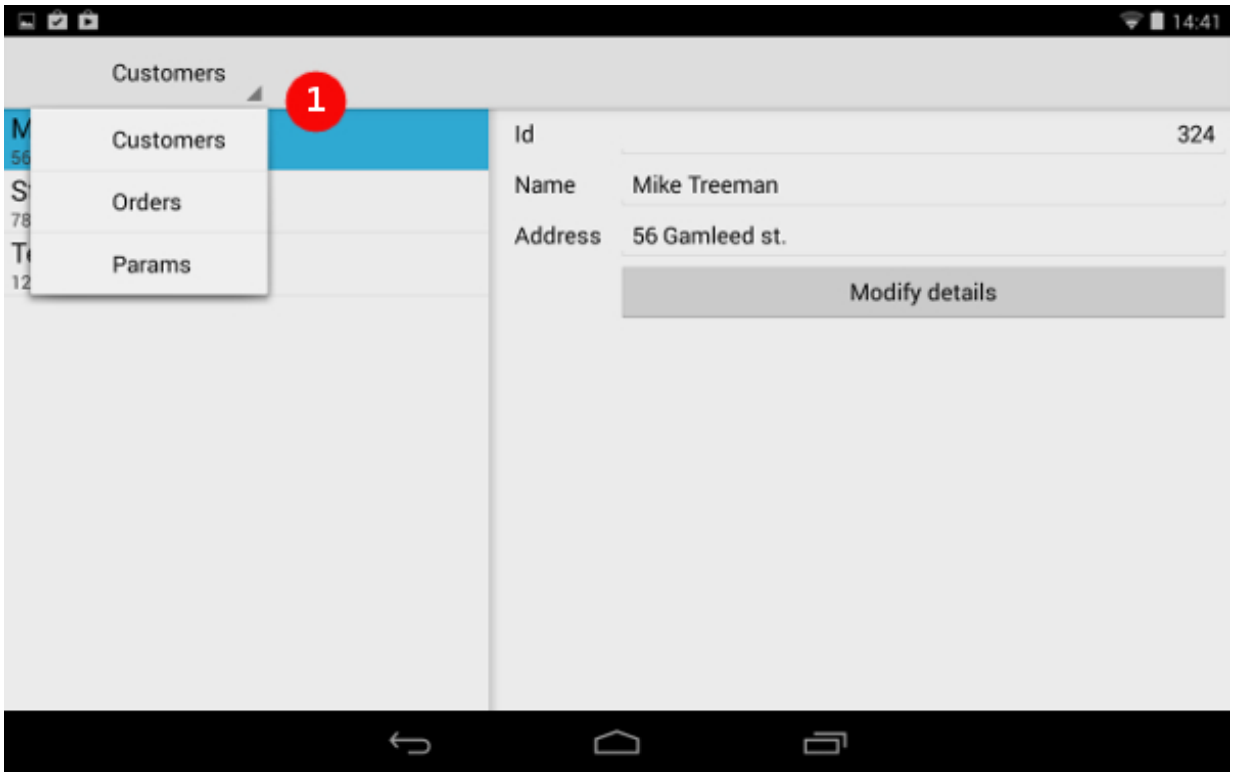
-- Case 2: Close regular windows created before the navigator window
OPEN WINDOW w1 WITH FORM "form1"
...
CLOSE WINDOW w1
...
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)
```

- On iOS devices, the navigator window displays in a typical iOS tab bar at the bottom of the screen:



To customize the iOS application, define the color of the iOS tab bar the iosTabBarTintColor Window-class style attribute.

- On Android™ devices, the navigator window displays in the top of the screen, in the view control of the action bar (2):



The navigator window will be controlled by a dedicated parallel dialog implementing a `MENU` instruction, with the action handlers to select the related window, when the corresponding action is fired.

> **Important:** The name of the actions in the navigator menu must match the name of the corresponding window, which is typically, the left-typed window when using split views.

The next example implements:

- The `w_main` window, and its corresponding controller, the `d_navigator` parallel dialog.
- The `w_customers` window as a left-pane, with the `d_customers` parallel dialog.
- The `w_orders` window as a right-pane, with the `d_orders` parallel dialog.
- The navigator `MENU` dialog implemens the `w_customer` and `w_orders` action handlers.

```
...
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)
START DIALOG d_navigator
OPEN WINDOW w_customers WITH FORM "customers" ATTRIBUTES(TYPE=LEFT)
START DIALOG d_customers
OPEN WINDOW w_orders WITH FORM "orders" ATTRIBUTES(TYPE=RIGHT)
START DIALOG d_orders
...
DIALOG d_navigator()
   MENU
       ON ACTION w_customers ATTRIBUTES(TEXT="Customers", IMAGE="smiley")
          CURRENT WINDOW IS w_customers
       ON ACTION w_orders ATTRIBUTES(TEXT="Orders")
          CURRENT WINDOW IS w_orders
   END MENU
END DIALOG
```

The functionality is the same on either mobile platforms: providing the user with the ability to navigate between multiple views efficiently. The rendering depends on the platform:

- On an iOS device, navigator window renders as a tab bar, displaying at the bottom of the screen.

- On an Android device, navigator window renders as a spinner, which is a drop-down menu in the action bar.

Rendering an HBox as a split view
Achieve a split view display with HBOX container and style attribute.

By defining a TABLE and a GRID container in a parent HBOX container, it is possible to get a splitview display by setting the splitViewRendering style attribute of the HBox class. When using this style attribute, the TABLE displays as a listview on the left of the screen, while the GRID displays as a form on the right.

First define a form with the HBOX container, TABLE and GRID. In the code example below, the HBOX container gets a STYLE attribute referencing a style named "splitview" in the .4st file:

```
LAYOUT
HBOX (STYLE="splitview")
TABLE
{
[c1  |c2          ]
[c1  |c2          ]
[c1  |c2          ]
[c1  |c2          ]
}
END
GRID
{
First name:   [f1                ]
Last name:    [f2                ]
...
}
END
END
...
```

The .4st file should look like follows:

```
<StyleList>
  <Style name="HBox.mystyle">
     <StyleAttribute name="splitViewRendering" value="yes" />
  </Style>
  ...
</StyleList>
```

The program must implement a dialog that handles both parts of the splitview. You typically implement a DISPLAY ARRAY to handle the TABLE, and refresh the right part of the screen contained in the GRID, with code in the BEFORE ROW control block:

```
DISPLAY ARRAY arr TO sr.*
    BEFORE ROW
      DISPLAY arr[arr_curr()].first_name TO f_first_name
      DISPLAY arr[arr_curr()].last_name TO f_last_name
END DISPLAY
```

Examples

Example applications using split views.

Example 1: Single split view application

This application uses a minimum amount of code to describe a typical implementation of parallel dialogs that result in a split view application, with a list in the left pane and the detail for the selected row in the right pane. It uses only one split view.

main.4gl

The code in the `MAIN` block creates the left pane/window and the right pane/window by specifiying the `TYPE` attribute in `OPEN WINDOW`.

The left window will display a form comprised of a table view of all records (`a1_list_view`), the other window contains a form with the detail view of a single record from the array (`a1_detail_view`)

The `START DIALOG` statements, along with the `WHILE fgl_eventLoop()` loop, creates the parallel dialog on which a split view depends.

```
DEFINE arr DYNAMIC ARRAY OF RECORD
            id INTEGER,
            name VARCHAR(15),
            date DATE,
            comment VARCHAR(30)
  END RECORD
DEFINE curr_pa SMALLINT

MAIN
  CLOSE WINDOW SCREEN
  CALL populate_array()

  OPEN WINDOW w_left WITH FORM "list_view"
       ATTRIBUTES(TYPE=LEFT)
  START DIALOG d_list_view

  OPEN WINDOW w_right WITH FORM "detail_view"
       ATTRIBUTES(TYPE=RIGHT)
  START DIALOG d_detail_view

  WHILE fgl_eventLoop()
  END WHILE

END MAIN

DIALOG d_list_view()
  DISPLAY ARRAY arr TO sr.*
                ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
      BEFORE ROW -- in BEFORE ROW, we restart the details view
        CURRENT WINDOW IS w_right
        TERMINATE DIALOG d_detail_view
        LET curr_pa = arr_curr()
        DISPLAY BY NAME arr[curr_pa].*
        DISPLAY SFMT("tapped row %1",arr_curr()) TO info
        START DIALOG d_detail_view
        CURRENT WINDOW IS w_left
  END DISPLAY
END DIALOG

DIALOG d_detail_view()
  MENU
    ON ACTION an_action
      MESSAGE "The action an_action was selected!"
    ON ACTION details
      IF edit_details() THEN
```

```
         DISPLAY BY NAME arr[curr_pa].*
      END IF
  END MENU
END DIALOG

FUNCTION edit_details()
  -- A modal dialog disables all parallel dialogs
  OPEN WINDOW w_details WITH FORM "details"
       ATTRIBUTES(TYPE=POPUP, STYLE="popup")
  LET int_flag=FALSE
  INPUT BY NAME
        arr[curr_pa].name,
        arr[curr_pa].comment
      WITHOUT DEFAULTS
  CLOSE WINDOW w_details
  RETURN (int_flag==FALSE)
END FUNCTION

FUNCTION populate_array()
  DEFINE i INT
  FOR i=1 TO 40
    LET arr[i].id=i
    LET arr[i].name="item "||i
    LET arr[i].date=TODAY
    LET arr[i].comment="item-detail "||i
  END FOR
END FUNCTION
```

Left form definition file (list_view.per)

This form definition file provides the table, or list, of records in the array. Even though four table columns are defined, only two display.

```
LAYOUT (TEXT="Items")
TABLE
{
[c1    |c2             ]
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.id;
EDIT c1=FORMONLY.name;
PHANTOM FORMONLY.date;
EDIT c2=FORMONLY.comment;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

Right form definition file (detail_view.per)

This form definition file displays the details for a single record in the array.

```
LAYOUT (TEXT="Details")
GRID
{
Id      [f01              ]
Name    [f02              ]
Date    [f03              ]
Comment [f04              ]
Info    [f05              ]
```

```
        [b1_details        ]
}
END
END
ATTRIBUTES
EDIT f01=FORMONLY.id;
EDIT f02=FORMONLY.name, SCROLL;
EDIT f03=FORMONLY.date;
EDIT f04=FORMONLY.comment, SCROLL;
EDIT f05=FORMONLY.info;
BUTTON b1_details:details,TEXT="Modify details";
END
```

Detail form definition file (details.per)

This is a simple form containing a two fields that will be used in the program by the `edit_details()` function to modify item details.

```
LAYOUT (TEXT="Edit details")
GRID
{
Name:    [f01                  ]
Comment: [f02                  ]
         [                     ]
}
END
END
ATTRIBUTES
EDIT f01=FORMONLY.name, SCROLL;
TEXTEDIT f02=FORMONLY.comment, STRETCH=BOTH;
END
```

Example 2: Multiple split views with navigation bar
This example shows how to write an application that handles two split views, each having a left and right pane, with a top level navigation pane that allows the end user to easily switch between the two split views.

main.4gl

This module implements the window creation and the parallel dialogs to control their content.

The code in the `MAIN` block creates four windows:

- The main window is the navigation window/pane, defined by the `TYPE=NAVIGATION` attribute. Only the `d_navigator()` main dialog is started.
- Two other windows are created for the customer list and details, in the `customers()` function. This function is called when the main dialog starts. The function checks if the `w_customers` window exists and if needed, opens the splitview windows and starts the dialogs handling customer records. If windows already exists, it performs a `CURRENT WINDOW IS w_customers`, to select the customer pane.
- The second window showing orders and its corresponding dialog are created in the `orders()` function, using the same programming pattern as in the `customers()` function.
- When the user selects one of the main dialog actions, it calls either the `customers()`, the `orders()`, or the `params()` function, to show the corresponding pane.
- The configuration pane is handled in the `params()` function, with the corresponding `d_params_menu` dialog: When selected, the form is in read-only mode by default. The menu implements the "modify" action to edit the parameters. This action will create a modal dialog, that stops temporarly the parallel dialogs.

```

```

Example 3: Split view using an HBox
This app uses a minimum amount of code to show a split view implementation using an hbox container.

Styles definition file (mystyles.4st)

For this example, we start with the style file. The style file specifies the `splitViewRendering` attribute for the `HBox` container when the style is set to `mysplitview`.

```
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <Style name="HBox.mysplitview">
     <StyleAttribute name="splitViewRendering" value="yes" />
  </Style>
</StyleList>
```

Form definition file (splitview.per)

The form definition file defines a `HBOX` container using the `mysplitview` style. It contains a `TABLE` followed by a `GRID`. The table will become the left pane of the split view app, and the grid will become the right pane of the split view app.

```
LAYOUT
  HBOX (STYLE="mysplitview")
    TABLE
    {
    [c1            |c2                            ]
    [c1            |c2                            ]
    [c1            |c2                            ]
    [c1            |c2                            ]
    }
    END
    GRID
    {
    <GROUP g1                                       >
      Name:          [lb_name             :lb_id  ]
      E-mail:        [lb_email                    ]
      Address:       [lb_address                  ]
      City:          [lb_city                     ]
    <                                               >
    <GROUP g2                                       >
      Phone:         [lb_phone                    ]
      Mobile:        [lb_mobile                   ]
    <                                               >
    }
    END
  END
END

ATTRIBUTES

Drag & drop

Explains programming techniques for the drag & drop feature.

- Understanding drag & drop on page 1412
- Syntax of drag & drop interaction blocks on page 1412
- Default drag & drop operation on page 1413
- Control block execution order on page 1413
- Handle drag & drop data with MIME types on page 1413

- Examples on page 1415
  - Example 1: Two lists side-by-side with drag & drop on page 1415

Understanding drag & drop

Drag & drop is a well know feature of graphical applications, allowing the end user to use the mouse to drag an element of a window to another window in the same program or into an external application. The front-end platform/device must support this feature.

> **Important:** This feature is not supported on mobile platforms.

Drag & drop can be implemented in regular tables and tree-views controlled by a singular `DISPLAY ARRAY` or a `DISPLAY ARRAY` sub-dialog within a `DIALOG` instruction. Drag & drop is not supported in other dialog contexts, such as a singular `INPUT`, `INPUT ARRAY` or `CONSTRUCT`.

With drag & drop, end users can:

- Move drag-able objects between lists and tree-views in the same Genero form or program.
- Move drag-able objects between lists and tree-views in different Genero forms and programs.
- Move drag-able objects between other desktop applications and tables / tree-views in Genero programs.

Drag & drop control is implemented in a `DISPLAY ARRAY` with specific interaction blocks, to handle the events related to the drag and drop operation. These specific blocks will be triggered when drag and drop events arrive from the front-end.

- ON DRAG_START
- ON DRAG_FINISHED
- ON DRAG_ENTER
- ON DRAG_OVER
- ON DROP

Each of these interaction blocks takes a `ui.DragDrop` object as a parameter. A reference variable to that object must be declared before the dialog. In the interaction block, the `ui.DragDrop` object can be used to configure the drag & drop action to take. For example, a "drag enter" event can be refused.

The `ON DRAG_START` and `ON DRAG_FINISHED` triggers apply to the source of the drag & drop operation; the dialog where the object was dragged. The other triggers provide notification to the drop target dialog, used to inform the program when the different drop events occur and to let the target accept or reject the drop action.

This example illustrates the use of a drag & drop interaction block with the `ui.DragDrop` control object:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
    ON DRAG_ENTER(dnd)
      IF ok_to_drop THEN
        CALL dnd.setOperation("move")
      ELSE
        CALL dnd.setOperation(NULL)
      END IF
...
END DISPLAY
```

Syntax of drag & drop interaction blocks

The `ON DRAG*` / `ON DROP` interaction blocks implement drag & drop operations.

```
{ ON DRAG_START ( dnd-object )
| ON DRAG_FINISHED ( dnd-object )
```

```
| ON DRAG_ENTER( dnd-object )
| ON DRAG_OVER ( dnd-object )
| ON DROP ( dnd-object ) }
    dialog-statement
    [...]
```

1. *dnd-object* is a variable referencing an object of the class `ui.DragDrop`.

Default drag & drop operation

By default, all `DISPLAY ARRAY` dialogs implement a default drag operation that copies all selected rows to the drag & drop buffer as a tab-separated list of values.

The user code equivalent to the default drag & drop operation would look like this:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
  ON DRAG_START(dnd)
    CALL dnd.setOperation("copy")
    CALL dnd.setMimeType("text/plain")
    CALL dnd.setBuffer(DIALOG.selectionToString("sr"))
...
END DISPLAY
```

Control block execution order

The table below shows the order in which the runtime system executes the control blocks related to drag & drop events:

Table 293: Control block execution order for drag & drop events

Context / User action	Control Block execution order
The user starts to drag an object from the source dialog.	**1.** `ON DRAG_START` (in source dialog)
The mouse cursor enters the drop target dialog.	**1.** `ON DRAG_ENTER` (in target dialog)
After entering the target dialog, the mouse cursor moves from row to row, or user chooses to change the drop operation (move or copy).	**1.** `ON DRAG_OVER` (in target dialog)
The user releases the mouse button over the target dialog.	**1.** `ON DROP` (in target dialog) **2.** `ON DRAG_FINISHED` (in source dialog)

Handle drag & drop data with MIME types

If a drag & drop is intended to work only in the same application, data can be passed with variables in the context of the current program. For example, in a program using two tables where the user can drag & drop elements between the two lists, identify the selected rows and update the program arrays accordingly. When drag & drop is limited to the current application, avoid the drop outside the current application.

When a drag & drop operation comes from (or goes to) external applications, data can be of various types/formats: plain text, formatted text, documents, images, sounds, videos, and so on. In order to handle the drag & drop data, you must identify the type of data held in the drag & drop buffer. The type of data in the buffer is identified by the MIME type (Multiple Internet Mail Extensions). MIME types are a widely used internet standard specification, first introduced to identify the content of e-mail attachments.

Only text data can be passed with drag & drop; binary data is not supported. However, you can pass files by using the `fgl_getfile()` file transfer function, and identify the file with a URI (text-uri-list MIME type). For a working example, see the demos in `FGLDIR/demo/DragAndDrop`.

Example of MIME types:

- text/plain
- text/uri-list
- text/x-vcard

You can also define your own MIME type, as long as it does not conflict with existing standard MIME types. For example:

- text/my-remote-file
- text/my-customer-record

If you do not specify a MIME type when the drag starts, the type defaults to text/plain, and the dialog will by default copy the data from selected rows into the drag & drop buffer. To prevent drag & drop to external applications, you must pass an application-specific MIME type to the `ui.DragDrop.setMimeType()` method, to be sure that other applications do not recognize the MIME type and will deny the drop.

Preparing the dragged object for external targets

If the program implements drag & drop of objects that can be dropped to external programs, you must specify the MIME type of the object and copy the data to the drag & drop buffer, so that the external application can identify the data format and receive it.

In the `ON DRAG_START` block, you must call the `ui.DragDrop.setMimeType()` method to define the MIME type of the object, and copy the text data into the buffer with the `ui.DragDrop.setBuffer()` method.

This example shows a `DISPLAY ARRAY` dialog preparing the drag & drop buffer to export VCard data from a dragged row:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
  ON DRAG_START(dnd)
    -- Define the MIME type and copy text data to DnD buffer
    CALL dnd.setMimeType("text/x-vcard")
    CALL dnd.setBuffer( buildVCardData( arr[arr_curr()].cid ) )
    CALL dnd.setOperation("copy")
...
END DISPLAY
```

Receiving the dragged object from external sources

This describes how to handle the drop action when the target dialog receives an object dragged from an external source, by identifying the MIME type of the object.

In the `ON DRAG_ENTER` block, you must call the `ui.DragDrop.selectMimeType()` method to check that data is available in a format identified by the MIME type, passed as a parameter. If the type of data is available in the buffer, the method returns `TRUE`. Later, when the dragged object is dropped (`ON DROP`), you can get the previously selected MIME type with `ui.DragDrop.getSelectedMimeType()` before calling `ui.DragDrop.getBuffer()` to retrieve the actual data.

The next example shows the usage of those methods: In `ON DRAG_ENTER`, the program checks available MIME types, and denies the drop operation if the buffer does not hold any of the MIME types that can be treated by the program. In `ON DROP`, the program calls `getSelectMimeType()` to check what MIME

type was selected, retrieves the data with `getBuffer()` , then inserts a new row and puts the data in dedicated fields according to the MIME type:

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
  ON DRAG_ENTER(dnd)
    -- Set operation to NULL if unexpected MIME type found
    CASE
    WHEN dnd.selectMimeType("text/plain")
    WHEN dnd.selectMimeType("text/uri-list")
    OTHERWISE
      CALL dnd.setOperation(NULL)
    END CASE
...
  ON DROP(dnd)
    -- Select MIME type and get data from buffer
    LET row = dnd.getLocationRow()
    CALL DIALOG.insertRow("sr", row)
    IF dnd.getSelectMimeType() == "text/plain" THEN
      LET arr[row].text_data = dnd.getBuffer()
    END IF
...
END DISPLAY
```

Examples

See demo directory for more Drag & Drop examples.

Example 1: Two lists side-by-side with drag & drop

```
MAIN
    DEFINE drag_index, drop_index, i INT
    DEFINE drag_source, drag_value SRING
    DEFINE arr_left, arr_right DYNAMIC ARRAY OF STRING
    DEFINE dnd ui.DragDrop
    CONSTANT S_LEFT="sr_left"
    CONSTANT S_RIGHT="sr_right"

    OPEN FORM f FROM "dnd"
    DISPLAY FORM f

    FOR i = 1 TO 10
       LET arr_left[i] = "left " || i
       LET arr_right[i] = "right" || i
    END FOR

    INITIALIZE drag_index TO NULL

    DIALOG ATTRIBUTES(UNBUFFERED)

        DISPLAY ARRAY arr_left TO sr_left.*
        ON DRAG_START(dnd)
            LET drag_source = S_LEFT
            LET drag_index = arr_curr()
            LET drag_value = arr_left[drag_index]
        ON DRAG_FINISHED(dnd)
            INITIALIZE drag_source TO NULL
        ON DRAG_ENTER(dnd)
            IF drag_source IS NULL THEN
                CALL dnd.setOperation(NULL)
            END IF
```

```
        ON DROP(dnd)
            IF drag_source == S_LEFT THEN
                CALL dnd.dropInternal()
            ELSE
                LET drop_index = dnd.getLocationRow()
                CALL DIALOG.insertRow(S_LEFT, drop_index)
                CALL DIALOG.setCurrentRow(S_LEFT, drop_index)
                LET arr_left[drop_index] = drag_value
                CALL DIALOG.deleteRow(S_RIGHT, drag_index)
            END IF
        END DISPLAY

        DISPLAY ARRAY arr_right TO sr_right.*
        ON DRAG_START(dnd)
            LET drag_source = S_RIGHT
            LET drag_index = arr_curr()
            LET drag_value = arr_right[drag_index]
        ON DRAG_FINISHED(dnd)
            INITIALIZE drag_source TO NULL
        ON DRAG_ENTER(dnd)
            IF drag_source IS NULL THEN
                CALL dnd.setOperation(NULL)
            END IF
        ON DROP(dnd)
            IF drag_source == S_RIGHT THEN
                CALL dnd.dropInternal()
            ELSE
                LET drop_index = dnd.getLocationRow()
                CALL DIALOG.insertRow(S_RIGHT, drop_index)
                CALL DIALOG.setCurrentRow(S_RIGHT, drop_index)
                LET arr_right[drop_index] = drag_value
                CALL DIALOG.deleteRow(S_LEFT, drag_index)
            END IF
        END DISPLAY

    ON ACTION cancel
        EXIT DIALOG

    END DIALOG
END MAIN
```

Web components

Understanding web components

External graphical components can be integrated into forms by using the `WEBCOMPONENT` form item type.

A `WEBCOMPONENT` form field is a form element that defines an area in the form layout to hold an external component, typically not available as a native widget on the front-end platform.

Web components are designed for a specific need, and usually have advanced and powerful features which can bring added value to your applications. For example, you can find chart and graph widgets, calendar widgets, drawing widgets, and more. Such specialized widgets are not part of the standard GUI toolkits used by Genero front-ends. They need to be integrated as external components.

> **Important:** Depending on the type of front-end, the web components can have limitations: When using native front-ends (GDC, GMA, GMI), the web components are implemented with a "webview" widget, which is not a full-featured web browser.
>
> The main web component limitations on native front-ends are:
>
> - lack of plugin support,
> - less accurate javascript engine,
> - lack of advanced html+css features.

Some web components are free, and some are licensed, so you should take the cost into account before integrating a new web component in your application.

Web components can be implemented with two different techniques:

1. Using an URL specification, by setting the URL as value of the `WEBCOMPONENT` field at runtime. This is the easiest way to implement a web component. The widget is controlled with URL values by the program, but requires some additional coding to handle URLs, instead of flat field values.
2. Using an gICAPI object (based on JavaScript™), by defining the `COMPONENTTYPE` attribute in the form file. This kind of web component requires some JavaScript coding, to write a form field "plugin", which is usable in a normal dialog instruction, that behaves as all the other widgets in terms of value setting/getting.

The content and/or behavior of a web component can be controlled in the program code by using the field value. To detect events inside the web component, the program dialogs must implement an `ON CHANGE` control block, that will be fired immediately after a user action on the web component.

WEBCOMPONENT item type

Defines a specialized form item that holds an external component.

WEBCOMPONENT item basics

The `WEBCOMPONENT` form item defines a form field that will hold an external component, implemented with a front-end plug-in mechanism.

This topic describes the `WEBCOMPONENT` item type in form definition files, a complete section is dedicated to web component programming.

Defining a WEBCOMPONENT

The `COMPONENTTYPE` attribute identifies gICAPI external objects to be used for the field. The `PROPERTIES` attribute is typically used to define attributes that are specific to a given gICAPI-based web component. For example, a chart component might have properties to define x-axis and y-axis labels. For more details, see Using a gICAPI web component on page 1422.

If the COMPONENTTYPE attribute is not used, the web component will be a URL-based web component. For more details, see Using a URL-based web component on page 1419.

Some front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 818.

Where to use a WEBCOMPONENT

A WEBCOMPONENT form item can be defined in two different ways:

1. With an item tag and a WEBCOMPONENT item definition on page 949 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a WEBCOMPONENT stack item on page 927 in a STACK container.

Defining the widget size

The size of a WEBCOMPONENT widget can be controlled in grid-based or stack-based layout, according to several attributes such as SIZEPOLICY and STRETCH.

For more details about image sizing, see Controlling the web component layout on page 1418.

Controlling the web component layout

Web component sizing basics

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars. Such widgets are generally resizeable. Therefore, the WEBCOMPONENT form item must be large and stretchable.

Viewport zooming on mobile devices

In order to avoid automatic viewport zooming with mobile applications, consider adding a meta tag with name='viewport' in the HTML file of your gICAPI-based web components, with initial and maximal scale attributes set to 1:

```
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
```

> **Note:** Don't use such responsive meta tag, if your web component isn't specifically designed to be responsive.

Web component size in grid-based layout

In a grid-bases layout, the item tag of the WEBCOMPONENT defines the default dimensions of the web component area:

```
LAYOUT
GRID
{
<GROUP g1                   >
[f1            ][f2         ]
[f3                         ]
 ...
<                           >
[f5                         ]
[                           ]
[                           ]
[                           ]
}
END
```

In the ATTRIBUTES section, use the SIZEPOLICY, SCROLLBARS and STRETCH attributes, to define the sizing policy of a web component field:

```
WEBCOMPONENT f5 = FORMONLY.mymap,
   SIZEPOLICY = FIXED,
   STRETCH = BOTH;
```

By default, the WEBCOMPONENT widget gets the size of the form item (like SIZEPOLICY=FIXED). When SIZEPOLICY=INITIAL, the web component is scaled to the right size after the first webpage is loaded and stays at that size. When SIZEPOLICY=DYNAMIC, the web component is resized after each load of a new webpage so that no scrollbars should appear.

Web component size layout in stack-based layout

In a stack-based layout, a WEBCOMPONENT item is defined with other items in a logical presentation order, without any size information:

```
LAYOUT
 STACK
  GROUP (TEXT="Chart example")
    COMBOBOX FORMONLY.chart_type, NOT NULL,
             INITIALIZER=chart_type_init;
    WEBCOMPONENT FORMONLY.chart,
                 COMPONENTTYPE = "chartjs",
                 STYLE="regular";
  END
 END
END
```

By default, the WEBCOMPONENT widget size will adapt to the content of the web component: It will stretch vertically to the appropriate size, in order to show the complete web component content.

To limit the size of the WEBCOMPONENT widget, you can use the HEIGHT attribute in the form definition:

```
WEBCOMPONENT FORMONLY.chart,
             HEIGHT = 5,        -- 5 lines
             ...
```

> **Note:** If the HEIGHT attribute of the web component is defined in the form file, it fixes the widget height, which may result in vertical scrollbars inside the widget. This is like using SIZEPOLICY=FIXED for a web component in a grid-based layout.

If the HEIGHT attribute is not specified in the .per file, the front-end will take the height attribute of the HTML elements of the web component HTML file into account, for example when using a <canvas /> element:

```
<body>
  <canvas id="myChart" height="100px" />
```

Using a URL-based web component

This section describes how to add a *URL-based web component* to your application.

To implement an URL-based web component:

URL-based web components are hosted on a third-party server and provide a specific service, such as a geographical location on a map. Make sure that the service is available.

1. Identify the URL of the hosted web component you want to use.
2. In the form file, define a WEBCOMPONENT field, without a COMPONENTTYPE attribute.

See Defining a URL-based web component in forms on page 1420 for more details.

3. In the program, set the URL of the hosted web component in the form field value.

   See Specifying the URL source of a web component on page 1420 for more details.

4. In the program, detect user interactions with an `ON CHANGE` control block, and control the URL-based web component with dedicated front calls.

   See Controlling the URL web component in programs on page 1421 for more details.

Defining a URL-based web component in forms

Adding a WEBCOMPONENT to the form file

To define a URL-based web component field, add a form field with the `WEBCOMPONENT` item type, without the `COMPONENTTYPE` attribute:

```
WEBCOMPONENT f001 = FORMONLY.mymap;
```

A web component field is typically defined with the `FORMONLY` prefix, as the data for the field is rarely stored in a database column.

The field type (and its corresponding program variable) must be a character string type. Consider using the `STRING` type to avoid any size limitation for the URL specification.

Sizing policy for web component fields

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars, which are generally resizeable. Use the appropriate form item attributes to get the expected layout and behavior. For more details, see Controlling the web component layout on page 1418.

Example

```
LAYOUT
GRID
{
[wc                        ]
[                          ]
[                          ]
[                          ]
[                          ]
}
END
END
ATTRIBUTES
WEBCOMPONENT wc = FORMONLY.mychart,
         STRETCH = BOTH;
END
```

Specifying the URL source of a web component

The content of URL-based web components is defined by the form field value. It can only be set by program.

Setting the initial URL

When the current form defines a `WEBCOMPONENT` form item without the `COMPONENTTYPE` attribute, it is a URL-based web component. The program can set the URL dynamically in field value:

```
DISPLAY "wc-URL" TO wc-field
```

or with:

```
DEFINE wc_field STRING
LET wc_field = "wc-URL"
DISPLAY BY NAME wc_field
```

or by using the variable in an `INPUT` dialog with the `UNBUFFERED` option:

```
DEFINE rec RECORD
   name STRING,
   mymap STRING
 END RECORD
...
LET rec.mymap = "http://www.openstreetmap.org"
INPUT BY NAME rec.* WITHOUT DEFAULTS
      ATTRIBUTES(UNBUFFERED)
   ...
```

Once the URL of the web component is defined, the initial URL content is shown by the front-end, and the end user can interact with it.

Changing the URL

During program execution, you can assigning another URL to the web component field value. The content will be updated to show the new URL.

This example implements a `MENU` dialog with actions that set different URLs to the web component field, changing the content based on the selected action:

```
MENU "test"
   ON ACTION map_1
      DISPLAY "http://www.openstreetmap.org" TO wc_field
   ON ACTION map_2
      DISPLAY "http://www.wikimapia.org" TO wc_field
   ON ACTION map_3
      DISPLAY "http://maps.google.com" TO wc_field
END MENU
```

Controlling the URL web component in programs

URL-based web components can be controlled with the field value and with front calls

Detecting user interaction in a web component with ON CHANGE

The content of an URL-based web component is defined by the field value.

When the end user interacts with the content, and if the remote service points to a different URL, the field value changes.

The URL change can be detected by implementing an `ON CHANGE` control block for the web component field. The trigger will be fired immediately when the URL changes:

```
DEFINE rec RECORD
           num INTEGER,
           name STRING,
           map STRING
       END RECORD
...
INPUT BY NAME rec.* WITHOUT DEFAULTS
    ATTRIBUTES(UNBUFFERED)
    ...
    ON CHANGE map
```

```
        CALL map_changed(rec.map)
    ...
```

Controlling URL-based web components with front calls

The web component can be manipulated with specific front calls. The web component-specific front calls are provided in the "`webcomponent`" front call module.

The `call` front call that can be used for general purposes. It takes as parameters the name of the form field, a JavaScript function to call, and optional parameters as required. The JavaScript function must be implemented in the HTML content pointed by the URL of the web component field. The front call returns the result of the JavaScript function.

```
DEFINE title STRING
CALL ui.Interface.frontCall("webcomponent", "call",
     ["formonly.url_field", "eval", "document.title"],
     [title] )
```

The `getTitle` function is another useful `webcomponent` front call that can get the title of the HTML document of the web component:

```
DEFINE info STRING
CALL ui.Interface.frontCall("webcomponent", "getTitle",
     ["formonly.url_field"], [info] )
```

Some providers return key information in the title of the HTML document.

Using a gICAPI web component

This section describes how to add a *gICAPI-based web component* to your application.

To implement a gICAPI-based web compoent:

1. Identify the web component you want to use and get the source code (HTML, JavaScript™, CSS).
2. Implement the gICAPI interface script for the web component.

   See The gICAPI web component interface script on page 1423 for more details about the gICAPI interface script implementation.
3. Define the location where the front end can find the gICAPI interface files. This depends on the front end technology used by your application.

   See Deploying the gICAPI web component files on page 1426 for more details.
4. Define a `WEBCOMPONENT` field in the form file. Use the `COMPONENTTYPE` attribute to define the root HTML file name describing the gICAPI web component.

   See Defining a gICAPI web component in forms on page 1428 for more details.
5. Use the web component in the dialog of the program.

   See Controlling the gICAPI web component in programs on page 1429 for more details.
6. If image resources are required by your web component, you must provide them as part of the gICAPI web component assets, or provide them from the program with a specific API.

   See Using image resources with the gICAPI web component on page 1430 for more details.

HTML document and JavaScript for the gICAPI object

A gICAPI web component is identified by an HTML document containing the JavaScript interface (or a reference to the .js file).

The HTML document is defined by the `COMPONENTTYPE` attribute of the `WEBCOMPONENT` form field. The name specified in this attribute will be used to identify the HTML file:

```
WEBCOMPONENT wc = FORMOMLY.chart,
```

```
    COMPONENTTYPE = "mychart"; -- Identifies "mychart.html"
```

The HTML document must reference (or contain) the JavaScript implementing the gICAPI interface:

```
<!DOCTYPE html>
<html>
<head>
  <title>The title</title>
  <script language="JavaScript" type="text/javascript" src="wc_echo.js"></
script>
</head>
<body>
<div style="background-color:green;width:3000px;height:3000px;" >
here
</div>
</body>
</html>
```

The gICAPI web component interface script

The gICAPI web components are controlled on the front end through a `gICAPI` interface object, defined in an JavaScript™ script.

gICAPI interface basics

The goal of the gICAPI interface is to manage communication between the program and the web component with a basic API, to handle the interaction events, the focus and the value of the web component field.

The interface script is written in JavaScript™ and bound to the `WEBCOMPOMENT` form field by using an HTML document as container.

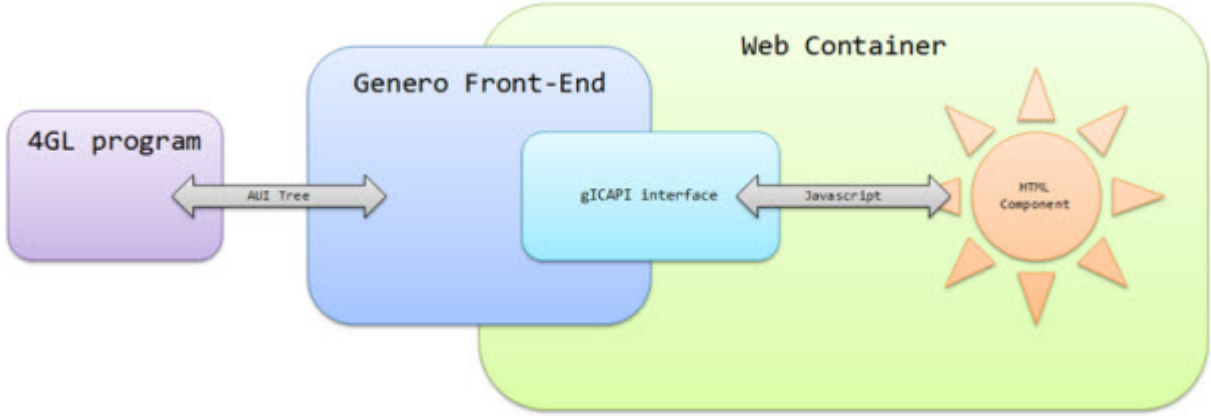

Figure 100: Web Component communication management

The gICAPI web component API relies on a published global JavaScript™ object named `gICAPI`.

Predefined function for gICAPI interface initialization

The `onICHostReady()` global function must be implemented, to execute code after the `gICAPI` interface has been initialized.

> **Note:** The `gICAPI` object is ready in the context of `onICHostReady()`.

The programming interface of the gICAPI class is identified by a version number, to make sure that the user code corresponds to the current gICAPI implementation. Verify that t runtime version number matches the gICAPI version used during development, by checking the value passed as parameter to `onICHostReady()`.

> **Note:** The `onICHostReady()` function is mandatory to check the gICAPI interface version, and to implement the assignment of `gICAPI.on*` callback functions as described later in this topic.

Table 294: Function to handle the gICAPI interface

Method	Description
`onICHostReady( version String )`	Called when the gICAPI web component interface is ready. The version passed in the parameter allows you to check that your component is compatible with the API, and initialization code can be execute in this function.

In order to check the interface version, implement the `onICHostReady()` function as follows:

```
onICHostReady = function(version) {
    if ( version != 1.0 )
        alert('Invalid API version');
    // More initialization code...
}
```

gICAPI callbacks to handle events coming from the program

The `on*` functions must be implemented as callbacks (functions assigned to `gICAPI` object members), in order to detect changes comming from the program (such as a web component field value modification with `onData()`).

> **Important:** The `gICAPI` object must be instanciated, before defining and assigning these methods. The `gICAPI` object is created and initialized by the web component framework before calling the `onICHostReady()` global function. Therefore, `on*` callback methods are typically defined and assigned to the `gICAPI` object, inside the body of the `onICHostReady()` function.

```
onICHostReady = function(version) {

    if ( version != 1.0 )
        alert('Invalid API version');

    current_color = "#000000";

    gICAPI.onProperty = function(properties) {
        var ps = eval('(' + properties + ')');
        document.getElementById("title").innerHTML = ps.title;
    }

    ...
```

Table 295: Object methods of gICAPI (program to component)

Method	Description
`onData( data String )`	Called when the program value of the form field is updated by the runtime system (for example, when doing a `DISPLAY` *`variable`* `TO` *`wc_field`*) or when the VM returns the validated value, after a `gICAPI.SetData()` was performed by the web component. The VM value is provided in the `data` parameter. When the `onData()` function is fired, you will typicaly assign the data value to the web component, or check that the VM has validated your `SetData()` request, when the value sent and the value returned by the VM do match.

Method	Description
	The data must be a string, it is not a scalar value, it is typically serialized as a JSON string. **Note:** Use util.JSON classes to serialize / de-serialize structured data (i.e. RECORDs or ARRAYs)
`onFocus( polarity Boolean )`	Called when the runtime system / program changes the focus (for example, with a `NEXT FIELD` instruction, or when the user tabs through the form fields). If the web component gains the focus, `polarity` is set to `true`. If the web component loses the focus, `polarity` is set to `false`. **Note:** This function is also called after a `gICAPI.setFocus()`, if the runtime system has accepted to set the focus to the web component field.
`onProperty( properties String )`	Called when one of the properties of the component is set at form creation time, or when a property is changed dynamically once the form and web component are loaded. The format used to pass the property set is JSON. **Note:** Each time this function is called, all properties are provided in the parameter.

gICAPI functions to send events to the program

Table 296: Object methods of gICAPI (component to program)

Method	Description
`Action( action String )`	Triggers an action event, which will execute the corresponding `ON ACTION` code. If the named action is not available (not active or does not exist), this function has no effect.
`SetData( data String )`	Registers data to be sent to the program, to set the form field value. The data must be a string, it is not a scalar value, it is typically serialized as a JSON string. **Note:** The gICAPI-based web component field must be the current field (i.e. the web component field must have the focus), otherwise `SetData()` will be ignored. The value change is transmitted to the runtime system when the web component field loses the focus. If you want to transmit the value change the runtime system immediately, `gICAPI.SetData()` must be used in conjunction with `gICAPI.Action()`, in order to fire an action. After a `SetData()` the value is sent to the VM which can accept or reject the field value change. In order to detect that the VM has accepted the value, the `onData()` function will be called with the same value as the value sent by `SetData()`. The web component then receives an indication that the VM has accepted the value change. **Note:** Data is transmitted as plain text; Sending a large amount of data is not recommended.
`SetFocus()`	Generates a focus change request. The tabbing order and focus management is controlled by the runtime system: If the focus change request succeeds, `gICAPI.onFocus()` will be called with the `true` parameter.

Method	Description
	The focus request may fail when: • the current field does not satisfy field constraints (`VERIFY`, data type conversion, and so on.) • due to program logic (`AFTER FIELD ...`, `NEXT FIELD`).

Deploying the gICAPI web component files
Deploy web component files to the front-end platform before using gICAPI web components.

Deploying the HTML document and the JavaScript gICAPI interface

The gICAPI web component files (main HTML file, additional JavaScript files and other potential assets) must be available on the platform where the front-end executes. According to your configuration, Genero supports several solutions to provide the gICAPI web component files from a single location. In a distributed configuration with many individual front-end nodes, consider centralizing the gICAPI files on a server, instead of copying the gICAPI web component files manually to each front-end device.

> **Important:** If the main gICAPI HTML document references external JavaScript files, put these files in the same directory as the HTML file referencing them.

Deploying gICAPI web component files with the GAS (using any front-end)

When using the Genero Application Server, the gICAPI web component files must be deployed as part of the application program files.

The `.xcf` configuration file of your application must define the base path to search for HTML web component files. This base path is defined by the `WEB_COMPONENT_DIRECTORY` entry of the `EXECUTION` element:

```
<APPLICATION ...
  <EXECUTION>
     ...
     <WEB_COMPONENT_DIRECTORY>$(application.path)/webcomponents</
WEB_COMPONENT_DIRECTORY>
     ...
```

The HTML document must be located in a sub-directory below the base path, using the same name as defined by the `COMPONENTTYPE` attribute. As result, the complete path to the HTML document will be:

`base-path/component-type/component-type``.html`

> **Note:** The above example uses the default value of the `WEB_COMPONENT_DIRECTORY` parameter. If you locate your gICAPI web component files under *`appdir`*`/webcomponents/`*`component-type`*, you do not need to set this element in the `.xcf` file.

For example, if the form file defines the `COMPONENTTYPE` attribute as follows:

```
WEBCOMPONENT wc = FORMOMLY.mychart,
   COMPONENTTYPE = "3DChart";
```

If `WEB_COMPOMENT_DIRECTORY` is defined as "`$(application.path)/webcomponents`", and `application.path` is "`/opt/var/gas/appdata/app/myapp`", the HTML document will be found in:

- `/opt/var/gas/appdata/app/myapp/webcomponents/3DCshart/3DChart.html`

To simplify deployment of gICAPI web components with the GAS, consider using the `fglgar` utility. For more details, see GAS documentation.

> **Note:** Unlike other front-ends, the GAS will not ask the VM for gICAPI web component files through the FGLIMAGEPATH mechanism, as described in the next section. The FGLIMAGEPATH mechanism applies only to front-ends using direct connection.

Centralizing gICAPI web component files for GMA, GMI and GDC front-ends (direct connection)

When using a front-end with a direct connection (i.e. not through the GAS), you can automatically transfer web component files to the front-end. Locate the gICAPI web component files on the computer where programs execute and set the FGLIMAGEPATH on page 182 environment variable. The web component files are automatically transferred if the program executes on a server and the gICAPI web component files are not found locally by the front-end.

When using FGLIMAGEPATH, gICAPI web component files are searched in the following order:

1. *FGLIMAGEPATH-location*`/webcomponents/`*component-type*`/`*component-type*`.html`
2. *FGLIMAGEPATH-location*`/`*component-type*`.html`

If assets such as `.js`, `.css`, `.png` files are referenced by a relative path name in the HTML content, the resources are also transferred via the FGLIMAGEPATH mechanism. If the assets use an absolute path with a concrete URL scheme (`http://something`), the HTML viewer will try to get the resource from the URL location.

> **Note:** Providing gICAPI web component files through FGLIMAGEPATH simplifies the development process for mobile applications, as you do not have to copy the files to the device.

For example, if you define the gICAPI web component field as follows:

```
WEBCOMPONENT wc = FORMOMLY.mychart,
   COMPONENTTYPE = "3DChart";
```

If the FGLIMAGEPATH search path contains "`/opt/myapp`", and the gICAPI files are located under /opt/myapp/webcomponents/3DChart", the gICAPI web component HTML document will be found on the server at:

- `/opt/myapp/webcomponents/3DChart/3DChart.html`

Deploying gICAPI web component files for an embedded mobile application

When running the application on mobile (i.e. in embedded mode), the gICAPI web component files (along with other assets) can be deployed on the device: The files will be found locally on the device.

> **Note:** The GDC front-end supports also local gICAPI file lookup in the GDC installation directory. However, this solution is supported for backward compatibility: Consider centralizing the gICAPI web component files on the application server, by using the GAS or the FGLIMAGEPATH mechanism as described above.

Mobile front-ends make a local search for gICAPI web component files in the following order:

1. *appdir*`/webcomponents/`*component-type*`/`*component-type*`.html`
2. *appdir*`/`*component-type*`.html`

Here *component-type* is the name defined by the `COMPONENTTYPE` attribute in the form definition file.

For more details about *appdir* on mobile devices, see Deploying mobile apps on Android devices on page 2572 and Deploying mobile apps on iOS devices on page 2584.

Defining the gICAPI files search path by program

To define the base URL to the web component files for a given application, you can also use the setWebComponentPath on page 1901 front call. The URL must be a well formatted absolute URL (e.g. `"http://myserver/components"` or `"file:///c:/components"`).

Important: This front-call is provided for backward compatibility, consider using one of the other mechanisms described in this topic.

Recommended web component directory layout

When using the default settings in any configuration (i.e. no FGLIMAGEPATH defined, default GAS settings), put the gICAPI web component files under a `webcomponents` directory, along with the other program files, for example:

```
appdir
appdir/main.42m
appdir/form1.42f
appdir/form2.42f
appdir/webcomponents/3DChart
appdir/webcomponents/3DChart/3DChart.html
appdir/webcomponents/3DChart/3DChart.js
appdir/webcomponents/3DChart/3DChart.css
appdir/webcomponents/3DChart/icon_close.png
...
```

Defining a gICAPI web component in forms

When defining a gICAPI web component in a form specification file, you can also provide a sizing policy and define additional properties.

Adding a WEBCOMPONENT to the form file

To define an gICAPI web component field, add a form field with the `WEBCOMPONENT` item type and the `COMPONENTTYPE` attribute. The `COMPONENTTYPE` attribute is mandatory when defining a gICAPI web component; it defines the root HTML file name describing the gICAPI web component.

A web component field is typically defined with the `FORMONLY` prefix, as the data for the field is rarely stored in a database column.

Sizing policy for web component fields

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars, which are generally resizeable. Use the appropriate form item attributes to get the expected layout and behavior. For more details, see Controlling the web component layout on page 1418.

Defining gICAPI web component properties

Since web component field definitions are generic, you must use the `PROPERTIES` attribute to set specific parameters for the component.

The `PROPERTIES` attribute can define a list of:

- simple properties (*`name = value`*),
- array properties (*`name = ( value1, value2, ... )`*)
- map/dictionary properties (*`name = ( sub-name1 = value1,sub-name2 = value2, ... )`*)

where *name* is a simple identifier, and where *values* can be numeric or string literals.

Component properties defined in the `PROPERTIES` attribute are transmitted to the web component through the `onProperty()` method of the `gICAPI` object.

The name of a property defined in the `PROPERTIES` attribute is converted to lowercase by the form compiler. To avoid mistakes, a good programming pattern is to define properties in lowercase, in both the interface script and in the form definition file. Property names are not checked at compile time, so nonexistent or mistyped properties will be ignored at runtime.

Example

```
LAYOUT
GRID
{
[wc                        ]
[                          ]
[                          ]
[                          ]
[                          ]
}
END
END
ATTRIBUTES
WEBCOMPONENT wc = FORMONLY.mychart,
         COMPONENTTYPE = "3DCharts",
         STRETCH = BOTH,
         PROPERTIES = ( type = "bars",
                        x_label = "Months",
                        y_label = "Sales" );
END
```

Controlling the gICAPI web component in programs

Controlling the gICAPI-based web components with ON ACTION

Once a `WEBCOMPONENT` field is defined in the form file with the `COMPONENTTYPE` attribute pointing to an HTML content file, it can be used as a regular edit field in program dialogs. The data of the gICAPI web component is transmitted with the field value, and usually needs to be serialized and deserialized (typically in JSON), when the data is not a simple scalar value.

When the web component field value is changed in the program, the `onData()` method of the `gICAPI` object is fired, and you can parse the serialized string in your JavaScript.

In order to detect web component value changes in the program, you need to combine the `gICAPI.setData()` and `gICAPI.Action()` methods, to transmit the value and to fire an action, that will be handled by an `ON ACTION` block.

> **Note:** The `ON CHANGE` trigger is not executed automatically for gICAPI-based web components, just by using `gICAPI.SetData()`.

The next example serializes and de-serializes a dymamic array using the JSON format:

```
IMPORT util
...
DEFINE mywc STRING
DEFINE data_array DYNAMIC ARRAY OF RECORD ...
...
...
INPUT BY NAME mywc, ...
      ATTRIBUTES(WITHOUT DEFAULTS, UNBUFFERED)
   ...
   ON ACTION set_wc_values -- Bound to form button
      LET mywc = util.JSON.stringify( data_array )

   ON ACTION wc_data_changed -- Triggered by gICAPI.Action()
      CALL util.JSON.parse( mywc, data_array )
...
```

> **Important:** All data will be transmitted through the abstract user interface protocol: Transmitting a lot of data will not be efficient and is likely to slow down your application.

Controlling the gICAPI-based web components with properties

Use the `PROPERTIES` attribute in the form specification, to define the configuration of the field. When a property of the web component is modified, the `onProperty()` method of the `gICAPI` object in the JavaScript will be invoked. Note that the complete property set will be passed, even if a single property is modified. Use JSON utilities to handle property set:

```
gICAPI.onProperty = function(propertySet) {
    var ps = eval('(' + propertySet + ')');
    document.getElementById("title").innerHTML = ps.title;
}
```

Controlling gICAPI-based web components with front calls

The web component can be manipulated with specific front calls. The web component-specific front calls are provided in the "`webcomponent`" front call module.

The `call` front call that can be used for general purposes. It takes as parameters the name of the form field, a JavaScript function to call, and optional parameters as required. The JavaScript function must be implemented in the HTML content of the gICAPI web component field. The front call returns the result of the JavaScript function.

```
DEFINE title STRING
CALL ui.Interface.frontCall("webcomponent", "call",
     ["formonly.mychart", "eval", "document.title"],
     [title] )
```

The `getTitle` function is another useful `webcomponent` front call that can get the title of the HTML document of the web component:

```
DEFINE info STRING
CALL ui.Interface.frontCall("webcomponent", "getTitle",
     ["formonly.url_field"], [info] )
```

Some providers return key information in the title of the HTML document.

Using image resources with the gICAPI web component

This section explains how to use image resources in a gICAPI web component.

Image resources in gICAPI web components

In some cases, web components require image resources, which can be classified as follows:

1. Common (static) image resources, that are part of the gICAPI web component implementation. This category of image resource can be referenced with absolute URLs (retrieved automatically by the HTML viewer), or can be deployed as part of the gICAPI web component assets, when referenced with relative URLs.
2. Private (variable) image resources, that are displayed by the program at runtime. This category of image resource can be referenced with absolute URLs (retrieved automatically by the HTML viewer), or can be provided by using the `ui.Interface.filenameToURI()` / FGLIMAGEPATH mechanism (as described below).

Referencing image resources in HTML

Image resources are typically referenced in HTML within the `<img/>` element, by setting the `src` attribute to a relative or absolute URL:

The following example uses an absolute URL:

```
<img src="http://www.4js.com/images/smiley.gif" alt="Smiley face" height=
 "42" width= "42" >
```

This example uses a relative URL:

```
<img src="smiley.gif" alt="Smiley face" height= "42" width= "42" >
```

The gICAPI web component framework can automatically retrieve image resources. If the value is not an absolute or relative URL that can be resolved by the HTML viewer, the image resources are retrieved from the Genero application using the the `ui.Interface.filenameToURI()` / FGLIMAGEPATH mechanism.

Providing static images in gICAPI web component files

To provide common static images as assets of your gICAPI web component, provide the image files along with the main HTML file, typically in a dedicated directory. For example, if you define the following directory structure:

```
3DChart/3DChart.html
3DChart/images/redraw.gif
3DChart/images/fetchdata.gif
```

The HTML content of the web component can reference common static images as follows:

```
<img src="images/redraw.gif" alt="Smiley face" height= "42" width= "42" >
```

Providing application images from Genero programs

Some gICAPI web components display variable image resources provided at runtime. For example, a photo gallery web component displaying pictures. Such image resources are usually private to the application.

To use image resources that are not static images part of the gICAPI web component assets:

1. Reference absolute URLs directly in the HTML content (in `"src"` attributes of image elements) with `http:`, `https:` or `file:` shemes, to be retrieved automatically by the HTML viewer, or:
2. Reference image resources in the HTML content with the URI returned from the `ui.Interface.filenameToURI()` method, to provide image files from the platform where the application executes (can be a server or mobile device):
   - When running the application on a server behind the GAS, the `filenameToURI()` method will convert the local file path to a URL that will make the image file available through the GAS.
   - When using a direct connection to the front-end (typical GDC desktop configuration with application running on a server), the file name will be returned as is and the images will then be transmitted through the FGLIMAGEPATH mechanism, as described in Providing the image resource on page 784.
   - When running apps on mobile devices, the `filenameToURI()` method will build the complete path to the local file, according to the list of directories defined in the FGLIMAGEPATH environment variable. The image resource is then directly read from the device file system.

   Try Example 5: Application images in gICAPI web component on page 1445, to see this method in practice.

Examples

Several examples show you how to include Web components in your program.

Example 1: URL-based web component using Google maps

This example shows how to implement a simple mobile application using a `WEBCOMPONENT` field interacting with Google maps

The form file: webcomp.per

```
LAYOUT
GRID
{
[f1                    ]
[                      ]
[                      ]
[                      ]
[                      ]
[                      ]
[                      ]
[                      ]
[f2                    ]
[f3                    ]
[                      ]
}
END
END
ATTRIBUTES
WEBCOMPONENT f1 = FORMONLY.mymap, STRETCH=BOTH;
BUTTONEDIT f2 = FORMONLY.location, ACTION=set_loc;
TEXTEDIT f3 = FORMONLY.value, STRETCH=X;
END
```

The program file: webcomp.4gl

```
MAIN
    CONSTANT c_gmaps = "http://maps.google.com/"
    DEFINE rec RECORD
                mymap STRING,
                location STRING,
                value STRING
           END RECORD
    OPEN FORM f1 FROM "webcomp"
    DISPLAY FORM f1
    LET rec.location = "Paris"
    LET rec.mymap = c_gmaps||"?q="||rec.location
    INPUT BY NAME rec.* WITHOUT DEFAULTS
          ATTRIBUTES(UNBUFFERED)
        ON ACTION set_loc
           LET rec.mymap = c_gmaps||"?q="||rec.location
           LET rec.value = rec.mymap
        ON CHANGE mymap
           LET rec.value = rec.mymap
           MESSAGE "URL has changed! "||CURRENT HOUR TO FRACTION(3)
    END INPUT
END MAIN
```

Example 2: Calling a JavaScript function of a gICAPI web component

This example shows how to call a JavaScript function with the "call" front call

The form file: wc_echo.per

```
ACTION DEFAULTS
  ACTION data_available(DEFAULTVIEW=NO)
```

```
END
LAYOUT
GRID
{
[data                                  ]
[                                      ]
[                                      ]
}
END
END
ATTRIBUTES
WEBCOMPONENT data = formonly.data,
   COMPONENTTYPE="wc_echo",
   STRETCH=BOTH;
END
```

The HTML file: wc_echo.html

```
<!DOCTYPE html>
<html>
<head>
  <title>The title</title>
  <script language="JavaScript" type="text/javascript" src="wc_echo.js"></
script>
</head>
<body>
<div style="background-color:green;width:3000px;height:3000px;" >
here
</div>
</body>
</html>
```

The JavaScript file: wc_echo.js

```
function echoString(str) {
  return str;
}

function echoObject(ostr) {
  var o = JSON.parse(ostr);
  // do something and return back
  return JSON.stringify(o);
}

onICHostReady = function(version) {

   if ( version != 1.0 )
      alert('Invalid API version');

   gICAPI.onProperty = function(p) {
      var myObject = eval('(' + p + ')');
      if (myObject.url!="") {
        setTimeout( function () {
          downloadURL(myObject.url);
        }, 0);
      }
   }

}
```

The program file: wc_echo.4gl

```
MAIN
  OPEN FORM f FROM "wc_echo"
  DISPLAY FORM f
  MENU "test"
    COMMAND "echo"
      CALL echo()
    COMMAND "exit"
      EXIT MENU
  END MENU
END MAIN

FUNCTION echo()
  DEFINE a,title,ut STRING
  TRY
    CALL ui.Interface.frontCall("webcomponent","call",
            ["formonly.data","eval","Math.floor(5/2)"],[ut])
    CALL ui.Interface.frontCall("webcomponent","getTitle",
            ["formonly.data"],[title])
    CALL ui.Interface.frontCall("webcomponent","call",
            ["formonly.data","echoString","hello"],[a])
    MESSAGE "ut:",ut,",a:",a,",title:",title
  CATCH
     ERROR err_get(status)
  END TRY
END FUNCTION
```

Example 3: Implementing Google+ authentication with a URL-based web component
This example shows how to authenticate the user with a google+ account on a mobile platform, using the OAuth technology.

The form file: wc_oauth.per

```
LAYOUT(text="Proceed to the authorization")
GRID
{
[f1                ]
[                  ]
[                  ]
}
END
END
ATTRIBUTES
WEBCOMPONENT f1 = FORMONLY.wc_oauth, STRETCH=BOTH;
END
```

The Google+ API utility file: wc_oauth.4gl

```
# Google+ Authorization API:
# See https://developers.google.com/accounts/docs/OAuth2InstalledApp

IMPORT com
IMPORT util

# The persistant datastore

Example 4: Color picker gICAPI web component
This topic describes the different steps to implement a gICAPI-based web component.

Introduction

In this example, we will implement a simple color picker, that will allow the user the select a color from a predefined set. Colors are drawn as square boxes using SVG graphics, user can change the current selected color with a separate `COMBOBOX` field, modify the title of the HTML body, and query for the color list with a `webcomponent.call` front call.

The HTML file is described in detail, and complete code example with program and form file is available at the end of this topic.

HTML code description

As any HTML source code, the file starts with the typical HTML tags:

```
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
```

Note: The "viewport" meta is provided to adjust the viewport size for mobile devices.

The JavaScript™ code needs to the enclosed in a `<script>` element:

```
<script language="JavaScript">
```

Global variables are defined to hold information that must be persistent during the web component life:

```
var current_color;
var wanted_color;
var has_focus;
```

The global function `onICHostReady()` will be called by the front end, when the web component interface is ready. The version passed as parameter allows you to check that your component code is compatible with the current gICAPI framework, and to define and assign the `gICAPI.on*` callback methods (these will be defined in the body of the `onICHostReady()` function:

```
onICHostReady = function(version) {

    if ( version != 1.0 )
        alert('Invalid API version');

    ... some initialization code ...

    gICAPI.onProperty = function(propertySet) {
        ... see below for function body ...
    }

    gICAPI.onData = function(data) {
        ... see below for function body ...
    }

    gICAPI.onFocus = function(polarity) {
        ... see below for function body ...
    }

}
```

At this point, the gICAPI interface is ready and the `gICAPI` object can be used.

The `onProperty()` method is called when a web component property changes (properties will be initialized at form creation, or changed during form usage). In this code example, when the property "title" is changed by the program, the element with id="title" is updated with the new title. The `eval` built-in JavaScript function is used to convert the JSON string property set to a JSON object, to find the "title" property:

```
gICAPI.onProperty = function(propertySet) {
    var ps = eval('(' + propertySet + ')');
    document.getElementById("title").innerHTML = ps.title;
}
```

Note: The `ON ACTION change_title` in the dialog code will change the title property after the form initialization, to show that the `onProperty()` function can also be invoked after the web component field creation.

The `showFocusRectangle()` function shows a border around the specified color item (SVG element), according to the color identifier passed as parameter and the focus status (focus can be true, false or -1, to keep the current border color and just modify the position of the border):

```
showFocusRectangle = function(color, focus) {
```

```
    // See complete code example for details
}
```

The `changeColor()` function implements a color change, by registering a field value change with `gICAPI.SetData()`, and by triggering a specific action with `gICAPI.Action()`, to inform the program that a color was selected:

```
changeColor = function(color) {
    current_color = color;
    showFocusRectangle(current_color, true);
    gICAPI.SetData(current_color);
    gICAPI.Action("color_selected");
}
```

Next lines implement the `onFocus()` function, executed when the web component gets or loses the focus. The code distinguishes the case when the focus is gained (by a mouse click on a color item), selecting a new color with a call to `changeColor()`, and the case when the focus is set to the web component by the runtime system. A blue border will be added to the current color item, when the component gets the focus, and the border color is reset to gray when the focus is lost.:

```
gICAPI.onFocus = function(polarity) {
    if ( polarity == true ) {
        has_focus = true;
        if (wanted_color != undefined) {
            changeColor(wanted_color);
            wanted_color = undefined;
        } else {
            showFocusRectangle(current_color, true);
        }
    } else {
        has_focus = false;
        showFocusRectangle(current_color, false);
    }
}
```

The `onData()` function must be implemented to detect web component value changes done in the program, and to acknowledge . This will be triggered by assigning the `rec.webcomp` variable in the dialog code, typically in the `ON CHANGE color` block, when modifying the combobox value. The `showFocusRectangle()` function moves the focus border to the color item corresponding to the color identifier passed as parameter.:

```
gICAPI.onData = function(data) {
    current_color = data;
    showFocusRectangle(current_color, -1);
}
```

The `selectColor()` function will be called through the `onclick` event of the `<rect>` SVG elements representing colors. If the web component does not have the focus yet, the function will call `gICAPI.SetFocus()`, in order to ask the runtime system, if the focus can go to the web component field. If the runtime system accepts to set the focus to the web component field, the `onFocus()` method will be called with `true` as parameter, and will handle the requested color change (using `wanted_color`). if the focus cannot be set to the web component, the `onFocus()` method will not be called:

```
selectColor = function(color) {
    if (has_focus) {
        changeColor(color);
    } else {
        wanted_color = color;
        gICAPI.SetFocus();
        // Color item change is done in onFocus(), because
```

```
        // VM may refuse to set the focus to the wc field.
    }
}
```

> **Note:** The only way to detect that the focus was gained by the web compoment field, is when `onFocus(true)` is called.

End the JavaScript element with the `</script>` ending tag:

```
</script>
```

Close the HTML head element with the `</head>` ending tag:

```
</head>
```

The rest of the HTML page defines the graphical elements for the color picker, with a <h3> title and and an `<svg>` element containing `<rect>` element to show clickable color items. Note the `<rect>` element with `id="focus_rectangle"`, used to show a border for the current color item:

```
<body height="100%" width="100%">
<h3 id="title">no-title</h3>

<svg id="svg_container" width="230" height="130">

  <rect x="5" y= "5" rx="5" ry="5" width="30" height="30"
        id="#FFFFCC"
        style="fill:#FFFFCC;stroke:black;stroke-width:1"
        onclick="selectColor('#FFFFCC')" />
  ...

  <rect x="178" y= "73" rx="7" ry="7" width="34" height="34"
        id="focus_rectangle"
        style="fill:none;stroke:gray;stroke-width:3" />

</svg>

</body>
```

Example 5: Application images in gICAPI web component
This topic shows how to display application images in a gICAPI-based web component.

Introduction

In this example, we will focus on the technique to display application images dynamically in gICAPI web component HTML content, by using the `ui.Interface.filenameToURI()` method.

This sample application can be used with any Genero front-end configuration (as a web application with the GAS, in direct (development) mode with GDC/GMA/GMI, or as a mobile app running on a device)

For gICAPI programming basics, see Example 4: Color picker gICAPI web component on page 1437.

The complete code example with program and form file is available at the end of this topic.

HTML code description

The HTML source file starts with the typical HTML tags:

```
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
```

The JavaScript™ code defines the `onICHostReady()`. This function checks for the API version and defines the `set_image()` JavaScript function that will set the `src` attribute in the image element:

```
<script language="JavaScript">
  onICHostReady = function(version) {

    if ( version != 1.0 )
        alert('Invalid API version');

    set_image = function(ressource) {
        var ie=document.getElementsByName("myimage")[0];
        ie.src=ressource;
    }

  }
</script>
```

Close the HTML head element with the `</head>` ending tag:

```
</head>
```

The body of the HTML page contains two elements:

- an `h2` title,
- the `image` element, identified by a name:

```
<body height="100%" width="100%">
    <h2>Testing application images in gICAPI Web Component</h2>
    <img name="myimage" />
  </body>
```

```
</html>
```

Application directory structure

In order to easily build and install on mobile devices, create the following directory structure:

```
top-dir
|
|-- fglprofile
|-- main.4gl
|-- main.42m
|-- myform.per
|-- myform.42f
|-- images                  (application image files)
|   |-- image01.jpg
|   |-- image02.jpg
|   |-- image03.jpg
|   ...
|-- webcomponents
|   |-- mywebcomp
|       |-- mywebcomp.html
|
|-- gmi
|   |-- iOS resources       (icons, etc)
|   ...
|-- gma
|   |-- Android resources   (icons, etc)
|   ...
|
```

For more details about building mobile apps from the command line, see Deploying mobile apps on page 2572.

Providing image files

Copy some of your favorite images in the "`images`" directory.

The sample program will scan this directory to fill a combobox and let you choose the image to be displayed:

```
FUNCTION init_image_list(cb)
    DEFINE cb ui.ComboBox
    DEFINE h INTEGER,
           fn STRING
    LET
 h=os.Path.dirOpen(os.Path.join(base.Application.getProgramDir(),"images"))
    WHILE h > 0
        LET fn = os.Path.dirNext(h)
        IF fn IS NULL THEN EXIT WHILE END IF
        IF fn=="." OR fn==".." THEN CONTINUE WHILE END IF
        CALL cb.addItem(fn, fn)
    END WHILE
END FUNCTION
```

> **Note:** When deployed on a mobile device, the images directory will be part of the application program files. Thus to access the directory you need to add the `base.Application.getProgramDir` on `page 1705` path. For more details, see Directory structure for GMA apps on page 2572 and Directory structure for GMI apps on page 2584.

In the program code, the `ON CHANGE image` interaction block will perform a front call to set the image resource in the gICAPI web component:

```
  ON CHANGE image
     LET rec.uri = ui.Interface.filenameToURI(rec.image)
     CALL ui.Interface.frontCall("webcomponent","call",
                      ["formonly.wc","set_image",rec.uri],[])
```

FGLIMAGEPATH environment settings

In order to find image resources when not executing behing a GAS, you need to define the FGLIMAGEPATH environment variable as follows:

```
$ FGLIMAGEPATH=$PWD/images:.
```

For deployed mobile applications, the FGLIMAGEPATH environment variable must be set in the default fglprofile file, by using the $FGLAPPDIR place holder:

```
mobile.environment.FGLIMAGEPATH = "$FGLAPPDIR/images:."
```

For more details about FGLIMAGEPATH settings, see Providing the image resource on page 784.

Complete source code

File `myform.per`:

```
LAYOUT
GRID
{
Current image: [f1                  ]
Image URI:     [f2                  ]

Canvases

Canvases are form drawing areas.

- Understanding canvases on page 1449
- CANVAS item definition on page 936
- Syntax of canvas nodes on page 1450
- Using canvases on page 1451
  - Canvas drawing area on page 1451

- Step by step canvas example on page 1452
- Canvas drawing functions on page 1453

Understanding canvases

A canvas element defines a drawing area in a form, to show basic colored shapes.

> **Important:** This feature is not supported on mobile platforms.

Canvas can draw lines, rectangles, ovals, circles, texts, arcs, and polygons. Keys can be bound to graphical elements for selection with a right or left mouse click.

In programs, you select a given canvas area by name and you create the shapes in the abstract user interface tree by using the built-in DOM API, or helper functions.

The painted canvas is automatically displayed on the front end when an interactive instruction is executed, such as `MENU` or `INPUT`.

Each canvas element is identified by a unique number (id). You can use this identifier to bind mouse clicks to canvas elements.

> **Note:** Consider using Web Components for specific drawing needs (charts, graphics). For example using SVG graphics in a Web Component is more powerfull as the Canvas framework.

CANVAS item definition

Defines an area in which you can draw shapes, in a grid-based layout.

Syntax

```
CANVAS item-tag: item-name [  , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *item-name* identifies the form item.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

`COMMENT`, `HIDDEN`, `TAG`.

Usage

Define the rendering and behavior of a canvas drawing area item tag, with a `CANVAS` element in the `ATTRIBUTES` section.

> **Note:** The `CANVAS` feature is deprecated, consider using a `WEBCOMPONENT` with SVG graphics.

Example

```
LAYOUT
GRID
{
[cvs1             ]
[                 ]
[                 ]
 ...

}
END
END

ATTRIBUTES
```

```
CANVAS cvs1: canvas1;
...
```

Syntax of canvas nodes

Canvas areas are defined in forms with the following XML syntax:

```
<Canvas colName="name" >
{ <CanvasArc canvasitem-attribute="value" [...] />
| <CanvasCircle canvasitem-attribute="value"[...] />
| <CanvasLine canvasitem-attribute="value"[...] />
| <CanvasOval canvasitem-attribute="value"[...] />
| <CanvasPolygon canvasitem-attribute="value"[...] />
| <CanvasRectangle canvasitem-attribute="value"[...] />
| <CanvasText canvasitem-attribute="value"[...] />
} [...]
</Canvas>
[...]
```

Table 297: Types of canvas element

Name	Description
CanvasArc	Arc defined by the bounding square top left point, a diameter, a start angle, a end angle, and a fill color.
CanvasCircle	Circle defined by the bounding square top left point, a diameter, and a fill color.
CanvasLine	Line defined by a start point, an end point, width, and a fill color.
CanvasOval	Oval defined by rectangle (with start point and endpoint), and a fill color.
CanvasPolygon	Polygon defined by a list of points, and a fillcolor.
CanvasRectangle	Rectangle defined by a start point, an end point,and a fill color.
CanvasText	Text defined by a start point, an anchor hint, the text, and a fill color.

Table 298: Attributes of canvas elements

Name	Values	Description
startX	INTEGER (0->1000)	X position of starting point.
startY	INTEGER (0->1000)	Y position of starting point.
endX	INTEGER (0->1000)	X position of ending point.
endY	INTEGER (0->1000)	Y position of ending point.
xyList	STRING	Space-separated list of Y X coordinates. For example: "23 45 56 78" defines (x=23,y=45) (x=56,y=78).
width	INTEGER	Width of the shape.

Name	Values	Description
`height`	`INTEGER`	Height of the shape.
`diameter`	`INTEGER`	Diameter for circles and arcs.
`startDegrees`	`INTEGER`	Beginning of the angular range occupied by an arc.
`extentDegrees`	`INTEGER`	Size of the angular range occupied by an arc.
`text`	`STRING`	The text to draw.
`anchor`	`"n","e","w","s"`	Anchor hint to give the draw direction for texts.
`fillColor`	`STRING`	Name of the color to be used for the element.
`acceleratorKey1`	`STRING`	Name of the key associated to a left button click.
`acceleratorKey3`	`STRING`	Name of the key associated to a right button click.

Using canvases

Canvas drawing area

The canvas area represents an abstract drawing page where you define size and location of shapes with coordinates from (0,0) to (1000,1000).

The origin point (0,0), is on the left-bottom of the drawing area.

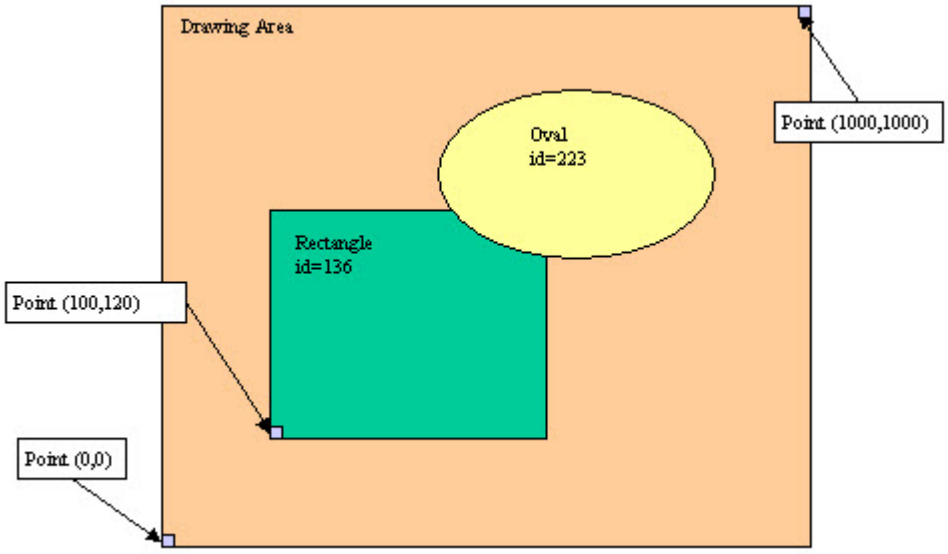

Figure 101: Canvas area diagram

The drawing area is defined in the form file with a `CANVAS` form item. At runtime, you draw the content of canvas areas in the Abstract User Interface tree: In a form defining canvas areas, the Abstract User Interface tree contains empty `<Canvas>` nodes that you can fill with canvas items.

A canvas node is identified in the program by the `name` attribute. You can get the canvas node by name with the `Window.getElement(`*name*`)` method.

You cannot drop canvas area nodes, as they are read-only in a form definition.

Step by step canvas example

First define a drawing area in the form file with the CANVAS form item type. In this example, the name of the canvas field is '`canvas01`'. This field name identifies the drawing area:

```
DATABASE FORMONLY
LAYOUT
GRID
{
  Canvas example:
  [ca01                         ]
  [                             ]
  [                             ]
  [                             ]
  [                             ]
  [                             ]
}
END
END
ATTRIBUTES
CANVAS ca01: canvas01;
END
```

In programs, you draw canvas shapes by creating canvas nodes in the abstract user interface tree with the DOM API utilities.

Define a variable to hold the DOM node of the canvas and a second to handle children created for shapes:

```
DEFINE c, s om.DomNode
```

Define a window object variable; open a window with the form containing the canvas area; get the current window object, and then get the canvas DOM node:

```
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "form1"
LET w = ui.Window.getCurrent()
LET c = w.findNode("Canvas","canvas01")
```

Create a child node with a specific type defining the shape:

```
LET s = c.createChild("CanvasRectangle")
```

Set attributes to complete the shape definition:

```
CALL s.setAttribute( "fillColor", "red" )
CALL s.setAttribute( "startX", 10 )
CALL s.setAttribute( "startY", 20 )
CALL s.setAttribute( "endX", 100 )
CALL s.setAttribute( "endY", 150 )
```

It is possible to bind keys / actions to Canvas items in order to let the end user select elements with a mouse click. You can assign a function key for left-button mouse clicks with the `acceleratorKey1` attribute, while `acceleratorKey2` is used to detect right-button mouse clicks. The function keys you can bind are F1 to F255. If the user clicks on a Canvas item bound to key actions, the corresponding action handler will be executed in the current dialog. Several canvas items can be bound to the same action keys; In order to identify what items have been selected by a mouse click, you can use the

`drawGetClickedItemId()` function of `fgldraw.4gl`. This method will return the AUI tree node id of the Canvas items that was selected (i.e. s.getId()).

```
... Create the Canvas item with s node variable ...
CALL s.setAttribute( "acceleratorKey1", "F50" )
MENU "test"
   COMMAND KEY (F50)
      IF drawGetClickedItemId() = s.getId() THEN
        ...
      END IF
...
END MENU
```

To clear a given shape in the canvas, remove the element in the canvas node:

```
CALL c.removeChild(s)
```

To clear the drawing area completely, remove all children of the canvas node:

```
LET s=c.getFirstChild()
WHILE s IS NOT NULL
  CALL c.removeChild(s)
  LET s=c.getFirstChild()
END WHILE
```

Canvas drawing functions

This table describes the helper functions provided to ease canvas usage. Use these functions or use the DOM API to directly create canvas elements in the form. The helper functions are implemented in `FGLDIR/src/fgldraw.4gl`. See the source file for more details.

Table 299: CANVAS Built-in functions provided for backward compatibility with version 3

Name	Description
`drawInit()`	Initializes the drawing API. It is mandatory to call this function at the beginning of your program, before the first display instruction.
`drawSelect()`	Selects a canvas area for drawing.
`drawDisableColorLines()`	By default, simple lines drawn with `drawLine()` are colored by `drawFillColor()`. Pass `TRUE` to the function to get black lines.
`drawFillColor()`	Defines the fill color for shapes and lines. Color value are named colors like "red", "green", "blue"...
`drawLineWidth()`	Defines the width of lines.
`drawAnchor()`	Defines the anchor hint for texts.
`drawLine()`	Draws a line in the selected canvas.
`drawCircle()`	Draws a circle in the selected canvas.
`drawArc()`	Draws an arc in the selected canvas.
`drawRectangle()`	Draws a rectangle in the selected canvas.
`drawOval()`	Draws an oval in the selected canvas.
`drawText()`	Draws a text in the selected canvas.

Name	Description
`drawPolygon()`	Draws a polygon in the selected canvas.
`drawClear()`	Clears the selected canvas.
`drawButtonLeft()`	Enables left mouse click on a canvas element.
`drawButtonRight()`	Enables right mouse click on a canvas element.
`drawClearButton()`	Disables all mouse clicks on a canvas element.
`drawGetClickedItemId()`	Returns the id of the last clicked canvas element

Start menus

Start menus define a tree of application programs that can be started.

- Understanding start menus on page 1454
- Syntax of start menu files (.4sm) on page 1454
- Using start menus on page 1456
  - Loading a start menu from an XML file on page 1456
  - Creating the start menu dynamically on page 1456
- Examples on page 1456
  - Example 1: Start menu in XML format on page 1456
  - Example 2: Start menu created dynamically on page 1457

Understanding start menus

The start menu defines a tree of commands that start programs on the application server where the runtime system executes.

> **Important:** This feature is not supported on mobile platforms.

It is recommended that you create a specific program dedicated to running the start menu. This program must create (or load) a start menu, and then perform an interactive instruction to enter the interaction loop.

The start menu must be defined in the abstract user interface tree under the "`UserInterface`" root node.

The start menu is unique for a program and cannot be redefined.

When a start menu command is selected by the user, the runtime system automatically starts a child process with the command specified in the command attribute.

Syntax of start menu files (.4sm)

Start menus are defined in a .4sm file with the following XML syntax:

```
<StartMenu [ startmenu-attribute="value"[...] ] >
  group[...]
</StartMenu>
```

where *group* is:

```
<StartMenuGroup group-attribute="value"
    [...]>{ <StartMenuSeparator/>| <StartMenuCommand
     command-attribute="value"
    [...] />|
    group}
    [...]
</StartMenuGroup>
```

1. *startmenu-attribute*defines a property of the `StartMenu`.
2. *command-attribute* defines a property of a `StartMenuCommand`.
3. *group-attribute* defines a property of a `StartMenuGroup`.

Table 300: Attributes of the StartMenu node

Attribute	Type	Description
`name`	`STRING`	Identifies the StartMenu, can be omitted.
`text`	`STRING`	Defines the text to be displayed as title.

Table 301: Attributes of the StartMenuGroup node

Attribute	Type	Description
`disabled`	`INTEGER`	Indicates if the group must be disabled (grayed, cannot be selected).
`hidden`	`INTEGER`	Indicates if the group is hidden or visible.
`image`	`STRING`	Defines the icon to be used for this group.
`name`	`STRING`	Identifies the start menu group, can be omitted.
`text`	`STRING`	Defines the text to be displayed for this group.

Table 302: Attributes of the StartMenuCommand node

Attribute	Type	Description
`disabled`	`INTEGER`	Indicates if the item must be disabled (grayed, cannot be selected).
`comment`	`STRING`	Specifies the comment to be shown for this command.
`exec`	`STRING`	Defines the command to be executed when the user selects this command.
`hidden`	`INTEGER`	Indicates if the command is hidden or visible.
`image`	`STRING`	Defines the icon to be used for this command.
`name`	`STRING`	Identifies the StartMenu item, can be omitted.
`text`	`STRING`	Defines the text to be displayed for this command.

Attribute	Type	Description
waiting	INTEGER	Defines if the command must be started without waiting (0, default) or waiting (1).

Table 303: Attributes of the StartMenuSeparator node

Attribute	Type	Description
name	STRING	Identifies the StartMenu separator, can be omitted.

Using start menus
To use start menus, you must understand how they work and how to structure the code.
Loading a start menu from an XML file

To load a start menu definition file, use the utility method provided by the `ui.Interface` built-in class:

```
CALL ui.Interface.loadStartMenu("standard")
```

Creating the start menu dynamically

You can create a startmenu dynamically with the `om.DomNode` class:

First, get the abstract user interface root node:

```
DEFINE aui om.DomNode
LET aui = ui.Interface.getRootNode()
```

Next, create a node with the "`StartMenu`" tag name:

```
DEFINE sm om.DomNode
LET sm = aui.createChild("StartMenu")
```

Next, create a "`StartMenuGroup`" node to group a couple of command nodes:

```
DEFINE smg om.DomNode
LET smg = sm.createChild("StartMenuGroup")
CALL smg.setAttribute("text","Programs")
```

Then, create "`StartMenuCommand`" nodes for each program and, if needed, add "`StartMenuSeparator`" nodes to separate entries:

```
DEFINE smc, sms om.DomNode
LET smc = smg.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Orders")
CALL smc.setAttribute("exec","fglrun orders.42r")
LET smc = smg.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Customers")
CALL smc.setAttribute("exec","fglrun customers.42r")
LET sms = smg.createChild("StartMenuSeparator")
LET smc = smg.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Items")
CALL smc.setAttribute("exec","fglrun items.42r")
```

Examples
Example 1: Start menu in XML format

```
<StartMenu>
```

```
   <StartMenuGroup text="Ordering" >
      <StartMenuCommand text="Orders" exec="fglrun orders.42r"
                    disabled="1" />
      <StartMenuCommand text="Customers" exec="fglrun custs.42r"
                    image="smiley" />
      <StartMenuCommand text="Items" exec="fglrun items.42r"
                    waiting="1" />
   <StartMenuCommand text="Reports" exec="fglrun reports.42r"
                comment="Run reports" />
   </StartMenuGroup>
   <StartMenuGroup text="Configuration" >
      <StartMenuCommand text="Database" exec="fglrun dbseconf.42r" />
      <StartMenuCommand text="Users" exec="fglrun userconf.42r" />
      <StartMenuCommand text="Printers" exec="fglrun prntconf.42r" />
   </StartMenuGroup>
</StartMenu>
```

Example 2: Start menu created dynamically

```
MAIN
  DEFINE aui om.DomNode
  DEFINE sm  om.DomNode
  DEFINE smg om.DomNode
  DEFINE smc om.DomNode

  LET aui = ui.Interface.getRootNode()

  LET sm = aui.createChild("StartMenu")

  LET smg = createStartMenuGroup(sm,"Ordering")
  LET smc = createStartMenuCommand(smg,"Orders","fglrun orders.42r",NULL)
  LET smc = createStartMenuCommand(smg,"Customers","fglrun custs.42r",NULL)
  LET smc = createStartMenuCommand(smg,"Items","fglrun items.42r",NULL)
  LET smc = createStartMenuCommand(smg,"Reports","fglrun reports.42r",NULL)
  LET smg = createStartMenuGroup(sm,"Configuration")
  LET smc = createStartMenuCommand(smg,"Database","fglrun
 dbseconf.42r",NULL)
  LET smc = createStartMenuCommand(smg,"Users","fglrun userconf.42r",NULL)
  LET smc = createStartMenuCommand(smg,"Printers","fglrun
 prntconf.42r",NULL)

  MENU "Example"
    COMMAND "Quit"
      EXIT PROGRAM
  END MENU

END MAIN

FUNCTION createStartMenuGroup(p,t)
  DEFINE p om.DomNode
  DEFINE t STRING
  DEFINE s om.DomNode
  LET s = p.createChild("StartMenuGroup")
  CALL s.setAttribute("text",t)
  RETURN s
END FUNCTION

FUNCTION createStartMenuCommand(p,t,c,i)
  DEFINE p om.DomNode
  DEFINE t,c,i STRING
  DEFINE s om.DomNode
  LET s = p.createChild("StartMenuCommand")
  CALL s.setAttribute("text",t)
```

```
  CALL s.setAttribute("exec",c)
  CALL s.setAttribute("image",i)
  RETURN s
END FUNCTION
```

Window containers (WCI)

WCI containers define window containers to group several programs in a parent multiple document interface presentation.

- Understanding the Window Container Interface on page 1458
- Configuration of WCI parent programs on page 1458
- Configuration of WCI child programs on page 1459
- Implement tabbed WCI containers on page 1459

Understanding the Window Container Interface

By default, application windows are displayed independently in separate windows on the front-end window manager. This mode is well known as SDI, "Single Document Interface".

The user interface can be configured to group program windows in a parent container. This is known as MDI, "Multiple Document Interface". In Genero, Multiple Document Interface is called WCI: *Window Container Interface*.

> **Important:** WCI is typically a desktop application feature and is not supported with other front-ends (web and mobile).

The WCI can be used to group several programs together in a parent window. The parent program is the container for the other programs, defined as children of the container. The container program can have its own windows, but this makes sense only for temporary modal windows (with style="dialog").

WCI configuration is done dynamically at the beginning of programs, with methods of the `ui.Interface` built-in class.

Configuration of WCI parent programs

The WCI container program is a separate program of a special type, dedicated to contain other program windows. On the front-end, container programs automatically display a parent window that will hold all child program windows that will attach to the container.

The WCI container program must indicate that its type is special (`ui.Interface.setType()` method), and must identify itself (`ui.Interface.setName()` method):

```
MAIN
  CALL ui.Interface.setName("parent1")
  CALL ui.Interface.setType("container")
  CALL ui.Interface.setText("SoftStore Manager")
  CALL ui.Interface.setSize("600px","1000px")
  CALL ui.Interface.loadStartMenu("mystartmenu")
  MENU "Main"
    COMMAND "Help" CALL help()
    COMMAND "About" CALL aboutbox()
    COMMAND "Exit" EXIT MENU
  END MENU
END MAIN
```

You can define the initial size of the parent container window with the `ui,interface.setSize(height,width)` method.

When the program is identified as a container, a global window is automatically displayed as an container window. The default toolbar and the default topmenu are displayed and a startmenu can be used. Other windows created by this kind of program can be displayed, inside the container (`windowType="normal"`

) or as dialog windows (`windowType="modal"`). Window styles can be applied to the parent window by using the default style specification (`name="Window.main"`).

Configuration of WCI child programs

WCI children programs must attach to a parent container by giving the name of the container program:

```
MAIN
   CALL ui.Interface.setName("custapp")
   CALL ui.Interface.setType("child")
   CALL ui.Interface.setText("Customers")
   CALL ui.Interface.setContainer("parent1")
   ...
END MAIN
```

Multiple container programs can be used to group programs by application modules.

The client displays a system error and the programs stops when:

- A child program is started, but the parent container is not
- A container program is started twice

When the parent container program is stopped, other applications are automatically stopped by the front-end. This will result in a runtime error **-6313** on the application server side. To avoid this, you should control that there are no more running child programs before terminating the parent container program. The WCI container program can query for the existence of children with the `ui.Interface.getChildCount()` and `ui.Interface.getChildInstances()` methods:

```
MAIN
  CALL ui.Interface.setName("parent1")
  CALL ui.Interface.setType("container")
  CALL ui.Interface.setText("SoftStore Manager")
  CALL ui.Interface.setSize("600px","1000px")
  CALL ui.Interface.loadStartMenu("mystartmenu")
  MENU "Main"
    COMMAND "Help" CALL help()
    COMMAND "About" CALL aboutbox()
    COMMAND "Exit"
      IF ui.Interface.getChildCount()>0 THEN
         ERROR "You must first exit the child programs."
      ELSE
         EXIT MENU
      END IF
  END MENU
END MAIN
```

Implement tabbed WCI containers

WCI container can also display the child programs in a folder tab, when the presentation style attribute `tabbedContainer` is set to `yes`.

With a tabbed window container, the style attribute `tabbedContainerCloseMethod` defines how to close the current page.

Values can be:

- `"container"` (default), the container has a close button on the top right corner, which closes the current tab.
- `"page"`, each page has its own close button.
- `"both"`, each page and the container have a close button.
- `"none"`, no close button is shown.

The close button is enabled depending on the window style attribute.

Reports

- Report instructions on page 1480
- Report operators on page 1486
- Report aggregate functions on page 1489
- Report engine configuration on page 1492

Understanding reports

A *report* can arrange and format the data according to your instructions and display the output on the screen, send it to a printer, or store it as a file for future use.

To implement a report, a program must include two distinct components:

- The *report driver* specifies what data the report includes.
- The *report routine* formats the data for output.

The report driver retrieves the specified rows from a database, stores their values in program variables, and sends these - one input record at a time - to the report routine. After the last input record is received and formatted, the runtime system calculates any aggregate values based on all the data and sends the entire report to some output device.

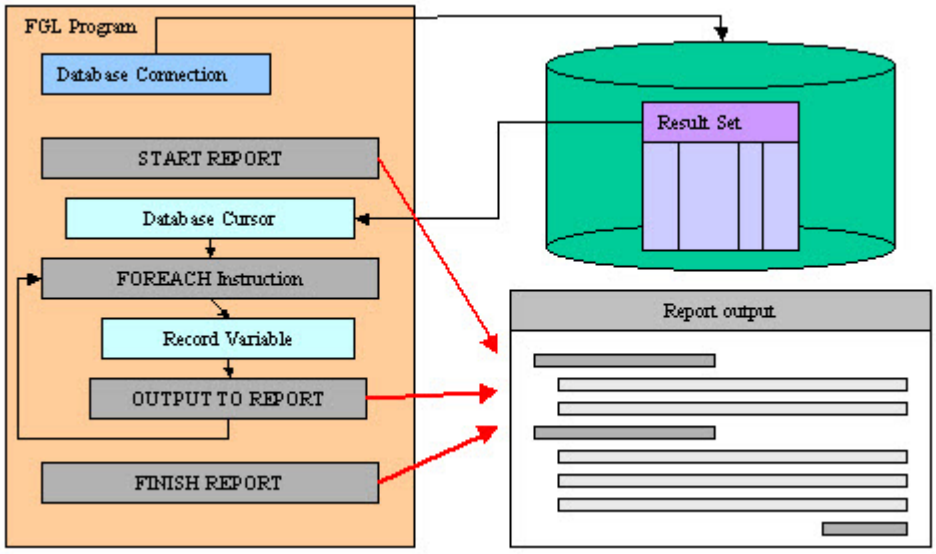

Figure 102: Report driver and database cursor

By separating the two tasks of data retrieval and data formatting, the runtime system simplifies the production of recurrent reports and makes it easy to apply the same report format to different data sets.

The report engine supports the following features:

- The option to display report output to the screen, to the printer, to a file or to a SAX handler to transform the output following XML standards.

- Full control over page layout, including first page header and generic page headers , page trailers, columnar presentation, and row grouping.
- Facilities for creating the report either from the rows returned by a cursor or from input records assembled from any other source, such as output from several different `SELECT` statements through the report driver.
- Control blocks to manipulate data from a database cursor on a row-by-row basis, either before or after the row is formatted by the report.
- Aggregate functions that can calculate frequencies, percentages, sums , averages , minimum, and maximum values.
- The `USING` operator and other built-in functions and operators for formatting and displaying information in output from the report.
- The `WORDWRAP` operator to format long character strings that occupy multiple lines of output from the report.
- The option to execute other language statements while generating a report.
- Stopping a report in the report definition code, with `EXIT REPORT` or `TERMINATE REPORT`.

The report engine supports one-pass reports and two-pass reports. The one-pass requires sorted data to be produced by the report driver in order to handle row grouping with the `BEFORE GROUP` / `AFTER GROUP` blocks. The two-pass record handles sort automatically and does not need sorted data from the report driver. During the first pass, the report engine sorts the data and stores the sorted values in a temporary file in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

XML output for reports

For better integration with external tools based on XML standards, reports can produce XML output.

The purpose of XML-based reports is to sort and group data, not to decorate. Data decoration and formatting can be done by external tools, or you can redirect the XML report output to a SAX document handler object to process the output and generate for example HTML pages.

- Writing an XML report driver and routine on page 1461
- Structure of XML report output on page 1462
- Conditional statement output in XML reports on page 1462

Writing an XML report driver and routine

To produce an XML report, you must start the report with the `TO XML HANDLER` clause in the `START REPORT` instruction, and then use the `PRINTX` statement inside the report routine:

```
MAIN
  ...
  START REPORT orders_report
       TO XML HANDLER om.XmlWriter.createFileWriter("orders.xml")
  ...
END MAIN

REPORT order_report(rec)
  ...
  FORMAT
    ON EVERY ROW
      PRINTX NAME = order rec.*
  ...
END REPORT
```

If all the reports of the program must generate XML output, you can also use the global function `fgl_report_set_document_handler()`.

Structure of XML report output

The generated XML output contains the structure of the formatted pages, with page header, page trailer and group sections. Every `PRINTX` instruction will generate a `<Print>` node with a list of `<Item>` nodes containing the data. The XML processor can use this structure to format and render the output as needed.

If a new report is started with `START REPORT` instruction inside a `REPORT` routine producing XML, and if there is no destination specified in the `START REPORT` instruction, the sub-report inherits the XML output target of the parent, and sub-report nodes will be merged into the parent XML output.

The output of an XML report will have the following node structure:

```
<Report ...>
  <PageHeader pageNo="...">
     ...
  </PageHeader>
  <Group>
    <BeforeGroup>
      <Print name="...">
        <Item name="..." type="..." value="..." isoValue="..." />
        <Item name="..." type="..." value="..." isoValue="..." />
        ...
      </Print>
      ...
    </BeforeGroup>
    <OnEveryRow>
      <Print name="...">
        <Item name="..." type="..." value="..." isoValue="..." />
        <Item name="..." type="..." value="..." isoValue="..." />
        ...
      </Print>
      ...
    </OnEveryRow>
    ...
    <AfterGroup>
      <Print name="...">
        <Item name="..." type="..." value="..." isoValue="..." />
        <Item name="..." type="..." value="..." isoValue="..." />
        ...
      </Print>
    </AfterGroup>
    ...
  </Group>
  ...
  <OnLastRow ...>
     ...
  </OnLastRow>

  <PageTrailer ...>
     ...
  </PageTrailer>

</Report>
```

Conditional statement output in XML reports

If `PRINTX` commands are used inside program flow control instructions like `IF`, `CASE`, `FOR`, `FOREACH` and `WHILE`, the XML output will contain additional nodes to identify such conditional print instructions:

```
<For>
  <ForItem>
    <Print name="...">
```

```
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </ForItem>
  ...
</For>
```

```
<While>
  <WhileItem>
    <Print name="...">
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </WhileItem>
  ...
</While>
```

```
<Foreach>
  <ForeachItem>
    <Print name="...">
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </ForeachItem>
  ...
</Foreach>
```

```
<Case>
  <When id="position">
    <Print name="...">
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </When>
  ...
</Case>
```

```
<If>
  <IfThen>
    <Print name="...">
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </IfThen>
  <IfElse>
    <Print name="...">
      <Item name="..." type="..." value="..." isValue="..." />
    </Print>
    ...
  </IfElse>
</If>
```

That information can be useful to process an XML report output.

The report driver

The *report driver* retrieves data, starts the report engine and sends the data (as input records) to be formatted by the REPORT routine.

Usage

A report driver can be part of the MAIN program block, or it can be in one or more functions.

The report driver typically consists of a loop (such as WHILE , FOR, or FOREACH) with the following statements to process the report:

Table 304: Report driver statements

Instruction	Description
START REPORT	This statement is required to instantiate the report driver.
OUTPUT TO REPORT	Provide data for one row to the report driver.
FINISH REPORT	Normal termination of the report.
TERMINATE REPORT	Cancels the processing of the report.

A report driver is started by the START REPORT instruction. Once started, data can be provided to the report driver through the OUTPUT TO REPORT statement. To instruct the report engine to terminate output processing, use the FINISH REPORT instruction. To cancel a report from outside the report routine, use TERMINATE REPORT (from inside the report routine, you cancel the report with EXIT REPORT).

In order to handler report interruption, the report driver can check if the INT_FLAG variable is TRUE to stop the loop when the user asked to interrupt the report execution.

It is possible to execute several report drivers at the same time. It is even possible to invoke a report driver inside a REPORT routine, which is different from the current driver.

The programmer must make sure that the runtime system will always execute these instructions in the following order:

1. START REPORT
2. OUTPUT TO REPORT
3. FINISH REPORT

Example

```
SCHEMA stores7
MAIN
  DEFINE rcust RECORD LIKE customer.*
  DATABASE stores7
  DECLARE cu1 CURSOR FOR SELECT * FROM customer
  LET int_flag = FALSE
  START REPORT myrep
  FOREACH cu1 INTO rcust.*
     IF int_flag THEN EXIT FOREACH END IF
     OUTPUT TO REPORT myrep(rcust.*)
  END FOREACH
  IF int_flag THEN
    TERMINATE REPORT myrep
  ELSE
    FINISH REPORT myrep
  END IF
```

```
END MAIN
```

START REPORT

The START REPORT instruction initializes a report execution.

Syntax

```
START REPORT report-routine
  [ TO to-clause ]
  [ WITH dimension-option [,...]]
```

where *to-clause* is one of:

```
{ SCREEN
| PRINTER
| [FILE] filename
| PIPE program [ IN FORM MODE |  IN LINE MODE ]
| XML HANDLER sax-handler-object
| OUTPUT destination-expr [ DESTINATION { program  | filename} ]
}
```

where *dimension-option* is one of:

```
{ LEFT MARGIN = m-left
| RIGHT MARGIN = m-right
| TOP MARGIN = m-top
| BOTTOM MARGIN = m-bottom
| PAGE LENGTH = m-length
| TOP OF PAGE = c-top
}
```

1. *report-routine* is the name of the REPORT routine.
2. *filename* is a string expression specifying the file that receives report output.
3. *program* is a string expression specifying a program, a shell script, or a command line to receive report output.
4. *destination-expr* is a string expression that specifies one of: SCREEN, PRINTER, FILE, PIPE, PIPE IN LINE MODE, PIPE IN FORM MODE.
5. *sax-handler-object* is a variable referencing an om.SaxDocumentHandler instance.
6. *m-left* is the left margin in number of characters. The default is 5.
7. *m-right* is the right margin in number of characters. The default is 132.
8. *m-top* is the top margin in number of lines. The default is 3.
9. *m-bottom* is the bottom margin in number of lines. The default is 3.
10. *m-length* is the total number of lines on a report page. The default page length is 66 lines.
11. *c-top* is a string that defines the page-eject character sequence.

Usage

The START REPORT statement initializes a report. The instruction allows you to specify the report output destination and the page dimensions and margins.

START REPORT typically precedes a loop instruction such as FOR, FOREACH, or WHILE in which OUTPUT TO REPORT feeds the report routine with data. After the loop terminates, FINISH REPORT completes the processing of the output.

```
DEFINE file_name VARCHAR(200), page_size INTEGER
...
```

```
START REPORT myrep
  TO FILE file_name
  WITH PAGE LENGTH = page_size
```

If a START REPORT statement references a report that is already running, the report is re-initialized; any output might be unpredictable.

Output specification

The TO clause can be used to specify a destination for output. If you omit the TO clause, the Genero runtime system sends report output to the destination specified in the report routine definition. If the report routine does not define an OUTPUT clause, the report output is sent by default to the report viewer when in GUI mode, or to the screen when in TUI mode.

Report output can be specified dynamically as follows:

- The TO FILE option can specify the *filename* as a character variable that is assigned at runtime.
- The TO PIPE option can specify the *program* as a character variable that is assigned at runtime.
- The TO OUTPUT option can specify the report output with a string expression, described later in detail.

The SCREEN option specifies that output is to the report window. The way the report is displayed to the end user depends on whether you are in TUI mode or GUI mode. In TUI mode, the report output displays to the terminal screen. In GUI mode, the report output displays in a dedicated popup window called the Report Viewer.

The PRINTER option instructs the runtime system to output the report to the device or program defined by the DBPRINT environment variable.

When using the FILE option, you can specify a file name as the report destination. Output will be sent to the specified file. If the file exists, its content will be overwritten by the new report output. The FILE keyword is optional, but it's best to include it to make your code more readable.

The PIPE option defines a program, shell script, or command line to which the report output must be sent, using the standard input channel. When using the TUI mode, you can use the IN [LINE|FORM] MODE option to specify whether the program is in line mode or in formatted mode when report output is sent to a pipe.

The TO OUTPUT option allows you to specify one of the output options dynamically at runtime. The character string expression must be one of: "SCREEN", "PRINTER", "FILE", "PIPE", "PIPE IN LINE MODE", " PIPE IN FORM MODE". If the expression specifies "FILE" or "PIPE", you can also specify a *filename* or *program* in a character variable following the DESTINATION keyword.

The XML HANDLER option indicates that the report output will be generated as XML and redirected to a SAX-document handler. When using XML output, the report result can be shown in the Genero Report Engine installed on the front-end workstation. See XML output for more details.

Page dimensions specification

The WITH clause defines the dimensions of each report page and the left, top, right and bottom margins. The values corresponding to a margin and page length must be valid integer expressions. The margins can be defined in any order, but a comma "," is required to separate two page dimensions options.

- The LEFT MARGIN clause defines the number of blank spaces to include at the start of each new line of output. The default is 5.
- The RIGHT MARGIN clause defines the total number of characters in each line of output, including the left margin. If you omit this but specify FORMAT EVERY ROW, the default is 132.
- The TOP MARGIN clause specifies how many blank lines appear above the first line of text on each page of output. The default is 3.
- The BOTTOM MARGIN clause specifies how many blank lines follow the last line of output on each page. The default is 3.

- The PAGE LENGTH clause specifies the total number of lines on each page, including data, the margins, and any page headers or page trailers from the FORMAT section. The default page length is 66 lines.

In addition to the page dimension options, the TOP OF PAGE clause can specify a page-eject sequence for a printer. On some systems, specifying this value can reduce the time required for a large report to produce output, because SKIP TO TOP OF PAGE can substitute this value for multiple line feeds.

OUTPUT TO REPORT

The OUTPUT TO REPORT instruction provides a data row to the report execution.

Syntax

```
OUTPUT TO REPORT report-name ( parameters )
```

1. *report-name* is the name of the report to which the *parameters* should be sent.
2. *parameters* is the data that needs to be sent to the report.

Usage

The OUTPUT TO REPORT instruction feeds the report routine with a single set of data values (called an *input record*), which corresponds usually to one printed line in the report output.

An input record is the ordered set of values returned by the expressions that you list between the parentheses following the report name in the OUTPUT TO REPORT statement. The specified values are passed to the report routine, as part of the input record. The input record typically corresponds to a retrieved row from the database.

The set of values is usually grouped in a RECORD variable and best practice is to define a user defined type (TYPE) in order to ease the variable definitions required in the code implementing the report driver and the report routine definition, for example:

```
SCHEMA stores
TYPE t_cust RECORD LIKE customer.*
...
DEFINE r_cust t_cust
...
  OUTPUT TO REPORT cust_report(r_cust.*)
...
REPORT cust_report(r)
  DEFINE r t_cust
  ...
```

The OUTPUT TO REPORT statement is included within a WHILE, FOR, or FOREACH loop, so that the program passes data to the report one input record at a time. The next example uses a FOREACH loop to fetch data from the database and pass it as input record to a report:

```
SCHEMA stores
DEFINE o LIKE orders.*
...
DECLARE order_c CURSOR FOR
  SELECT orders.*
    FROM orders ORDER BY ord_cust
  START REPORT order_list
  FOREACH order_c INTO o.*
    OUTPUT TO REPORT order_list(o.*)
  END FOREACH
  FINISH REPORT order_list
...
```

Special consideration should be taken regarding row ordering with reports: For example if the report groups rows with `BEFORE GROUP OF` or `AFTER GROUP OF` sections, the rows must be ordered by the column specified in these sections, and rows should preferably be ordered by the report driver to avoid two-pass reports.

If `OUTPUT TO REPORT` is not executed, none of the control blocks of the report routine are executed, even if the program also includes the `START REPORT` and `FINISH REPORT` statements.

The members of the input record that you specify in the expression list of the `OUTPUT TO REPORT` statement must correspond to elements of the formal argument list in the REPORT definition in their number and their position, and must be of compatible data types. At compile time, the number of parameters passed with the `OUTPUT TO REPORT` instruction is not checked against the `DEFINE` section of the report routine. This is a known behavior of the language.

Arguments of the `TEXT` and `BYTE` data types are passed by reference rather than by value; arguments of other data types are passed by value. A report can use the `WORDWRAP` operator with the `PRINT` statement to display `TEXT` values. A report cannot display `BYTE` values; the character string <byte value> in output from the report indicates a `BYTE` value.

FINISH REPORT

The `FINISH REPORT` instruction finalizes a report execution.

Syntax

```
FINISH REPORT report-name
```

1. *report-name* is the name of the report to be ended.

Usage

`FINISH REPORT` closes the report driver. Therefore, it must be the last statement in the report driver and must follow a `START REPORT` statement that specifies the name of the same report.

`FINISH REPORT` must be the last statement in the report driver.

`FINISH REPORT` does the following:

1. Completes the second pass, if report is a two-pass report. These 'second pass' activities handle the calculation and output of any aggregate values that are based on all the input records in the report, such as `COUNT(*)` or `PERCENT(*)` with no `GROUP` qualifier.
2. Executes any `AFTER GROUP OF` control blocks.
3. Executes any `PAGE HEADER`, `ON LAST ROW`, and `PAGE TRAILER` control blocks to complete the report.
4. Copies data from the output buffers of the report to the destination.
5. Closes the Select cursor on any temporary table that was created to order the input records or to perform aggregate calculations.

TERMINATE REPORT

The `TERMINATE REPORT` instruction cancels a report execution.

Syntax

```
TERMINATE REPORT report-name
```

1. *report-name* is the name of the report to be canceled.

Usage

`TERMINATE REPORT` cancels the report processing. It is typically used when the program (or the user) becomes aware that a problem prevents the report from producing part of its intended output, or when the user interrupted the report processing.

`TERMINATE REPORT` has the following effects:

- Terminates the processing of the current report.
- Deletes any intermediate files or temporary tables that were created in processing the report.

The `EXIT REPORT` instruction has the same effect, except that it can be used inside the report definition.

The report routine

The *report routine* implements the body of a report, with formatting instructions.

Syntax

```
[PUBLIC|PRIVATE] REPORT report-name (argument-list)
 [ define-section ]
 [ output-section ]
 [  sort-section ]
 [ format-section ]
END REPORT
```

where *define-section* is:

```
DEFINE variable-definition [,...]
```

where *output-section* is:

```
OUTPUT
[
  REPORT TO
  {
   SCREEN
 | PRINTER
 | [ FILE ] filename
 | PIPE program [ IN FORM MODE |  IN LINE MODE ]
  }
]
[
  [ WITH ]
  [ LEFT MARGIN m-left ]
  [ RIGHT MARGIN m-right]
  [ TOP MARGIN m-top ]
  [ BOTTOM MARGIN m-bottom ]
  [ PAGE LENGTH m-length ]
  [ TOP OF PAGE c-top]
 ]
```

where *sort-section* is:

```
 ORDER [ EXTERNAL ] BY report-variable [,...]
```

where *format-section* is:

```
FORMAT EVERY ROW
```

or:

```
FORMAT
  control-block
  [ report-only-fgl-statement | sql-statement | report-statement ]
  [...]
[...]
```

where *control-block* can be one of:

```
{
[ FIRST ]  PAGE HEADER
|  ON EVERY ROW
|  BEFORE GROUP OF report-variable
|  AFTER GROUP OF report-variable
|  PAGE TRAILER
|  ON LAST ROW
}
```

Note:

1. *variable-definition* follows the `DEFINE` instruction syntax and declares *report-variables* .
2. *report-variable* is the name of a variable declared in the `DEFINE` section.
3. *report-only-fgl-statement* is a subset of all the regular language statements.
4. *sql-statement* is a valid static SQL statement.

Usage

The report definition formats input records. Like the `FUNCTION` or `MAIN` statement, it is a program block that can be the scope of local variables. It is not, however, a function; it is not reentrant, and `CALL` cannot invoke it. The report definition receives data from its driver in sets called input records. These records can include program records, but other data types are also supported. Each input record is formatted and printed as specified by control blocks and statements within the report definition. Most statements and functions can be included in a report definition, and certain specialized statements and operators for formatting output can appear only in a report definition.

Like `MAIN` or `FUNCTION`, the report definition must appear outside any other program block. It must begin with the `REPORT` statement and must end with the `END REPORT` keywords.

Some statements are prohibited in a `REPORT` routine control block. For example, it is not possible to use `CONSTRUCT`, `INPUT`, `DEFER`, `DEFINE`, `REPORT`, `RETURN` instructions in a control block of a report.

By default, report routines are public; They can be called by any other module of the program. If a report routine is only used by the current module, you may want to hide that routine to other modules, to make sure that it will not be called by mistake. To keep a report routine local to the module, add the `PRIVATE` keyword before the report header. Private report routines are only hidden to external modules, all function of the current module can still call local private report routines.

The *define section* declares the data types of local variables used within the report, and of any variables (the input records) that are passed as arguments to the report by the calling statement. Reports without arguments or local variables do not require a `DEFINE` section.

The *output-section* can set margin and page size values, and can also specify where to send the formatted output. Output from the report consists of successive pages, each containing a fixed number of lines whose margins and maximum number of characters are fixed.

The *sort-section* specifies how the rows have to be sorted. The specified sort order determines the order in which the runtime system processes any `GROUP OF` control blocks in the `FORMAT` section.

The *format-section* is required. It specifies the appearance of the report, including page headers, page trailers, and aggregate functions of the data. It can also contain control blocks that specify actions to take

before or after specific groups of rows are processed. (Alternatively, it can produce a default report by only specifying `FORMAT EVERY ROW`).

The report prototype

When defining a report routine, the report name must immediately follow the `REPORT` keyword. The name must be unique among function and report names within the program. Its scope is the entire program.

The list of formal arguments of the report must be enclosed in parentheses and separated by commas. These are local variables that store values that the calling routine passes to the report. The compiler issues an error unless you declare their data types in the subsequent `DEFINE` section of the report routine. You can include a program record in the formal argument list, but you cannot append the `.*` symbols to the name of the record. Arguments can be of any data type except ARRAY, or a record with an ARRAY member.

When you call a report, the formal arguments are assigned values from the argument list of the `OUTPUT TO REPORT` statement. These actual arguments that you pass must match, in number and position, the formal arguments of the `REPORT` routine. The data types must be compatible, but they need not be identical. The runtime system can perform some conversions between compatible data types.

The names of the actual arguments and the formal arguments do not have to match.

You must include the following items in the list of formal arguments:

- All the values for each row sent to the report in the following cases:
  - If you include an `ORDER BY` section or `GROUP PERCENT(*)` function
  - If you use a global aggregate function (one over all rows of the report) anywhere in the report, except in the `ON LAST ROW` control block
  - If you specify the `FORMAT EVERY ROW` default format
- Any variables referenced in the following group control blocks:
  - `AFTER GROUP OF`
  - `BEFORE GROUP OF`

DEFINE section in REPORT

Defines report parameters and local variables.

Syntax

The syntax of the report `DEFINE` section is the same as for the `DEFINE` statement, except that you cannot define arrays or array members for records.

Usage

This section declares a data type for each formal argument in the `REPORT` prototype and for any additional local variables that can be referenced only within the `REPORT` program block. The `DEFINE` section is required if you pass arguments to the report or if you reference local variables in the report.

For declaring local report variables, the same rules apply to the `DEFINE` section as to the `DEFINE` statement in `MAIN` and `FUNCTION` program blocks. There are some differences and exceptions, however:

- Report arguments cannot be of type `ARRAY`.
- Report arguments cannot be records that include `ARRAY` members.
- Report local variables are not allocated on the stack at every `OUTPUT TO REPORT` call: The scope of the variables in the `DEFINE` section is local to the report routine, but the lifetime is the duration of the program, like module or global variables. In other words, report variables persist across `OUTPUT TO REPORT` calls.

data types of local variables that are not formal arguments are unrestricted. You must include arguments in the report prototype and declare them in the `DEFINE` section, if any of the following conditions is true:

- If you specify `FORMAT EVERY ROW` to create a default report, you must pass all the values for each record of the report.
- If an `ORDER BY` section is included, you must pass all the values that `ORDER BY` references for each input record of the report.
- If you use the `AFTER GROUP OF` control block, you must pass at least the arguments that are named in that control block.
- If an aggregate that depends on all records of the report appears anywhere except in the `ON LAST ROW` control block, you must pass each of the records of the report through the argument list.

Aggregates dependent on all records include:

- `GROUP PERCENT(*)` (anywhere in a report).
- Any aggregate without the `GROUP` keyword (anywhere outside the `ON LAST ROW` control block).

If your report calls an aggregate function, an error might result if any argument of an aggregate function is not also a format argument of the report. You can, however, use global or module variables as arguments of aggregates if the value of the variable does not change while the report is executing.

A report can reference variables of global or module scope that are not declared in the `DEFINE` section. Their values can be printed, but they can cause problems in aggregates and in `BEFORE GROUP OF` and `AFTER GROUP OF` clauses. Any references to non-local variables can produce unexpected results, however, if their values change while a two-pass report is executing.

OUTPUT section in REPORT

Specifies report destination and page format options.

Syntax

```
 OUTPUT
[
  REPORT TO
  {
      SCREEN
    | PRINTER
    | [ FILE ] filename
    | PIPE [ IN FORM MODE | IN LINE MODE ] program
   }
]
[
  [ LEFT MARGIN m-left ]
  [ RIGHT MARGIN m-right ]
  [ TOP MARGIN m-top ]
  [ BOTTOM MARGIN m-bottom ]
  [ PAGE LENGTH m-length ]
  [ TOP OF PAGE c-top]
]
```

1. *program* defines the name of a program, shell script, command receiving the output.
2. *filename* defines the file which receives the output of the report.
3. *m-left* is the left margin in number of characters. The default is 5.
4. *m-right* is the right margin in number of characters. The default is 132.
5. *m-top* is the top margin in number of lines. The default is 3.
6. *m-bottom* is the bottom margin in number of lines. The default is 3.
7. *m-length* is the total number of lines on a report page. The default page length is 66 lines.
8. *c-top* is a string that defines the page-eject character sequence.

Usage

The OUTPUT section can specify the destination and dimensions for output from the report and the page-eject sequence for the printer. If you omit the OUTPUT section, the report uses default values to format each page. This section is superseded by any corresponding START REPORT specifications.

The OUTPUT section can direct the output from the report to a printer, file, or pipe, and can initialize the page dimensions and margins of report output. If PRINTER is specified, the DBPRINT environment variable specifies which printer.

The START REPORT statement of the report driver can override all of these specifications by assigning another destination in its TO clause or by assigning other dimensions, margins, or another page-eject sequence in the WITH clause.

Because the size specifications for the dimensions and margins of a page of report output that the OUTPUT section can specify must be literal integers, consider defining page dimensions in the START REPORT statement, where you can use variables to assign these values dynamically at runtime.

ORDER BY section in REPORT

Forces a sort order of unsorted data rows in reports.

Syntax

```
ORDER [ EXTERNAL ] BY report-variable [ DESC | ASC ] [,...]
```

1. *report-variable* identifies one of the variables passed to the report routine to be used for sorting rows.

Usage

When grouping rows in a report, values that the report definition receives from the report driver are significant in determining how BEFORE GROUP OF or AFTER GROUP OF control blocks will process the data in the formatted report output.

The ORDER BY section defines how the variables of the input records are to be sorted. It is required if the report driver does not send sorted data to the report. The specified sort order determines the order in which the runtime system processes any GROUP OF control blocks in the FORMAT section.

If you omit the ORDER BY section, the runtime system processes input records in the order received from the report driver and processes any GROUP OF control blocks in their order of appearance in the FORMAT section. If records are not sorted in the report driver , the GROUP OF control blocks might be executed at random intervals (that is, after any input record) because unsorted values tend to change from record to record.

If you specify only one variable in the GROUP OF control blocks, and the input records are already sorted in sequence on that variable by the SELECT statement, you do not need to include an ORDER BY section in the report.

Specify ORDER EXTERNAL BY if the input records have already been sorted by the SELECT statement used by the report driver. The list of variables after the keywords ORDER EXTERNAL BY control the execution order of GROUP BY control blocks.

Without the EXTERNAL keyword, the report becomes a two-pass report , meaning that the report engine processes the set of input records twice. During the first pass, the report engine sorts the data and stores the sorted values in a temporary table in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

With the EXTERNAL keyword, the report engine only needs to make a single pass through the data: it does not need to build the temporary table in the database for sorting the data. However, If the report routine contains aggregations functions such as GROUP PERCENT(*) , the report will become a two-pass report because such aggregation function needs all rows to compute the value.

The DESC or ASC clause defines the sort order.

FORMAT section in REPORT

Defines the formatting directives inside a report routine.

Syntax

Default format:

```
FORMAT EVERY ROW
```

Custom format:

```
FORMAT
 control-block
    [ report-statement
    | report-only-fgl-statement
    | sql-statement
    ]
  [...]
 [...]
```

where *control-block* can be one of:

```
{
[ FIRST ] PAGE HEADER
|  ON EVERY ROW
|  BEFORE GROUP OF report-variable
|  AFTER GROUP OF report-variable
|  PAGE TRAILER
|  ON LAST ROW
}
```

1. *report-statement* is any report-specific instruction.
2. *report-only-fgl-statement* is any language instruction supported in the report routine.
3. *sql-statement* is any SQL statement supported by the language.
4. *report-variable* is the name of a variable declared in the DEFINE section.

Usage

A report definition must contain a FORMAT section.

The FORMAT section determines how the output from the report will look. It works with the values that are passed to the REPORT program block through the argument list or with global or module variables in each record of the report. In a source file, the FORMAT section begins with the FORMAT keyword and ends with the END REPORT keywords.

The FORMAT section is made up of the following control blocks:

- FIRST PAGE HEADER
- PAGE HEADER
- PAGE TRAILER
- BEFORE GROUP OF
- AFTER GROUP OF
- ON EVERY ROW
- ON LAST ROW

If you use the FORMAT EVERY ROW, no other statements or control blocks are valid. The EVERY ROW keywords specify a default output format, including every input record that is passed to the report.

Control blocks define the structure of a report by specifying one or more statements to be executed when specific parts of the report are processed.

If a report driver includes START REPORT and FINISH REPORT statements, but no data records are passed to the report, no control blocks are executed. That is, unless the report executes an OUTPUT TO REPORT statement that passes at least one input record to the report; then neither the FIRST PAGE HEADER control block nor any other control block is executed

Apart from BEFORE GROUP OF and AFTER GROUP OF, each control block must appear only one time.

More complex FORMAT sections can contain control blocks like ON EVERY ROW or BEFORE GROUP OF, which contain statements to execute while the report is being processed. Control blocks can contain report execution statements and other executable statements.

A control block may invoke most language statements, except those listed in prohibited statements.

The BEFORE/AFTER GROUP OF control blocks can include aggregate functions to instruct the report engine to automatically compute such values.

A *report-statement* is a statement specially designed for the report format section. It cannot be used in any other part of the program.

The sequence in which the BEFORE GROUP OF and AFTER GROUP OF control blocks are executed depends on the sort list in the ORDER BY section, regardless of the physical sequence in which these control blocks appear within the FORMAT section.

FORMAT EVERY ROW
Default format specification of a report.

A report routine written with FORMAT EVERY ROW formats the report in a simple default format, containing only the values that are passed to the REPORT program block through its arguments, and the names of the arguments. You cannot modify the EVERY ROW statement with any of the statements listed in report execution statements, and neither can you include any control blocks in the FORMAT section.

The report engine uses as column headings the names of the variables that the report driver passes as arguments at runtime. If all fields of each input record can fit horizontally on a single line, the default report prints the names across the top of each page and the values beneath. Otherwise, it formats the report with the names down the left side of the page and the values to the right, as in the previous example. When a variable contains a null value, the default report prints only the name of the variable, with nothing for the value.

The following example is a brief report specification that uses FORMAT EVERY ROW. We assume here that the cursor that retrieved the input records for this report was declared with an ORDER BY clause, so that no ORDER BY section is needed in this report definition:

```
DATABASE stores7

REPORT simple( order_num, customer_num, order_date )

  DEFINE order_num LIKE orders.order_num,
        customer_num LIKE orders.customer_num,
        order_date LIKE orders.order_date

  FORMAT EVERY ROW

END REPORT
```

The example would produce the following output:

```
order_num customer_num order_date
     1001         104  01/20/1993
     1002         101  06/01/1993
     1003         104  10/12/1993
```

```
      1004          106  04/12/1993
      1005          116  12/04/1993
      1006          112  09/19/1993
      1007          117  03/25/1993
      1008          110  11/17/1993
      1009          111  02/14/1993
      1010          115  05/29/1993
      1011          104  03/23/1993
      1012          117  06/05/1993
```

FIRST PAGE HEADER
Defines the printing commands for the first page of a report.

This control block specifies the action that the runtime system takes before it begins processing the first input record. You can use it, for example, to specify what appears near the top of the first page of output from the report.

Because the runtime system executes the `FIRST PAGE HEADER` control block before generating any output, you can use this control block to initialize variables that you use in the `FORMAT` section.

If a report driver includes `START REPORT` and `FINISH REPORT` statements, but no data records are passed to the report, this control block is not executed. That is, unless the report executes an `OUTPUT TO REPORT` statement that passes at least one input record to the report, neither the `FIRST PAGE HEADER` control block nor any other control block is executed.

As its name implies, you can also use a `FIRST PAGE HEADER` control block to produce a title page as well as column headings. On the first page of a report, this control block overrides any `PAGE HEADER` control block. That is, if both a `FIRST PAGE HEADER` and a `PAGE HEADER` control block exist, output from the first appears at the beginning of the first page, and output from the second begins all subsequent pages.

The `TOP MARGIN` (set in the `OUTPUT` section) determines how close the header appears to the top of the page.

Consider the following notes when programming the `FIRST PAGE HEADER` control block:

1. You cannot include a `SKIP` integer `LINES` statement inside a loop within this control block.
2. The `NEED` statement is not valid within this control block.
3. If you use an `IF…THEN…ELSE` statement within this control block, the number of lines displayed by any `PRINT` statements following the `THEN` keyword must be equal to the number of lines displayed by any `PRINT` statements following the `ELSE` keyword.
4. If you use a `CASE`, `FOR`, or `WHILE` statement that contains a `PRINT` statement within this control block, you must terminate the `PRINT` statement with a semicolon (;). The semicolon suppresses any `LINEFEED` characters in the loop, keeping the number of lines in the header constant from page to page.
5. You cannot use a `PRINT` filename statement to read and display text from a file within this control block

Corresponding restrictions also apply to `CASE`, `FOR`, `IF`, `NEED`, `SKIP`, `PRINT`, and `WHILE` statements in `PAGE HEADER` and `PAGE TRAILER` control blocks.

PAGE HEADER
Defines the printing commands for the top of all pages of a report.

This control block is executed whenever a new page is added to the report. The `PAGE HEADER` control block specifies the action that the runtime takes before it begins processing each page of the report. It can specify what information, if any, appears at the top of each new page of output from the report.

The `TOP MARGIN` specification (in the `OUTPUT` section) affects how many blank lines appear above the output produced by statements in the `PAGE HEADER` control block.

You can use the `PAGENO` operator in a `PRINT` statement within a `PAGE HEADER` control block to automatically display the current page number at the top of every page.

The FIRST PAGE HEADER control block overrides this control block on the first page of a report.

New group values can appear in the PAGE HEADER control block when this control block is executed after a simultaneous end-of-group and end-of-page situation.

The runtime system delays the processing of the PAGE HEADER control block until it encounters the first PRINT, SKIP, or NEED statement in the ON EVERY ROW, BEFORE GROUP OF, or AFTER GROUP OF control block. This order guarantees that any group columns printed in the PAGE HEADER control block have the same values as the columns printed in the ON EVERY ROW control block.

The details that apply to FIRST PAGE HEADER also apply to PAGE HEADER.

PAGE TRAILER
Defines the printing commands for the tail of all pages of a report.

The PAGE TRAILER control block specifies what information, if any, appears at the bottom of each page of output from the report.

The runtime system executes the statements in the PAGE TRAILER control block before the PAGE HEADER control block when a new page is needed. New pages can be initiated by any of the following conditions:

- PRINT attempts to print on a page that is already full.
- SKIP TO TOP OF PAGE is executed.
- SKIP n LINES specifies more lines than are available on the current page.
- NEED specifies more lines than are available on the current page.

You can use the PAGENO operator in a PRINT statement within a PAGE TRAILER control block to automatically display the page number at the bottom of every page, as in this example:

```
PAGE TRAILER
   PRINT COLUMN 28, PAGENO USING "page <<<<"
```

The BOTTOM MARGIN specification (in the OUTPUT section) affects how close to the bottom of the page the output displays the page trailer.

The details that apply to FIRST PAGE HEADER also apply to PAGE TRAILER.

BEFORE/AFTER GROUP OF
Defines printing commands of row grouping sections withing a report.

The BEFORE/AFTER GROUP OF control blocks specify what action the runtime system takes respectively before or after it processes a group of input records. Group hierarchy is determined by the ORDER BY specification in the SELECT statement or in the report definition.

A group of records is all of the input records that contain the same value for the variable whose name follows the AFTER GROUP OF keywords. This group variable must be passed through the report arguments. A report can include no more than one AFTER GROUP OF control block for any group variable.

When the runtime system executes the statements in a BEFORE/AFTER GROUP OF control block, the report variables have the values from the first / last record of the new group. From this perspective, the BEFORE/AFTER GROUP OF control block could be thought of as the "on first / last record of group" control block.

Each BEFORE GROUP OF block is executed in order, from highest to lowest priority, at the start of a report (after any FIRST PAGE HEADER or PAGE HEADER control blocks, but before processing the first record) and on these occasions:

- Whenever the value of the group variable changes (after any AFTER GROUP OF block for the old value completes execution)
- Whenever the value of a higher-priority variable in the sort list changes (after any AFTER GROUP OF block for the old value completes execution)

The runtime system executes the AFTER GROUP OF control block on these occasions:

- Whenever the value of the group variable changes.
- Whenever the value of a higher-priority variable in the sort list changes.
- At the end of the report (after processing the last input record but before the runtime system executes any ON LAST ROW or PAGE TRAILER control blocks). In this case, each AFTER GROUP OF control block is executed in ascending priority.

How often the value of the group variable changes depends in part on whether the input records have been sorted by the SELECT statement:

- If records are already sorted, the BEFORE/AFTER GROUP OF block executes before the runtime system processes the first record of the group.
- If records are not sorted, the BEFORE GROUP OF block might be executed after any record because the value of the group variable can change with each record. If no ORDER BY section is specified, all BEFORE/AFTER GROUP OF control blocks are executed in the same order in which they appear in the FORMAT section. The BEFORE/AFTER GROUP OF control blocks are designed to work with sorted data.

You can sort the records by specifying a sort list in either of the following areas:

- An ORDER BY section in the report definition
- The ORDER BY clause of the SELECT statement in the report driver

To sort data in the report definition (with an ORDER BY section), make sure that the name of the group variable appears in both the ORDER BY section and in the BEFORE GROUP OF control block.

To sort data in the ORDER BY clause of a SELECT statement, perform the following tasks:

- Use the column name in the ORDER BY clause of the SELECT statement as the group variable in the BEFORE GROUP OF control block.
- If the report contains BEFORE or AFTER GROUP OF control blocks, make sure that you include an ORDER EXTERNAL BY section in the report to specify the precedence of variables in the sort list.

If you specify sort lists in both the report driver and the report definition, the sort list in the ORDER BY section of the REPORT takes precedence. When the runtime system starts to generate a report, it first executes the BEFORE GROUP OF control blocks in descending order of priority before it executes the ON EVERY ROW control block. If the report is not already at the top of the page, the SKIP TO TOP OF PAGE statement in a BEFORE GROUP OF control block causes the output for each group to start at the top of a page.

If the sort list includes more than one variable, the runtime system sorts the records by values in the first variable (highest priority). Records that have the same value for the first variable are then ordered by the second variable and so on until records that have the same values for all other variables are ordered by the last variable (lowest priority) in the sort list.

The ORDER BY section determines the order in which the runtime system processes BEFORE GROUP OF and AFTER GROUP OF control blocks. If you omit the ORDER BY section, the runtime system processes any GROUP OF control blocks in the lexical order of their appearance within the FORMAT section.

If you include an ORDER BY section, and the FORMAT section contains more than one BEFORE GROUP OF or AFTER GROUP OF control block, the order in which these control blocks are executed is determined by the sort list in the ORDER BY section. In this case, their order within the FORMAT section is not significant because the sort list overrides their lexical order.

The runtime system processes all the statements in a BEFORE GROUP OF or AFTER GROUP OF control block on these occasions:

- Each time the value of the current group variable changes.
- Each time the value of a higher-priority variable changes. How often the value of the group variable changes depends in part on whether the input records have been sorted. If the records are sorted, AFTER GROUP OF executes after the runtime system processes the last record of the group of records; BEFORE GROUP OF executes before the runtime system processes the first records with the same

value for the group variable. If the records are not sorted, the BEFORE GROUP OF and AFTER GROUP OF control blocks might be executed before and after each record because the value of the group variable might change with each record. All the AFTER GROUP OF and BEFORE GROUP OF control blocks are executed in the same lexical order in which they appear in the FORMAT section.

In the AFTER GROUP OF control block, you can include the GROUP keyword to qualify aggregate report functions like AVG(), SUM(), MIN(), or MAX():

```
AFTER GROUP OF r.order_num
  PRINT r.order_date, 7 SPACES,
     r.order_num USING"###&", 8 SPACES,
       r.ship_date, " ",
       GROUP SUM(r.total_price) USING"$$$$,$$$,$$$.&&"
AFTER GROUP OF r.customer_num
  PRINT 42 SPACES, "------------------"
  PRINT 42 SPACES, GROUP SUM(r.total_price) USING"$$$$,$$$,$$$.&&"
```

Using the GROUP keyword to qualify an aggregate function is only valid within the AFTER GROUP OF control block. It is not valid, for example, in the BEFORE GROUP OF control block.

After the last input record is processed, the runtime system executes the AFTER GROUP OF control blocks before it executes the ON LAST ROW control block.

ON EVERY ROW
Defines printing commands for each row in a report.

The ON EVERY ROW control block specifies the action to be taken by the runtime system for every input record that is passed to the report definition.

The runtime system executes the statements within the ON EVERY ROW control block for each new input record that is passed to the report. The following example is from a report that lists all the customers, their addresses, and their telephone numbers across the page:

```
ON EVERY ROW
  PRINT r.fname, " ", r.lname, " ",
       r.address1, " ", r.cust_phone
```

The runtime system delays processing the PAGE HEADER control block (or the FIRST PAGE HEADER control block, if it exists) until it encounters the first PRINT, SKIP, or NEED statement in the ON EVERY ROW control block.

If a BEFORE GROUP OF control block is triggered by a change in the value of a variable, the runtime system executes all appropriate BEFORE GROUP OF control blocks (in the order of their priority) before it executes the ON EVERY ROW control block. Similarly, if execution of an AFTER GROUP OF control block is triggered by a change in the value of a variable, the runtime system executes all appropriate AFTER GROUP OF control blocks (in the reverse order of their priority) before it executes the ON EVERY ROW control block.

ON LAST ROW
Defines the printing commands of the last row in a report.

The ON LAST ROW control block specifies the action that the runtime system is to take after it processes the last input record that was passed to the report definition and encounters the FINISH REPORT statement.

The statements in the ON LAST ROW control block are executed after the statements in the ON EVERY ROW and AFTER GROUP OF control blocks if these blocks are present.

When the runtime system processes the statements in an ON LAST ROW control block, the variables that the report is processing still have the values from the final record that the report processed. The ON LAST ROW control block can use aggregate functions to display report totals.

Prohibited report routine statements

Language statements that have no meaning inside a report definition routine are prohibited. These statements are some of the statements that are not valid within any control block of the FORMAT section of a REPORT program block, such as interactive statements (CONSTRUCT, INPUT, DIALOG, MENU), program block definitions (FUNCTION, REPORT), and some flow control instructions like RETURN.

A compile-time error is issued if you attempt to include any of these statements in a control block of a report. You can call a function that includes some of these statements, but this is not recommended.

Two-pass reports

The report engine supports *two-pass reports*, to order rows automatically.

The one-pass report requires sorted data to be produced by the report driver in order to handle before/after groups properly. The two-pass report handles sorts internally and does not need sorted data from the report driver. During the first pass, the report engine sorts the data and stores the sorted values in a temporary file in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

A report is defined as a two-pass report if it includes any of the following items:

- An ORDER BY section without the EXTERNAL keyword.
- The GROUP PERCENT(*) aggregate function anywhere in the report.
- Any aggregate function that has no GROUP keyword in any control block other than ON LAST ROW.

Two-pass reports create temporary tables. The FINISH REPORT statement uses values from these tables to calculate any global aggregates, and then deletes the tables. Since two-pass reports create temporary tables, the report engine requires a database connection, and the database server must support temporary tables with indexes.

Consider avoiding two-pass reports when a regular report is possible.

Report instructions

The report instruction listed in this section can appear only in control blocks of the FORMAT section of a report routine.

EXIT REPORT

Cancels the report processing.

Syntax

```
EXIT REPORT
```

Usage

EXIT REPORT cancels the report processing. It must appear in the FORMAT section of the report definition. It is useful after the program (or the user) becomes aware that a problem prevents the report from producing part of its intended output.

EXIT REPORT has the following effects:

- Terminates the processing of the current report.
- Deletes any intermediate files or temporary tables that were created in processing the report.

You cannot use the RETURN statement as a substitute for EXIT REPORT. An error is issued if RETURN is encountered within the definition of a report.

PRINT

Formats and prints a row of data in a report routine.

Syntax

```
PRINT
 {
    expression
  | COLUMN left-offset
  | PAGENO
  | LINENO
  | num-spaces SPACES
  | [GROUP] COUNT(*) [ WHERE condition ]
  | [GROUP] PERCENT(*) [ WHERE condition]
  | [GROUP] AVG( variable ) [ WHERE condition]
  | [GROUP] SUM( variable ) [ WHERE condition]
  | [GROUP] MIN( variable ) [ WHERE condition]
  | [GROUP] MAX( variable ) [ WHERE condition]
  | char-expression WORDWRAP [ RIGHT MARGIN rm ]
  | FILE "file-name"
 } [,...]
  [ ; ]
```

1. *expression* is any legal language expression.
2. *left-offset* is described in COLUMN.
3. *num-spaces* is described in SPACES.
4. *char-expression* is a string expression or a TEXT variable.
5. *filename* is a string expression , or a quoted string, that specifies the name of a text file to include in the output from the report.

Usage

The PRINT instruction is used in a report routine to output a line of data.

The PRINT statement can include character data in the form of an ASCII file, a TEXT variable, or a comma-separated expression list of character expressions in the output of the report. (For TEXT variable or filename, you cannot specify additional output in the same PRINT statement.)

If a BYTE value is used in the PRINT statement, the output will show the "<byte value>" text for this element when the report output is regular text. If the report output is XML, the BYTE value is converted to Base64 before it is written to the output stream.

PRINT statement output begins at the current character position, sometimes called simply the current position. On each page of a report, the initial default character position is the first character position in the first line. This position can be offset horizontally and vertically by margin and header specifications and by executing any of the following statements:

- The SKIP statement moves it down to the left margin of a new line.
- The NEED statement can conditionally move it to a new page.
- The PRINT statement moves it horizontally (and sometimes down).

Unless you use the keyword CLIPPED or USING, values are displayed with widths (including any sign) that depend on their declared data types.

Table 305: Default print width for data types

Data type	Default Print Width
BYTE	N/A

Data type	Default Print Width
CHAR	Length of character data type declaration.
DATE	DBDATE dependent, 10 if DBDATE = "MDY4/"
DATETIME	From 2 to 25, as implied in the data type declaration.
DECIMAL	(2 + p + s), where p is the precision and s is the scale from the data type declaration.
FLOAT	14
INTEGER	11
INTERVAL	From 3 to 25, as implied in the data type declaration.
MONEY	(2 + c + p + s), where c is the length of the currency defined by DBMONEY and p is the precision and s is the scale from the data type declaration.
NCHAR	Length of character data type declaration.
NVARCHAR	Length current value in the variable.
SMALLFLOAT	14
SMALLINT	6
STRING	Length current value in the variable.
TEXT	Length current value in the variable.
VARCHAR	Length current value in the variable.

Unless you specify the FILE or WORDWRAP option, each PRINT statement displays output on a single line. For example, this fragment displays output on two lines:

```
PRINT fname, lname
PRINT city, ", ", state, " ", zip-code
```

If you terminate a PRINT statement with a semicolon, however, you suppress the implicit LINEFEED character at the end of the line. The next example has the same effect as the PRINT statements in the previous example:

```
PRINT fname;
PRINT lname
PRINT city, ", ", state, " ", zip-code
```

The expression list of a PRINT statement returns one or more values that can be displayed as printable characters. The expression list can contain report variables , built-in functions and operators. Some of these can appear only in a REPORT program block such as PAGENO, LINENO, PERCENT.

If the expression list applies the USING operator to format a DATE or MONEY value, the format string of the USING operator takes precedence over the DBDATE , DBMONEY , and DBFORMAT environment variables.

The PRINT FILE statement reads the contents of the specified filename into the report, beginning at the current character position. This statement permits you to insert a multiple-line character string into the output of a report. If *filename* stores the value of a TEXT variable, the PRINT FILE *file-name*

statement has the same effect as specifying PRINT *text-variable*. (But only PRINT variable can include the WORDWRAP operator)

Aggregate report functions summarize data from several records in a report. The syntax and effects of aggregates in a report resemble those of SQL aggregate functions but are not identical.

The expression (in parentheses) that SUM(), AVG(), MIN(), or MAX() takes as an argument is typically of a number or INTERVAL data type; ARRAY, BYTE, RECORD, and TEXT are not valid. The SUM(), AVG(), MIN() , and MAX() aggregates ignore input records for which their arguments have null values, but each returns NULL if every record has a null value for the argument.

The GROUP keyword is an optional keyword that causes the aggregate function to include data only for a group of records that have the same value for a variable that you specify in an AFTER GROUP OF control block. An aggregate function can only include the GROUP keyword within an AFTER GROUP OF control block.

The optional WHERE clause allows you to select among records passed to the report, so that only records for which the boolean expression is TRUE are included.

Example

The following example is from the FORMAT section of a report definition that displays both quoted strings and values from rows of the customer table:

```
FIRST PAGE HEADER
  PRINT COLUMN 30, "CUSTOMER LIST"
  SKIP 2 LINES
  PRINT "Listings for the State of ", thisstate
SKIP 2 LINES
  PRINT "NUMBER", COLUMN 12, "NAME", COLUMN 35, "LOCATION",
        COLUMN 57, "ZIP", COLUMN 65, "PHONE"
  SKIP 1 LINE
PAGE HEADER
  PRINT "NUMBER", COLUMN 12, "NAME", COLUMN 35, "LOCATION",
        COLUMN 57, "ZIP", COLUMN 65, "PHONE"
  SKIP 1 LINE
ON EVERY ROW
  PRINT customer_num USING "###&", COLUMN 12, fname CLIPPED,
       1 SPACE, lname CLIPPED, COLUMN 35, city CLIPPED, ", ",
       state, COLUMN 57, zip-code, COLUMN 65, phone
```

PRINTX

Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

Syntax

```
PRINTX [NAME = identifier] expression
```

1. *identifier* is the name to be used in the XML node.
2. *expression* is any legal language expression.

Usage

The PRINTX statement is similar to PRINT, except that when XML is produced by the report, the XML print element will be named as specified. If the NAME clause is omitted or the report is run in non-XML mode, then PRINTX does exactly the same as PRINT.

To generate XML output, you must redirect the report output into a SAX document handler with the `TO XML HANDLER` clause of `START REPORT`:

```
START REPORT orders_report
   TO XML HANDLER om.XmlWriter.createFileWriter("orders.xml")
```

Note that when using XML output, `BYTE` values are converted to Base64 before they are printed with the `PRINTX` instruction.

Example

```
REPORT (fname, lname, ...)
  DEFINE fname VARCHAR(20),
         lname VARCHAR(20)
  ...
  FORMAT
    ...
    ON EVERY ROW
       PRINTX NAME=customer fname, lname
...
```

With the above code, the variable names will appear in the graphical report designer as "`customer.fname`" and "`customer.lname`".

NEED

Specifies the number of rows needed in a report section.

Syntax

```
NEED num-lines LINE[S]
```

1. *num-lines* is the number of lines.

Usage

This statement has the effect of a conditional `SKIP TO TOP OF PAGE` statement, the condition being that the number to which the integer expression evaluates is greater than the number of lines that remain on the current page.

The `NEED` statement can prevent the report from dividing parts of the output that you want to keep together on a single page. In this example, the `NEED` statement causes the `PRINT` statement to send output to the next page unless at least six lines remain on the current page:

```
  AFTER GROUP OF r.order_num
    NEED 6 LINES
    PRINT " ", r.order_date, "  ", GROUP SUM(r.total_price)
```

The `LINES` value specifies how many lines must remain between the line above the current character position and the bottom margin for the next `PRINT` statement to produce output on the current page. If fewer than `LINES` remain on the page, the report engine prints both the `PAGE TRAILER` and the `PAGE HEADER`.

The `NEED` statement does not include the `BOTTOM MARGIN` value when it compares `LINES` to the number of lines remaining on the current page. `NEED` is not valid in `FIRST PAGE HEADER`, `PAGE HEADER`, or `PAGE TRAILER` blocks.

PAUSE

Pauses a report displayed to the screen.

Syntax

```
PAUSE [ "comment" ]
```

1. *comment* is an optional comment to be displayed.

Usage

Output is sent by default to the screen unless the START REPORT statement or the OUTPUT section specifies a destination for report output.

The PAUSE statement can be executed only if the report sends its output to the screen. It has no effect if you include a TO clause in either of these contexts:

- In the OUTPUT section of the report definition.
- In the START REPORT statement of the report driver.

Include the PAUSE statement in the PAGE HEADER or PAGE TRAILER block of the report. For example, the following code causes the runtime system to skip a line and pause at the end of each page of report output displayed on the screen:

```
  PAGE TRAILER
    SKIP 1 LINE
    PAUSE "Press return to continue"
```

SKIP

Skips a given number of lines in a report.

Syntax

```
SKIP { num-lines LINE[S] | TO TOP OF PAGE }
```

1. *num-lines* is the number of lines.

Usage

The SKIP statement allows you to insert blank lines into report output or to skip to the top of the next page as if you had included an equivalent number of PRINT statements without specifying any expression list.

The LINE and LINES keywords are synonyms in the SKIP statement.

Output from any PAGE HEADER or PAGE TRAILER control block appears in its usual location.

The SKIP n LINES statement cannot appear within a CASE statement, a FOR loop, or a WHILE loop.

The SKIP TO TOP OF PAGE statement cannot appear in a FIRST PAGE HEADER , PAGE HEADER or PAGE TRAILER control block.

Example

```
  FIRST PAGE HEADER
    PRINT "Customer List"
    SKIP 2 LINES
    PRINT "Number        Name               Location"
    SKIP 1 LINE
  PAGE HEADER
    PRINT "Number        Name               Location"
```

```
    SKIP 1 LINE
  ON EVERY ROW
    PRINT r.customer_num, r.fname, r.city
```

Report operators

Report operators can be used to print dynamic report information.

LINENO

Contains the current line number in a report.

Syntax

```
LINENO
```

Usage

This operator takes no operand but returns the value of the line number of the report line that is currently printing.

The report engine calculates the line number by calculating the number of lines from the top of the current page, including the `TOP MARGIN`.

Example

In this example, a `PRINT` statement instructs the report to calculate and display the current line number, beginning in the tenth character position after the left margin:

```
  ON EVERY ROW
    IF LINENO > 9 THEN
      PRINT COLUMN 10, "Line:", LINENO USING "<<<"
    END IF
```

PAGENO

Contains the current page number in a report.

Syntax

```
PAGENO
```

Usage

This operator takes no operand but returns the number of the page the report engine is currently printing.

You can use `PAGENO` in the `PAGE HEADER` or `PAGE TRAILER` block, or in other control blocks to number the pages of a report sequentially.

Example

If you use the SQL aggregate `COUNT(*)` in the `SELECT` statement to find how many records are returned by the query, and if the number of records that appear on each page

of output is both fixed and known, you can calculate the total number of pages, as in this example:

```
  FIRST PAGE HEADER
    SELECT COUNT(*) INTO cnt FROM customer
    LET y = cnt/50 -- Assumes 50 records per page
  ON EVERY ROW
    PRINT COLUMN 10, r.customer_num, ...
  PAGE TRAILER
    PRINT PAGE PAGENO USING "<<" OF cnt USING "<<"
```

If the calculated number of pages was 20, the first page trailer would be:

```
Page 1 of 20
```

PAGENO increments with each page, so the last page trailer would be:

```
Page 20 of 20
```

SPACES

Generates the given number of blank characters.

Syntax

```
num-spaces SPACES
```

1. *num-spaces* is the number of spaces.

Usage

This operator returns a string of blanks, equivalent to a quoted string containing the specified number of blanks.

In a PRINT statement, these blanks are inserted at the current character position.

Its operand must be an integer expression that returns a positive number, specifying an offset (from the current character position) no greater than the difference (right margin - current position). After PRINT SPACES has executed, the new current character position has moved to the right by the specified number of characters.

Outside PRINT statements, SPACES and its operand must appear within parentheses: (*n* SPACES).

Example

```
ON EVERY ROW
   LET s = (6 SPACES), "=ZIP"
   PRINT r.fname, 2 SPACES, r.lname, s
```

WORDWRAP

Splits a character string to match a given margin limit.

Syntax

```
WORDWRAP [ RIGHT MARGIN position ]
```

1. *position* defines the temporary right margin, as a number of characters, counting from the left.

Usage

The WORDWRAP operator automatically wraps successive segments of long character strings onto successive lines of report output. Any string value that is too long to fit between the current position and the right margin is divided into segments and displayed between temporary margins:

- The current character position becomes the temporary left margin.
- Unless you specify RIGHT MARGIN, the right margin defaults to 132, or to the size value from the RIGHT MARGIN clause of the OUTPUT section or START REPORT instruction.

Specify WORDWRAP RIGHT MARGIN *integer* to set a temporary right margin as a number of characters, counting from the left edge of the page. This value cannot be smaller than the current character position or greater than right margin defined for the report. The current character position becomes the temporary left margin. These temporary values override the specified or default left and right margins of the report.

After the PRINT statement has executed, any explicit or default margins defined in the RIGHT MARGIN clause of the OUTPUT section or START REPORT instruction are restored.

The following PRINT statement specifies a temporary left margin in column 10 and a temporary right margin in column 70 to display the character string that is stored in the variable called mynovel:

```
PRINT COLUMN 10, mynovel WORDWRAP RIGHT MARGIN 70
```

The data string can include printable ASCII characters. It can also include the TAB (ASCII 9), LINEFEED (ASCII 10), and ENTER (ASCII 13) characters to partition the string into words that consist of substrings of other printable characters. Other non-printable characters might cause runtime errors. If the data string cannot fit between the margins of the current line, the report engine breaks the line at a word division, and pads the line with blanks at the right.

From left to right, the report engine expands any TAB character to enough blank spaces to reach the next tab stop. By default, tab stops are in every eighth column, beginning at the left-hand edge of the page. If the next tab stop or a string of blank characters extends beyond the right margin, the report engine takes these actions:

1. Prints blank characters only to the right margin.
2. Discards any remaining blanks from the blank string or tab.
3. Starts a new line at the temporary left margin.
4. Processes the next word.

The report engine starts a new line when a word plus the next blank space cannot fit on the current line. If all words are separated by a single space, this action creates an even left margin. The following rules are applied (in descending order of precedence) to the portion of the data string within the right margin:

- Break at any LINEFEED, or ENTER, or LINEFEED, ENTER pair.
- Break at the last blank (ASCII 32) or TAB character before the right margin.
- Break at the right margin, if no character farther to the left is a blank, ENTER, TAB, or LINEFEED character.

The report engine maintains page discipline under the WORDWRAP option. If the string is too long for the current page, the report engine executes the statements in any page trailer and header control blocks before continuing output onto a new page.

For Japanese locales, a suitable break can also be made between the Japanese characters. However, certain characters must not begin a new line, and some characters must not end a line. This convention creates the need for KINSOKU processing, whose purpose is to format the line properly, without any prohibited word at the beginning or ending of a line.

Reports use the wrap-down method for WORDWRAP and KINSOKU processing. The wrap-down method forces down to the next line characters that are prohibited from ending a line. A character that precedes

another that is prohibited from beginning a line can also wrap down to the next line. Characters that are prohibited from beginning or ending a line must be listed in the locale. The runtime system tests for prohibited characters at the beginning and ending of a line, testing the first and last visible characters. The KINSOKU processing only happens once for each line. That is, no further KINSOKU processing occurs, even if prohibited characters are still on the same line after the first KINSOKU processing.

Report aggregate functions

Report aggregate functions can be used to compute data.

COUNT

Counts a number of rows in a report according to a condition.

Syntax

```
[GROUP] COUNT(*) [ WHERE condition ]
```

1. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

This aggregate report instruction returns the total number of records qualified by the optional `WHERE` condition.

The `WHERE` condition is evaluated after any `OUTPUT TO REPORT` execution. Even if it is typically used in `AFTER GROUP OF` blocks, the aggregate expression is not evaluated in that block: Changing values of the `WHERE` clause in the `AFTER GROUP` context will not have an immediate effect.

Using the `GROUP` keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the `AFTER GROUP OF` control block.

Example

The following fragment of a report definition uses the `AFTER GROUP OF` control block and `GROUP` keyword to form sets of records according to how many items are in each order. The last `PRINT` statement calculates the total price of each order, adds a shipping charge, and prints the result. Because no `WHERE` clause is specified here, `GROUP SUM()` combines the *total_price* of every item in the group included in the order.

```
  AFTER GROUP OF number
    SKIP 1 LINE
    PRINT 4 SPACES, "Shipping charges for the order: ",
            ship_charge USING "$$$$.&&"
    PRINT 4 SPACES, "Count of small orders: ",
         GROUP COUNT(*) WHERE total_price < 200.00 USING
 "##,###"
    SKIP 1 LINE
    PRINT 5 SPACES, "Total amount for the order: ",
          ship_charge + GROUP SUM(total_price) USING "$$,$$$,$$
$.&&"
```

PERCENT

Calculates the percentage of rows matching a condition.

Syntax

```
[GROUP] PERCENT(*) [ WHERE condition ]
```

1. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

This aggregate report instruction returns the percentage of the total number of records qualified by the optional `WHERE` condition.

Using the `GROUP` keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the `AFTER GROUP OF` control block.

This aggregate instruction makes a two-pass report when not using the `GROUP` keyword and is used in any control block other than `ON LAST ROW`, or when using the `GROUP PERCENT(*)` anywhere in the report.

SUM

Calculates the total of a report parameter according to a condition.

Syntax

```
[GROUP] SUM(expression) [ WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

This aggregate report instruction evaluates as the total of expression among all records or among records qualified by the optional `WHERE` clause and any `GROUP` specification.

Using the `GROUP` keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the `AFTER GROUP OF` control block.

Input records for which the *expression* evaluates to `NULL` values are ignored.

By default, if all input record values are `NULL` , the result of the aggregate is `NULL`. However, you can control this behavior and force the runtime system to return zero instead of `NULL` with the `report.aggregateZero` FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the `GROUP` keyword and is used in any control block other than `ON LAST ROW`.

AVG

Calculates the average of a report parameter according to a condition.

Syntax

```
[GROUP] AVG(expression) [ WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

This aggregate report instruction evaluates as the average (that is, the arithmetic mean value) of expression among all records or among records qualified by the optional WHERE clause and any GROUP specification.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the *expression* evaluates to NULL values are ignored.

By default, if all input record values are NULL , the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW.

MIN

Calculates the minimum value of a report parameter according to a condition.

Syntax

```
[GROUP] MIN(expression) [ WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

For number, currency, and interval values, MIN(*expression*) aggregate report instruction returns the minimum value for *expression* among all records or among records qualified by the WHERE clause and any GROUP specification.

For DATETIME or DATE data values, greater than means later and less than means earlier in time. Character strings are sorted according to their first character. If your program is executed in the default (U.S. English) locale, for character data types, greater than means after in the ASCII collating sequence, where a> A> 1, and less than means before in the ASCII sequence, where 1< A< a.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the *expression* evaluates to NULL values are ignored.

By default, if all input record values are NULL , the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW.

MAX

Calculates the maximum value of a report parameter according to a condition.

Syntax

```
[GROUP] MAX(expression) [ WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

Usage

For number, currency, and interval values, the MAX(*expression*) aggregate report instruction returns the maximum value for *expression* among all records or among records qualified by the WHERE clause and any GROUP specification.

For DATETIME or DATE data values, greater than means later and less than means earlier in time. Character strings are sorted according to their first character. If your program is executed in the default (U.S. English) locale, for character data types, greater than means after in the ASCII collating sequence, where a> A> 1, and less than means before in the ASCII sequence, where 1< A< a.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the *expression* evaluates to NULL values are ignored.

By default, if all input record values are NULL , the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW.

Report engine configuration

Report engine behavior can be controlled with FGLPROFILE settings.

By default, aggregate instructions such as SUM() return a NULL value if all input record values are NULL.

You can force the report engine to return a zero decimal value with the following FGLPROFILE setting:

```
Report.aggregateZero = {true|false}
```

When this entry is set to true, the SUM() , AVG() , MAX() and MIN() aggregate functions return zero when all values are NULL.

Default value of the configuration parameter is false (i.e. aggregate functions evaluate to null if all items are null)

When using GROUP aggregates with this entry is set to true, the aggregate instruction will still return NULL in the first AFTER GROUP OF output of the report. Zero values will be returned starting from second group output. This behavior is expected, for backward compatibility with older versions.

You should not use the Report.aggregateZero entry if you don't need that specific behavior.

Programming tools

These topics cover programming with the Genero Business Development Language.

- Command line tools on page 1493
- Compiling source files on page 1508
- Source code edition on page 1516
- Source documentation on page 1517
- The preprocessor on page 1522
- The debugger on page 1531
- The profiler on page 1556
- Optimization on page 1559
- Logging options on page 1563

Command line tools

The different command line tools provided for BDL programming.

- fglrun on page 1493
- fglform on page 1495
- fgl2p on page 1496
- fglcomp on page 1497
- fgllink on page 1499
- fglmkmsg on page 1500
- fglmkext on page 1500
- fgldb on page 1501
- fgldbsch on page 1502
- fglmkstr on page 1503
- fglwsdl on page 1503
- fglpass on page 1506

fglrun

The fglrun tool is the runtime system program that executes p-code programs.

Syntax

```
fglrun [options] program [argument [...]]
```

1. *options* are described in Table 306: fglrun options on page 1493.
2. *program* is a .42r or .42m p-code program.
3. *argument* is an argument passed to the program

Options

Table 306: fglrun options

Option	Description
-V	Display version information for the tool.
-h	Displays options for the tool. Short help.

Option	Description
`-i { mbcs }`	Displays information. • `-i mbcs` displays information about multibyte character set settings.
`-d`	Start in debug mode. See The debugger on page 1531 for more details.
`-e extfile[,...]`	Specify a C extension module to be loaded. This option can take a comma-separated list of extensions.
`-l`	Link p-code modules together, see Compiling source files on page 1508.
`-o { progname.42r | libname.42x }`	Output file specification when using the `-l` link option, it can be a 42r program or a 42x library.
`-b`	Displays compiler version information of the module, see Compiling source files on page 1508.
`-p`	Generate profiling information to stderr (UNIX™ only). See The profiler on page 1556.
`-M`	Display a memory usage diagnostic when program ends. See Check runtime system memory leaks on page 1561.
`-m`	Check for memory leaks. If leaks are found, displays memory usage diagnostic and stops with status 1. See Check runtime system memory leaks on page 1561.
`--java-option=option`	Passes Java™ runtime options when initializing the JNI interface. See Java™ Interface for more details.
`--print-imports`	Loads the specified modules and prints all `IMPORT FGL` instructions that should be used in each module. See Compiling source files on page 1508.
`--start-guilog=logfile`	Log all GUI protocol exchange in a file. The GUI log file can then be replayed with the `--run-guilog` option.
`--run-guilog=logfile`	Replays a GUI log created with the `--start-guilog` option.
`--gui-listen=port`	Instructs the runtime system to listen to a TCP port for incoming GUI connections. For more details see Connecting with a front-end on page 755.
`--module-size module`	Show the amount of limited pcode size for a module.
`--program-size program`	Show the amount of limited pcode size for an entire program.

Usage

The `fglrun` command line tool executes p-code programs, for example:

```
fglrun myprogram.42r -x 123
```

The program file must contain the `MAIN` routine.

The arguments passed to the program can be queried with the arg_val() built-in function.

The .42r or .42m extension is optional:

```
fglrun myprogram -x 123
```

> **Note:** First `fglrun` tries to find the program file with the name provided in the command line. If the file is not found, the extension is removed (if it is present in the provided file name), and a new search is done by adding the `.42r` extension. If the file is still not found, `fglrun` tries with the `.42m` extension. As result, a program file `myprogram.42m` will be found and loaded, even if you pass `myprogram.42r` to `fglrun`. Specify no `.42r` or `.42m` extension, to avoid mistakes and simplify migration from `.42r` linked programs to `.42m`-only modules (using `IMPORT FGL`).

fglform

The fglform tool compiles form specification files into XML formatted files used by the programs.

Syntax

```
fglform [options] srcfile[.per]
```

1. *options* are described in Table 307: fglform options on page 1495.
2. *srcfile*.per is the form specification file.

Options:

Table 307: fglform options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-i { mbcs }`	Displays information. `-i mbcs` displays information about multibyte character set settings.
`-m`	Extract localized strings.
`-M`	Write error messages to standard output instead of creating a **.err** error file.
`-W { all }`	Display warning messages. Only `-W all` option is supported for now.
`-E`	Preprocess only.
`-p option`	Preprocessing control, where *option* can be one of: • `nopp`: Disable preprocessing. • `noli`: No line number information (only with -E option). • `fglpp`: Use # syntax instead of & syntax.

Option	Description
`-I path`	Provides a path to search for include files.
`-D ident`	Defines the macro 'ident' with the value 1.

Usage

The `fglform` command line tool compiles a .per form specification file into a .42f compiled version:

```
fglform custform.per
```

The .per extension is optional, if not used, fglform will automatically search for files with this extension.

The .42f compiled version is an XML formatted file used by programs when a form definition is loaded with the `OPEN FORM` or `OPEN WINDOW WITH FORM` instructions.

fgl2p

The fgl2p tool compiles source files and assembles p-code modules into a .42r program or a .42x library.

Syntax

To create a library:

```
fgl2p [options] -o outfile.42x { pcmod.42m | srcfile.4gl } [...]
```

To create a program:

```
fgl2p [options] -
o outfile.42r { pcmod.42m | srcfile.4gl | library.42x } [...]
```

1. *options* are described in Table 308: fgl2p options on page 1496.
2. *outfile*.42r is the name of the program to be created.
3. *outfile*.42x is the name of the library to be created.
4. *pcmod*.42m is a p-code module compiled with fglcomp.
5. *source*.4gl is a program source file.
6. *library*.42x is the name of a library to be linked.

Options

Table 308: fgl2p options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-o outfile.ext`	Output file specification, where *ext* can be 42r for a program or 42x for a library.
otheroption	Other options are passed to the linker or compiler.

Usage

The `fgl2p` command line tool can compile .4gl source files and link .42m p-code modules together, to create a .42x library or a .42r program file.

```
fgl2p -o myprog.42x module1.4gl module2.42m lib1.42x
```

This tool is provided for convenience, in order to create programs or libraries in one command line. It uses the fglcomp and the fgllink tools to compile and link modules together.

fglcomp

The `fglcomp` tool compiles `.4gl` source files into `.42m` p-code modules.

Syntax

```
fglcomp [options] srcfile[.4gl]
```

1. *options* are described in Table 309: fglcomp options on page 1497.
2. *srcfile* .4gl is the program source file.
3. The .4gl extension is optional.

Options

Table 309: fglcomp options

Option	Description
`-V` or `--version`	Display version information for the tool.
`-h` or `--help`	Display options for the tool. Short help.
`-i { mbcs }`	Display information. `-i mbcs` displays information about multibyte character set settings.
`-S`	Dump Static SQL statements found in the source to stdout.
`-m`	Extract %"string" localized strings from source to stdout.
`-M`	Write error messages to standard output instead of creating a .err error file.
`-W what`	Display warning messages. For a complete description, see Arguments for the -W option on page 1498.
`-E`	Preprocess only. See The preprocessor on page 1522 for more details.
`--timestamp`	Add compilation timestamp to build information in 42m header.
`-p option`	Preprocessing control, where *option* can be one of: • `nopp`: Disable preprocessing. • `noli`: No line number information (only with `-E` option). • `fglpp`: Use # syntax instead of & syntax.

Option	Description
`-G`	Produce .c and .h globals interface files for C-Extensions.
`-I` *`path`*	Provides a path to search for include files. See The preprocessor on page 1522 for more details.
`-D` *`ident`*	Defines the macro 'ident' with the value 1. See The preprocessor on page 1522 for more details.
`-U` *`ident`*	Undefines the macro 'ident'. See The preprocessor on page 1522 for more details.
`--build-doc`	Generate source documentation.
`--doc-private`	When using the `--build-doc` option, include `PRIVATE` symbols to the documentation.
`--build-rdd`	Generate the .rdd data definition during compilation.
`--verbose`	Print detailed compilation information.
`--implicit=`*`type`*	Specify whether or not to compile imported modules, where *type* can be one of: • `none`: Disable any implicit compilation. • `42m`: Compileimported modules if needed (the default).
`-r` or `--resolve-calls`	Throw an error on references to undeclared functions. Each external function must be made known to the compiler by `IMPORT FGL`. When using this option, the linking phase is no longer needed; a source (`4gl`) file compiled with this option must not be linked. See IMPORT FGL module on page 372 for more details.
`--java-option=`*`option`*	Passes Java™ runtime options when initializing the JNI interface. See Java™ Interface for more details.

Usage

The `fglcomp` command line tool compiles a .4gl into a .42m p-code module:

```
fglcomp customers.4gl
```

If a compilation error occurs, the compiler generates an error file with an `.err` extension. The error file contains the original source code with error messages. Use the option `-M` to display the error messages to standard error instead of producing the `.err` file.

Arguments for the -W option

The `-W` option can be used to check for wrong language usage, that must be supported for backward compatibility. When used, this option helps to write better source code.

The argument following `-W` option can be one of `return`, `unused`, `stdsql`, `print`, `error` or `all`.

- Using `-W all` enables all warning flags.
- Using `-W error` makes the compiler stop if any warning is raised, as if an error occurred.
- The `-W unused` option displays a message for all unused variables.
- The `-W return` option displays a warning if the same function returns different number of values with several `RETURN` statements.
- The `-W stdsql` option displays a message for all non-portable SQL statements or language instructions.
- The `-W print` option displays a message when the `PRINT` instruction is used outside a `REPORT`.
- The `-W implicit` option warns on references to undeclared functions. A function is undeclared if not defined in the current module or in any imported module. This warning is silently ignored if `IMPORT FGL` is not used.
- The `-W apidoc` option prints a warning for invalid source documentation tags when using the --build-doc option.

The `-W` option also supports the negative form of arguments by using the `no-` prefix as in: `no-return`, `no-unused`, `no-stdsql`. You might need to use these negative form in order to disable some warning when using the `-W all` option:

```
fglcomp -Wall -Wno-stdsql customers.4gl
```

Switches will be enabled/disabled in the order of appearance in the command line.

fgllink

The fgllink tool assembles p-code modules produced with fglcomp into a .42r program or a .42x library.

Syntax

To create a library:

```
fgllink [options] -o outfile.42x module.42m [...]
```

To create a program:

```
fgllink [options] -o outfile.42r { module.42m | library.42x } [...]
```

1. *options* are described in Table 310: fgllink options on page 1499.
2. *outfile*.42r is the name of the program to be created.
3. *outfile*.42x is the name of the library to be created.
4. *module*.42m is a p-code module compiled with fglcomp.
5. *library*.42x is the name of a library to be linked.

Options

Table 310: fgllink options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-e extfile[,...]`	Specify a C extension module to be loaded. This option can take a comma-separated list of extensions.
`-o { progname.42r | libname.42x }`	Output file specification, it can be a 42r program or a 42x library.

Option	Description
otheroption	Other options are passed to fglrun for linking.

Usage

The `fgllink` command line tool links .42m p-code modules together to create a .42x library or a .42r program file.

```
fgllink -o myprog.42x module1.42m module2.42m lib1.42x
```

> **Note:** `fgllink` is a wrapper calling fglrun with the **-l** option.

fglmkmsg

The fglmkmsg tool compiles .msg message files into a binary version used by programs.

Syntax

```
fglmkmsg [options] srcfile [outfile]
```

1. *options* are described in Table 311: fglmkmsg options on page 1500.
2. *srcfile* is the source message file.
3. *outfile* is the destination file.

Options

Table 311: fglmkmsg options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-r msgfile`	De-compiles a binary message file.

Usage

The `fglmkmsg` command line tool compiles a .msg message file into a .iem compiled version:

```
fglmkmsg mess01.msg
```

For backward compatibility, you can specify the output file as second argument:

```
fglmkmsg mess01.msg mess01.iem
```

The .iem compiled version can be used by BDL programs, for example, when the `HELP` clause is used in a `MENU` or `INPUT` instruction.

fglmkext

The fglmkext tool compiles and links a user C Extension.

Syntax

```
fglmkext [options] source.c [...]
```

1. *options* are described in Table 312: fglmkext options on page 1501.
2. *source* is a C source file implementing C extension functions.

Options

Table 312: fglmkext options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-o` *`libname`*	Output file specification, defines the C Extension library name.

Usage

The `fglmkext` command line tool compiles and links a C Extension library.

The command can be used with a single source file, the name of the library will default to the name of the specified source:

```
fglmkext myext.c
```

If a single C source file is provided, must define the `usrFunctions` C extension interface structure as well as the functions to be used from a BDL program.

In order to specify a library name, use the `-o` option, several C source files can also be specified. For example, on a UNIX platform:

```
fglmkext -o mycext.so module_a.c module_b.c
```

fgldb

The fgldb tool is an interface program for remote debugging.

Syntax 1: Debugging an application running on a server

```
fgldb -p process-id
```

1. *process-id* is the process identifier of the fglrun-bin / fglrun.exe program.

Syntax 2: Debugging an app running on a mobile device

```
fgldb -m host[:port] ]
```

1. *host* is the host (or IP address) of the mobile device where the program executes, default is "localhost".
2. *port* is the TCP port number to connect to, default is 6400.

Options

Table 313: fgldb options

Option	Description
`-V`	Display version information for the tool.

Option	Description
`-h`	Displays options for the tool.
`-p process-id`	Attach to a running process to debug
`-m host[:port]`	Attach to a running process to debug

Usage

The `fgldb` command line tool is an interface for remote debugging, attaching to a Genero program running on a server or on a mobile device (or mobile emulator).

fgldbsch

The fgldbsch tool generates the database schema files from an existing database.

Syntax

```
fgldbsch -db dbname [options]
```

1. *dbname* is the name of the database from which the schema is to be extracted.
2. *options* are described in Table 314: fgldbsch options on page 1502.

Options

Table 314: fgldbsch options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-H`	Display long help.
`-v`	Enable verbose mode (display information messages).
`-ct`	Display data type conversion tables.
`-cx dbtype`	Display data type conversion table for the give database type.
`-db dbname`	Specify the database as *dbname*. This option is required to generate the schema files.
`-dv dbdriver`	Specify the database driver to be used.
`-un user`	Define the user name for database connection as *user*.
`-up pswd`	Define the user password for database connection as *pswd*.
`-ow owner`	Define the owner of the database tables as *owner*.
`-cv string`	Specify the data type conversion rules by character positions in *string*.
`-of name`	Specify output files prefix, default is database name.

Option	Description
`-tn` *tabname*	Extract the description of a specific table.
`-ie`	Ignore tables with columns having data types that cannot be converted.
`-cu`	Generate upper case table and column names.
`-cl`	Generate lower case table and column names.
`-cc`	Generate case-sensitive table and column names.
`-sc`	Extract shadow columns.
`-st`	Extract system tables.
`-om`	Run schema extractor in old fglschema mode (accepts -c and -r options)

Usage

The `fgldbsch` command line tool extracts the schema description for any database supported by the product.

The .sch schema file is mandatory to compiler forms or source modules using the `SCHEMA` instruction.

fglmkstr

The fglmkstr tool compiles .str localized string resource files.

Syntax

```
fglmkstr [options] source-file[.str]
```

1. *options* are described in Table 315: fglmkstr options on page 1503.
2. *source-file* is the .str string file. You can omit the file extension.

Options

Table 315: fglmkstr options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.

Usage

The `fglmkstr` command line tool is used to compile .str localized string files into .42s files.

fglwsdl

The fglwsdl tool produces web services stub files for client or server programs (from WSDL / XSD).

Syntax

```
fglwsdl command [options] parameter
```

1. *command* indicates what operation must be done by fglwsdl.

2. *options* are described in Commands and options on page 1504.
3. *parameter* depends on the *command* used.

Commands and options

Table 316: fglwsdl commands

Command	Description
`-V`	Display version information
`-h`	Display this help
`-l`	List services from a WSDL or variables from a XSD
`-c [`*`options`*`] `*`wsdl-spec`*	Generate client stub (default) to be used in a GWS client application. *wsdl-spec* is the name of a WSDL description file or the URL of a WSDL description for a published web service. Typically, `http://`*`host/service`*`?WSDL`. The *options* are listed in Table 317: WSDL Options on page 1504 and Table 319: Common options on page 1505.
`-s [`*`options`*`] `*`wsdl-spec`*	Generate server stub to be used in a GWS server application. *wsdl-spec* is the name of a WSDL description file or the URL of a WSDL description for a published web service. Typically, `http://`*`host/service`*`?WSDL`. The *options* are listed in Table 317: WSDL Options on page 1504 and Table 319: Common options on page 1505.
`-x [`*`options`*`] `*`xsd-spec`*	Generate BDL data types from a XML schema (XSD). *xsd-spec* is the name of an XML schema file or the URL of an XSD schema resource on the web. The *options* are listed in Table 318: XSD Options on page 1505 and Table 319: Common options on page 1505.
`-regex `*`regex value`*	Validate the *value* against the *regex* regular expression described in XML schema specification.

Table 317: WSDL Options

Options	Description
`-o `*`file`*	Specify a base name for the output files.
`-n `*`service port`*	Generate only for the given service name and port type.
`-b `*`binding`*	Generate only for the given binding.
`-prefix `*`name`*	Add *name* as the prefix of the generated web service functions, variables and types. (*name* can contain %s for servicename, %p for portname and %f for filename)
`-compatibility`	Generate a Genero 1.xx compatibility client stub.
`-fRPC`	Force RPC convention; use RPC Convention to generate the code, regardless of what the WSDL information contains.
`-disk`	Save WSDL and all dependencies from an URL on the disk. **Note:** To generate code at the same time, you must use the option -c, -s, or both. Otherwise, no code is generated.
`-domHandler`	Generates the use of DOM in the client stub and calls to callback handlers.

Options	Description
`-alias`	Generates FGLPROFILE Logical names in place of URLs for the client stub.
`-soap11`	Generates only client and server stubs supporting SOAP 1.1 protocol.
`-soap12`	Generates only client and server stubs supporting SOAP 1.2 protocol.
`-ignoreFaults`	Do not generate extra code to handle soap faults.
`-wsa <yes|no>`	Force support of WS-Addressing 1.0 if **yes**, disable support of WS-Addressing 1.0 if **no**, otherwise support WS-Addressing 1.0 according to the WSDL definition.

Table 318: XSD Options

Options	Description
`-o` *`file`*	Name of the output file. If *file* has no extension, .inc is added.
`-n` *`name [ns]`*	Generate only for the given variable name and namespace (if there is one).
`-prefix` *`name`*	Add *name* as the prefix of the generated data types.
`-disk`	Save XSD and all dependencies from an URL on the disk. **Note:** No code is generated.

Table 319: Common options

Options	Description
`-comment`	Add XML comments to the generation.
`-fArray`	Force XML array generation instead of XML list when possible. If the WSDL contains an XML definition of a BDL list, generate a BDL array matching the same definition.
`-fInheritance`	Force generation of XML choice records for all inheritance types found in the schemas, otherwise only for abstract types and elements.
`-fInlineTypes`	Force generation of TYPE definitions for all global inlined types found in the schemas.
`-noFacets`	Don't generate facet constraints restricting the value-space of simple data type.
`-legacyTypes`	Don't generate BIGINT, TINYINT and BOOLEAN data types.
`-ignoreMixed`	Ignore attribute mixed="true" in XML schemas when generating code.
`-ext` *`schema`*	Add an external schema. See option '-extDir'.
`-extDir` *`directory`*	Add all external schema files ending with .xsd in the directory. **Note:** External schemas for dependencies won't be included in the WSDL description or in the XSD schema if their location attributes are missing. Use this option to add a missing external schema for a WSDL or XSD dependency.
`-noValidation`	Disable XML schema validation warnings.
`-autoNsPrefix` *`nb`*	Automatic prefix generation for variables and types using a substring of the namespace by removing the nb first elements (-1 means only the last element). For example: If a variable belongs to the namespace `http://www.mycompany.com/Global/Service`, a value of -1 will give `Service` as a prefix, and a value of 1 will give `Global_Service` as a prefix.

Options	Description
`-nsPrefix` *`ns value`*	Add *value* as prefix of the generated variables and types belonging to namespace ns (supersede the -prefix and the -autoNsPrefix option, and can be called several times).

Table 320: Network options (when specifying an URL)

Options	Description
`-noHTTP`	Disable HTTP - search for the WSDL description or the XML schema and its dependencies on the client instead of the internet. Useful, for example, if a company has restricted access to the internet.
`-proxy` *`location`*	Connect via proxy where *location* is host[:port] or ip[:port].
`-pAuth` *`login pass`*	Proxy authentication login and password.
`-hAuth` *`login pass`*	HTTP authentication login and password.
`-cert` *`cert`*	File of the X509 PEM-encoded certificate for HTTPS purpose.
`-key` *`key`*	File of the PEM-encoded private key for HTTPS purpose.
`-wCert` *`cert`*	Certificate name in the Windows™ keystore for HTTPS purpose (Windows™ only).
`-CA` *`list`*	A filename with the list of concatenated X509 PEM-encoded certificate authorities. (On Windows™, if not set, the Certificate Authority list of the key store is used).

Usage

The `fglwsdl` command line tool produces the WSDL description of a web service that will be accessed by a GWS client application, or to define a WSDL description to creating a corresponding GWS server application. The tool generates the BDL data types from XML schemas (also known as XSD).

To access a remote web service, you must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org) , or on other sites such as XMethods (http://www.xmethods.net).

fglpass

The fglpass tool allows you to encrypt passwords.

Syntax

```
fglpass [options]
```

1. *options* are described in fglpass options.

Options

Table 321: fglpass options

Command	Description
`-V`	Display version information
`-Vssl`	Display SSL version
`-h`	Display this help

Command	Description
`-e`	Encrypt the password with a RSA key or certificate and encode it in BASE64 form
`-d`	Decode the BASE64 form of the password and decrypt it with a RSA private key
`-w` *`cert`*	Windows™ certificate name to encrypt the password (Windows™ only)
`-c` *`cert`*	File of the PEM-encoded certificate to encrypt the password
`-k` *`key`*	File of the PEM-encoded private key to encrypt or decrypt the password
`-enc64` *`file`*	File to be BASE64 encoded (result to stdout)
`-dec64` *`file`*	BASE64 encoded file to be decoded (result to stdout)
`-agent:`*`port files`*	Start password agent on specified port to serve the list of private key files

Usage

The `fglpass` command line tool allows you to:

- Encrypt a password using a RSA key or X.509 certificate and encode it in BASE64 form.
- Run a password agent that returns (in a protected way) the passwords that grant access to the different private keys used in all your applications.
- Encode a file in BASE64 form and decode it back.

For security reasons, it is recommended to avoid storing clear passwords in a file, or leave private keys unprotected without a password. The fglpass command can be used to encrypt passwords.

fglWrt

The fglWrt tool is used to manage product licenses.

Syntax

```
fglWrt [options]
```

1. *options* are described in Table 322: fglmkstr options on page 1507.

Options

Table 322: fglmkstr options

Option	Description
`-V`	Display version information for the tool.
`-h`	Displays options for the tool. Short help.
`-l` *`license`*	Installs a license. **Note:** To escape when prompted to enter a license key, type "`stop`" at the prompt.

Option	Description
`-m` *key*	Maintenance key specification.
`-u`	Check for active users.
`-k` *key*	Installation key for license validation.
`-d`	Remove current installed license.
`-i`	Clears the list of registered user sessions.
`-a` *option*	Check or view options, possible options are: • ps : Shows processes on this machine. • cpu : Shows number of CPU in the computer. • hostname : Shows name of this machine. • info license : Shows license information. • info stat : Shows statitics of license server. • info users : Shows all registered active users. • info up : Shows if license server is up.

Usage

The `fglWrt` command line tool is used to install, upgrade or delete licenses.

If no license is installed, it is not possible to use Genero Business Development Language.

Compiling source files

Describes how to build the runtime files from source files.

- Compiling form files on page 1508
- Compiling message files on page 795
- Compiling source code on page 1510
- Importing modules on page 1511
- Linking libraries on page 1511
- Linking programs on page 1512
- Using makefiles on page 1515
- Module build information on page 1515

Compiling form files

Form specification files (with .per file extension) must be compiled to runtime form files (with .42f file extension) by using the fglform tool. Compiled form files are XML independent from the platform and processor architecture.

The following lines show a compilation in a UNIX™ shell session:

```
$ cat form.per
LAYOUT
GRID
{
[f01   ]
}
END
END
ATTRIBUTES
f01 = FORMONLY.field1;
```

```
END

$ fglform form.per

$ ls -s form.42f
   4 form.42f
```

If an error occurs, the compiler writes an error file with the .err extension.

```
$ cat form.per
LAYOUT
GRID
{
}

$ fglform form.per
The compilation was not successful.  Errors found: 1.
 The file 'form.err' has been written.

$ cat form.err
LAYOUT
GRID
{
}
# A grammatical error has been found at '}', expecting SCR_TEXT.
# See error number -6803.
```

With the `-M` option, you can force the compiler to display an error message instead of generating an .err error file (line break added for documentation readability):

```
$ fglform -M form.per
form.per:4:1:4:1:error:(-6803)
 A grammatical error has been found at '}', expecting SCR_TEXT.
```

By default, the compiler does not raise any warnings. You can turn on warnings with the `-W` option:

```
$ cat form.per
LAYOUT
GRID
{
[f01     ]
}
END
END
ATTRIBUTES
f01 = FORMONLY.field1, WIDGET="COMBO";
END

$ fglform -Wall form.per
form.per:9: warning (-8005) Deprecated feature: The WIDGET attribute is
 obsolete
```

Compiling message files

In order to use message files in a program, the message source files (with .msg extension) must be compiled with the fglmkmsg utility to produce compiled message files (with .iem extension).

The following command line compiles the message source file mess01.msg:

```
fglmkmsg mess01.msg
```

This creates the compiled message file mess01.iem.

For backward compatibility, you can specify the output file as second argument:

```
fglmkmsg mess01.msg mess01.iem
```

The .iem compiled version of the message file must be distributed on the machine where the programs are executed.

Compiling string files

The source string files (with `.str` extension) must be compiled to binary files (with `.42s` extension) in order to be loaded by the runtime system.

To compile a source string file, use the `fglmkstr` compiler.

```
$ fglmkstr filename.str
```

The `fglmkstr` tool generates a `.42s` file with the *filename* prefix.

> **Important:** When compiling a `.str` source string file, you must set the locale (character set) corresponding to the encoding used in the `.str` file.

Compiling source code

Source code modules (with .4gl file extension) must be compiled to p-code modules (with .42m file extension) by using the fglcomp tool. Compiled p-code modules are independent from the platform and processor architecture.

The following lines show a compilation in a UNIX™ shell session:

```
$ cat prog.4gl
MAIN
  DISPLAY "hello"
END MAIN

$ fglcomp prog.4gl

$ ls -s prog.42m
   4 prog.42m
```

If an error occurs, the compiler writes an error file with the .err extension.

```
$ cat prog.4gl
MAIN
  LET x = "hello"
END MAIN

$ fglcomp prog.4gl
Compilation was not successful. Errors found: 1.
 The file prog.4gl has been written.

$ cat prog.err
MAIN
  LET x = "hello"
| The symbol 'x' does not represent a defined variable.
| See error number -4369.
END MAIN
```

With the `-M` option, you can force the compiler to display an error message instead of generating an .err error file:

```
$ fglcomp prog.4gl
xx.4gl:2:8 error:(-4369) The symbol 'x' does not represent a defined
 variable.
```

By default, the compiler does not raise any warnings. You can turn on warnings with the `-W` option:

```
$ cat prog.4gl
MAIN
  DATABASE test1
  SELECT COUNT(*) FROM x, OUTER(y) WHERE x.k = y.k
END MAIN

$ fglcomp -W stdsql prog.4gl
xx.4gl:3: warning: SQL statement or language instruction with specific SQL
 syntax.
```

When a warning is raised, you can use the `-W error` option to force the compiler to stop as if an error was found. For more details about the `-W` option, see Arguments for the -W option on page 1498.

Consider also using the `--verbose` option of the compiler to get detailed information about the source compilation:

```
$ fglcomp --verbose main.4gl
[parsing main.4gl]
[compiling: fglcomp --import-by=main --verbose  mod1]
[parsing mod1.4gl]
[compiling: fglcomp --import-by=main,mod1 --verbose  mod2]
[parsing mod2.4gl]
[writing mod2.42m]
[loading mod2.42m]
[writing mod1.42m]
[loading mod1.42m]
[writing main.42m]
```

Importing modules

With the `IMPORT FGL` instruction, module symbols such as variables, types and constants can be referenced in the importing module.

The next source example imports the *myutils* and *account* modules, and uses the *init()* and *set_account()* functions of the imported modules. The first function call is qualified with the module name - this is optional but required to resolve ambiguities when the same function name is used by different modules:

```
IMPORT FGL myutils
IMPORT FGL account
MAIN
  CALL myutils.init()
  CALL set_account("CFX4559")
  ...
END MAIN
```

Linking libraries

Compiled 42m modules can be grouped in libraries by using the fgllink linker. The library files get the 42x extension. If none of the modules defines the `MAIN` block, the linker creates a library; if a `MAIN` block is present, the linker creates a program, that should use a 42r extension.

Note that linking is supported for backward compatibility, you should use `IMPORT FGL` instead.

Library linking is done with the fglrun tool by using the `-l` option. The fgllink tool can be used for convenience, it is a simple script calling `fglrun -l`.

The following lines show a link procedure to create a library in a UNIX™ shell session:

```
$ fglcomp fileutils.4gl
  $ fglcomp userutils.4gl
  $ fgllink -o libutils.42x fileutils.42m userutils.42m
```

When you create a library, all functions of the 42m modules used in the link command are registered in the 42x file.

Keep in mind that the 42x library file does not contain the 42m p-code. When deploying your application, you must provide all compiled 42m modules.

When creating a 42x library, all functions must be uniquely defined; otherwise, error -6203 will be returned by the linker.

The 42x libraries are typically used to link the final 42r programs:

```
$ fglcomp mymain.4gl
  $ fgllink -o myprog.42r mymain.42m libutils.42x
```

The 42r programs must be re-linked if the content of 42x libraries have changed. In this example, if a function of the userutils.4gl source file was removed, you must recompile userutils.4gl, re-link the libutils.42x library and re-link the myprog.42r program.

It is possible to create a library by referencing other 42x library files in the link command, as long as 42M modules can be found:

```
$ fglcomp module_1.4gl
  $ fglcomp module_2.4gl
  $ fgllink -o lib_A.42x module_1.42m
  $ fgllink -o lib_B.42x module_2.42m lib_A.42x $ fgllink -o myprog.42r
 lib_B.42x
    -- will hold functions of module_1 and module_2.
```

If you do not specify an absolute path for a file, the linker searches by default for .42m modules and .42x libraries in the current directory. You can specify a search path with the FGLLDPATH environment variable.

If you are using C-Extensions, you may need to use the `-e` option to specify the list of extension modules, if the `IMPORT` keyword is not used:

```
$ fgllink -e extlib,extlib2,extlib3 -o libutils.42x fileutils.42m
 userutils.42m
```

Linking programs

Genero programs are created by linking several .42m modules and/or .42x libraries together, where one of the modules defines a `MAIN` block. By convention, the resulting program file gets the 42r extension.

Note that linking is supported for backward compatibility, you should use `IMPORT FGL` instead. When using `IMPORT FGL` to import all modules used by a program, the link stage is no longer required (you can directly execute the 42m module containing the `MAIN` block).

Program linking is done with the fglrun tool by using the `-l` option. The fgllink tool can be used for convenience; it is a simple script calling `fglrun -l`.

The following lines show a link procedure to create a program in a UNIX™ shell session:

```
$ fglcomp main.4gl
```

```
$ fglcomp store.4gl
$ fgllink -o stores.42r main.42m store.42m
```

The purpose of the linking phase is to check for missing function symbols, and reference all the symbols in the resulting .42r program file. Any function used in the .42m modules specified in the link line must be provided. Missing symbols will result in a -1338 linker error. Note that this applies only to programs: When linking a 42x library, there can be references to undefined functions:

```
$ cat main.4gl
MAIN
  CALL myfunc()
END MAIN

$ fglcomp main.4gl
$ fgllink -o prog.42r main.42m
ERROR(-1338):The function 'myfunc' has not been defined in any module in the
 program.
```

The generated 42r program files do not contain the 42m p-code. When deploying your application, you must provide all 42m modules, as well as 42r program files. Since 42x library files are only used to build programs, you do not have to deploy 42x library files.

If you omit the -o option in the fgllink command, the default output file will have the .42x extension and the name of the module containing the `MAIN` block. The .42r file extension is used by convention to distinguish a program dictionary file from a library dictionary file.

When linking a 42r program by using 42x libraries, the modules defined in a library are included only if one of the symbols in the module is used by the program. However, all symbols of 42m modules specified in the command line will always be referenced in the resulting 42r program file. The same function symbols can be defined in distinct libraries; the linker will select the function of the first library that was specified in the command line.

All symbols referenced in a module must exist in the final 42r program dictionary file. If a symbol is not found, the runtime system stops with error -1338. This error is fatal and cannot be trapped with an exception handler.

When linking a 42r program, global symbols must be unique; otherwise, error -6203 will be returned by the linker. The same error will be returned when linking a 42x library by using modules defining the same functions.

If you do not specify an absolute path for a file, the linker searches by default for .42m modules and .42x libraries in the current directory. You can specify a search path with the FGLLDPATH environment variable:

```
$ FGLLDPATH=/usr/dev/lib/maths:/usr/dev/lib/utils
$ export FGLLDPATH
$ ls /usr/dev/lib/maths
mathlib1.42x
mathlib2.42x
mathmodule11.42m
mathmodule12.42m
mathmodule22.42m
$ ls /usr/dev/lib/utils
fileutils.42m
userutils.42m
dbutils.42m
$ fgllink -o myprog.42r mymodule.42m mathlib1.42x fileutils.42m
```

In this example the linker will find the specified files in the `/usr/dev/lib/maths` and `/usr/dev/lib/utils` directories defined in FGLLDPATH.

When creating a .42r program by linking .42m modules with .42x libraries, if the same function is defined in a .42m and in a module of a 42x library, the function of the specified .42m module will be selected by the linker, and the function of the library will be ignored. However, the linker will raise error -6203 if two .42m modules specified in the link command define the same function.

The link procedure searches recursively for the functions used by the program. For example, if the `MAIN` block calls function FA in module MA, and FA calls FB in module MB, all functions from module MA and MB will be included in the 42r program definition.

When linking a program with modules using the `IMPORT FGL` instruction, you do not have to specify the imported modules in the link line, since these modules will be loaded dynamically at runtime. However, any symbol used by the imported module must be resolved by the linker. Therefore, if the imported module uses functions that come from other modules which are not imported by this module, these non-imported modules must be specified in the link command line. For example, if the main module imports module MA to call the function FA, which in turn calls a function FB from module MB, but MA does not import MB, you will have to specify MB in the link line to have the linker resolve the FB function.

When linking a .42r program by using a .42x library, if none of the functions of a module in the .42x library are used in the program, the complete module is excluded by the linker. This may cause undefined function errors at runtime, such as when a function is only used in a dynamic call (an initialization function, for example.)

The following case illustrates this behavior:

```
$ cat x1.4gl
function fx11()
end function
function fx12()
end function

$ cat x2.4gl
function fx21()
end function
function fx22()
end function

$ cat prog.4gl
main
  call fx11()
end main

$ fglcomp x1.4gl
$ fglcomp x2.4gl
$ fglcomp prog.4gl

$ fgllink -o lib.42x x1.42m x2.42m

$ fgllink -o prog.42r prog.42m lib.42x
```

Here, module `x1.42m` (with functions `fx11` and `fx12`) will be referenced in the .42r program file, but functions of module `x2.42m` will not. At runtime, any dynamic call to functions `fx21()` or `fx22()` will fail with an un-trappable error -1338.

If you are using C-Extensions, you may need to use the -e option to specify the list of extension modules if the `IMPORT` keyword is not used:

```
$ fgllink -e extlib,extlib2,extlib3 -o stores.42r main.42m store.42m
```

Using makefiles

Most UNIX™ platforms provide the make utility program to compile projects. The make program is an interpreter of makefiles. These files contain directives to compile and link programs and/or generate other kind of files.

When developing on Microsoft™ Windows™ platforms, you may use the NMAKE utility provided with Visual C++, however this tool does not have the same behavior as the UNIX™ make program. To have a compatible make on Windows™, you can install a GNU make or third party UNIX™ tools such as Cygwin.

For more details about the make utility, see the platform-specific documentation.

The follow example shows a typical makefile for Genero applications:

```
#-----------------------------------------------------
# Generic makefile rules to be included in Makefiles
.SUFFIXES: .42s .42f .42m .42r .str .per .4gl .msg .hlp
FGLFORM=fglform -M
FGLCOMP=fglcomp -M
FGLLINK=fglrun -l
FGLMKMSG=fglmkmsg
FGLMKSTR=fglmkstr
FGLLIB=$$FGLDIR/lib/libfgl4js.42x
all::
.msg.hlp:
        $(FGLMKMSG) $*.msg $*.hlp
.str.42s:
        $(FGLMKSTR) $*.str $*.42s
.per.42f:
        $(FGLFORM) $*.per
.4gl.42m:
        $(FGLCOMP) $*.4gl
clean::
        rm -f *.hlp *.42? *.out
#----------------------------
# Makefile example
include Makeincl
FORMS=\
 customers.42f\
 orderlist.42f\
 itemlist.42f
MODULES=\
 customerInput.42m\
 zoomOrders.42m\
 zoomItems.42m
customer.42x: $(MODULES)
        $(FGLLINK) -o customer.42x $(MODULES)
all:: customer.42x $(FORMS)
```

Module build information

The compiler version used to build the 42m modules must be compatible to the runtime system used to execute the programs. The fglcomp compiler writes version information in the generated 42m files. This can be useful on site, if you need to check the version of the compiler that was used to build the 42m nodules.

To extract build information, run fglrun with the `-b` option:

```
$ fglrun -b mymodule.42m
  3.00.00 /home/devel/stores/mymodule.4gl 24
```

The output shows the following fields:

1. The Genero product version (`3.00.00`)
2. The full path of the source file (`/home/devel/stores/mymodule.4gl`)
3. The internal identifier of the p-code version (23)

fglrun -b can read the header of p-code modules compiled with older versions of fglcomp and display version information for such old modules. If fglrun cannot recognize a p-code module, it returns with an execution status that is different from zero.

When reading build information of a 42x or 42r file, fglrun scans all modules used to build the library or program. You will see different versions in the first column if the modules were compiled with different versions of fglcomp. However, it's not recommended that you mix versions on a production site:

```
$ fglrun -b myprogram.42r
  3.00.00 /home/devel/stores/mymodule1.4gl 24
  3.10.02 /home/devel/stores/mymodule2.4gl 24
  3.00.01 /home/devel/stores/mymodule3.4gl 24
```

To check if the version of the runtime system corresponds to the p-code version, run fglrun with the `-V` option:

```
$ fglrun -V
fglrun 3.00.00 internal-build-number
Genero virtual machine
Target l64xl212
...
```

If you need to write timestamp information in the p-code modules, you can use the `--timestamp` option of fglcomp:

```
$ fglcomp --timestamp mymodule.4gl
  $ fglrun -b mymodule.42m
  2008-12-24 11:22:33 2.11.05-1169.84 /home/devel/stores/mymodule.4gl 15
```

> **Important:** When using the `--timestamp` compiler option to write build timestamp information in p-code modules, you will not be able to easily compare 42m files (based on a checksum, for example): Without the timestamp, fglcomp generates exactly the same p-code module if the source file was not modified.

Source code edition

Simple helper to better render sources in configurable text editors.

These topics concern source code editing. You are free to use your preferred source code editor to write your programs.

- Choosing the correct locale on page 1516
- Avoid Tab characters in screen layouts on page 1517
- Code completion and syntax highlighting with VIM on page 1517

Choosing the correct locale

Before starting to edit source files, you must identify and configure the editor with the locale (character set) you want to use in your sources.

The language supports single-byte and multibyte character sets. When developing multilingual applications, we recommend that you write .per and .4gl source files in ASCII, and externalize language-dependent messages in string resource files.

Avoid Tab characters in screen layouts

When editing .per form files, avoid using Tab characters in sources, especially in the LAYOUT or SCREEN sections of forms. Different kinds of text or source code editors can expand Tab characters differently, according to the configuration settings. As a result, if two programmers are using different Tab expansion settings, the form layout will display in different ways. If used in a grid area, a Tab character will be interpreted as 8 blanks by fglform.

It is legal to use Tab characters in the rest of the .per file or .4gl sources (for example, to indent the code).

Code completion and syntax highlighting with VIM

If you are using the vim editor, automatic code completion and syntax highlighting is supported by fglcomp and fglform compilers.

In order to use auto completion with vim, you need at least vim version 7 with the Omni Completion feature.

To get the benefit of this feature with the vim editor, do this:

> **Note:** In the next lines, *user-vim-dir* is `~/.vim` on Unix platforms, and `%USERPROFILE%\vimfiles` on Windows platforms. And *home-dir* is `$HOME` on Unix platforms, and `%USERPROFILE%` on Windows platforms.

1. Copy `$FGLDIR/lib/fglcomplete.vim` into the *`user-vim-dir`*`/autoload` directory.
2. Copy `$FGLDIR/lib/fgl.vim` into the *`user-vim-dir`*`/syntax` directory.
3. Copy `$FGLDIR/lib/per.vim` into the *`user-vim-dir`*`/syntax` directory.
4. Add the following lines to your VIM resrouces file (*`home-dir`*`/.vimrc` file):

```
autocmd Filetype fgl setlocal omnifunc=fglcomplete#Complete
autocmd Filetype per setlocal omnifunc=fglcomplete#Complete
syntax on
au BufNewFile,BufRead *.per setlocal filetype=per
```

You can now use automatic code completion; open a .4gl or .per file, start to edit the file, and when you are in vim insert mode, press `CTRL-X` + `CTRL-O`, to get a list of language elements to complete the instruction syntax or expression.

> **Note:** For convenience, `TAB` can also be used to get the completion list as with the `CTRL-X` + `CTRL-O` key combinations. However, `TAB` will only show the completion list, if the edit cursor in after a keyword: At the beginning of the line, `TAB` adds indentation characters.

For more details about vim, see http://www.vim.org.

Source documentation

Explains how to automatically generate documentation from your sources.

- Understanding source code documentation on page 1518
- Prerequisites for source documentation generation on page 1518
- Documentation structure on page 1518
- Adding comments to sources on page 1519
  - Commenting a function on page 1519
  - Commenting a module on page 1521
  - Commenting a package on page 1521
  - Commenting a project on page 1521
- Run the documentation generator on page 1521

Understanding source code documentation

Documenting sources is an important task in software development, to share the code among applications and achieve better re-usability.

Source documentation must be concise, clear, and complete. However, documenting sources can be boring and subject to mistakes if large repetitive documentation sections have to be written by hand.

Source documentation can be produced automatically with the fglcomp compiler. The compiler can generate source documentation from the .4gl files of your project with minimum effort. The resulting source documentation is generated in simple HTML format and can be published on a web server.

Source documentation is generated with the `--build-doc` option of fglcomp. To extract documentation from a .4gl source:

```
fglcomp --build-doc filename.4gl
```

You can generate default documentation from the existing sources. For a better description of the code, add special #+ comments in your sources to describe code elements such as functions, function parameters, and return values.

By default, only `PUBLIC` symbols are documented. If you want to include `PRIVATE` symbols, use the `--doc-private` option:

```
fglcomp --build-doc --doc-private filename.4gl
```

Prerequisites for source documentation generation

To generate the HTML pages, fglcomp first generates `.xa` files which must be converted to `.html` files. The conversion from `.xa` to `.html` is done with an XSLT processor using the `.xsl` style sheets files provided in `FGLDIR/lib/fgldoc/`

You must have an XSLT processor installed on the machine where the documentation is generated.

- On UNIX™, fglcomp runs the `FGLDIR/lib/fgldoc/Transform.sh` script to convert `.xa` files to `.html` files. Therefore you need the `xsltproc` command line XSLT processor (from the libxml package).
- On Windows™, fglcomp runs the `FGLDIR\lib\fgldoc\Transform.js` script to convert `.xa` files to `.html` files. To run the `Transform.js` script, you must have `cscript.exe` installed with the Microsoft™.XMLDOM class (this is the case on recent Windows™ versions).

  Note: If the default result of the transformation does not fit your needs, the style sheets provided in `FGLDIR/lib/fgldoc` can be adapted to generate different HTML files.

Documentation structure

The source documentation structure is based on the well-known Java-doc technique. The generated documentation reflects the structure of your sources; in order to have nicely structured source documentation, you must have a nicely structured source tree.

The source documentation elements are structured as follows (elements in *italic* must be created by hand, others are generated files):

- Top/root directory (the root of your project)
  - *`overview.4gl`* (description of the project)
  - `overview-summary.html`
  - `overview-frame.html`
  - `allclasses-frame.html`
  - `index-all.html`
  - `index.html`

- `fgldoc.css`
- *sub-directory1* (package)
  - *sub-directory11* (package)
  - ...
  - *sub-directory12* (package)
    - *sub-directory121* (package)
      - *`package-info.4gl`* (description of the package/directory)
      - `package-summary.html`
      - `package-frame.html`
      - *source1211.4gl* (module)
      - `source1211.html`
      - *source1212.4gl* (module)
        - `#+ Module 1212 comment` (description of the module)
        - `#+ Function 12121 comment` (description of the function)
        - function12121
        - `#+ Function 12121 comment`
        - function12122
        - ...
      - `source1212.html`
      - *source1213.4gl* (module)
      - `source1213.html`
      - ...
- *sub-directory2* (package)
- ...
- *sub-directory3* (package)
- ...

First create a file named `overview.4gl` in the top directory of the project. This file contains the overall description of the project. In that directory, the documentation generator creates the files `overview-summary.html`, `overview-frame.html`, `allclasses-frame.html`, `index-all.html`, `index.html` and `fgldoc.css` .

The documentation generator can scan sub-directories to build the documentation for a whole project; each source directory defines a package. For each directory (i.e. package), the generator creates a `package-summary.html` and a `package-frame.html` file. If a file with the name `package-info.4gl` exists, it will be scanned to complete the `package-summary.html` file with the package description.

The documentation generator creates a *filename* .html file for each .4gl source module, seen as a *class* in the documentation.

Adding comments to sources

Commenting a function

To comment a function, add some lines starting with #+, before the function body. The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the function. This description will be placed in the function summary table. The next paragraph is long text describing the function in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the @ "at" sign.

Table 323: Supported @ tags

Tag	Description
`@code`	Indicates that the next lines show a code example using the function.
`@param` *`name description`*	Defines a function parameter identified by *name*, explained by a *description*. *name* must match the parameter name in the function declaration.
`@returnType` *`fglType`* `[,...]`	Defines the data type of the value returned by the function. If the function returns several values, write a comma-separated list of types.
`@return` *`description`*	Describes the values returned by the function. Several @return comment lines can be written.

Example

```
#+ Compute the amount of the orders for a given customer
#+
#+ This function calculates the total amount of all orders for
 the
#+ customer identified by the cust_id number passed as
 parameter.
#+
#+ @code
#+ DEFINE total DECIMAL(10,2)
#+ CALL total = ordersTotal(r_customer.cust_id)
#+
#+ @param cid Customer identifier
#+
#+ @returnType DECIMAL(10,2)
#+ @return The total amount as DECIMAL(10,2)
#+
FUNCTION ordersTotal(cid)
   DEFINE cid INTEGER
   DEFINE ordtot DECIMAL(10,2)
   SELECT SUM(ord_amount) INTO ordtot
        FROM orders WHERE orders.cust_id = cid
   RETURN ordtot
END FUNCTION
```

Commenting a report

To comment a report, add some lines starting with #+, before the report body. The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the report. This description will be placed in the function summary table. The next paragraph is long text describing the report in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the @ "at" sign.

Table 324: Supported @ tags

Tag	Description
`@code`	Indicates that the next lines show a code example using the report.
`@param` *`name description`*	Defines a report parameter identified by *name*, explained by a *description*. *name* must match the parameter name in the report declaration.

Commenting a module

To comment a .4gl module, you can add #+ lines at the beginning of the source, before module element declarations such as module variable definitions.

Example

```
#+ This module implements customer information handling
#+
#+ This code uses the 'customer' and 'custdetail' database
 tables.
#+ Customer input, query and list handling functions are defined
 here.
#+
DEFINE r_cust RECORD
   cust_id INTEGER,
   cust_name VARCHAR(50),
   cust_address VARCHAR(200)
END RECORD
```

Commenting a package

To describe a complete directory (i.e. package), you must create a `package-info.4gl` file in the directory and add a #+ comment in the file. The comment will be added to the `package-summary.html` file.

Commenting a project

In the top directory of your sources, you must create a `overview.4gl` file with a #+ comment describing the project. This file is mandatory in order to generate the tree of HTML pages for an entire project, as it is used as the starting point by fglcomp.

Run the documentation generator

Follow this procedure to produce the source documentation.

Follow this procedure to produce the source documentation.

1. Go to the top directory of your sources.
2. Create a file named `overview.4gl`, with a #+ comment describing your project.
3. Go to the subdirectories and create files named `package-info.4gl` with a #+ comment describing the package.
4. Edit the 4gl modules to add #+ comments to functions that must be documented.
5. Go back to the top directory of your sources.
6. Run `fglcomp --build-doc overview.4gl`

Use the `-W apidoc` compiler option to get warnings for invalid comment tags. For example, when a @param tag is missing for a function parameter.

7. To test the result, load the generated `index.html` file in your preferred browser.

The preprocessor

A typical preprocessor like in the C language.

- Understanding the preprocessor on page 1522
- Compilers command line options on page 1522
- File inclusion on page 1523
- Simple macro definition on page 1525
- Function macro definition on page 1527
- Stringification operator on page 1529
- Concatenation operator on page 1529
- Predefined macros on page 1530
- Undefining a macro on page 1530
- Conditional compilation on page 1530

Understanding the preprocessor

The preprocessor is used to transform your sources before compilation. It allows you to include other files and to define macros that will be expanded when used in the source. It behaves similar to the C preprocessor, with some differences.

> **Important:** The preprocessor should be avoided if there is an alternative in the native language. For example, instead of defining program constants with a &define macro, use the `CONSTANT` instruction. Other language features such as `IMPORT FGL` increase code readability and modular programming, without the need of a preprocessor. The preprocessor might be desupported in a future version.

The preprocessor transforms files as follows:

- The source file is read and split into lines.
- Continued lines are merged into one long line if it is part of a preprocessor definition.
- Comments are not removed unless they appear in a macro definition.
- Each line is split into a list of lexical tokens.

The preprocessor implements the following features:

1. File inclusion
2. Conditional compilation
3. Macro definition and expansion

There are two kind of macros:

1. Simple macros
2. Function macros

If a preprocessing directive is invalid, the compilers will generate a .err file with the preprocessing error included in the source file at the line position where the problem exists. When using the `-M` option, preprocessor errors will be printed to stderr, like regular compiler errors.

Compilers command line options

Preprocessor options can be used with fglcomp and fglform compilers.

File inclusion path

The `-I` option defines a path used to search files included by the `&include` directives:

```
-I path
```

Macro definition

The `-D` option defines a macro with the value 1, so that it can be used conditional directives like `&ifdef`:

```
-D identifier
```

The `-U` option undefines a macro. The macro will not be defined, even if it is defined with the `-D` option later in the command line, or when it is defined in the code with a `&define` directive:

```
-U identifier
```

However, predefined macros such as `__LINE__` can't be undefined with the `-U` option.

Preprocessing only

```
-E
```

By using the `-E` option, only the preprocessing phase is done by the compilers. Result is dumped in standard output.

Preprocessing options

```
-p [nopp|noln|fglpp]
```

When using option `-p nopp`, it disables the preprocessor phase.

By using option `-p noln` with the `-E` preprocessing-only option, you can remove line number information and unnecessary empty lines.

By default, the preprocessor expects an ampersand '&' as preprocessor symbol for macros. The option `-p fglpp` enables the old syntax, using the sharp '#' as preprocessor symbol. The sharp '# ' syntax is not compatible with single-line comments.

Examples

```
fglcomp -E -D DEBUG -I /usr/sources/headers program.4gl
```

```
fglcomp -E -p fglpp -I /usr/sources/headers program.4gl
```

```
fglcomp -E -p nopp -I /usr/sources/headers program.4gl
```

File inclusion

The `&include` directive instructs the preprocessor to include a file.

Syntax

```
&include "filename"
```

1. *filename* is searched first in the directory containing the current file, then in the directories listed in the include path. (-I option). The file name can be followed by spaces and comments.

Usage

The included file will be scanned and processed before continuing with the rest of the current file.

Source: File A

```
First line
&include "B"
Third line
```

Source: File B

```
Second line
```

Result:

```
& 1 "A"
First line
& 1 "B"
Second line
& 3 "A"
Third line
```

These preprocessor directives inform the compiler of its current location with special preprocessor comments, so the compiler can provide the right error message when a syntax error occurs.

The preprocessor-generated comments use the following format:

```
& number "filename"
```

where:

- *number* is the current line in the preprocessed file
- *filename* is the current file name

Recursive inclusions

Recursive inclusions are not allowed. Doing so will fail and output an error message.

The following example is incorrect:

Source: File A

```
&include "B"
```

Source: File B

```
HELLO
&include "A"
```

```
fglcomp -M A.4gl output
```

```
B.4gl:2:1:2:1:error:(-8029) Multiple inclusion of the source file 'A'.
```

Including the same file several times is allowed:

Source: File A

```
&include "B"
&include "B"  -- correct
```

Source: File B

```
HELLO
```

Result:

```
& 1 "A"
& 1 "B"
HELLO
& 2 "A"
& 1 "B"
HELLO
```

Simple macro definition

A simple macro is identified by its name and body.

Syntax

```
&define identifier body
```

1. *identifier* is the name of the macro. Any valid identifier can be used.
2. *body* is any sequence of tokens until the end of the line.

After substitution, the macro definition is replaced with blank lines.

Usage

As the preprocessor scans the text, it substitutes the macro body for the name identifier.

The following example show macro substitution with 2 simple macros:

Source: File A

```
&define MAX_TEST 12
&define HW "Hello world"

MAIN
  DEFINE i INTEGER
  FOR i=1 TO MAX_TEST
    DISPLAY HW
  END FOR
END MAIN
```

Result:

```
& 1 "A"

MAIN
  DEFINE i INTEGER
  FOR i=1 TO 12
    DISPLAY "Hello world"
  END FOR
```

```
END MAIN
```

The macro definition can be continued on multiple lines, but when the macro is expanded, it is joined to a single line as follows:

Source: File A

```
&define TABLE_VALUES 1, \
                     2, \
                     3
DISPLAY TABLE_VALUES
```

Result:

```
& 1 "A"

DISPLAY 1, 2, 3
```

The source file is processed sequentially, so a macro takes effect at the place it has been written:

Source: File A

```
DISPLAY X
&define X "Hello"
DISPLAY X
```

Result:

```
& 1 "A"
DISPLAY X

DISPLAY "Hello"
```

The macro body is expanded only when the macro is applied:

Source: File A

```
&define AA BB
&define BB 12
DISPLAY AA
```

Result:

```
& 1 "A"

DISPLAY 12
```

- AA is first expanded to BB.
- The text is re-scanned and BB is expanded to 12.
- When the macro AA is defined, BB is not known yet; but it is known when the macro AA is used.

In order to prevent infinite recursion, a macro cannot be expanded recursively.

Source: File A

```
&define A B
&define B A
&define C C
```

```
A C
```

Result:

```
& 1 "A"

A C
```

- A is first expanded to B.
- B is expanded to A.
- A is not expanded again as it appears in its own expansion.
- C expands to C and can not be expanded further.

Note: It is also possible to define a macro with the `-D` command line option of compilers.

Function macro definition

Function macros are preprocessor macros which can take arguments.

Syntax

```
&define identifier( arglist ) body
```

1. *identifier* is the name of the macro. Any valid identifier can be used.
2. *body* is any sequence of tokens until the end of the line.
3. *arglist* is a list of identifiers separated with commas and optionally whitespace.
4. There must be no space or comment between the macro name and the opening parenthesis. Otherwise the macro is not a function macro, but a simple macro.

Usage

Function macros take arguments that are replaced in the body by the preprocessor.

Source: File A

```
&define function_macro(a,b) a + b
&define simple_macro (a,b) a + b
function_macro( 4 , 5 )
simple_macro (1,2)
```

Result:

```
& 1 "A"

4 + 5
(a,b) a + b (1,2)
```

A function macro can have an empty argument list. In this case, parenthesis are required for the macro to be expanded. As we can see in the next example, the third line is not expanded because it there is no '`()`' after `foo`. The function macro cannot be applied even if it has no arguments.

Source: File A

```
&define foo() yes
foo()
foo
```

Result:

```
& 1 "A"

yes
foo
```

The comma separates arguments. Macro parameters containing a comma can be used with parenthesis. In this example, the second line has been substituted, but th third line produced an error, because the number of parameters is incorrect.

Source: File A

```
&define one_parameter(a) a
one_parameter((a,b))
one_parameter(a,b)
```

```
fglcomp -M output
```

```
source.4gl:3:1:3:1:error:(-8039) Invalid number of parameters
 for macro one_parameter.
```

Macro arguments are completely expanded and substituted before the function macro expansion.

A macro argument can be left empty.

Source: File A

```
&define two_args(a,b) a b
two_args(,b)
two_args(,)
two_args()
two_args(,,)
```

```
fglcomp -M output
```

```
source.4gl:4:1:4:1:error:(-8039) Invalid number of parameters
 for macro two_args.
source.4gl:5:1:5:1:error:(-8039) Invalid number of parameters
 for macro two_args.
```

Macro arguments appearing inside strings are not expanded.

Source: File A

```
&define foo(x) "x"
foo(toto)
```

Result:

```
& 1 "A"

"x"
```

Stringification operator

Transforms a preprocessor macro element to a string.

Syntax

```
#param
```

1. *param* is a parameter of the macro

Usage

The stringification operator # converts a preprocessor macro parameter to a string.

When a macro parameter is used with a preceding #, it is replaced by a string containing the literal text of the argument.

The argument is not macro expanded before the substitution.

Source: File A

```
&define disp(x) DISPLAY #x
disp(abcdef)
```

Result:

```
& 1 "A"
DISPLAY "abcdef"
```

Concatenation operator

Concatenates two parameters of a preprocessor macro.

Syntax

```
token1 ## token2
```

1. *token1* is a parameter of the macro or a simple token.
2. *token2* is a parameter of the macro or a simple token.

Usage

The double-sharp operator ## can be used to merge two tokens while expanding a macro and create a single token.

All tokens can not be merged. Usually these tokens are identifiers, or numbers.

The concatenation result produces an identifier.

Source: File A

```
&define COMMAND(NAME) #NAME, NAME ## _command
COMMAND(quit)
```

Result:

```
& 1 "A"

"quit", quit_command
```

Predefined macros

The preprocessor predefines 2 macros:

1. `__LINE__` expands to the current line number. Its definition changes with each new line of the code.
2. `__FILE__` expands to the name of the current file as a string constant. Ex: "subdir/file.inc"

These macros are often used to generate error messages.

An `&include` directive changes the values of `__FILE__` and `__LINE__` to correspond to the included file.

Undefining a macro

Un-defines a preprocessor macro.

Syntax

```
&undef identifier
```

1. *identifier* is a preprocessor constant.

Usage

If a macro is redefined without having been undefined previously, the preprocessor issues a warning and replaces the existing definition with the new one. First un-define a macro with the `&undef` directive.

Source: File A

```
&define HELLO "hello"
DISPLAY HELLO
&undef HELLO
DISPLAY HELLO
```

Result:

```
& 1 "A"

DISPLAY "hello"
DISPLAY HELLO
```

> **Note:** It is also possible to undefine a macro with the `-U` command line option of compilers. However, predefined macros can't be undefined with this option.

Conditional compilation

Integrate code lines conditionally.

Syntax 1

```
&ifdef identifier
...
[&else
...]
&endif
```

Syntax 2

```
&ifndef identifier
...
[&else
...]
&endif
```

1. *identifier* is a preprocessor constant.

Usage

The `&ifdef` and `&ifndef` preprocessor macros can be used to integrate code lines conditionally according to the existence of a preprocessor constant.

The constant is defined with a `&define` or with the `-D` option in the command line.

Even if the condition is evaluated to false, the content of the `&ifdef` block is still scanned and tokenized. Therefore, it must be lexically correct.

Sometimes it is useful to use some code if a macro is not defined. You can use `&ifndef`, that evaluates to true if the macro is not defined.

Source: File A

```
&define IS_DEFINED
&ifdef IS_DEFINED
DISPLAY "The macro is defined"
&endif  /* IS_DEFINED */
```

Result:

```
& 1 "A"

DISPLAY "The macro is defined"
```

The debugger

Describes the command-line debugger to find easily bugs in your programs.

- Understanding the debugger on page 1531
- Prerequisites to run the debugger on page 1532
- Starting fglrun in debug mode on page 1532
- Attaching to a running program on page 1533
- Debugging on a mobile device on page 1534
- Stack frames in the debugger on page 1535
- Setting a breakpoint programmatically on page 1536
- Expressions in debugger commands on page 1536
- Debugger commands on page 1537

Understanding the debugger

The debugger is a feature built in the runtime system (`fglrun`) that allows you to control the execution of a program step by step, so that you can find logical and runtime errors.

There are three debug modes possible with the Genero runtime system:

1. Start the fglrun program from the command line with the `-d` option. For more details, see Starting fglrun in debug mode on page 1532.
2. Attaching with the `fgldb` tool, to a running fglrun process, for debugging through a TCP socket. For more details, see Attaching to a running program on page 1533.
3. Connect directly with the `fgldb` tool, to the debug TCP port of a runtime system running on a mobile device in standalone mode. For more details, see Debugging on a mobile device on page 1534.

The debugger supports a subset of the standard GNU C/C++ debugger called gdb.

In command line mode, the debugger shows the following prompt

```
(fgldb)
```

A command is a single line of input. It starts with a command name, which may be followed by arguments whose meaning depends on the command name. For example, the command `step` accepts as an argument the number of times to step:

```
(fgldb) step 5
```

You can use command abbreviations. For example, the 'step' command abbreviation is 's':

```
(fgldb) s 5
```

Possible command abbreviations are shown in the command's syntax.

A blank line as input to the debugger (pressing just the RETURN or ENTER keys) usually causes the previous command to repeat. However, commands whose unintentional repetition might cause problems will not repeat in this way.

Prerequisites to run the debugger

Before starting the debugger, make sure you have properly set the FGLSOURCEPATH environment variable, to let the debugger find the source files.

UNIX™ example:

```
$ FGLSOURCEPATH="/usr/app/source:/home/scott/sources"
$ export FGLSOURCEPATH
```

Windows™ example:

```
C:\> set FGLSOURCEPATH=C:\app\sources;C:\scott\sources
```

By default, if FGLSOURCEPATH is not defined, the debugger searches for sources in the current directory and in directories defined by FGLLDPATH.

Make sure that the following FGLPROFILE entry is not define or defined as false:

```
fglrun.ignoreDebuggerEvent = false
```

Starting fglrun in debug mode

To start the fglrun runtime system in debug mode, use the `-d` option of fglrun, for example:

```
fglrun -d myprog
```

This mode is typically used in development environments when using the command line tools.

The debugger can be used from the command line shell, but can also be called from a graphical debugging tool that understands the debugging commands of `fglrun -d`. The syntax of the commands is similar to the gdb debugger.

The debugger can for example be used alone in the command line mode or with a graphical shell compatible with gdb such as `ddd`:

```
ddd --debugger "fglrun -d myprog"
```

Attaching to a running program

Basics

Use the `fgldb` command with the `-p` option to switch the runtime system into debug mode when an application is running on a server.

> **Note:** The `fgldb` command must be executed on the machine where the fglrun process executes.

The `fgldb` command line tool takes the fglrun-bin (Unix) / fglrun.exe (Windows) process id as value for the `-p` argument.

> **Note:** Before starting a debug session, make sure that you fulfill the prerequisites for debugging.

Debug a program running on a UNIX server

First, identify the process id of the fglrun-bin or fglrun.exe program running on your server.

For example, on a Unix platform, use the `ps` command:

```
$ ps a | grep fglrun-bin
10646 pts/0    S+     0:00 /opt/myapp/fgl/lib/fglrun-bin stockinfo.42m
```

> **Note:** Inspect the GAS log files to find the id of an fglrun process running behind a GAS application server. Enable full log reports in the GAS to get detailed information about process execution.

You may want to debug processes that use a lot of machine resources (processor, memory or open files). Use a system utility to find a process id by resources used (e.g., the `top` command on Linux).

Execute the fgldb tool with the process id of the program you want to attach to:

```
$ fgldb -p 10646
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

The `(fgldb)` prompt indicates that you are now connected to the fglrun process, and the program flow is suspended. To continue with the program flow, enter the "`continue`" debugger command:

```
(fgldb) continue
Continuing.
```

The application will then resume. To suspend the program again and enter debugger commands, press CTRL-C in the debug console. `fgldb` will display the interrupt message and return control to the debugger:

```
...
Continuing.
^CINTERRUPT
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

At this point, you can enter debugger commands. For example, set a break point and continue until the break point is reached:

```
(fgldb) b 427
Breakpoint 2 at 0x00000000: file contacts.4gl, line 427.
(fgldb) continue
Continuing.
Breakpoint 2, edit_contact() at contacts.4gl:427
427     IF new THEN
(fgldb)
```

To finish the debug session, close the connection with the "`detach`" debugger command:

```
(fgldb) detach
Connection closed by foreign host.
```

Debugging on a mobile device

Basics

When an app was created with debug mode and is running in on a device, it is possible to switch the runtime system in debug mode, by using the `fgldb` command tool with the `-m` option.

> **Important:** The app must have be created in debug mode. Apps created in release mode cannot be debugged with the `fgldb` tool. For more details, check how to build mobile apps with debug mode in the Deploying mobile apps on page 2572 section.
>
> **Important:** On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

The `fgldb` command line tool takes two arguments: The host (or IP address) of the mobile device, and an optional TCP port number to connect to. For mobile devices, the debug TCP port is `6400`. Note that this is the same port the mobile front-end is listening to for GUI connection, when working in GUI client/server mode.

> **Note:** Before starting a debug session, make sure that you fulfill the prerequisites for debugging.

Debugging an app running on a physical device

Considering the mobile device IP address is "`192.168.1.23`", and the application is running locally on a physical mobile device, you can open a debug session from the development machine as follows:

```
$ fgldb -m 192.168.1.23:6400
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

The `(fgldb)` prompt indicates that you are now connected to the fglrun process on mobile device, and the program flow is suspended. To continue with the program flow, enter the "`continue`" debugger command:

```
(fgldb) continue
Continuing.
```

The application will then resume on the mobile device. To suspend the program again and enter debugger commands, press CTRL-C in the debug console: `fgldb` will show the interrupt message and give you the control back:

```
...
Continuing.
```

```
^CINTERRUPT
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

At this point, you can for example set a break point and continue until the break point is reached:

```
(fgldb) b 427
Breakpoint 2 at 0x00000000: file contacts.4gl, line 427.
(fgldb) continue
Continuing.
Breakpoint 2, edit_contact() at contacts.4gl:427
427     IF new THEN
(fgldb)
```

To finish the debug session, close the connection with the "`detach`" debugger command:

```
(fgldb) detach
Connection closed by foreign host.
```

Debugging an app running on an Android device emulator

When the mobile application is executing on an Android device emulator in the same machine as the development environment, you must first redirect the 6400 TCP port.

First you must connect to the emulator terminal, using the telnet TCP port 5554:

```
$ telnet localhost 5554
```

When connected on the device emulator, redirect the port 6400 as follows:

```
$ redir add tcp:6400:6400
$ quit
```

You may also want to redirect the port 6480, to be able to show GMA service debug information from a browser with the http://localhost:6480 URL:

```
$ redir add tcp:6480:6480
```

Finally, quit the device emulator telnet session with:

```
$ quit
```

Stack frames in the debugger

Each time your program performs a function call, information about the call is saved in a block of data called a *stack frame*. Each frame contains the data associated with one call to one function.

The stack frames are allocated in a region of memory called the *call stack*. When your program is started, the stack has only one frame, that of the function `main`. This is the initial frame, also known as the *outermost frame*. As the debugger executes your program, a new frame is made each time a function is called. When the function returns, the frame for that function call is eliminated.

The debugger assigns numbers to all existing stack frames, starting with zero for the innermost frame, one for the frame that called it, and so on upward. These numbers do not really exist in your program; they are assigned by the debugger to allow you to designate stack frames in commands.

Each time your program stops, the debugger automatically selects the currently executing frame and describes it briefly. You can use the frame command to select a different frame from the current call stack.

Setting a breakpoint programmatically

You can set a breakpoint in the program source code with the BREAKPOINT instruction. If the program flow encounters this instruction, the program stops as if the break point was set by the break command:

```
MAIN
  DEFINE i INTEGER
  LET i=123
  BREAKPOINT
  DISPLAY i
END MAIN
```

The BREAKPOINT instruction is simply ignored when running in normal mode.

Expressions in debugger commands

Some debugger commands such as display take an expression as argument. The Genero debugger supports a reduced syntax for command expressions described in this section. For a detailed description of comparison operators, constant values and operands, see Expressions.

Syntax

```
  variable
| char-const
| int-const
| dec-const
| NULL
| TRUE
| FALSE
| expression IS [NOT] NULL
| expression = expression
| expression == expression
| expression <= expression
| expression => expression
| expression < expression
| expression > expression
| expression + expression
| expression - expression
| expression * expression
| expression / expression
| expression OR expression
| expression AND expression
| NOT expression
| - expression
| ( expression )
```

Note:

1. *variable* is a program variable name.
2. *char-const* is character string literal delimited by single or double quotes.
3. *int-const* is an integer literal.
4. *dec-const* is a decimal number literal.
5. *expression* is a combination of one or more listed syntax elements.

Example

```
(fgldb) display a + 1000
1: a = 1140.50
```

Debugger commands

Table 325: Summary of debugger commands

Command	Description
`backtrace / where`	Print a summary of how your program reached the current state (back trace of all stack frames).
`break`	Set a break point at the specified line or function.
`call`	Call a function in the program.
`clear`	Clear breakpoint at some specified line or function.
`continue`	Continue program being debugged.
`define`	Define a new command name.
`delete`	Delete some breakpoints or auto-display expressions.
`detach`	Closes a remote debug connection.
`disable`	Disable some breakpoints.
`display`	Print the values of expression *EXP* each time the program stops.
`down`	Select and print the function called by the current function.
`echo`	Print the specified text.
`enable`	Re-activate breakpoints that have previously been disabled.
`finish`	Execute until selected stack frame returns.
`frame`	Select and print a stack frame.
`help`	Print list of debugger commands.
`ignore`	Set ignore-count of a breakpoint number N to COUNT.
`info`	Provide information about the status of the program.
`list`	List specified function or line.
`next`	Step program; continue with the next source code line at the same level.
`output`	Print the current value of the specified expression; do not include value history and do not print newline.
`print`	Print the current value of the specified expression.
`ptype`	Print the type of a variable
`quit`	Exit the debugger.
`run`	Start the debugged program.

Command	Description
set	Evaluate an expression and assign the result to a variable.
source	Execute a file of debugger commands.
signal	Continue program giving it the signal specified by the argument.
step	Step program until it reaches a different source line.
tbreak	Set a temporary breakpoint.
tty	Set terminal for future runs of program being debugged.
undisplay	Cancel some expressions to be displayed when the program stops.
until	Continue running until a specified location is reached.
up	Select and print the function that called the current function.
watch	Set a watchpoint for an expression. A watchpoint stops the execution of your program whenever the value of an expression changes.
whatis	Prints the data type of a variable.

backtrace / where
The `backtrace` commands prints a summary of how your program reached the current state.

Syntax

```
backtrace
```

Usage

The `backtrace` command prints a summary of your program's entire stack, one line per frame. Each line in the output shows the frame number and function name.

`bt` and `where` are aliases for the `backtrace` command.

Example

```
(fgldb) backtrace
#1 addcount() at mymodule.4gl:6
#2 main() at mymodule.4gl:2
(fgldb)
```

break
The `break` command defines a break point to stop the program execution at a given line or function.

Syntax

```
break [ { [module.]function
```

```
      | [module:]line } ]
          [ if condition ]
```

1. *function* is a function name.
2. *module* is the name of a specific source file, without extension.
3. *line* is a source code line.
4. *condition* is an expression evaluated dynamically.

Usage

The `break` command sets a break point at a given position in the program.

When the program is running, the debugger stops automatically at breakpoints defined by this command.

If a *condition* is specified, the program stops at the breakpoint only if the *condition* evaluates to TRUE.

If you do not specify any location (function or line number), the breakpoint is created for the current line. For example, if you write "break if var = 1", the debugger adds a conditional breakpoint for the current line, and the program will only stop if the variable is equal to 1 when reaching the current line again.

Example

```
(fgldb) break mymodule:5
Breakpoint 2 at 0x00000000: file mymodule.4gl, line 5.
```

call

The `call` command calls a function in the program.

Syntax

```
call function-name ( [ expression [,...] ] )
```

1. *function-name* is the name of the function to call.
2. *expression* is a combination of variables, constants and operators.

Usage

The `call` command invokes a function of the program and returns the control to the debugger.

The return values of the function are printed as a comma-separated list delimited by curly braces.

Example

```
MAIN
  DEFINE i INTEGER

  LET i = 1
  DISPLAY i
END MAIN

FUNCTION hello ()
  RETURN "hello", "world"
END FUNCTION
```

```
(fgldb) br main
Breakpoint 1 at 0x00000000: file t.4gl, line 4.
(fgldb) run
Breakpoint 1, main() at t.4gl:4
```

```
4         LET i = 1
(fgldb) call hello()
$1 =  { "hello" , "world" }
(fgldb)
```

clear
The `clear` command clears the breakpoint at a specified line or function.

Syntax

```
clear [ { function | [ module: ] line } ]
```

1. *function* is a function name.
2. *module* is a specific source file.
3. *line* is a source code line.

Usage

With the `clear` command, you can delete breakpoints according to where they are in your program.

Use the `clear` command with no arguments to delete any breakpoints at the next instruction to be executed in the selected stack frame.

Use the delete command to delete individual breakpoints by specifying their breakpoint numbers.

Example

```
(fgldb) clear mymodule:5
Deleted breakpoint 2
(fgldb)
```

continue
The `continue` command continues the execution of the program after a breakpoint.

Syntax

```
continue [ignore-count]
```

1. *ignore-count* defines the number of times to ignore a breakpoint at this location.

Usage

The `continue` command continues the execution of the program until the program completes normally, another breakpoint is reached, or a signal is received.

`c` is an alias for the `continue` command.

Example

```
(fgldb) continue
...
(program output)
...
Program exited normally.
```

define
The `define` command allows you to specify a user-defined sequence of commands.

Syntax

```
define command-name
command
 [...]
end
```

1. *command-name* is the name assigned to the command sequence.
2. *command* is a valid debugger command.
3. **end** indicates the end of the command sequence.

Usage

The `define` command allows you to create a user-defined command by assigning a command name to a sequence of debugger commands that you specify. You may then execute the command that you defined by entering the command name at the debugger prompt.

User commands may accept up to ten arguments separated by white space.

Example

```
(fgldb) define myinfo
> info breakpoints
> info program
> end
(fgldb)
```

delete
The `delete` command allows you to remove breakpoints that you have specified in your debugger session.

Syntax

```
delete breakpoint
```

1. *breakpoint* is the number assigned to the breakpoint by the debugger.

Usage

The `delete` command allows you to remove breakpoints when they are no longer needed in your debugger session.

If you prefer you may disable the breakpoint instead, see the `disable` command.

`d` is an alias for the `delete` command.

Example

```
(fgldb) delete 1
(fgldb) run
Program exited normally.
(fgldb)
```

detach
The `detach` command closes the TCP connection of a remove debug session.

Syntax

```
detach
```

Usage

The `detach` command must be used to terminate a remove debug session, by closing the debug TCP connection.

Example

```
(fgldb) detach
```

disable
The `disable` command disables the specified breakpoint.

Syntax

```
disable breakpoint
```

1. *breakpoint* is the number assigned to the breakpoint by the debugger.

Usage

The `disable` command instructs the debugger to ignore the specified breakpoint when running the program.

Use the `enable` command to reactivate the breakpoint for the current debugger session.

Example

```
(fgldb) disable 1
(fgldb) run
Program exited normally.
(fgldb)
```

display
The `display` command displays the specified expression's value each time program execution stops.

Syntax

```
display expression
```

1. *expression* is a combination of variables, constants and operators.

Usage

The `display` command allows you to add an expression to an automatic display list. The values of the expressions in the list are printed each time program execution stops. Each expression in the list is assigned a number to identify it.

This command is useful in tracking how the values of expressions change during the program's execution.

Example

```
(fgldb) display a
1: a = 6
(fgldb) display i
2: i = 1
(fgldb) step
2: i = 1
1: a = 6
16       for i = 1 to 10
(fgldb) step
2: i = 2
1: a = 6
17       let a = a+1
(fgldb)
```

down
The down command moves down in the call stack.

Syntax

```
down
```

Usage

The down command moves the focus of the debugger down from the frame currently being examined, to the frame of its callee.

The command selects and prints the function called by the current function.

See stack frames for a brief description of frames.

```
(fgldb) down
#0 query_cust() at custquery.4gl:22
22    CALL cleanup()
(fgldb)
```

echo
The echo command prints the specified text as prompt.

Syntax

```
echo text
```

1. *text* is the specific text to be output.

Usage

The echo command allows you to generate exactly the output that you want.

Special characters can be included in text using C escape sequences, such as '\n' to print a newline. No newline is printed unless you specify one. In addition to the standard C escape sequences, a backslash followed by a space stands for a space. A backslash at the end of text can be used to continue the command onto subsequent lines.

Example

```
(fgldb) echo hello\n
hello
(fgldb)
```

enable
The `enable` command enables breakpoints that have previously been disabled.

Syntax

```
enable breakpoint
```

1. *breakpoint* is the number assigned to the breakpoint by the debugger.

Usage

The `enable` command allows you to reactivate a breakpoint in the current debugger session.

The breakpoint must have been disabled using the `disable` command.

Example

```
(fgldb) disable 1
(fgldb) run
Program exited normally.
(fgldb) enable 1
(fgldb) run
Breakpoint 1, at mymodule.4gl:5
```

finish
The `finish` command continues the execution of a program until the current function returns normally.

Syntax

```
finish
```

Usage

The `finish` command instructs the program to continue running until just after the function in the selected stack frame returns, and then stop.

The returned value, if any, is printed.

Example

```
(fgldb) finish
Run till exit myfunc() at module.4gl:10
Value returned is $1 = 123
(fgldb)
```

frame
The `frame` command selects and prints a stack frame.

Syntax

```
frame [ number ]
```

1. *number* is the stack frame number of the frame that you wish to select.

Usage

The `frame` command allows you to move from one stack frame to another, and to print the stack frame that you select. Each stack frame is associated with one call to one function within the currently executing program. Without an argument, the current stack frame is printed.

See stack frames for a brief discussion of frames.

Example

```
(fgldb) frame
#0 query_cust() at testquery.4gl:42
(fgldb)
```

help
The `help` command provides information about debugger commands.

Syntax

```
help [command]
```

1. *command* is the name of the debugger command for which you wish information.

Usage

The `help` command displays a short explanation of a specified command.

Enter the `help` command with no arguments to display a list of debugger commands.

Example

```
(fgldb) help delete
Delete some breakpoints or auto-display expressions
```

ignore
The `ignore` command defines the number of times a breakpoint must be ignored.

Syntax

```
ignore breakpoint count
```

1. *breakpoint* is the breakpoint number.
2. *count* is the number of times the breakpoint will be ignored.

Usage

The `ignore` command defines the number of times a breakpoint is ignored when the program flow reaches that breakpoint.

The next *count* times the breakpoint is reached, the program execution will continue, and no breakpoint condition is checked.

You can specify a *count* of zero to make the breakpoint stop the next time it is reached.

When using the continue command to resume the execution of the program from a breakpoint, you can specify a an ignore count directly as an argument.

Example

```
(fgldb) br main
Breakpoint 1 at 0x00000000: file t.4gl, line 4.
(fgldb) ignore 1 2
Will ignore next 2 crossings of breakpoint 1.
(fgldb) run           1
Program exited normally.
(fgldb) run           1
Program exited normally.
(fgldb) run
Breakpoint 1, main() at t.4gl:4
4         LET i = 1
(fgldb)
```

info

The `info` command describes the current state of your program.

Syntax

```
info { breakpoints
|sources
| program
|  variables
|  locals
| files
| line { function
|        | module:line }
}
```

1. *function* is a function name of the program.
2. *module:line* defines a source code line in a module.

Usage

The `info` command describes the state of your program.

- `info breakpoints` lists the breakpoints that you have set.
- `info sources` prints the names of all the source files in your program.
- `info program` displays the status of your program.
- `info variables` displays global variables.
- `info locals` displays the local variables of the current function.
- `info files` lists the files from which symbols were loaded.
- `info line` *`function`* prints the program addresses for the first line of the function named *function*.
- `info line` *`module:line`* prints the starting and ending addresses of the compiled code for the source line specified. See the list command for all the ways that you can specify the source code line.

Example

```
(fgldb) info sources
Source files for which symbols have been read in:
mymodule.4gl, fglwinexec.4gl, fglutil.4gl, fgldialog.4gl,
 fgldummy4js.4gl
(fgldb)
```

list
The `list` command prints source code lines of the program being executed.

Syntax

```
list [ function
     | [module:]line]
```

Usage

The `list` command prints source code lines of your program, by default it begins with the current line.

Example

```
(fgldb) run
Breakpoint 1, at mymodule.4gl:5
5    CALL addlist()
(fgldb) list
5    CALL add_customer(cust_rec.*)
6    MESSAGE "Customer record was added"
...
14  END FUNCTION
(fgldb)
```

next
The `next` command continues running the program by executing the next source line in the current stack frame, and then stops.

Syntax

```
next [count]
```

1. *count* defines the number of lines to execute before stopping.

Usage

The `next` command allows you to execute your program one line of source code at a time. The `next` command is similar to `step`, but function calls that appear within the line of code are executed without stepping into the function code.

When the next line of code at the original stack level that was executing when you gave the `next` command is reached, execution stops.

Using a *count* parameter will repeat the `step` command *count* times.

After reaching a breakpoint, the `next` command can be used to examine a troublesome section of code more closely.

n is an alias for the `next` command.

Example

```
(fgldb) next
5    CALL add_customer(cust_rec.*)
(fgldb) next
6    MESSAGE "Customer record was added"
(fgldb) next 2
8    RETURN TRUE
```

output
The `output` command prints only the value of the specified expression, suppressing any other output.

Syntax

```
output expression
```

1. *expression* is a combination of variables, constants and operators.

Usage

The `output` command prints the current value of the expression and nothing else, no newline character, no "expr=", etc.

The usual output from the debugger is suppressed, allowing you to print only the value.

Example

```
(fgldb) output cust_rec.cust_id
87324(fgldb)
```

print
The `print` command displays the current value of the specified expression.

Syntax

```
print expression
```

1. *expression* is a combination of variables, constants and operators.

Usage

The `print` command allows you to examine the data in your program.

It evaluates and prints the value of the specified expression from your program, in a format appropriate to its data type.

p is an alias for the `print` command.

Example

```
(fgldb) print cust_rec.cust_id
$1 = 87324
(fgldb)
```

ptype
The `ptype` command prints the data type or structure of a variable.

Syntax

```
ptype variable-name
```

1. *variable-name* is the name of the variable.

Example

```
(fgldb) ptype cust_rec
type = RECORD
    cust_num INTEGER,
    cust_name VARCHAR(10),
    cust_address VARCHAR(200)
END RECORD
```

quit
The `quit` command terminates the debugger session.

Syntax

```
quit
```

Usage

The `quit` command allows you to exit the debugger.

`q` is an alias for the `quit` command.

Example

```
(fgldb) quit
```

run
The `run` command starts the program.

Syntax

```
run [argument [...] ]
```

1. *argument* is an argument to be passed to the program.

Usage

The `run` command causes your program to execute until a breakpoint is reached or the program terminates normally.

Example

```
(fgldb) run a b c
Breakpoint 1, at mymodule.4gl:3
3      CALL add_cust(cust_rec.*)
```

```
(fgldb)
```

set
The `set` command allows you to configure your debugger session and change program variable values.

Syntax

```
set { annotate {1|0}
    | environment envname[=value]
    | prompt ptext
    | set print elements elemcount
    | variable varname=expression
    | verbose {on|off}
    }
```

1. *ptext* is the string to which the prompt should be set.
2. *varname* is the program variable to be set to *expression*.
3. *expression* is a combination of variables, constants and operators.
4. *envname* is the environment variable to be set to *value*.
5. *elemcount* is the number of elements to define.

Usage

The `set` command allows to change program variables and/or debug environment settings.

`set variable` sets an program variable, to be taken into account when continuing program execution. The right operand can be an expression.

`set prompt` changes the prompt text. The text can be set toady string. A space is not automatically added after the prompt string, allowing you to determine whether to add a space at the end of the prompt string.

`set environment` sets an environment variable, where *value* may be any string. If the *value* parameter is omitted, the variable is set to a null value. The variable is set for your program, not for the debugger itself.

`set verbose on` forces the debugger to display additional messages about its operations, allowing you to observe that it is still working during lengthy internal operations.

`set annotate 1` switches the output format of the debugger to be more machine readable (this command is used by GUI front-ends like ddd or xxgdb)

`set print elements elemcount` defines the maximum number of array elements to be printed by the debugger when displaying a program array.

Example

```
(fgldb) set prompt ($)
($)
```

On UNIX™ systems, if your SHELL variable names a shell that runs an initialization file, any variables you set in that file affect your program. You may wish to move setting of environment variables to files that are only run when you sign on, such as .login or .profile.

source
The `source` command executes a file of debugger commands.

Syntax

```
source cmdfile
```

1. *cmdfile* is the name of the file containing the debugger commands.

Usage

The `source` command allows you to execute a command file of lines that are debugger commands.

The lines in the file are executed sequentially.

The commands are not printed as they are executed, and any messages are not displayed.

Commands are executed without asking for confirmation.

An error in any command terminates execution of the command file.

Example

Using the text file `cmdfile.txt`, which contains the single line with a `break` command:

```
$ cat cmdfile.txt
break 10

$ fglrun -d myprog
(fgldb) source cmdfile.txt
Breakpoint 2 @ 0x00000000: file mymod.4gl, line 10.
(fgldb)
```

signal
The `signal` command sends an interruption signal to the program.

Syntax

```
signal signal
```

Usage

The `signal` comment resumes execution where your program stopped, but immediately give it the signal *signal*.

signal can be the name or the number of a signal.

For example, on many systems signal 2 and signal SIGINT are both ways of sending an interrupt signal. The `signal SIGINT` command resumes execution of your program where it has stopped, but immediately sends an interrupt signal. The source line that was current when the signal was received is displayed.

Note: The current version only allows then signal `SIGINT`.

Example

```
(fgldb) signal SIGINT
Program exited normally.
16      for i = 1 to 10
```

```
(fgldb)
```

step
The `step` command continues running the program by executing the next line of source code, and then stops.

Syntax

```
step [count]
```

1. *count* defines the number of lines to execute before stopping.

Usage

The `step` command allows you to "step" through your program, executing one line of source code at a time.

When a function call appears within the line of code, that function is also stepped through.

A common technique is to set a breakpoint prior to the section or function that is causing problems, run the program till it reaches the breakpoint, and then step through it line by line.

Using a *count* parameter will repeat the `step` command *count* times.

`s` is an alias for the `step` command.

Example

```
(fgldb) step
4     CALL add_customer(cust_rec.*)
(fgldb) step 2
6     MESSAGE "Customer record was added"
```

tbreak
The `tbreak` command sets a temporary breakpoint.

Syntax

```
tbreak [ { function | [ module: ] line } ] [ if condition ]
```

1. *function* is a function name.
2. *module* is a specific source file.
3. *line* is a source code line.
4. *condition* is an expression evaluated dynamically.

Usage

The `tbreak` command sets a breakpoint for one stop only.

The breakpoint is set in the same way as with the `break` command, but the breakpoint is automatically deleted after the first time your program stops there.

If a *condition* is specified, the program stops at the breakpoint only if the *condition* evaluates to true.

If you do not specify any location (function or line number), the breakpoint is created for the current line. For example, if you write "`tbreak if var = 1`", the debugger adds a conditional breakpoint for the current line, and the program will only stop if the variable is equal to 1 when reaching the current line again.

Example

```
(fgldb) tbreak 12
Breakpoint 2 at 0x00000000: file custmain.4gl, line 12.
(fgldb)
```

tty
The `tty` command resets the default program input and output for future run commands.

Syntax

```
tty filename
```

1. *filename* is the file which is to be the default for program input and output.

Usage

The `tty` command instructs the debugger to redirect program input and output to the specified file for future run commands.

The redirection is for your program only; your terminal is still used for debugger input and output.

Example

```
(fgldb) tty /dev/ttyS0
(fgldb)
```

undisplay
The `undisplay` command cancels expressions to be displayed when the program execution stops.

Syntax

```
undisplay itemnum
```

1. *itemnum* is the number of the expressions for which the display is cancelled.

Usage:

When the `display` command is used, each expression displayed is assigned an item number.

The `undisplay` command allows you to remove expressions from the list to be displayed, using the item number to specific the expression to be removed.

Example

```
(fgldb) step
2: i = 2
1: a = 20
9     FOR  i = 1 TO 10
(fgldb) undisplay 2
(fgldb) step
1: a = 20
10   LET cont = TRUE
(fgldb)
```

until
The `until` command continues running the program until the specified location is reached.

Syntax

```
until [ { function | [ module: ] line } ]
```

1. *function* is a function name.
2. *module* is a specific source file.
3. *line* is a source code line.

Usage

The `until` command continues running your program until either the specified location is reached, or the current stack frame returns.

This command can be used to avoid stepping through a loop more than once.

Example

```
(fgldb) until add_customer()
```

up
The `up` command selects and prints the function that called this one, or the function specified by the frame number in the call stack.

Syntax

```
up [frames]
```

1. *frames* says how many frames up to go in the stack. The default is 1.

Usage

The `up` command moves towards the outermost frame, to frames that have existed longer. To print the function that called the current function, use the `up` command without an argument.

See stack frames for a brief description of frames.

Example

```
(fgldb) up
#1 main() at customain.4gl:14
14    CALL query_cust()
(fgldb)
```

watch
The `watch` command sets a watchpoint for an expression.

Syntax

```
watch expression [if boolean-expression]
```

1. *expression* is a combination of variables, constants and operators.
2. *boolean-expression* is an optional boolean expression.

Usage

The `watch` command stops the program execution when the value of the expression changes.

If *boolean-expression* is provided, the `watch` command stops the execution of the program if the expression value has changed and the *boolean-expression* evaluates to true.

The watchpoint cannot be set if the program is not in the context where *expression* can be evaluated. Before using a watchpoint, you typically set a breakpoint in the function where the *expression* makes sense, then you run the program, and then you set the watchpoint. This example illustrates this procedure.

Example

```
MAIN
   DEFINE i INTEGER

   LET i = 1
   DISPLAY i
   LET i = 2
   DISPLAY i
   LET i = 3
   DISPLAY i

 END MAIN
```

```
(fgldb) break main
breakpoint 1 at 0x00000000: file test.4gl, line 4
(fgldb) run
Breakpoint 1, main() at test.4gl:4
4      LET i = 1
(fgldb) watch i if i >= 3
Watchpoint 1:  i
(fgldb) continue
1
2
Watchpoint 1:  i

Old value = 2
New value = 3
main() at t.4gl:9
9         DISPLAY i
(fgldb)
```

whatis

The `whatis` command prints the data type of a variable.

Syntax

```
whatis variable-name
```

1. *variable-name* is the name of the variable.

Usage

The `whatis` command can be used to show the data type of a program variable.

The program variable must exist in the current scope.

Example

```
(fgldb) run
Breakpoint 1, main() at t.4gl:4
4         LET i = 1
(fgldb) whatis i
type = INTEGER
(fgldb)
```

The profiler

Find out what function is the bottleneck in your program.

- Syntax of the program profiler on page 1556
- Usage on page 1556
  - Understanding the profiler on page 1556
  - Profiler output: Flat profile on page 1556
  - Profiler output: Call graph on page 1557
- Example on page 1558

Syntax of the program profiler

Start the fglrun tool with the `-p` option in order to activate the program profiler.

```
fglrun -p program[.42r] [argument [...]]
```

1. *program* is the name of the BDL program.
2. *argument* is a command line argument passed to the program.

Profiling statistics will be collected during program execution, and printed when the program ends.

Usage

Understanding the profiler

The profiler is a tool built in the runtime system that allows you to know where your program spends time, and which function calls which function.

The profiler can help to identify pieces of your program that are slower than expected.

In order to enable the profiler during the execution of a program, you must start fglrun with the **-p** option, for example:

```
fglrun -p myprog
```

When the program ends, the profiler dumps profiling information to standard error.

The times reported by the profiler can change from one execution to the other, depending on the available system resources. You better execute the program several times to get an average time.

The profiler does not support parent/child recursive calls, when a child function calls its parent function (i.e. Function P calls C which calls P again). In this case the output will show negative values, because the time spend in the parent function is subtracted from the time spend in the child function.

Profiler output: Flat profile

The section "flat profile" contains the list of the functions called while the programs was running. It is presented as a five-column table.

Table 326: Flat profile columns

Column Name	Description
`count`	number of calls for this function
`%total`	Percentage of time spent in this function. Includes time spent in subroutines called from this function.
`%child`	Percentage of time spent in the functions called from this function.
`%self`	Percentage of time spent in this function excluding the time spent in subroutines called from this function.
`name`	Function name

Note: 100% represents the program execution time.

Profiler output: Call graph

The section "Call graph" provides for each function:

1. The functions that called it, the number of calls, and an estimation of the percentage of time spent in these functions.
2. The functions called, the number of calls, and an estimation of the time that was spent in the subroutines called from this function.

Table 327: Call graph columns

Column name	Description
`index`	Each function has an index which appears at the beginning of its primary line.
`%total`	Percentage of time spent in this function. Includes time spent in subroutines called from this function.
`%self`	Percentage of time spent in this function excluding the time spent in subroutines called from this function.
`%child`	Percentage of time spent in the functions called from this function.
`calls/of`	Number of calls / Total number of calls
`name`	Function name

Output example:

```
index  %total  %self  %child  calls/of  name
```

```
...
      1.29    0.10    1.18      1/2        <-- main
     24.51    1.18   23.33      1/2        <-- fb
[4]     25.80    1.29   24.51        2        *** fc
     24.51    1.43   23.08      7/8        --> fa
```

Description:

- The three stars `***` indicate the function that is analyzed: `fb`.
- `fc` consumed 25.80% of the CPU time, 24.51% was in the called functions, 1.29% in the `fc` function code.
- `fc` has been called two times (one time by `main` and a second time by `fb`)
- `fc` has called the `fa` function 7 times.
- `fa` has been called 8 times in the program.

Example

Sample program

```
MAIN
  DISPLAY "Profiler sample"
  CALL fB()
  CALL fC(2)
END MAIN

FUNCTION fA(s,n_a)
  DEFINE s STRING
  DEFINE n_a,i INTEGER
  FOR i=1 TO n_a
    DISPLAY "fA "||s||" n:"||i
  END FOR
END FUNCTION

FUNCTION fB()
  CALL fA("fB",10)
  CALL fC(5)
END FUNCTION

FUNCTION fC(n_c)
  DEFINE n_c INTEGER
  WHILE n_c > 0
    CALL fA("fC",2)
    LET n_c=n_c-1
  END WHILE
END FUNCTION
```

Running the profiler

```
Flat profile (order by self)
   count  %total  %child   %self name
       25    88.0     0.0    88.0  rts_display
       72     6.3     0.0     6.3  rts_Concat
        8    85.4    82.0     3.4  fa
        2    25.8    24.5     1.3  fc
        8     0.3     0.0     0.3  rts_forInit
        1    85.6    85.4     0.2  fb
        1    99.9    99.6     0.3  main
```

```
Call gr
```

```
index   %total  %self  %child  calls/of  name

Runtime system basics

Dynamic module loading

A Genero Business Development Language program is made of several 42m modules. Modules a linked together, or the dependency is defined with the `IMPORT FGL` instruction.

Except when using the debugger, modules are loaded dynamically when a module element (.i.e symbol) is required by the caller. For example, when executing a `CALL` instruction, the runtime system checks if the module of the function is already in memory. If not, the module is first loaded, then module variables are instantiated, and then the function is called.

Running programs are not affected by file replacements and will continue to run with an image of the module file that was originally loaded. However, replacing program modules during execution should be used with care: Since `.42m` modules are loaded dynamically on demand (when a symbol of the module is referenced), some modules may not yet be loaded, even if the program instance is already started. When replacing a module while programs are running, invalid symbol errors can occur if the module to be loaded does not correspond to the rest of the program modules that were loaded before the file replacements. See following scenario:

1. Program starts with V1 of `main.42m`, needing V1 of module `libutil.42m` (loaded later on demand).
2. Administrator upgrades application and installs `main.42m` and `libutil.42m` version V2.
3. Program running with V1 copy of `main.42m` calls a function from `libutil.42m`: runtime loads V2 of that module, while V1 is expected.

When live application updates are mandatory, consider installing new program and resource files (V2) in a different directory as the currently running version (V1), and use the FGLLDPATH and FGLRESOURCEPATH environment variables to point to the new files when starting a new (V2) program instance.

Note that on Windows™ platforms, program files currently in use cannot be overwritten, because of Windows™ OS memory mapping limitations. You need to turn off memory mapping with the FGLPROFILE entry `fglrun.mmapDisable`.

Elements shared by multiple programs

The (`.42m`) p-code module instructions and other elements such as constants are shared among several programs running on the same machine.

Localized string resource files (.42s) are also shared among all fglrun processes running on a computer.

These files are loaded with the system memory mapping facility, which allows multiple processes to access the same unique memory area.

Elements shared by multiple modules

By definition, global variables are visible to all modules of a program, and thus shared among all modules of the program. While global variables are an easy way to share data among multiple modules, it is not recommended that you use too many global variables.

The data type definitions are only defined once in memory and shared by all modules of a program instance. By data type definition we mean the type descriptions, not the data itself. This applies only to the equivalent data types used in different modules.

Objects private to a program

Program objects such as global variables, module variables as well as resources used by the user interface and SQL connections and cursors, are private to a program.

This implies that each of these objects requires private memory to be allocated. If memory is an issue, do not allocate unnecessary resources. For example, don't create windows / load forms or declare / prepare cursors until these are really needed by the program. When the resource is not longer needed, consider freeing them (`CLOSE WINDOW`, `FREE cursor`).

Check runtime system memory leaks

To improve the quality of the runtime system, fglrun supports the `-M` / `-m` options to count the creation of built-in class objects and some internal objects. This allows to check for memory leaks in the runtime system: The runtime system counts the object creations and destructions for each class. The right-most column of the output is the different between created and destroyed objects, it must show a zero for all type of objects.

The options described here are provided for debugging purpose only. The output format is subject of changes. These option can also be removed in a next version of the product.

```
$ fglrun -M stores.42r
FunctionI         :       10 -      10 =      0
Module            :        3 -       3 =      0
...
FieldType         :       19 -      19 =      0
```

The `-M` option displays memory counters at the end of the program execution.

The `-m` option checks for memory leaks, and displays memory counters at the end of the program execution if leaks were found.

Each line shows the number of objects allocated, and the number of objects freed. If the difference is not zero, there is a memory leak.

If you are doing automatic regression tests, we recommend that you run all your programs with `fglrun -m` to check for memory leaks in the runtime system.

Optimize your programs

This section lists some programming tips and tricks to optimize the execution of your application.

Finding program bottlenecks

The best way to find out why a program is slow (and also, to optimize an already fast-running program), it to use the profiler.

This tool is included in the runtime system, and generates a report that shows what function in your program is the most time-consuming.

Optimizing SQL statements

SQL statement execution is often the code part of the program that consumes a lot of processor, disk and network resources. Therefore, it is critical to pay attention to SQL execution.

Advice for this can be found in SQL Programming.

Passing small CHAR parameters to functions

Function parameters of most data types are passed by value (i.e. the value of the caller variable is copied on the stack, and then copied back into a local variable of the called function.) When large data types are used, this can introduce a performance issue.

For example, the following code defines a logging function that takes a CHAR(2000) as parameter:

```
FUNCTION log_msg( msg )
  DEFINE msg CHAR(2000)
  CALL myLogChannel.writeLine(msg)
END FUNCTION
```

If you call this function with a string having 19 bytes:

```
CALL log_msg( "Start processing..." )
```

When doing this call, the runtime system copies 19 characters on the stack, calls the function, and then copies the value into the local variable. Since the values in CHAR variables must always have a length matching the variable definition size, the runtime system fills the remaining 1981 positions with blanks. As result, each time you call this function, a 2000 characters long variable is created on the stack.

By using a VARCHAR(2000) (or a STRING) data type in this function, you optimize the execution because no trailing blanks need to be added.

Compiler removes unused variables

When declaring a large static array without any reference to that variable in the rest of the module, you will not see the memory grow at runtime. The compiler has removed its definition from the 42m module.

To get the defined variable in the 42m module, you must at least use it once in the source (for example, with a LET statement). Note that memory might only be allocated when reaching the lines using the variable.

Saving memory by splitting modules

Program modules (42m) are loaded dynamically on demand. If a program only needs some independent functions of a given module, all module resources will be allocated just to call these functions. By independent, we mean functions that do not use module objects such as variables defined outside function or SQL cursors. To avoid unnecessary resource allocation, you can extract these independent functions into another module and save a lot of memory at runtime.

If you are using 42x libraries, it is recommended that you create libraries with the 42m modules that belong to the same functionality group. For example, group all accounting modules together in an accounting library. By doing this, programmers using the 42x libraries are not dependent from module reorganizations.

Libraries are supported for backward compatibility, you should consider using the IMPORT FGL instruction to define module dependency and get modules loaded dynamically when needed.

Saving memory by using STRING variables

The CHAR and VARCHAR data types are provided to hold string data from a database column. When you define a CHAR or VARCHAR variable with a length of 1000, the runtime system must allocate the entire size, to be able to fetch SQL data directly into the internal string buffer.

For character string data that is not stored in the database, consider using the STRING data type. The STRING type is similar to VARCHAR, except that you don't need to specify a maximum length and the internal string buffer is allocated dynamically as needed. Thus, by default, a STRING variable initially requires just a bunch of bytes, and grows during the program life time, with a limitation of 65534 bytes.

A STRING variable should typically be used to build SQL statements dynamically, for example from a CONSTRUCT instruction. You may also use the STRING type for utility function parameters, to hold file names for example.

After a large STRING variable is used, it should be cleared with a LET or a INITIALIZE TO NULL instruction. However, this is only needed for STRING variables declared as global or module variables. The variables defined in functions will be automatically destroyed when the program returns from the function.

The base.StringBuffer build-in class should be used for heavy string manipulation and modifications. String data is not copied on the stack when an object of this class is passed to a function, or when the string is modified with class methods. This can have a big impact on performance when very large strings are processed.

Saving memory by using dynamic arrays

The language supports both static arrays and dynamic arrays. For compatibility reasons, static arrays must be allocated in their entirety. This can result in huge memory usage when big structures are declared, such as:

```
DEFINE my_array ARRAY[100,50] OF RECORD
```

```
      id CHAR(200),
      comment1 CHAR(2000),
      comment2 CHAR(2000)
END RECORD
```

If possible, replace such static arrays with dynamic arrays:

```
DEFINE my_array DYNAMIC ARRAY OF RECORD
      id CHAR(200),
      comment1 CHAR(2000),
      comment2 CHAR(2000)
END RECORD
```

However, be aware that dynamic arrays have a slightly different behavior than static arrays.

Logging options

Logging solutions allow to display exchanges between components when a program executes.

Genero provides several options to get debug information, as well as logging features, to ease regression test implementation:

- Logging the runtime errors in a file with STARTLOG().
- Getting the stack trace with `base.Application.getStackTrace()`
- Displaying the GUI protocol exchange in stderr with FGLGUIDEBUG.
- Log front-end protocol exchange with fglrun --start-guilog option.
- Displaying the SQL statements execution in stderr with FGLSQLDEBUG.

Extending the language

These topics cover extending Genero Business Development Language with other languages and external components.

The Java™ interface

The *Java™ interface* allows you to import Java classes and instantiate Java objects in your programs.

The Java interface gives access to the huge standard Java libraries, as well as commercial libraries for specific purposes.

The methods of Java objects can be called with other Java objects referenced in program, as well as with native language data types such as `INTEGER`, `DECIMAL`, `CHAR`.

The Java interface of Genero has the following limitations:

1. It is not possible to use Java generic types such as java.util.Vector<E>, with a type parameter (for ex: `Vector<MyClass> v = new Vector<MyClass>()`). However, it is possible to instanciate these classes without a type parameter (for ex: `Vector v = new Vector()`).
2. Database connections cannot be shared between Java and Genero programs.
3. Java graphical objects cannot be used in Genero forms.

   Note: On Android™ mobile devices, some system functions can only be accessed in the context of a JVM. Use the Java™ interface with the `com.fourjs.gma.vm.FglRun` class to access such system specifics.

Prerequisites and installation

Learn about Java™ and OOP

Before starting with the Java™ interface, if you are not familiar with Java™ and Object Oriented Programming, we strongly recommend that you learn more about this language from the different tutorials and courses you can find on the internet.

Java software requirements

In order to use the Java™ Interface in your application programs, you need the Java software installed and properly configured.

- Install a Java™ Development Kit on development sites (if you need to compile your own Java classes)
- Install a Java™ Runtime Environment on production sites (on the server where your programs are running)

The Java™ classes defined by Genero (`com.fourjs.fgl.lang.*`) are compiled with `javac -source 1.5 -target 1.5`, to be Java™ **1.5+** compatible. Therefore the minimum theoretical Java™ version is **1.5**. However, according to the platform, the minimum required version is **Java™ 1.6** or **1.7**.

The version of the installed Java software can be shown with the command:

```
java --version
```

In order to execute Java byte code, the Genero runtime system uses the JNI interface. The JVM is loaded as a shared library and its binary format must match the binary format of the Genero runtime system. For example, a 64-bit Genero package requires a 64-bit JVM.

When implementing Java classes for Genero Mobile for Android (GMA), check the JDK version required by the Android™ SDK. For more information, see the Android Studio web site.

How to set up Java™

This short procedure describes how to set up a Java™ environment to be used with Genero.

1. Download the latest JDK from your preferred Java™ provider. On production sites, you only need a Java™ Runtime Environment (JRE).
2. Install the package on your platform by following the vendor installation notes.

3. Set the PATH environment variable to the directory containing the Java™ compiler (javac), and to the Java™ Virtual Machine (java).
4. Configure your environment to let the dynamic linker find the `libjvm.so` shared library on UNIX™ or the `JVM.DLL` on Microsoft™ Windows™. For example, on a Linux/Intel you add `$JAVA_HOME/lib/i386/server` to LD_LIBRARY_PATH.

   Note: On Microsoft™ Windows™ platforms, make sure that the PATH envrionment variable does not contain double quotes arround the path to the `JVM.DLL` dynamic library, otherwise the DLL loader will fail to load the JVM. On Mac OS X, the JVM lib can be found from the JAVA_HOME directory, For more details, see Platform-specific notes for the JVM on page 1566
5. Set the CLASSPATH or pass the `--java-option=-Djava.class.path=<pathlist>` option to fglrun with the directories of the Java™ packages you want to use. You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with language specific classes such as `com.fourjs.fgl.lang.FglDecimal` or `com.fourjs.fgl.lang.FglRecord`.
6. Try your JDK by compiling a small java sample and executing it.

Platform-specific notes for the JVM

On some platforms like HP-UX® and AIX®, you must pay attention to additional configuration settings in order to use the Java™ Interface. For more details, see the OS specific notes in the installation guide.

On Microsoft™ Windows™ platforms, make sure that the PATH envrionment variable does not contain double quotes arround the path to the `JVM.DLL` dynamic library, otherwise the DLL loader will fail to load the JVM.

On Android™ devices, Java classes must be part of the `.apk` package and can be used without any further configuration.

On Mac OS X, the usage of DYLD_LIBRARY_PATH is strongly discouraged, especially since OS X 10.11 this environment variable is no longer exported in sub processes. In order to load the JVM, the runtime system will first try a regular dlopen("libjvm"). If this system call fails, the runtime system will lookup for the `libjvm.dylib` library under the typical `$JAVA_HOME/jre` directories (for example, `$JAVA_HOME/jre/bin/client`).

Note: In order to find JAVA_HOME on Mac OS X, use the `/usr/libexec/java_home` tool:

```
export JAVA_HOME=`/usr/libexec/java_home`
```

Getting started with the Java™ interface

Import a Java™ class

In order to use a Java™ class in your program code, you must first import the class with the `IMPORT JAVA` instruction:

```
IMPORT JAVA java.util.regex.Pattern
```

This will import the specified Java™ class into the current program module. Object references can now be defined for this class.

Define an object reference variable

Before creating a Java™ object in your program, you must declare a program variable to reference the object. The type of the variable must be the name of the Java™ class, and can be fully qualified if needed:

```
IMPORT JAVA java.util.regex.Pattern
MAIN
  DEFINE p1 Pattern
  DEFINE p2 java.util.regex.Pattern
```

```
END MAIN
```

The variables declared with a class are only the handles to reference an object (i.e. the object is not yet created).

Instantiate a Java™ class

To create a new Java™ object, use `ClassName.create()`, and assign the value returned by the `create()` method to a program variable declared with the Java™ class name:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
    DEFINE sb StringBuffer
    LET sb = StringBuffer.create()
END MAIN
```

If the Java™ class constructor uses parameters, pass the parameters to the `create()` method:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
    DEFINE sb1, sb2 StringBuffer
    -- Next code line uses StringBuffer(String str) constructor
    LET sb1 = StringBuffer.create("abcdef")
    -- Next code line uses StringBuffer(int capacity) constructor
    LET sb2 = StringBuffer.create(2048)
END MAIN
```

Calling a method of a class

Class methods (static method in Java™) can be called without instantiating an object of the class. Static method invocation must be prefixed with the class name. In the next example, the `compile()` class method of Pattern class returns a new instance of a Pattern object:

```
IMPORT JAVA java.util.regex.Pattern
MAIN
    DEFINE p Pattern
    LET p = Pattern.compile("[,\\s]+")
END MAIN
```

If you define a variable with the same name as a Java™ class, you must fully qualify the class when calling static methods, as shown in this example:

```
IMPORT JAVA java.util.regex.Pattern
IMPORT JAVA java.util.regex.Matcher
MAIN
    DEFINE Pattern Pattern
    DEFINE Matcher Matcher
    -- static method, needs full qualifier
    LET Pattern = java.util.regex.Pattern.compile("[a-z]+")
    -- regular instance method, Pattern resolves to variable
    LET Matcher = Pattern.matcher("abcdef")
END MAIN
```

Note that in Genero, program variables are case-insensitive (Pattern = pattern).

Calling a method of an object

Once the class has been instantiated as an object, and the object reference has been assigned to a variable, you can call a method of the Java™ object by using the variable as the prefix:

```
IMPORT JAVA java.util.regex.Pattern
```

```
IMPORT JAVA java.util.regex.Matcher
MAIN
    DEFINE p Pattern
    DEFINE m Matcher
    LET p = java.util.regex.Pattern.compile("[a-z]+")
    LET m = p.matcher("abcdef")
    DISPLAY m.matches()
END MAIN
```

In this example, the last line of the `MAIN` module calls an object method that returns a boolean value that is converted to an `INTEGER` and displayed.

Advanced programming

Using JVM options

When using the Java™ interface, you can instruct fglrun or fglcomp to pass Java™ VM specific options during JNI initialization, by using the `--java-option` command line argument.

In the next example, fglrun will pass `-verbose:gc` to the Java™ Virtual Machine:

```
$ fglrun --java-option=-verbose:gc myprog.42r
```

If you want to pass several options to the JVM, repeat the `--java-option` argument as in this example:

```
$ fglrun --java-option=-verbose:gc --java-option=-esa myprog.42r
```

You may want to pass the Java™ class path as command line option to fglrun with `-Djava.class.path` option as in the next example:

```
$ fglrun --java-option=-Djava.class.path=$FGLDIR/lib/fgl.jar:$MYCLASSPATH
 myprog.42r
```

Regarding class path specification, the `java` runtime or `javac` compiler provide the `-cp` or `-classpath` options but when loading the JVM library from fglrun or fglcomp, only `-Djava.class.path` option is supported by the JNI interface.

Case sensitivity with Java™

The Java™ language is case-sensitive. Therefore, when you write the name of a Java™ package, class or method in a .4gl source, it must match the exact name as if you were writing a Java™ program. The fglcomp compiler takes care of this, and writes case-sensitive class and method names in the .42m p-code modules.

```
IMPORT JAVA java.util.regex.Pattern
MAIN
  DEFINE p java.util.regex.PATTERN   -- Note the case error
END MAIN
```

With this code example, fglcomp will raise error -6622 at line 3, because the "java/util/PATTERN" name cannot be found.

Method overloading in Java™

The Java™ language allows method overloading; the parameter count and the parameter data types of a method are part of the method identification. Thus, the same method name can be used to implement different versions of the Java™ method, taking different parameters:

```
DEFINE int2 SMALLINT, int4 INTEGER, flt FLOAT
```

```
-- Next call invokes method display(short) of the Java class
CALL myobj.display(int2)

-- Next call invokes method display(int) of the Java class
CALL myobj.display(int4)

-- Next call invokes method display(double) of the Java class
CALL myobj.display(flt)

-- Next call invokes method display(short,int) of the Java class
CALL myobj.display(int2,int4)
```

Passing Java™ objects to functions

Java™ objects must be instantiated and referenced by a program variable. The object reference is stored in the variable and can be passed as a parameter or returned from a program function. The Java™ objects are passed by reference to functions. This means that the called function does not get a clone of the object, but rather a handle to the original object. The function can then manipulate and modify the original object provided by the caller:

```
IMPORT JAVA java.lang.StringBuffer

MAIN
  DEFINE x java.lang.StringBuffer
  LET x = StringBuffer.create()
  CALL change(x)
  DISPLAY x.toString()
END MAIN

FUNCTION change(sb)
  DEFINE sb java.lang.StringBuffer
  CALL sb.append("abc")
END FUNCTION
```

Similarly, Java™ object references can be returned from functions:

```
IMPORT JAVA java.lang.StringBuffer

MAIN
  DEFINE x java.lang.StringBuffer
  LET x = build()
  DISPLAY x.toString()
END MAIN

FUNCTION build()
  DEFINE sb java.lang.StringBuffer
  LET sb = StringBuffer.create()   -- Creates a new object.
  CALL sb.append("abc")
  RETURN sb  -- Returns the reference to the object, not a copy/clone.
END FUNCTION
```

Garbage collection of unused objects

Java™ objects do not need to be explicitly destroyed; as long as an object is referenced by a variable, on the stack or in an expression, it will remain. When the last reference to an object is removed, the object is destroyed automatically.

The next example shows how a unique object can be referenced twice, using two variables:

```
FUNCTION test()
  -- Declare 2 variables to reference a StringBuffer object
```

```
  DEFINE sb1, sb2 java.lang.StringBuffer
  -- Create object and assign reference to variable
  LET sb1 = StringBuffer.create()
  -- Same object is now referenced by 2 variables
  LET sb2 = sb1
  -- Object is modified through first variable
  CALL sb1.append("abc")
  -- Object is modified through second variable
  CALL sb2.append("def")
  -- Shows content of StringBuffer object
  DISPLAY sb1.toString()
  -- Same output as previous line
  DISPLAY sb2.toString()
  -- Object is only referenced by second variable
  LET sb1 = NULL
  -- sb2 removed from stack, object is no longer referenced and is
 destroyed.
END FUNCTION
```

Using the method return as an object

If a Java™ method returns an object, you can use the method call directly as an object reference to call another method:

```
IMPORT JAVA java.util.regex.Pattern
MAIN
  DEFINE p Pattern
  LET p = Pattern.compile("a*b")
  IF p.matcher("aaaab").matches() THEN
    DISPLAY "It matches..."
  END IF
END MAIN
```

In this code example, the `matcher()` method of object p is invoked and returns an object of type `java.util.regex.Matcher`. The object reference returned by the `matcher()` method can be directly used to invoke the `matches()` method of the `Matcher` class.

Ignorable return of Java™ methods

Java™ allows you to ignore the return value of a method (as in C/C++):

```
StringBuffer sb = new StringBuffer;
sb.append("abc");  -- returns a new StringBuffer object but is ignored
```

In programs, you can call a Java™ method and ignore the return value:

```
IMPORT JAVA java.util.lang.StringBuffer
MAIN
  DEFINE sb StringBuffer
  LET sb = StringBuffer.create()
  LET sb = sb.append("abc")
  CALL sb.append("def")  -- typical usage
END MAIN
```

Static fields of Java™ classes

Java™ classes can have object and class ("static") fields. Java™ static class fields can be declared as "final" (read-only). It is not possible to change the object or class fields in programs, even if the field is not declared as "static final"; you can however read from it:

```
IMPORT JAVA java.lang.Integer
```

```
MAIN
  DISPLAY Integer.MAX_VALUE
END MAIN
```

Mapping native and Java™ data types

Java™ and Genero have different built-in data types. Unlike Genero, Java™ is a strongly typed language: You cannot call a method with a `String` if it was defined to get an `int` parameter. To call a Java™ method, Genero native typed values need to be converted to/from Java™ types such as `byte`, `int`, `short`, `char` or data objects such as `java.lang.String`. If possible, the fglrun runtime system will do this conversion implicitly.

The fglcomp compiler will raise the error -6606, if the native data type does not match the Java™ (primitive) type, using Widening Primitive Conversions. For example, passing a Genero `DECIMAL` when a Java™ `double` is expected will fail, but passing a `SMALLFLOAT` (equivalent to Java™ `float`) when a Java™ `double` is expected will compile and run.

Genero has advanced native data types such as `DECIMAL`, which do not have an equivalent primitive type or class in Java™. For such Genero types, you need to use a specific Java™ class provided in the `FGLDIR/lib/fgl.jar` package, like `com.fourjs.fgl.lang.FglDecimal`. You can then manipulate the Genero specific value in the Java™ code.

Genero also implements structured types with `RECORD` definitions, converted to `com.fourjs.fgl.lang.FglRecord` objects for Java™.

The Genero arrays cannot be used to call Java™ methods. You must use a native Java™ arrays instead.

In some cases you need to explicitly cast with the new `CAST( )` operator. See the section about `CAST( )` operator for more details.

This table shows the implicit conversions done by the runtime system when a Java™ method is called, or when a Java™ method returns a value or object reference:

Table 328: Implicit conversions by Genero with Java™ method / Java™ method returns

Genero data type	Java™ equivalent
`CHAR`	`java.lang.String`
`VARCHAR`	`java.lang.String`
`STRING`	`java.lang.String`
`DATE`	`com.fourjs.fgl.lang.FglDate`
`DATETIME`	`com.fourjs.fgl.lang.FglDateTime`
`INTERVAL`	`com.fourjs.fgl.lang.FglInterval`
`BIGINT`	`long` (64-bit signed integer)
`INTEGER`	`int` (32-bit signed integer)
`SMALLINT`	`short` (16-bit signed integer)
`TINYINT`	`tinyint` (8-bit signed integer)
`FLOAT`	`double` (64-bit signed floating point number)
`SMALLFLOAT`	`float` (32-bit signed floating point number)
`DECIMAL`	`com.fourjs.fgl.lang.FglDecimal`
`MONEY`	`com.fourjs.fgl.lang.FglDecimal`

Genero data type	Java™ equivalent
BYTE	`com.fourjs.fgl.lang.FglByteBlob`
TEXT	`com.fourjs.fgl.lang.FglTextBlob`
RECORD structure	`com.fourjs.fgl.lang.FglRecord`
Java™ Array	This is a native Java™ Array

Table 329: Native language data types that cannot be converted to Java™ types

Genero data type
ARRAY structures
Built-in classes

Using the DATE type

When calling a Java™ method with an expression evaluating to a DATE, the runtime system converts the DATE value to an instance of the `com.fourjs.fgl.lang.FglDate` class implemented in `FGLDIR/lib/fgl.jar`. You can then manipulate the date from within the Java™ code.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglDate` class.

The `com.fourjs.fgl.lang.FglDate` class implements following:

Table 330: Methods of the com.fourjs.fgl.lang.FglDate class

Method	Description
`String toString()`	Converts the DATE value to a String object representing the date in format: YYYY-MM-DD
`static void valueOf( String val)`	Creates a new `FglDate` object from a String object representing a date in the format YYYY-MM-DD.

In the Java™ code, you can convert the `com.fourjs.fgl.lang.FglDate` to a `java.util.Calendar` object as in this example:

```
public static void useDate(FglDate d) throws ParseException {
    SimpleDateFormat sdf = new SimpleDateFormat("yyyy-MM-dd");
    Calendar cal = Calendar.getInstance();
    cal.setTime( sdf.parse(d.toString()) );
    ...
}
```

If you need to create an `com.fourjs.fgl.lang.FglDate` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglDate
MAIN
  DEFINE d com.fourjs.fgl.lang.FglDate
  LET d = FglDate.valueOf("2008-12-23")
  DISPLAY d.toString()
END MAIN
```

Using the DATETIME type

When calling a Java™ method with an expression evaluating to a DATETIME, the runtime system converts the DATETIME value to an instance of the com.fourjs.fgl.lang.FglDateTime class implemented in FGLDIR/lib/fgl.jar. You can then manipulate the DATETIME from within the Java™ code.

You must add FGLDIR/lib/fgl.jar to the class path in order to compile Java™ code with com.fourjs.fgl.lang.FglDateTime class.

The com.fourjs.fgl.lang.FglDateTime class implements following:

Table 331: Fields of the com.fourjs.fgl.lang.FglDateTime class

Field	Description
`final static int YEAR`	Time qualifier for year
`final static int MONTH`	Time qualifier for month
`final static int DAY`	Time qualifier for day
`final static int HOUR`	Time qualifier for hour
`final static int MINUTE`	Time qualifier for minute
`final static int SECOND`	Time qualifier for second
`final static int FRACTION`	Time qualifier for fraction (start qualifier)
`final static int FRACTION1`	Time qualifier for fraction(1) (end qualifier)
`final static int FRACTION2`	Time qualifier for fraction(2) (end qualifier)
`final static int FRACTION3`	Time qualifier for fraction(3) (end qualifier)
`final static int FRACTION4`	Time qualifier for fraction(4) (end qualifier)
`final static int FRACTION5`	Time qualifier for fraction(5) (end qualifier)

Table 332: Methods of the com.fourjs.fgl.lang.FglDateTime class

Method	Description
`String toString()`	Converts the `DATETIME` value to a String object representing a datetime in the format `YYYY-MM-DD hh:mm:ss.fff`.
`static void valueOf( String val)`	Creates a new `FglDateTime` object from a String object representing a datetime value in the format: `YYYY-MM-DD hh:mm:ss.fff`
`static void valueOf( String val, int startUnit, int endUnit)`	Creates a new `FglDateTime` object from a String object representing a datetime value in the format `YYYY-MM-DD hh:mm:ss.fff`, using the qualifiers passed as parameter.
`static int encodeTypeQualifier( int startUnit, int endUnit)`	Returns the encoded type qualifier for a datetime with to datetime qualifiers passed: encoded qualifier = (length * 256) + (startUnit * 16) + endUnit Where *length* defines the total number of significant digits in this time data. For example, with `DATETIME YEAR TO MINUTE`: startUnit = YEAR length = 12 (YYYYMMDDhhmm) endUnit = MINUTE

In the Java™ code, you can convert the `com.fourjs.fgl.lang.FglDateTime` to a `java.util.Calendar` object as in this example:

```
public static void useDatetime(FglDateTime dt) throws ParseException {
   SimpleDateFormat sdf = new SimpleDateFormat("yyyy-MM-dd HH:mm:ss.SSS");
   Calendar cal = Calendar.getInstance();
   cal.setTime( sdf.parse(dt.toString()) );
   ...
}
```

If you need to create an `com.fourjs.fgl.lang.FglDateTime` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglDateTime
MAIN
  DEFINE dt com.fourjs.fgl.lang.FglDateTime
  LET dt = FglDateTime.valueOf("2008-12-23 11:22:33.123")
  LET dt = FglDateTime.valueOf("11:22:33.123",
               FglDateTime.HOUR, FglDateTime.FRACTION3)
  DISPLAY dt.toString()
END MAIN
```

The `valueOf()` method expects a string representing a complete date-time specification, from year to milliseconds, equivalent to a `DATETIME YEAR TO FRACTION(3)` data type.

Using the DECIMAL type

When calling a Java™ method with an expression evaluating to a `DECIMAL` , the runtime system converts the `DECIMAL` value to an instance of the `com.fourjs.fgl.lang.FglDecimal` class implemented in `FGLDIR/lib/fgl.jar`. You can then manipulate the `DECIMAL` from within the Java™ code.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglDecimal` class.

The `com.fourjs.fgl.lang.FglDecimal` class implements following:

Table 333: Methods of the com.fourjs.fgl.lang.FglDecimal class

Method	Description
`String toString()`	Converts the `DECIMAL` value to a String object.
`static void valueOf(String val)`	Creates a new `FglDecimal` object from a `String` object representing a decimal value.
`static void valueOf(int val)`	Creates a new `FglDecimal` object from an `int` value.

`static int encodeTypeQualifier(`
`  int precision,`
`  int scale)`
	Returns the encoded type qualifier for this decimal according to precision and scale.
	encoded qualifier = (precision * 256) + scale
	Use 255 as scale for floating point decimal.

In the Java™ code, you can convert the `com.fourjs.fgl.lang.FglDecimal` to a `java.lang.BigDecimal` as in following example:

```
public static FglDecimal divide(FglDecimal d1, FglDecimal d2){
    BigDecimal bd1 = new BigDecimal(d1.toString());
    BigDecimal bd2 = new BigDecimal(d2.toString());
    BigDecimal res = bd1.divide(bd2, BigDecimal.ROUND_FLOOR);
    return FglDecimal.valueOf(res.toString());
}
```

If you need to create an `com.fourjs.fgl.lang.FglDecimal` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglDecimal
MAIN
  DEFINE jdec com.fourjs.fgl.lang.FglDecimal
  LET jdec = FglDecimal.valueOf("123.45")
  DISPLAY jdec.toString()
END MAIN
```

Using the TEXT type

When calling a Java™ method with an expression evaluating to a `TEXT`, the runtime system converts the `TEXT` handle to an instance of the `com.fourjs.fgl.lang.FglTextBlob` class implemented in `FGLDIR/lib/fgl.jar`. You can then manipulate the LOB from within the Java™ code.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglTextBlob` class.

The `com.fourjs.fgl.lang.FglTextBlob` class implements following:

Table 334: Methods of the com.fourjs.fgl.lang.FglTextBlob class

Method	Description
`String toString()`	Converts the large text data to a simple `String`.
`static void valueOf( String val)`	Creates a new `FglTextBlob` object from a `String`.

In the Java™ code, you can pass a `com.fourjs.fgl.lang.FglTextBlob` object as in this example:

```
public static void useByte(FglTextBlob t) throws ParseException {
    String s = t.toString();
    ...
}
```

If you need to create an `com.fourjs.fgl.lang.FglTextBlob` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglTextBlob
MAIN
  DEFINE jtext com.fourjs.fgl.lang.FglTextBlob
  LET jtext = FglTextBlob.valueOf("abcdef..........")
  DISPLAY jtext.toString()
END MAIN
```

Using the BYTE type

When calling a Java™ method with an expression evaluating to a BYTE, the runtime system converts the BYTE handle to an instance of the `com.fourjs.fgl.lang.FglByteBlob` class implemented in `FGLDIR/lib/fgl.jar`. You can then manipulate the LOB from within the Java™ code.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglByteBlob` class.

The `com.fourjs.fgl.lang.FglByteBlob` class implements following:

Table 335: Methods of the com.fourjs.fgl.lang.FglByteBlob class

Method	Description
`String toString()`	Returns the HEX string representing the binary data.
`static void valueOf( String val)`	Creates a new `FglByteBlob` object from a String object representing the binary data in HEX format.

In the Java™ code, you can pass a `com.fourjs.fgl.lang.FglByteBlob` object as in this example:

```
public static void useByte(FglByteBlob b) throws ParseException {
    String s = b.toString();
    ...
}
```

If you need to create an `com.fourjs.fgl.lang.FglByteBlob` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglByteBlob
MAIN
  DEFINE jbyte com.fourjs.fgl.lang.FglByteBlob
  LET jbyte = FglByteBlob.valueOf("0FA5617BDE")
  DISPLAY jbyte.toString()
END MAIN
```

Using the INTERVAL type

When calling a Java™ method with an expression evaluating to an `INTERVAL`, the runtime system converts the `INTERVAL` value to an instance of the `com.fourjs.fgl.lang.FglInterval` class implemented in `FGLDIR/lib/fgl.jar`. You can then manipulate the `INTERVAL` from within the Java™ code.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglInterval` class.

The `com.fourjs.fgl.lang.FglInterval` class implements following:

Table 336: Fields of the com.fourjs.fgl.lang.FglInterval class

Field	Description
`final static int YEAR`	Time qualifier for year
`final static int MONTH`	Time qualifier for month
`final static int DAY`	Time qualifier for day
`final static int HOUR`	Time qualifier for hour
`final static int MINUTE`	Time qualifier for minute
`final static int SECOND`	Time qualifier for second
`final static int FRACTION`	Time qualifier for fraction (start qualifier)
`final static int FRACTION1`	Time qualifier for fraction(1) (end qualifier)
`final static int FRACTION2`	Time qualifier for fraction(2) (end qualifier)
`final static int FRACTION3`	Time qualifier for fraction(3) (end qualifier)
`final static int FRACTION4`	Time qualifier for fraction(4) (end qualifier)
`final static int FRACTION5`	Time qualifier for fraction(5) (end qualifier)

Table 337: Methods of the com.fourjs.fgl.lang.FglInterval class

Methods	Description
`String toString()`	Converts the `INTERVAL` value to a `String` object representing an interval in default format.
`static void valueOf(` `  String val)`	Creates a new `FglInterval` object from a `String` object representing an interval value in format: DD hh:mm:ss.fff

`static void valueOf(`
`  String val,`
`  int startUnit,`
	Creates a new `FglDateTime` object from a `String` object representing an interval value in standard format, using the qualifiers and precision passed as parameter.

Methods	Description
`int endUnit)`	

`static int encodeTypeQualifier(`
`  int startUnit,`
`  int length,`
`  int endUnit))`
	Returns the encoded type qualifier for an interval with to interval qualifiers and length passed:
	encoded qualifier = (*length* * 256) + (*startUnit* * 16) + *endUnit*
	Where *length* defines the total number of significant digits in this time data.
	For example, with INTERVAL DAY(5) TO FRACTION3:
	startUnit = DAY
	length = 13 (DDDDhhmmssfff)
	endUnit = FRACTION3

In the Java™ code, you can pass a `com.fourjs.fgl.lang.FglInterval` object as in this example:

```
public static void useInterval(FglInterval inv) throws ParseException {
    String s = inv.toString();
    ...
}
```

If you need to create an `com.fourjs.fgl.lang.FglInterval` object in your program, you can use the `valueOf()` class method as in this example:

```
IMPORT JAVA com.fourjs.fgl.lang.FglInterval
MAIN
  DEFINE inv com.fourjs.fgl.lang.FglInterval
  LET inv = FglInterval.valueOf("-510 12:33:45.123")
  DISPLAY inv.toString()
END MAIN
```

Identifying Genero data types in Java™ code

Java™ data types and Genero data types are different. To identify Genero types in Java™ code, you can use the `com.fourjs.fgl.lang.FglTypes` class implemented in `FGLDIR/lib/fgl.jar`.

You can for example identify the data type of a member of an FglRecord object.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglType` class.

The `com.fourjs.fgl.lang.FglTypes` class implements following:

Table 338: Fields of the com.fourjs.fgl.lang.FglTypes class

Field	Corresponding data type
`final static int BYTE`	BYTE
`final static int CHAR`	CHAR
`final static int DATE`	DATE
`final static int DATETIME`	DATETIME
`final static int DECIMAL`	DECIMAL
`final static int FLOAT`	FLOAT
`final static int INT`	INTEGER
`final static int SMALLFLOAT`	SMALLFLOAT
`final static int SMALLINT`	SMALLINT
`final static int VARCHAR`	VARCHAR
`final static int STRING`	STRING
`final static int RECORD`	RECORD structure
`final static int ARRAY`	ARRAY object

Using Genero records

When passing a `RECORD` to a Java™ method, the runtime system converts the `RECORD` to an instance of the `com.fourjs.fgl.lang.FglRecord` class implemented in `FGLDIR/lib/fgl.jar`.

The `FglRecord` object is a copy of the `RECORD` variable: Structure and members of the `FglRecord` object can be read within the Java™ code, but cannot be modified.

You must add `FGLDIR/lib/fgl.jar` to the class path in order to compile Java™ code with `com.fourjs.fgl.lang.FglRecord` class.

The `com.fourjs.fgl.lang.FglRecord` class implements the following methods:

Table 339: Methods of the com.fourjs.fgl.lang.FglRecord class

Method	Description
`int getFieldCount()`	Returns the number of record members.
`String getFieldName(int p)`	Returns the name of the record member at position *p*.
`FglTypes getType(int p)`	Returns the `FglTypes` constant of the record member at position *p*.
`String getTypeName(int p)`	Returns the string representation of the data type of the record member at position *p*.
`int getTypeQualifier(int p)`	Returns the encoded type qualifier of the record member at position *p*.
`int getInt(int p)`	Returns the int value of the record member at position *p*.
`int getFloat(int p)`	Returns the float value of the record member at position *p*.
`double getDouble(int p)`	Returns the double value of the record member at position *p*.
`String getString(int p)`	Returns the String representation of the value of the record member at position *p*.
`FglDecimal getDecimal(int p)`	Returns the `FglDecimal` value of the record member at position *p*.
`FglDate getDate(int p)`	Returns the `FglDate` value of the record member at position *p*.
`FglDateTime getDateTime(int p)`	Returns the `FglDateTime` value of the record member at position *p*.
`FglInterval getInterval(int p)`	Returns the `FglInterval` value of the record member at position *p*.
`FglByteBlob getByteBlob(int p)`	Returns the `FglByteBlob` value of the record member at position *p*.
`FglTextBlob getTextBlob(int p)`	Returns the `FglTextBlob` value of the record member at position *p*.

In the Java™ code, use the query methods of the `com.fourjs.fgl.lang.FglRecord` to identify the members of the `RECORD`:

```
public static void showMemberTypes(FglRecord rec){
    int i;
    int n = rec.getFieldCount();
    for (i = 1; i <= n; i++)
        System.out.println( String.valueOf(i) + ":" +
```

```
        rec.getFieldName(i) + " / " + rec.getTypeName(i) );
}
```

When assigning a RECORD to a com.fourjs.fgl.lang.FglRecord, *widening conversion* applies implicitly. But when assigning a com.fourjs.fgl.lang.FglRecord to a RECORD, *narrowing conversion* applies and you must explicitly CAST the original object reference to the type of the RECORD. The next example shows how to return an FglRecord object from a Java™ method:

```
-- PassRecord.4gl
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
IMPORT JAVA UseRecord
MAIN
    TYPE type1 RECORD
               id INTEGER,
               name VARCHAR(50)
           END RECORD
    DEFINE rec1, rec2 type1
    LET rec1.id = 123
    LET rec1.name = "McFly"
    LET rec2 = CAST(UseRecord.getRecord(rec1) AS type1)
END MAIN

-- UseRecord.java
import com.fourjs.fgl.lang.FglRecord;
public class UseRecord{
    public static FglRecord getRecord(FglRecord rec){
        ...
        return rec;
    }
}
```

Formatting data in Java™ code

To format numeric and date-time data in Java™ code, use the com.fourjs.fgl.lang.FglFormat class implemented in FGLDIR/lib/fgl.jar.

You must add FGLDIR/lib/fgl.jar to the class path in order to compile Java™ code with com.fourjs.fgl.lang.FglFormat class.

The com.fourjs.fgl.lang.FglFormat class provides an interface to the data formatting functions of the runtime system. This class is actually an equivalent of the USING operator in the language.

The com.fourjs.fgl.lang.FglFormat class implements the following:

Table 340: Methods of the com.fourjs.fgl.lang.FglFormat class

Method	Description
`static String format( int v, String fmt)`	Formats the integer value provided as Java™ int, according to fmt. Here fmt must specify a numeric format with [$@*#&<()+-] characters, as with the USING operator.
`static String format( double v, String fmt)`	Formats the FLOAT value provided as Java™ double, according to fmt. Here fmt must specify a numeric format with [$ @*#&<()+-. ,] characters, as with the USING operator.
`static String format( FglDate v,`	Formats the DATE value provided as FglDate, according to fmt. Here fmt must specify a date

Method	Description
`String fmt)`	format with `[mdy]`characters., as with the `USING` operator.
`static String format( FglDecimal v, String fmt)`	Formats the `DECIMAL` value provided as `FglDecimal`, according to fmt. Here fmt must specify a numeric format with `[ $ @*# $<()+-. ,]` characters, as with the `USING` operator.

Example of Java™ code using the `com.fourjs.fgl.lang.FglFormat` class:

```
public static void formatDecimal(FglDecimal dec){
    System.out.println( FglFormat.format(dec,"$#####&.&&" );
}
```

Character set mapping

Application programs use a given locale and character set, while Java™ uses its own charset internally for the `char` Java™ type (16- bit UNICODE).

When passing character strings to/from Java™ methods or when assigning program strings to `java.lang.String`, the runtime system handles character set conversion.

Using Java™ arrays

Java™ arrays and Genero arrays are different. In order to interface with Java™ arrays, the Genero language has been extended with a new kind of arrays, called "Java™ arrays".

Java™ arrays have to be created with a given length. Like native Java™ arrays, the length cannot be changed after the array is created.

To create a Java™ array in Genero, you must define a `TYPE` in order to call the `create()` type method of Java™ arrays. The type of the elements in a Java™ array must be one of the language types that have a corresponding primitive type in Java™ (such as INTEGER (int), FLOAT (double)), or it must be a Java™ class such as java.lang.String.

The Java™ arrays are passed to Java™ methods by reference, so the elements of the array can be manipulated in Java™. Further, Java™ arrays can be created in Java™ code and returned to the Genero program.

This example shows how to create a Java™ array in Genero, to instantiate a Java™ Array of `INTEGER` elements:

```
MAIN
  TYPE int_array_type ARRAY[] OF INTEGER
  DEFINE ja int_array_type
  LET ja = int_array_type.create(100)
  LET ja[10] = 123
  DISPLAY ja[10], ja[20]
  DISPLAY ja.getLength()
END MAIN
```

The next example shows a program creating a Java™ array of Java™ strings:

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
```

```
    LET names[1] = "aaaaaaa"
    DISPLAY names[1]
END MAIN
```

To create a Java™ array of structured `RECORD` elements, use the `com.fourjs.fgl.lang.FglRecord` class:

```
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
MAIN
  TYPE record_array_type ARRAY[]
       OF com.fourjs.fgl.lang.FglRecord
  DEFINE ra record_array_type
  TYPE r_t RECORD
       id INTEGER,
       name VARCHAR(100)
      END RECORD
  DEFINE r r_t
  LET ra = record_array_type.create(100)
  LET r.id = 123
  LET r.name = "McFly"
  LET ra[10] = r
  INITIALIZE r TO NULL
  LET r = CAST (ra[10] AS r_t)
  DISPLAY r.*
END MAIN
```

Java™ arrays of Java™ classes can be defined. The next example introspects the `java.lang.String` class by using Java™ array of `java.lang.reflect.Method` to query the list of methods from the `java.lang.String` class:

```
IMPORT JAVA java.lang.Class
IMPORT JAVA java.lang.reflect.Method
MAIN
  DEFINE c java.lang.Class
  DEFINE ma ARRAY[] OF java.lang.reflect.Method
  DEFINE i INTEGER
  LET c = Class.forName("java.lang.String")
  LET ma = c.getMethods()
  FOR i = 1 TO ma.getLength()
     DISPLAY ma[i].toString()
  END FOR
END MAIN
```

Java™ arrays can be created in the Java™ code, to be returned from a method and assigned to a program variable:

```
public static int [] createIntegerArray(int size) {
    return new int[size];
}
```

Passing variable arguments (varargs)

Java™ supports variable arguments in method definitions with the ellipsis notation, allowing callers to pass a different number of arguments according to the need. A typical example is a message print method:

```
import java.lang.String;

public class MyClass {
    public static void ShowStrings( String... sl ) {
        for ( String s : sl )
            System.out.println(s);
```

```
    }
}
```

In order to call such a method from the Genero program, create a Java™ array of the type of the variable argument, fill the array with objects and call the method with that array:

```
IMPORT JAVA java.lang.String
IMPORT JAVA MyClass

MAIN
    TYPE sl_t ARRAY[] OF java.lang.String
    DEFINE sl ARRAY[] OF java.lang.String
    LET sl = sl_t.create(2)
    LET sl[1] = "Value 1"
    LET sl[2] = "Value 2"
    CALL MyClass.ShowStrings(sl)
END MAIN
```

Since Java arrays have a static size, you must create the Java array with the exact number of variable arguments to be passed to the method.

If the Java class cannot be modified, consider implementing a function to wrap calls to the Java method, with a varying number of arguments. It can for example take a BDL dynamic array as parameter, to simplify the callers code:

```
IMPORT JAVA java.lang.String
IMPORT JAVA MyClass

MAIN
    DEFINE a DYNAMIC ARRAY OF STRING
    LET a[1] = "Value 1"
    LET a[2] = "Value 2"
    LET a[3] = "Value 3"
    CALL my_show_strings(a)
    LET a[4] = "Value 1"
    LET a[5] = "Value 2"
    CALL my_show_strings(a)
END MAIN

FUNCTION my_show_strings(sa)
    TYPE sl_t ARRAY[] OF java.lang.String
    DEFINE sa DYNAMIC ARRAY OF STRING
    DEFINE sl ARRAY[] OF java.lang.String
    DEFINE i INTEGER
    LET sl = sl_t.create(sa.getLength())
    FOR i=1 TO sa.getLength()
        LET sl[i] = sa[i]
    END FOR
    CALL MyClass.ShowStrings(sl)
END FUNCTION
```

If the Java class can be modified, a good practice is to write overloaded methods, using a static number of arguments:

```
public class MyClass {
    private static void _ShowStrings( String... sl ) {
        for ( String s : sl )
            System.out.println(s);
    }
    public static void ShowStrings(String s1) {
        _ShowStrings(s1);
    }
```

```
    public static void ShowStrings(String s1, String s2) {
        _ShowStrings(s1, s2);
    }
    public static void ShowStrings(String s1, String s2, String s3) {
        _ShowStrings(s1, s2, s3);
    }
}
```

The CAST operator

Important consideration has to be taken when assigning object references to different target types or classes. A *Widening Reference Conversion* occurs when an object reference is converted to a superclass that can accommodate any possible reference of the original type or class. A *Narrowing Reference Conversion* occurs when an object reference of a superclass is converted to a subtype or subclass of the original object reference. For example, in a vehicle class hierarchy with `Vehicle` and `Car` classes, `Car` is a subclass that inherits from the `Vehicle` superclass. When assigning a `Car` object reference to a `Vehicle` variable, Widening Reference Conversion takes place. When assigning a `Vehicle` object reference to a `Car` variable, Narrowing Reference Conversion occurs.

While widening conversion does not require casts and will not produce compilation or runtime errors, narrowing conversion needs the `CAST` operator to convert to the target type or class:

```
CAST( object_reference AS type_or_class )
```

The next example creates a `java.lang.StringBuffer` object, and assigns the reference to a `java.lang.Object` variable (implying Widening Reference Conversion); then the object reference is assigned back to the `java.lang.StringBuffer` variable (implying Narrowing Reference Conversion and `CAST` operator usage):

```
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE o java.lang.Object
  DEFINE sb java.lang.StringBuffer
  LET sb = StringBuffer.create()
  -- Widening Reference Conversion
  LET o = sb
  -- Narrowing Reference Conversion needs CAST()
  LET sb = CAST( o AS StringBuffer )
END MAIN
```

The INSTANCEOF operator

When manipulating an object reference with a variable defined with a superclass of the real class used to instantiate the object, you sometimes need to identify the real class of the object.

This is possible with the `INSTANCEOF` operator.

This operator checks whether the left operand is an instance of the type or class specified by the right operand:

```
object_reference INSTANCEOF type_or_class
```

This example creates a `java.lang.StringBuffer` object, assigns the reference to a `java.lang.Object` variable, and tests whether the class type of the object reference is a `java.lang.StringBuffer`:

```
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE o java.lang.Object
```

```
  LET o = StringBuffer.create()
  DISPLAY o INSTANCEOF StringBuffer    -- Shows 1 (TRUE)
END MAIN
```

Java exception handling

In order to catch Java™ exceptions within programs, use a TRY/CATCH block.

When a Java exception occurs, the runtime system sets the STATUS variable to the error code -8306.

The Java exception details (i.e. the name of the exception) can be found with the ERR_GET(STATUS) built-in function.

> **Important:** To get the Java exception type with ERR_GET(), do not execute other instructions before querying for the error message, otherwise the STATUS variable might be reset to zero and the Java exception details would be lost.

To easily identify the type of the Java exceptions in your code, consider writing a library function based on ERR_GET(), that recognizes most common Java exceptions, and converts them to integer codes:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE sb java.lang.StringBuffer
  LET sb = StringBuffer.create("abcdef")
  TRY
    CALL sb.deleteCharAt(50) -- out of bounds!
  CATCH
    DISPLAY err_get(STATUS)
    EXIT PROGRAM 1
  END TRY
END MAIN
```

> **Note:** As a general pattern, do not use TRY/CATCH or WHENEVER ERROR CONTINUE exception handlers if no exception is supposed to occur. By default the program will then stop and display the Java exception details.

Executing Java™ code with GMA

On Android™ devices running GMA apps, the Genero language can be extended with the Java interface.

The GMA executes a program in a JVM process and therefore does not require more resources to execute Java code.

We distinguish the following use cases where the Java interface of Genero can be used in GMA:

- Use classes from the standard Java or Android Java library.
- Implement and use user-defined Java classes, requiring GMA packaging.
- Implement and execute a user-defined Android activity, requiring GMA packaging.

Java may also be used to extend the GMA front-end with user-defined front calls. For details, see Implement front call modules for GMA on page 1620.

Standard Java™ and Android™ library usage

You can use Java classes that are part of the standard Java library and Android Java library.

Using standard Java within the GMA

Java classes provided in the standard Java library and in the Android Java library can be used directly by including the IMPORT JAVA *classname* keywords in the Genero code:

```
IMPORT JAVA java.lang.Runtime
IMPORT JAVA android.os.Build

MAIN
```

```
  DEFINE rtm Runtime, msg STRING

  LET rtm = java.lang.Runtime.getRuntime()

  LET msg = SFMT("Device:[%1] %2 - %3 (%4 procs)",
                 android.os.Build.MANUFACTURER,
                 android.os.Build.MODEL,
                 android.os.Build.SERIAL,
                 rtm.availableProcessors() )

  MENU "Test" ATTRIBUTES(STYLE="dialog", COMMENT=msg)
    ON ACTION ok
      EXIT MENU
  END MENU

END MAIN
```

The Android Java library does not include all the classes of a regular JRE. User interface classes are specific to the Android user interface framework. The list of standard Android Java packages can be found at http://developer.android.com/reference/packages.html.

Only non-interactive classes can be used in this context. To get a graphical user interface, you must implement an Android Activity, as described in Implement Android activities in GMA on page 1589.

Because Android apps are Java-based, the JVM and standard Java library is directly available. There is no need to bundle the Java library with your Genero program files when you deploy your app as .apk package.

When executing the Genero program on a computer in development mode, it is not possible to use classes that are specific to the Android Java library, because the Android Java library is not available in development mode at runtime.

You must compile your app code and deploy it on an Android device for execution. To compile your app code on the development platform, you need to setup the Java SDK environment and the CLASSPATH to the Android SDK library (android.jar).

> **Note:** For compilation, `JDK_HOME` can point to a 32-bit or 64-bit Java Development Kit installation, to match the Genero BDL architecture. However, the Android SDK is only available in 32-bit.

JVM context-dependent Android API calls

On an Android device, the GMA executes a Genero program in a JVM process. Some Android system APIs cannot be directly called from the Genero runtime system context; they must be called from the JVM context.

In order to call such APIs, you must import the `com.fourjs.gma.vm.FglRun` class and get the Android JVM thread context by calling the `getContext()` method of the `FglRun` class.

The `getContext()` method will return an instance of the `android.content.Context` class. For more details, see http://developer.android.com/reference/android/content/Context.html

> **Note:** To use this Android JVM interface, you must add the `android.jar` library (from the Android SDK) to the class path.

The `com.fourjs.gma.vm.FglRun` class implements the following methods:

Table 341: Methods of the com.fourjs.gma.vm.FglRun class

Method	Description
`Context getContext()`	Returns the Android JVM context object of the runtime system.

In the program code, use the `getContext()` method to get the JVM context and call specific Android APIs:

```
IMPORT JAVA android.app.Service
IMPORT JAVA android.content.Context
IMPORT JAVA android.util.DisplayMetrics
IMPORT JAVA android.view.WindowManager

IMPORT JAVA com.fourjs.gma.vm.FglRun

MAIN
    DEFINE w, h, d INT
    MENU "Java"
       ON ACTION test
          CALL android_screen_metrics() RETURNING w, h, d
          MESSAGE "Width: ", w, "\nHeight: ", h, "\nDensity: ", d
    END MENU
END MAIN

FUNCTION android_screen_metrics()
    DEFINE ctx android.content.Context,
           dm android.util.DisplayMetrics,
           wm android.view.WindowManager

    LET ctx = com.fourjs.gma.vm.FglRun.getContext()
    LET dm = android.util.DisplayMetrics.create()
    LET wm = CAST ( ctx.getSystemService("window")
                    AS android.view.WindowManager )
    CALL wm.getDefaultDisplay().getMetrics(dm)

    RETURN dm.widthPixels,
           dm.heightPixels,
           dm.densityDpi
END FUNCTION
```

Using front calls instead of pure Java

For maximum portability, consider implementing Android-specific extensions as custom front calls. When using the front call technology, apps can be executed in development (app running on the server) and in deployed mode (app running on the mobile device) with the same Genero code.

Implement Java user extensions in GMA

A GMA app can execute custom Java code.

In order to execute Java user code on the mobile device, the compiled Java classes need to be available to the Genero runtime system. They can then be imported with the `IMPORT JAVA` *`classname`* instruction.

When executing the Genero program on a computer in development mode, define the CLASSPATH to your .jar files. This allows the JVM loaded by the Genero runtime system find the appropriate Java classes.

When executing the Genero program on a mobile device, the compiled user Java classes must be included in the mobile app Android™ package (.apk), which is created in the Genero Studio deployment procedure.

Implement Android™ activities in GMA

Android activities can be bundled with your GMA app and called from the Genero code.

A Java-based extension that interacts with the end user must be implemented as an Android Activity, by using the `android.app.Android` class.

In order to use your Android Activity from the program, it must be integrated in the mobile app Android package (.apk), which is created in the Genero Studio deployment procedure.

This code example implements a simple Android Activity:

```
package com.myextension;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class MyActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        Button button = new Button(this);
        button.setText("Quit");
        setContentView(button);
        button.setOnClickListener(
             new View.OnClickListener() {
             public void onClick(View v) {
                 int resultCode = 0;
                 Intent resultData = new Intent();
                 resultData.putExtra("MyKey", "MyValue");
                 setResult(resultCode, resultData);
                 finish();
             }
        });
    }
}
```

In order to execute this activity from a Genero app, use the `startActivity` front call:

```
MAIN
    DEFINE data, extras STRING
    MENU
        ON ACTION activity ATTRIBUTES(TEXT="Call bundled activity")
            CALL ui.Interface.frontCall("android", "startActivityForResult",
                 ["android.intent.action.VIEW", NULL, NULL, NULL,
                  "com.myextension.MyActivity"],
                 [ data, extras ])
                 MESSAGE "data=",data," / extras=",extras
        ON ACTION quit
            EXIT MENU
    END MENU
END MAIN
```

> **Note:** The component name (fifth parameter) of the startActivity front call does normally take the APK package name followed by the Java Activity class name (*`apk-package-name/java-class-name`*). The APK Android package name can be defined for the application project in the Genero Studio. When using an user-defined activity that is part of the GMA binary archive, do not specify the APK package in the component parameter, because the Java Activity class will be included in the current APK package. This is true when using the customized GMA front-end in development mode, and in the final application that is deployed on the device. For more details about the component parameter, see startActivity (Android) on page 1942.

Packaging custom Java™ extensions for GMA

Custom Java extension must be integrated in the GMA to run on Android™ devices.

Genero Mobile apps for Android are created from Genero Studio, or from the command-line with gmabuildtool on page 2580: You need to provide the custom GMA binary archive containing your Java extensions, to Genero Studio or to gmabuildtool.

- Genero Studio finds the GMA binary archive from the GMADIR variable defined in the configuration settings.

- The gmabuildtool requires the Android Studio project directory used to build the custom GMA, to be specified with the `--build-project-folder-path` option.

Along with the GMA binary archive, you must provide the `.jar` files of your Java extensions, that will be used to compile Genero application code on the development machine, as well as the `.apk` Android packages of GMA, to deploy the front-end part on the device for client/server development (typically with user-defined front calls).

The original GMA binary archive is a zip file containing several `.aar` Android libraries. A customized GMA binary archive contains the `.aar` files from the GMA core libraries, the Genero runtime system core libraries, and custom `.aar` files build from your own Java libraries. The custom `.aar` libs are created from Android Studio. The minimum Android Studio version is 0.8.9.

To create a new GMA binary archive, the `extension.jar` file, and the `.apk` packages, including your Java extensions, perform the steps described in Custom GMA binary archive build on page 1591.

After completing these steps:

- When compiling application code, Genero Studio can find your `.jar` libraries to resolve Java symbols.
- When deploying the front-end only for client/server development, Genero Studio will find the .apk packages to be installed on the device.
- When building an Android app in Genero Studio, it will be created from the custom GMA binary archive that includes your Java extensions.
- When building an Android app with gmabuildtool, it can be created by specifying the custom GMA Android project directory with the `--build-project-folder-path` option.

Custom GMA binary archive build
Building a GMA binary archive with custom Java classes using Android™ Studio.

Android Studio must be installed, and minimum Android development skills are required.

1. Locate the original GMA binary archive on your computer. When using Genero Studio, the GMA binary archive is defined by the GMADIR variable in configuration settings. When not using Genero Studio, the GMA binary archive is provided as a separate package.

   The GMA binary archive consist of a set of files:

   - `fjs-gma-*-android-scaffolding.zip` : This file contains the original GMA core binary without custom extensions.
   - `fjs-gma-*-android-extension-project.zip` : This file contains the Android Studio project template to build your custom GMA.
2. Unzip the `fjs-gma-*-android-extension-project.zip` archive into a directory of your choice (*my_project_dir*).
3. From Android Studio, open the project from *my_project_dir*.
4. In the project definition, under the "`extension`" library, find `AndroidManifest.xml` and modify the "`package`" attribute of the "`manifest`" node. This package name identifies your extension library, it will not be used to build a final app in GST.
5. Add your Java sources to this Android Studio project, under the "`extension`" library.
6. Locate the `testapp` app in the project.

   This is a sample activity that can be customized, to test your GMA extension directly within the Android Studio environment.
7. Modify `testapp`, to call your extension (see code for details), build and run for testing.
8. Build the project in release mode.

   This creates the `extension.jar` file and a `fjs-gma-.*-scaffolding.zip` archive, containing the `.aar` Android libraries. The files are created under the *my_project_dir*`/extension/build/outputs` directory.
9. Unzip the new GMA binary archive (`fjs-gma-.*-scaffolding.zip`) into a temporary directory (*my_tmp_dir*).

10. Locate the `gradlew` script from the unzipped GMA binary archive (*my_tmp_dir*).
11. Execute the command `gradlew build`.

    This will create the new `.apk` packages of GMA. The `.apk` files are created in the *`my_tmp_dir`*`/app/build/outputs` directory.
12. Create a new directory (*my_gma_dir*).
13. Copy the new `*-scaffolding.zip` file, the `extension.jar` and the `.apk` packages to *my_gma_dir*.
14. Modify the CLASSPATH configuration variable in Genero Studio, to find the `extension.jar` file.

    This is required to let the Genero compiler find your Java classes.
15. When using Genero Studio, modify the GMADIR configuration variable to point to the *my_gma_dir* directory.This is required to let Genero Studio use your customized GMA binary to build apps. When using gmabuildtool to build apps from the command line, provide the custom GMA Android project directory with the `--build-project-folder-path` option.
16. Deploy the new GMA apk on the device, for client/server development purpose.

    When using Genero Studio, the IDE will find the .apk packages to be installed on the device from GMADIR.

Examples

Example 1: Using the regex package

```
IMPORT JAVA java.util.regex.Pattern
IMPORT JAVA java.util.regex.Matcher
MAIN
  DEFINE p Pattern
  DEFINE m Matcher
  LET p = Pattern.compile("[a-z]+,[a-z]+")
  DISPLAY p.pattern()
  LET m = p.matcher("aaa,bbb")
  IF m.matches() THEN
    DISPLAY "The string matches the pattern..."
  ELSE
    DISPLAY "The string does not match the pattern..."
  END IF
END MAIN
```

Example 2: Using the Apache POI framework

This example shows how to create an XLS file, using the Apache POI framework. You must download and install the Apache POI JAR file and make the CLASSPATH environment variable point to the POI JAR in order to compile and run this example. After execution, you should find a file named "itemlist.xls" in the current directory, which can be loaded with Microsoft™ Excel or Open Office Calc:

```
IMPORT JAVA java.io.FileOutputStream
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFWorkbook
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFSheet
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFRow
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFCell
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFCellStyle
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFFont
IMPORT JAVA org.apache.poi.ss.usermodel.IndexedColors

MAIN
    DEFINE fo FileOutputStream
    DEFINE workbook HSSFWorkbook
    DEFINE sheet HSSFSheet
```

```
    DEFINE row HSSFRow
    DEFINE cell HSSFCell
    DEFINE style HSSFCellStyle
    DEFINE headerFont HSSFFont
    DEFINE i, id INTEGER, s STRING

    LET workbook = HSSFWorkbook.create()

    LET style = workbook.createCellStyle()
    CALL style.setAlignment(HSSFCellStyle.ALIGN_CENTER)
    CALL style.setFillForegroundColor(
                IndexedColors.LIGHT_CORNFLOWER_BLUE.getIndex());
    CALL style.setFillPattern(HSSFCellStyle.SOLID_FOREGROUND);
    LET headerFont = workbook.createFont()
    CALL headerFont.setBoldweight(HSSFFont.BOLDWEIGHT_BOLD)
    CALL style.setFont(headerFont);

    LET sheet = workbook.createSheet()

    LET row = sheet.createRow(0)
    LET cell = row.createCell(0)
    CALL cell.setCellValue("Item Id")
    CALL cell.setCellStyle(style)
    LET cell = row.createCell(1)
    CALL cell.setCellValue("Name")
    CALL cell.setCellStyle(style)

    FOR i=1 TO 10
        LET row = sheet.createRow(i)
        LET cell = row.createCell(0)
        CALL cell.setCellType(HSSFCell.CELL_TYPE_NUMERIC)
        LET id = 100 + i
        CALL cell.setCellValue(id)
        LET cell = row.createCell(1)
        LET s = SFMT("Item #%1",i)
        CALL cell.setCellValue(s)
    END FOR

    LET fo = FileOutputStream.create("itemlist.xls");
    CALL workbook.write(fo);
    CALL fo.close();

END MAIN
```

Example 3: Using Java on Android™

This example shows how to access Android™ components throught Java, it includes:

- Access to the JDK API to get the number of cores on your device.
- Access to Android™ APIs to get the screen dimension, the device manufacturer and model (with no need for any additional authorization)
- Access to the Bluetooth stack to list the paired devices.

> **Note:** In your GM project, you need to ask for BLUETOOTH authorization.

C-Extensions

With *C-Extensions*, you can bind your own C libraries in the runtime system, to call C function from the application code.

- Understanding C-Extensions on page 1597
- Header files for ESQL/C typedefs on page 1598
- Creating C-Extensions on page 1598

- Calling program functions from C on page 1610
- Sharing global variables on page 1611
- Simple C-Extension example on page 1612
- Implementing C-Extensions for GMI on page 1613

Understanding C-Extensions

With *C-Extensions*, you can bind your own C libraries in the runtime system, to call C function from the application code. This feature allows you to extend the language with custom libraries, or existing standard libraries, by writing some 'wrapper functions' to interface with the Genero language.

On regular platforms, C-Extensions are implemented with shared libraries, that will be loaded by the fglrun program on demand.

> **Note:** Platforms such as iOS mobile devices deny to load shared libraries. In this case, you must re-link the virtual machine. For more details, see Implementing C-Extensions for GMI on page 1613.

Function parameters and returned values are passed/returned on the runtime stack, using pop/push functions. Be sure to pop and push the exact number of parameters/returns expected by the caller; otherwise, a fatal stack error will be raised at runtime.

In order to use a C-Extension in your program, you typically specify the library name with the `IMPORT` instruction at the beginning of the module calling the C-Extension functions. The compiler can then check for function existence and the library will be automatically loaded at runtime.

> **Note:**
>
> - The C code written in C-Extensions is usually platform specific and does not ease the migration of your application to a different operating system, especially when doing a lot of system calls.

Additionally, C data types that are defined differently according to the processor architecture (32 / 64 bits issues) can also be an issue.

- Make sure that the functions defined in your C-Extensions do not conflict with program functions. In case of conflict, you will get a compiler or a runtime error, according to the loading technique used.

Header files for ESQL/C typedefs

To compile C-Extensions using complex data types such as `DECIMAL`, `DATETIME/INTERVAL` or `BYTE/TEXT`, you need IBM® Informix® ESQL/C data type structure definitions such as `dec_t`, `dtime_t`, `intrvl_t`, as well as macros like `DECLEN()` or `TU_ENCODE()`. These definitions are not required if you use standard C types such as short, `int` or `char[]`.

The definition of the ESQL/C structures like `dec_t` are property of IBM®. However, a copy of the ESQL/C header files used during the port of Genero are distributed in `FGLDIR/include/esql`, with agreement from IBM®.

Some ESQL/C type definitions are platform specific. For example, the `mlong` typedef is different on 32-bit and 64-bit machines.

Creating C-Extensions

Custom C-Extensions must be provided to the runtime system as Shared Objects (.so) on UNIX™, and as Dynamically Loadable Libraries (.DLL) on Windows™.

In order to create a C-Extension, you must:

1. Define the list of user functions in the C interface file, by including the `fglExt.h` header file.
2. Compile the C interface file with your C compiler.
3. Modify your C source modules by including the `fglExt.h` header file.
4. Compile the C interface file and the C modules with the position-independent code option.
5. Create the shared library with the compiled C interface file and C modules by linking with the `libfgl` runtime system library.

Include the `fglExt.h` header file in the following way:

```
#include "f2c/fglExt.h"
```

When migrating from IBM® Informix® 4GL, it is possible that existing C-Extension sources include Informix® specific headers like `sqlhdr.h` or `decimal.h`. You can either remove or keep the original includes, but if you want to keep them, the Informix® specific header files must be included before the `fglExt.h` header file, in order to let `fglExt.h` detect that typedefs such as `dec_t` or `dtime_t` are already defined by Informix® headers. If you include Informix® headers after `fglExt.h`, you will get a compilation error. As `fglExt.h` defines all Informix-like typedef structures, you can remove the inclusion of Informix® specific header files.

The C functions that are implemented in the C-Extension libraries must be known by the runtime system. To do so, each C-Extension library must publish its functions in a `UsrFunction` array, which is read by the runtime system when the module is loaded. The `UsrFunction` array describes the user functions by specifying the name of the function, the C function pointer, the number of parameters and the number of returned values. You typically define the `UsrFunction` array in the C interface file.

After compiling the C sources, you must link them together with the `libfgl` runtime system library.

Carefully read the man page of the ld dynamic loader, and any documentation of your operating system related to shared libraries. Some platforms require specific configuration and command line options when linking a shared library, or when linking a program using a shared library (+s option on HP for example).

Linux™ command-line example:

```
gcc -c -I $FGLDIR/include -fPIC myext.c
```

```
gcc -c -I $FGLDIR/include -fPIC cinterf.c
gcc -shared -o myext.so myext.o cinterf.o -L$FGLDIR/lib -lfgl
```

Windows™ command-line example using Visual C 8.0 and higher (with SxS manifest for the DLL!):

```
cl /DBUILDDLL /I%FGLDIR%/include /c myext.c
cl /DBUILDDLL /I%FGLDIR%/include /c cintref.c
link /dll /manifest /out:myext.dll myext.obj cinterf.obj %FGLDIR%\lib
\libfgl.lib
mt -manifest myext.dll.manifest -outputresource:myext.dll
```

If you build your DLL with a version of Microsoft™ Visual C++ that is different from the version used to build FGLRUN.EXE, the DLL must get private dependencies other than the process default. For example, when the C-Extension DLL needs the Visual C 9.0 runtime library MSVCR90.DLL, while the FGLRUN.EXE was build with VC 10 and needs MSVCR100.DLL. Private dependencies is specified with the resource id `ISOLATIONAWARE_MANIFEST_RESOURCE_ID`, by adding the **;2** modifier at the end of the `-outputresource` option, after the filename:

```
mt -manifest myext.dll.manifest -outputresource:myext.dll;2
```

To simplify compilation and linking of a C-Extension library, it is also possible to use the fglmkext command line tool:

```
fglmkext -o myext.so module_a.c module_b.c
```

> **Note:** The fglmkext command line tool contains platform-specific C compiler and linker options required to build a C Extension library.

Creating Informix® ESQL/C Extensions

C-Extension libraries can be created from ESQL/C sources, as long as you have an Informix® ESQL/C compiler which is compatible with your Genero runtime system.

In order to create a C-Extension from ESQL/C sources, you must:

1. Define the list of user functions in the C interface file, by including the `fglExt.h` header file.
2. Compile the C interface file with your C compiler.
3. Modify your ESQL/C source modules by including the `fglExt.h` header file.
4. Compile the ESQL/C modules with the `esql` compiler, with the position-independent code option.
5. Create the shared library with the compiled C interface file and ESQL/C modules by linking with the `libfgl` runtime system library, and with the ESQL/C libraries (`esql -libs`), to resolve the ESQL/C symbols.

Include the `fglExt.h` header file in the following way:

```
#include "f2c/fglExt.h"
```

You can compile .ec extensions with the native Informix® esql compiler. This section describes how to use the Informix® esql compiler.

The following example shows how to compile and link an extension library with Informix® esql compiler:

Linux™ command-line example:

```
esql -c -I$FGLDIR/include myext.ec
gcc -c -I$FGLDIR/include -fPIC cinterf.c
gcc -shared -o myext.so myext.o cinterf.o -L$FGLDIR/lib -lfgl \
    -L$INFORMIXDIR/lib -L$INFORMIXDIR/lib/esql `esql -libs`
```

Windows™ command-line example (using Microsoft™ Visual C++):

```
esql -c myext.ec -I%FGLDIR%/include
cl /DBUILDDLL /I%FGLDIR%/include /c cintref.c
esql -target:dll -o myext.dll myext.obj cinterf.obj %FGLDIR%\lib\libfgl.lib
```

When using Informix® esql, you link the extension library with Informix® client libraries. These libraries will be shared by the extension module and the Informix® database driver loaded by the Genero runtime system. Since both the extension functions and the runtime database driver use the same functions to execute SQL queries, you can share the current SQL connection opened in the Genero program to execute SQL queries in the extension functions. However, mixing connection management instructions (`DATABASE`, `CONNECT TO`) as well as database creation can produce unexpected results. For example you cannot do a `CREATE DATABASE` in your ESQL/C extension, and expect that the main program can use this database to execute SQL statements.

The C interface file

To make your C functions visible to the runtime system, you must define all the functions in the *C interface file*.

The *C interface file* is a C source file that defines the `usrFunctions` array. This array defines C functions that can be called from programs.

The last record of the `usrFunctions` array must be a line with all the elements set to NULL/0, to define the end of the list.

Each element of the `usrFunctions` array must be filled following members:

1. The first member is the name of the function, provided as a `(const char *)` character string.
2. The second member is the C function symbol, provided as an `(int (*function) (int))` C function pointer.
3. The third member is the number of parameters passed to the function through the runtime stack, provided as an `(int)`.
4. The fourth member is the number of values returned by the function, provided as an `(int)`; use -1 to specify a variable number of arguments.

You typically do a forward declaration of your C functions, before the `usrFunctions` array initializer:

```
#include "f2c/fglExt.h"

int c_init(int);
int c_set_trace(int);
int c_get_message(int);

UsrFunction usrFunctions[]={
  { "init",         c_init,         0, 0 },
  { "set_trace",    c_set_trace,    1, 0 },
  { "get_message",  c_get_message,  1, 1 },
  { NULL,           NULL,           0, 0 }
};
```

Note that the `UsrFunction` structure contains an additional member, dedicated for internal use. If you experience compiler warnings because of un-initialized structure members, simply complete the C function definitions with a fifth zero value:

```
/* Avoids C compiler warnings because of un-initialized structure members */

UsrFunction usrFunctions[]={
  { "init",         c_init,         0, 0, 0 },
            /* member for internal use ---^ */
  ...
```

Linking programs using C-Extensions

When creating a 42r program or 42x library, the linker needs to resolve all function names, including C-Extension functions.

If extension modules are not specified explicitly in the source files with the `IMPORT` directive, you must give the extension modules with the `-e` option in the command line:

```
fgllink -e myext1,myext2,myext3 -o myprog.42r moduleA.42m moduleB.42m ...
```

The `-e` option of fgllink does not write C-Extension references into the .42r file. If you use the `-e` argument with the fgllink command, you must also use the `-e` argument with the fglrun command, in order to load the libraries at runtime.

The `-e` option is not needed when using the default `userextension` module, or if C-Extensions are specified with the `IMPORT` directive.

Loading C-Extensions at runtime

The runtime system can load several C-Extensions libraries, allowing you to properly split your libraries by defining each group of functions in separate C interface files.

> **Note:** When running iOS platforms, the C-Extensions are linked statically to the GMI application.

Directories are searched for the C-Extensions libraries according to the FGLLDPATH environment variable rules. See the environment variable definition for more details.

If the C-Extension library depends on other shared libraries, make sure that the library loader of the operating system can find theses shared objects: You may need to set the LD_LIBRARY_PATH environment variable on UNIX™ or the PATH environment variable on Windows™ to point to the directory where these other libraries are located.

There are three ways to bind a C-Extension with the runtime system:

1. Using the `IMPORT` instruction in sources.
2. Using the default C-Extension name.
3. Using the `-e` option of fglrun.

Using the IMPORT instruction

The `IMPORT` instruction allows you to declare an external module in a .4gl source file. It must appear at the beginning of the source file.

The name of the module specified after the `IMPORT` keyword is converted to lowercase by the compiler. Therefore it is recommended to use lowercase file names only.

The compiler and the runtime system automatically know which C-Extensions must be loaded, based on the `IMPORT` instruction:

```
IMPORT mylib1
MAIN
  CALL myfunc1("Hello World")  -- C function defined in mylib1
END MAIN
```

When the `IMPORT` instruction is used, no other action has to be taken at runtime. The module name is stored in the 42m p-code and is automatically loaded when needed.

Using the default C-Extension name

All modules using a function from a C-Extension should now use the `IMPORT` instruction, however this could be a major change to existing sources.

To simplify migration of existing C-Extensions, the runtime system loads by default a module with the name `userextension`. Create this shared library with your existing C-Extensions, and the runtime system will load it automatically if it is in the directories specified by FGLLDPATH.

Using the -e fglrun option

In some cases you need several C-Extension libraries, which are used by different group of programs, so you can't use the default `userextension` solution. However, you don't want to review all your sources in order to use the `IMPORT` instruction.

You can specify the C-Extensions to be loaded by using the `-e` option of fglrun. The `-e` option takes a comma-separated list of module names, and can be specified multiple times in the command line. The next example loads five extension modules:

```
fglrun -e myext1,myext2,myext3 -e myext4,myext5 myprog.42r
```

By using the `-e` option, the runtime system loads the modules specified in the command line instead of loading the default `userextension` module.

Runtime stack functions

To pass values between a C function and a program, the C function and the runtime system use the runtime stack.

Stack function basics

The parameters passed to the C function must be popped from the stack at the beginning of the C function, and the return values expected by the Genero BDL call must be pushed on the stack before leaving the C function.

The `int` parameter of the C function defines the number of input parameters passed on the stack, and the function must return an `int` value defining the number of values returned on the stack.

> **Note:** If you don't pop / push the specified number of parameters / return values, you corrupt the stack and get a fatal error.

Pop parameters from the stack

The runtime system library includes a set of functions to retrieve the values passed as parameters on the stack. This table shows the library functions provided to pop values from the stack into C buffers:

Table 342: Library functions provided to pop values from the stack into C buffers

Function	Data type	Details
`void popdate(int4 *dst);`	`DATE`	4-byte integer value corresponding to days since12/31/1899.
`void popint(mint *dst);`	`INTEGER`	System dependent integer value (int)
`void popshort(int2 *dst);`	`SMALLINT`	2-byte integer value
`void poplong(int4 *dst);`	`INTEGER`	4-byte integer value
`void popflo(float *dst);`	`SMALLFLOAT`	4-byte floating point value
`void popdub(double *dst);`	`FLOAT`	8-byte floating point value

Function	Data type	Details
`void popdec(dec_t *dst);`	`DECIMAL`	See structure definition in `$FGLDIR/include/f2c headers`
`void popquote(char *dst, int size);`	`CHAR(n)`	The `size` parameter defines the size of the char buffer (with the '\0'). The trailing blanks are kept.
`void popvchar(char *dst, int size);`	`VARCHAR(n)`	The `size` parameter defines the size of the char buffer (with the '\0'). The trailing blanks are kept.
`void popstring(char *dst, int size);`	`VARCHAR(n)`	The `size` parameter defines the size of the char buffer (with the '\0'). This function trims all the trailing spaces, even the last one. There is no way to distinguish from NULL if the string has only spaces.
`void popdtime(dtime_t *dst, int size);`	`DATETIME`	See structure definition in `$FGLDIR/include/f2c headers` `size = TU_DTENCODE(start, end)`
`void popinv(intrvl_t *dst, int size);`	`INTERVAL`	See structure definition in `$FGLDIR/include/f2c headers` `size = TU_IENCODE(len, start, end)`
`void poplocator(loc_t **dst);`	`BYTE`, `TEXT`	See structure definition in `$FGLDIR/include/f2c headers` **Important:** this function pops the pointer of a `loc_t` object!

When using a pop function, the value is copied from the stack to the local C variable and the value is removed from the stack.

In a Genero program, strings (`CHAR`, `VARCHAR`) are not terminated by `'\0'`. Therefore, the C variable must have one additional character to store the `'\0'`. For example, the equivalent of a `VARCHAR(100)` in Genero BDL programs is a `char x[101]` in C.

Stack introspection

A set of C API functions are provided to query information on the parameters passed on the stack to a C function. Query for the parameter type and the actual size of a character string value, to adapt the buffer receiving the parameter.

Table 343: Library functions to introspect the runtime stack

Function	Description
`const char *fglcapi_peekStackType(void)`	Returns the type name of the topmost value on the stack as a string. For example, if the value on the stack is a CHAR(100), the function returns the string "CHAR(100)". **Note:** If the current value on the stack is a string literal ("foo") then the type name is "STRING" not "CHAR(3)".
`int fglcapi_peekStackBufferSize(void)`	Returns the proposed size of a C char buffer, when getting character strings from the stack with a pop* function. String pop functions such as popquote() and popvchar() require a C char buffer to be allocated. To allocate the buffer dynamically, use the fglcapi_peekStackBufferSize() function to get the actual size of the string parameter passed on the stack. Allocating char buffers with the proposed size avoids truncating values returned from the stack. **Important:** The size returned by this function depends on the encoding (LC_CTYPE) and the character length semantics. For example, assuming the value passed on the stack is a CHAR(100), the function returns: • 101 (100 + 1) when using byte semantics. • 301 (3 * 100 + 1) when using UTF-8 and character length semantics. See Length semantics settings on page 314 for more details about these concepts.

Stack introspection example:

```
int my_function(int n)
{
    int sz;
    char *buf;
    sz = fglcapi_peekStackBufferSize();
    buf = malloc(sz);
    popstring(buf, sz);
    // ...
```

```
    free(buf);
    return 0;
}
```

Push returns on the stack

To return a value from the C function, you must use one of the functions provided in the runtime system library.

Table 344: Functions provided in the runtime system library to return a value from a C function

Function	Data type	Details
`void pushdate(int4 val);`	`DATE`	4-byte integer value corresponding to days since12/31/1899.
`void pushdec(const dec_t *val, const unsigned decp);`	`DECIMAL`	See structure definition in `$FGLDIR/include/f2c headers`
`void pushint(mint val);`	`INTEGER`	System dependent integer value (int)
`void pushlong(int4 val);`	`INTEGER`	4-byte integer value
`void pushshort(int2 val);`	`SMALLINT`	2-byte integer value
`void pushflo(float *val);`	`SMALLFLOAT`	4-byte floating point value. **Important:** This function takes a pointer!
`void pushdub(double *val);`	`FLOAT`	8-byte floating point value. **Important:** This function takes a pointer!
`void pushquote(const char *val, int len);`	`CHAR(n)`	len = strlen(val) (without '\0')
`void pushvchar(const char *val, int len);`	`VARCHAR(n)`	len = strlen(val) (without '\0')
`void pushdtime(const dtime_t *val);`	`DATETIME`	See structure definition in `$FGLDIR/include/f2c headers`
`void pushinv(const intrvl_t *val);`	`INTERVAL`	See structure definition in `$FGLDIR/include/f2c headers`

When using a push function, the value of the C variable is copied at the top of the stack; therefore the scope and lifespan of the C variable does not matter.

To simplify migration of IBM I4GL legacy C extensions using `ret*()` style functions, Genero supports the following synonyms:

Table 345: Return value functions synonyms

Function	Equivalent
`void retdate(int4 val)`	`pushdate`
`void retdec(const dec_t *val)`	`pushdec`
`void retmoney(const dec_t *val)`	`pushdec`
`void retint(int val)`	`pushint`
`void retlong(int4 val)`	`pushlong`
`void retshort(int2 val)`	`pushshort`
`void retflo(float *val)`	`pushflo`
`void retdub(double *val)`	`pushdub`
`void retquote(const char *val)`	`pushquote`
`void retstring(const char *val)`	`pushquote`
`void retvchar(const char *val)`	`pushvchar`
`void retdtime(const dtime_t *val)`	`pushdtime`
`void retinv(const intrvl_t *val)`	`pushinv`

Note: Pay attention to the `retdec()`, `retmoney()`, `retquote()` and `retvchar()` functions. These do not have the same signature as the equivalent `push*()` functions.

C-Extension data types and structures

C types are used to write C-Extensions.

The following C types are used to write C-Extensions.

Table 346: C types used to write C-Extensions

Type name	Description
`int4`	signed integer with a size of 4 bytes
`uint4`	unsigned integer with a size of 4 bytes
`int2`	signed integer with a size of 2 bytes
`uint2`	unsigned integer with a size of 2 bytes
`int1`	signed integer with a size of 1 byte
`uint1`	unsigned integer with a size of 1 byte
`mint`	signed machine-dependent C int
`muint`	unsigned machine-dependent C int
`mlong`	signed machine-dependent C long
`mulong`	unsigned machine-dependent C long
`dec_t`	`DECIMAL` data type structure
`dtime_t`	`DATETIME` data type structure
`intrvl_t`	`INTERVAL` data type structure

Type name	Description
loc_t	TEXT / BYTE locator structure

Basic data types

Basic data types such as bigint, int4 and int2 are provided to define variables that must hold BIGINT (bigint), SMALLINT (int2), INTEGER (int4) and DATE (int4) values. Standard char array can be used to hold CHAR and VARCHAR data.

DATE

No specific typedef exists for the DATE type; you can use the int4 type to store a DATE value.

DECIMAL/MONEY

The dec_t structure is provided to hold DECIMAL and MONEY values.

The internals of dec_t structure can be ignored during C-Extension programming, because decimal API functions are provided to manipulate any aspects of a decimal.

DATETIME

The dtime_t structure holds a DATETIME value.

Before manipulating a dtime_t, you must initialize its qualifier qt_qual, by using the TU_DTENCODE macro:

```
dtime_t dt;
dt.dt_qual = TU_DTENCODE(TU_YEAR, TU_SECOND);
dtcvasc( "2004-02-12 12:34:56", &dt );
```

INTERVAL

The intrvl_t structure holds an INTERVAL value.

Before manipulating a intrvl_t, you must initialize its qualifier in_qual, by using the TU_IENCODE macro:

```
intrvl_t in;
in.in_qual = TU_IENCODE(5, TU_YEAR, TU_MONTH);
incvasc( "65234-02", &in );
```

TEXT/BYTE Locator

The loc_t structure is used to declare host variables for a TEXT/BYTE values (simple large objects). Because the potential size of the data can be quite large, this is a locator structure that contains information about the size and location of the TEXT/BYTE data, rather than containing the actual data.

Table 347: Fields of the loc_t structure

Field name	Data type	Description
loc_indicator	int4	Null indicator; a value of -1 indicates a null TEXT/BYTE value. Your program can set the field to indicate the insertion of a null value. Database client libraries

Field name	Data type	Description
		set the value for selects and fetches.
loc_type	int4	data type - SQLTEXT (for TEXT values) or SQLBYTES (for BYTE values).
loc_size	int4	Size of the TEXT/BYTE value in bytes; your program sets the size of the large object for insertions. Database client libraries set the size for selects and fetches.
loc_loctype	int2	Location - LOCMEMORY (in memory) or LOCFNAME (in a named file). Set loc_loctype after you declare the locator variable and before this declared variable receives the large object value.
loc_buffer	char *	If loc_loctype is LOCMEMORY, this is the location of the TEXT/BYTE value; your program must allocate space for the buffer and store its address here.
loc_bufsize	int4	If loc_loctype is LOCMEMORY, this is the size of the buffer loc_buffer; If you set loc_bufsize to -1, database client libraries will allocate the memory buffer for selects and fetches. Otherwise, it is assumed that your program will handle memory allocation and de-allocation.
loc_fname	char *	If loc_loc_type is LOCFNAME, this is the address of the pathname string that contains the file.

Example

```
loc_t *pb1
double ratio;
char *source = NULL, *psource = NULL;
int size;

if (pb1->loc_loctype == LOCMEMORY) {
    psource = pb1->loc_buffer;
    size = pb1->loc_size;
} else if (pb1->loc_loctype == LOCFNAME) {
    int fd;
    struct stat st;
    fd = open(pb1->loc_fname, O_RDONLY);
    fstat(fd, &st);
```

```
    size = st.st_size;
    psource = source = (char *) malloc(size);
    read(fd, source, size);
    close(fd);
}
```

Calling C functions from programs

C-Extensions functions can be called from the program in the same way that you call a BDL function.

The C functions that can be called from programs must use the following signature:

```
int function-name( int )
```

Here *function-name* must be written in lowercase letters. The fglcomp compiler converts all BDL functions names (following a CALL keyword) to lowercase.

The C function must be declared in the `usrFunctions` array in the C interface file.

> **Important:** Parameters and return values must be pushed/popped on the runtime stack, by using the stack functions. Parameters passed to the C function must be popped in the reverse order of the BDL call list: `CALL c_fct( A, B, C ) => pop C, B, A`. However, values returned from the C function must be pushed in the same order as in the BDL returning clause: `push A, B, C => CALL c_fct() RETURNING A, B, C`.

In the next code example, the C-Extension module `mycext.c` defines the `c_fct()` function:

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#include "f2c/fglExt.h"

int c_fct( int n );

UsrFunction usrFunctions[]={
  {"c_fct",c_fct,2,2},
  {0,0,0,0}
};

int c_fct( int n )
{
   int rc;
   float price;
   char name[31];
   if (n != 2) exit(1);
   popflo(&price);
   popvchar(name, sizeof(name));
   printf(">> [%s] price:%f\n", name, price);
   pushint( strlen(name) );
   price = price * 2;
   pushflo( &price );
   return 0;
}
```

The C-Extension library is imported by the BDL module with `IMPORT`:

```
IMPORT mycext

MAIN
    DEFINE len INT, price2 FLOAT
    CALL c_fct("Hand gloves", 120.50)
```

```
          RETURNING len, price2
    DISPLAY "len = ", len
    DISPLAY "price2 = ", price2
END MAIN
```

Compilation and execution example on a Linux system:

```
$ gcc -I $FGLDIR/include -shared -fPIC -o mycext.so mycext.c

$ fglcomp myprog.4gl

$ fglrun myprog.42m
>> [Hand gloves] price:120.500000
len =          11
price2 =                   241.0
```

Calling program functions from C

It is possible to call an BDL function from a C-Extension function.

To call an BDL function from a C-Extension function, use the `fgl_call` macro:

```
fgl_call ( function-name, nb-params );
```

In this call, *function-name* is the name of the program function to call, and *nb-params* is the number of parameters pushed on the stack for the program function. The *function-name* must be written in lowercase letters; The fglcomp compiler converts all program functions names to lowercase.

The `fgl_call()` macro is converted to a function that returns the number of values returned on the stack.

> **Important:** Parameters and return values must be pushed/popped on the runtime stack, by using the stack functions. Parameters passed to the BDL function must be pushed in the same order as the BDL parameter list: `push A, B, C => FUNCTION fct( A, B, C )`. However, values returned from the BDL function must be popped in the reverse order of the BDL return clause: `RETURN A, B, C => pop C, B, A`.

The `myprog.4gl` BDL module defining the `MAIN` block and the `display_item()` function to be called from the C extension:

```
IMPORT mycext

MAIN
    CALL c_fct()
END MAIN

FUNCTION display_item(name, size)
   DEFINE name VARCHAR(30), size INTEGER
   DISPLAY name, size
   RETURN length(name), (size / 100)
END FUNCTION
```

The `mycext.c` C extension module calling the BDL function:

```
#include <stdlib.h>
#include <stdio.h>

#include "f2c/fglExt.h"

int c_fct( int n );

UsrFunction usrFunctions[]={
  {"c_fct",c_fct,0,0},
```

```
  {0,0,0,0}
};

int c_fct( int n )
{
   int rc, len;
   float size2;
   if (n != 0) exit(1);
   pushquote("Hand gloves", 11);
   pushint(54);
   rc = fgl_call( display_item, 2 );
   if (rc != 2) exit(1);
   popflo(&size2);
   popint(&len);
   printf(">> %d %f\n", len, size2);
   return 0;
}
```

Compilation and execution example on a Linux system:

```
$ gcc -I $FGLDIR/include -shared -fPIC -o mycext.so mycext.c

$ fglcomp myprog.4gl

$ fglrun myprog.42m
Hand gloves         54
>> 11 0.540000
```

Sharing global variables

While not recommended, you can share global variables declared in your program with a C module.

In order to share the global variables declared in your program, you must:

1. Generate the .c and .h interface files by using `fglcomp -G` with the module defining the global variables:

   ```
   GLOBALS
   DEFINE g_name CHAR(100)
   END GLOBALS
   ```

   ```
   fglcomp -G myglobals.4gl
   ```

   This will produce two files named `myglobals.h` and `myglobals.c`.
2. In the C module, include the generated header file and use the global variables directly:

   ```
   #include <string.h>
   #include "f2c/fglExt.h"
   #include "myglobals.h"

   int myfunc1(int c)
   {
      strcpy(g_name, "new name");
      return 0;
   }
   ```
3. When creating the C-Extension library, compile and link with the `myglobals.c` generated file.

   Tip: Using global variables is not recommended. It makes your code difficult to maintain. If you need persistent variables, use module variables and write set/get functions that you can interface with.

Simple C-Extension example

This example shows how to create a C-Extension library on Linux™ using gcc.

The command line options to compile and link shared libraries can change depending on the operating system and compiler/linker used.

The "split.c" file

```
#include <string.h>
#include "f2c/fglExt.h"

int fgl_split( int in_num );
int fgl_split( int in_num )
{
       char c1[101];
       char c2[101];
       char z[201];
       char *ptr_in;
       char *ptr_out;
       popvchar(z, 200); /* Getting input parameter */
       strcpy(c1, "");
       strcpy(c2, "");
       ptr_out = c1;
       ptr_in = z;
       while (*ptr_in != ' ' && *ptr_in != '\0')
       {
              *ptr_out = *ptr_in;
              ptr_out++;
              ptr_in++;
       }
       *ptr_out=0;
       ptr_in++;
       ptr_out = c2;
       while (*ptr_in != '\0')
       {
              *ptr_out = *ptr_in;
              ptr_out++;
              ptr_in++;
       }
       *ptr_out=0;
       pushvchar(c1, 100); /* Returning the first output parameter */
       pushvchar(c2, 100); /* Returning the second output parameter */
       return 2; /* Returning the number of output parameters (MANDATORY) */
}
```

The "splitext.c" C interface file

```
#include "f2c/fglExt.h"

int fgl_split(int);

UsrFunction usrFunctions[]={
  { "fgl_split", fgl_split, 1, 2 },
  { 0,0,0,0 }
};
```

Compile the C Module and the interface file

```
gcc -c -I $FGLDIR/include -fPIC split.c
```

```
gcc -c -I $FGLDIR/include -fPIC splitext.c
```

Create the shared library

```
gcc -shared -o libsplit.so split.o splitext.o -L$FGLDIR/lib -lfgl
```

The program "split.4gl"

```
IMPORT libsplit
MAIN
      DEFINE str1, str2 VARCHAR(100)
      CALL fgl_split("Hello World") RETURNING str1, str2
      DISPLAY "1: ", str1
      DISPLAY "2: ", str2
END MAIN
```

Compile the .4gl module

```
fglcomp split.4gl
```

Run the program without the -e option

```
fglrun split
```

Implementing C-Extensions for GMI

This section describes how to program C-Extensions for the GMI VM.

C-Extensions for GMI

With C-Extensions for GMI, you can address specific needs on iOS platforms, that are not available by default in the Genero language. For example, implement functions to interface with mobile specific hardware like sensors, card readers, scanners, bluetooth, etc.

The runtime system virtual machine build in the GMI for iOS platforms can be extended with the C-Extension technology. The basics to implement C-Extensions are the same for iOS as for Unix/Windows platforms, but there are some differences, explained in this section.

The main difference is that user libraries cannot be loaded dynamically on iOS and thus require a re-link of the GMI binary with the user-defined C-Extension library.

Writing C-Extension sources for GMI

C-Extension source files can be organized in several `.c` or `.m` files, but the final library name must be `userextension`.

For a first test, we recommend that you group all your C-Extension functions in a single sources file called `userextension.m`.

In the Objective C source file, you should add the following lines, to include typical iOS header files:

```
#include <Foundation/Foundation.h>
#include <UIKit/UIKit.h>
```

The Genero runtime system header file must be included as well:

```
#include "f2c/fglExt.h"
```

The C-Extension functions must be registered as usual, in a `UsrFunction` array, defining the number of input and output parameters:

```
UsrFunction usrFunctions[]={
  {"get_user_info",get_user_info,1,1},
  ...
  {NULL,NULL,0,0}
};
```

Using iOS C-Extensions in your program

The application code needs to be compiled on the development platform before it is deployed on the iOS device or simulator, by using the C-Extension library build for the development platform.

In your Genero program, import the C-Extension module with `IMPORT` userextension. You can also omit this `IMPORT` instruction, because the runtime system tries to find and load the `userextension` library by default. Note also that C-Extension function have a global scope, so you can omit to prefix the function name with the lib/module name:

```
IMPORT userextension
MAIN
   DEFINE info STRING
   LET info = get_user_info()
   ...
END MAIN
```

Compiler behavior regarding `IMPORT userextension` usage:

- With `IMPORT userextension`: The compiler can check references to functions defined in the extension. The programmer can qualify a function-name as `userextension.`*`function-name`*. But in this case, the `userextension.so` shared library must exist on the development platform.
- Without `IMPORT userextension`: The compiler can not check references to those functions. The compiler does not load the `userextension` module implicitly. C-Extension function names can not be qualified. In this case, the `userextension.so` library is not required for compilation, but it will be needed if the final program is linked, or if you want to execute/test the application in client/server development mode.

Compiling and linking with C-Extensions on the development platform

On the development machine, if you link 42r programs, or if you want the compiler to check for missing symbols (with the `-r` option), the `userextension` library must exist in the development environment.

> **Note:** At runtime, on the development machine, the extension library will be loaded at first extension function call. But when the application is deployed on the iOS device, the extension library will be part of the GMI/VM binary (because it is statically linked).

To create the `userextension` library for the development environment, you must build an Objective-C shared library.

If the C-Extension contains iOS API calls, it will not be possible to compile the extension library as is on the development machine: Write conditional pre-processor macros to hide the iOS specific code, and simulate the function behavior for the development platform:

```
#ifndef EMULATE_IOS
#include <Foundation/Foundation.h>
#include <UIKit/UIKit.h>
#endif
...
int get_user_info(int pc)
{
    char prop[101];
```

```
    char value[101];
    int z = (int) sizeof(prop);
    assert(pc==1);
    popvchar(prop, z);
#ifndef EMULATE_IOS
    ... here goes the iOS specific code ...
#else
    value[0] = '\0';
#endif
    pushvchar(value, (int) strlen(value));
    return 1;
}
```

Command line example to create a shared library with the XCode environment (note that we define the NOT_IOS_IMPL constant to compile the code without iOS specific API calls):

```
$ cc -shared -o userextension.dylib userextension.c \
      -D EMULATE_IOS -I $FGLDIR/include -L $FGLDIR/lib -lfgl
```

Building the iOS app with C extensions

Regular mobile iOS apps are created with the gmibuildtool on page 2592 command-line tool. However, if you want to build an iOS app using C extensions, you must setup a `Makefile` calling the `FGLDIR/lib/Makefile-gmi` generic makefile.

For more details, see Building iOS apps with Genero on page 2586

User-defined front calls

Front-ends can be extended with custom functions to access specific features.

It is possible to implement custom front-end functions to interface with platform-specific features, and use the feature from a Genero program through a front call. For example, you can implement a front-end function module interfacing with a bar code reader, to return bar codes to the Genero program.

This section describes how to implement your own front calls by front-end type. Because each front-end type uses different technologies, you must use native platform APIs to implement front calls.

Implement front call modules for GDC

Custom front call modules for the desktop front-end are implemented by using the API for GDC front calls in C language.

GDC custom front call basics

In order to extend the GDC with your own front calls, you must be familiar with C++ programming, and have a C++ compiler installed on your development platform.

GDC front call modules must be implemented as a Dynamic Linked Library (.DLL) on Windows™ platforms, as a shared library (.so) on Linux™, or as a Dynamic Library (.dyLib) under Mac Os X. This shared library must be deployed on each platform where the GDC front-end executes.

The GDC is able to automatically load the front call module and find the function, based on the module name and function name used in the Genero BDL front call (`ui.Interface.frontCall`).

The API for GDC front calls is based on the `frontEndInterface` front call interface structure, that is used to interface with the GDC core, in order to pass/return values to/from a front call.

Follow these steps to implement a custom front call module for the GDC:

1. Create a C source to implement your front call functions.

2. In the front call functions body:
   a. Check the number of parameters passed with the `getParamCount()` function.
   b. Pop parameter values with one of the `pop*()` functions.
   c. Perform the function task.
   d. Push the result values with one of the `push*()` functions.
   e. Return 0 on success, -1 otherwise.
3. Compile and link the shared library.
4. Deploy the shared library to the platform where GDC executes.

The front call interface structure

Information required to execute the front call is transmitted to the extension module through the front call interface structure. This structure contains a list of function pointers to:

- manage the stack (push or pop for each handled data type)
- get information about the function (number of in and out parameters)
- get information about the front-end (front call environment variables)

The following defines the front call interface structure:

```
struct frontEndInterface
  {
      short (* getParamCount) ();
      short (* getReturnCount) ();
      void (* popInteger) (long &, short &);
      void (* pushInteger) (const long, short);
      void (* popString) (char *, short &, short &);
      void (* pushString) (const char *, short, short);
      void (* getFrontEndEnv) (const char *, char *, short &);
      void (* popWString) (wchar_t *, short &, short &);
      void (* pushWString) (const wchar_t*, short, short);
  };
```

Important: The front call interface structure is defined for the C++ language.

Prototype of a front call function implementation

The prototype of each front call function must be:

```
int function_name ( const struct frontEndInterface &fci );
```

1. *function_name* is the name of your function.
2. `fci` is the front call interface structure.

The `fci` structure will be filled by the GDC and passed to the custom function. You can then use this structure to pop/push values from/to the stack, and get environment information from the core GDC.

The function must return 0 on success, -1 otherwise.

Front call environment variables

The front call function can query the GDC for front call environment variables, to get information about the context.

The following front call environment variables are supported:

Table 348: Supported front call environment variables for the GDC

Environment Variable	Description
`frontEndPath`	The path where the GDC front-end is installed.

Module initialization and finalization

The font-call module can define initialization and finalization functions. GDC will automatically call these functions as follows:

- `void initialize();`

  This function is called when the front call module library is loaded. If needed, perform variable initialization and resource allocation in this function.
- `void finalize();`

  This function is called when the GDC front-end stops. If needed, perform resource release in this function.

The API for custom front call implementation

Table 349: Front call interface functions

Function	Description
`short getParamCount();`	This function returns the number of parameters given to the function called.
`short getReturnCount();`	This function returns the number of returning values of the function called.
`void ( * getFrontEndEnv ) (const char * name, char * value, short & length );`	This function is used to get context information from the front-end. • `name` is the name of the front call environment variable. • `value` is the char buffer to hold the value of the variable. • `length` is the actual length of the value.
`void popInteger( long & value, short & isNull );`	This function is used to get an integer from the stack. • `value` is the reference to where the popped integer will be set. • `isNull` indicates whether the parameter is null.
`void pushInteger( const long value, short isNull );`	This function is used to push an integer on the stack. • `value` is the value of the integer. • `isNull` indicates whether the value is null.
`void popString( char * value, short & length, short & isNull );`	This function is used to get a string from the stack. • `value` is the pointer where the popped string will be set. • `length` is the length of the string.

Function	Description
	• `isNull` indicates whether the parameter is null.

`void pushString(`
`  const char * value,`
`  short length,`
`  short isNull );`
	This function is used to push a string on the stack.
	• `value` is the value of the string.
	• `length` the length of the string. A length of -1 indicates that the length is detected based on the content of the string.
	• `isNull` indicates whether the parameter is null.

`void ( * popWString )`
`(wchar_t *value,`
`short & length,`
`short & isNull);`
	This function is used to get a WideChar string from the stack.
	• `value` is the pointer where the popped string will be set.
	• `length` is the length of the string.
	• `isNull` indicates whether the parameter is null.

`void ( * pushWString )`
`(wchar_t *value,`
`short length,`
`short isNull);`
	This function is used to push a WideChar string on the stack.
	• `value` is the value of the string.
	• `length` the length of the string. A length of -1 indicates that the length is detected based on the content of the string.
	• `isNull` indicates whether the parameter is null.

Calling the custom front call from BDL

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as the first parameter and the front call function name as second parameter. The front call module name is defined by the name of the dynamic library (*module_name*.DLL, *module_name*.so or *module_name*.dylib).

For example, if you implement a front call module with the name "mymodule.so", the Genero program code must use the name "`mymodule`" as front call module name:

```
CALL ui.Interface.frontCall("mymodule", "myfunction", ["John DOE"], [msg])
```

Deploying the custom front call module

The shared library implementing the custom front call functions must be deployed on the platform where the GDC executes: Copy your custom front call modules in the bin directory of the GDC installation directory (i.e. `%GDCDIR%\bin`). This is also true when the GDC is deployed as ActiveX over the GAS.

Example

This example implements a simple front call function that computes the sum of two integer numbers. It takes two parameters and returns two values.

`mymodule.h`:

```
struct frontEndInterface
  {
      short (* getParamCount) ();
      short (* getReturnCount) ();
      void (* popInteger) (long &, short &);
```

```
      void (* pushInteger) (const long, short);
      void (* popString) (char *, short &, short &);
      void (* pushString) (const char *, short, short);
      void (* getFrontEndEnv) (const char *, char *, short &);
      void (* popWString) (wchar_t *, short &, short &);
      void (* pushWString) (const wchar_t*, short, short);
  };

#ifdef WIN32
#define EXPORT extern "C" __declspec(dllexport)
#else
#define EXPORT extern "C"
#endif

EXPORT void initialize();
EXPORT void finalize();
EXPORT int mysum(const frontEndInterface &fx);
```

`mymodule.cpp`:

```
#include "mymodule.h"
#include <stdio.h>
#include <string.h>

void initialize() {
}

void finalize() {
}

int mysum(const struct frontEndInterface &fci) {
  long param1, param2;
  short isNull1, isNull2;
  long sum;
  char msg[255];

  if (fci.getParamCount() != 2 || fci.getReturnCount() != 2) {
      return -1;
  }

  fci.popInteger(param2, isNull2);
  fci.popInteger(param1, isNull1);

  sum = param1 + param2;

  if (!isNull1 && !isNull2) {
    sum = param1 + param2;
    sprintf(msg, "%d + %d = %d", param1, param2, sum);
  } else {
    sum = 0;
    sprintf(msg, "Parameters are NULL");
  }

  fci.pushInteger(sum, 0);
  fci.pushString(msg, strlen(msg), 0);

  return 0;
}
```

To invoke the sum front-end function, use the `ui.Interface.frontCall()` method in your Genero program:

```
MAIN
```

```
  DEFINE res INT, msg STRING
  MENU
    ON ACTION frontcall ATTRIBUTES(TEXT="Call custom front call")
      CALL ui.Interface.frontCall("mymodule", "mysum",
                                  [100,250], [res,msg])
      DISPLAY "Result: ", res, "\n", msg
    ON ACTION quit
      EXIT MENU
  END MENU
END MAIN
```

Implement front call modules for GMA

Custom front call modules for the Android™ front-end are implemented by using the API for GMA front calls in Java™.

GMA custom front call basics

In order to extend the GMA with your own front calls, you must be familiar with Java programming concepts, and if you want to interface with Android apps, understand concepts such as Android Activity and Intent.

The API for GMA front calls is based on the following Java interfaces:

- `com.fourjs.gma.extension.v1.IFunctionCallController`
- `com.fourjs.gma.extension.v1.IFunctionCall`

The front call function controller (`IFunctionCallController`) is implemented by the GMA, it is used to notify function call results, raise runtime exceptions and invoke activities.

The front call function body (`IFunctionCall`) implements the actual custom front call code.

The steps to implement an `IFunctionCall` class are:

1. Create a Java source file with the name of the front call function, for example: "`getPhoneId.java`", that will implementing the `IFunctionCall` interface.
2. Define the Java package name identifying the front call module, for example: "`package com.mycompany.utilities;`".
3. Define a private `IFunctionCallController` object reference to handle the function controller.
4. Implement the `setFunctionCallController()` method for the function controller registration.
5. Implement the `invoke()` method to perform the actual front call task. In this method, use the controller's `returnValues()` method to return values from the front call. If needed, you can raise runtime errors with controller's `raiseError()` method. It is also possible to start an Android Activity with the `startActivity*` controller methods.
6. If an activity is started with controller's `startActivityForResult` method, implement the `onActivityResult()` method in the function body class, to handle the end of the activity, and call controller's `returnValues()` method to return values from the front call.
7. If needed, implement the `onSaveInstanceState()` and the `onRestoreInstanceState()` methods, to respectivly save and restore information when Android has to suspend the application.

> **Note:** In any case, the `IFunctionCall` class must either call the controller's `returnValues()` or `raiseError()` methods to give the control back to the Genero program.

The `com.fourjs.gma.extension.v1.IFunctionCall` interface

Table 350: Methods of the com.fourjs.gma.extension.v1.IFunctionCall interface

Method	Description
`void setFunctionCallController(IFunctionCallController` *`controller`*`)`	This method binds the front call function controller object to the function body object. The *controller* parameter is the `IFunctionCallController` object to bind with the front call function body object.
`abstract void invoke(Object[]` *`args`*`) throws IllegalArgumentException`	This method performs the front call. Is will be called when the front call is executed from the Genero program. The *args* parameter is a variable list of parameters passed to the front call. This corresponds to the third argument of ui.Interface.frontCall on page 395
`void onSaveInstanceState(Bundle` *`state`*`)`	Saves the state of an ongoing function call when Android needs to suspend the application. The *state* parameter is the bundle to save the state to.
`void onRestoreInstanceState(Bundle` *`state`*`)`	Restores the state of an ongoing function call, when Android needs to restore the application. The *state* parameter is the bundle to restore the state from.
`void onActivityResult(int` *`resultCode`*`, Intent` *`data`*`)`	Callback invoked when an activity started through `IFunctionCallController.startActivityForResult` finishes. The *resultCode* parameter is the integer result code returned by the child activity through its `setResult()` method. The *data* parameter is an Intent object, which can return result data to the caller (various data can be attached to Intent "extras").

The `com.fourjs.gma.extension.v1.IFunctionCallController` interface

Table 351: Methods of the com.fourjs.gma.extension.v1.IFunctionCallController interface

Method	Description
`void returnValues(IFunctionCall` *`functionCall`*`, Object...`*`values`*`)`	Notifies the controller that the front call function call has finished successfully. To be called typically at the end of the `IFunctionCall.invoke()` method. The *functionCall* parameter is the current `IFunctionCall` object invoked.

Method	Description
	The *values* parameter defines the variable list of front call function return values. This corresponds to the fourth parameter of ui.Interface.frontCall on page 395.
`void raiseError(IFunctionCall functionCall, String message)`	Notifies the controller of an error in the front call function call. This leads to a BDL runtime exception.To be called if needed within the `IFunctionCall.invoke()` method. The *functionCall* parameter is the current `IFunctionCall` object invoked. The *message* parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in ui.Interface.frontCall on page 395).
`void startActivity(IFunctionCall functionCall, Intent intent)`	Starts a new activity. The function call won't be notified of the end of the activity. The Genero program will run in parallel of this activity. The behavior is similar to a `RUN WITHOUT WAITING`. The *functionCall* parameter is the current `IFunctionCall` object invoked. The *intent* parameter describes the activity to start.
`void startActivityForResult(IFunctionCall functionCall, Intent intent)`	Starts a new activity. The function call won't be notified of the end of the activity. The Genero program will remain blocked as long as the started activity isn't finished. The behavior is similar to a `RUN`. The method `IFunctionCall.onActivityResult` will be called once the activity finishes. The *functionCall* parameter is the current `IFunctionCall` object invoked. The *intent* parameter describes the activity to start.
`Activity getCurrentActivity()`	Returns the current `Activity` object. Provided in case if you need to pass the current activity to an Android API requiring this object. **Important:** Don't use the returned activity to start other activities (don't call `Activity.startActivity` or `Activity.startActivityForResult`), use the helpers of the current interface instead.

Calling the custom front call from BDL

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as first parameter and the front call function name as

second parameter. The front call module name is defined by the Java package name of the custom class implementing the `IFunctionCall` interface, and the front call function name is defined by the name of the class.

For example, if you implement the following front call function:

```
package com.mycompany.utilities;
...
public class GetPhoneId implements IFunctionCall {
...
```

The Genero program code must pass the Java package name "`com.mycompany.utilities`" as front call module name and the class name "`GetPhoneId`" as front call function name:

```
CALL ui.Interface.frontCall("com.mycompany.utilities", "GetPhoneId", ["John
 DOE"], [msg])
```

Deploying the custom front call

The compiled Java classes implementing the front calls must be included in the mobile application Android package (.apk), which is created in the Genero Studio deployment procedure. The same GMA package building rules apply for front calls and for simple Java extensions. See Packaging custom Java extensions for GMA on page 1590 for more details.

Example

The next example implements a HelloWorld call as a front call module.

`HelloWorld.java`:

```
package com.mycompany.testmodule;

import android.content.Intent;
import android.os.Bundle;

import com.fourjs.gma.extension.v1.IFunctionCall;
import com.fourjs.gma.extension.v1.IFunctionCallController;

public class HelloWorld implements IFunctionCall {

    private IFunctionCallController mController;

    @Override
    public void setFunctionCallController(IFunctionCallController
 controller) {
        mController = controller;
    }

    @Override
    public void invoke(Object[] args) throws IllegalArgumentException {
        if (args.length != 1) {
            throw new IllegalArgumentException("HelloWorld takes one
 argument");
        }

        mController.returnValues(this, "Hello " + args[0].toString());
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
    }
```

```
    @Override
    public void onRestoreInstanceState(Bundle state) {
    }

    @Override
    public void onActivityResult(int returnCode, Intent data) {
    }
}
```

In order to invoke the HelloWorld front-end function, use the `ui.Interface.frontCall()` API in the Genero program:

```
MAIN
  DEFINE msg STRING
  MENU
    ON ACTION frontcall ATTRIBUTES(TEXT="Call custom front call")
      CALL ui.Interface.frontCall("com.mycompany.testmodule", "HelloWorld",
 ["John DOE"], [msg])
    ON ACTION quit
      EXIT MENU
  END MENU
END MAIN
```

Implement front call modules for GMI

Custom front call modules for the iOS front-end are implemented by using the API for GMI front-calls in Objective-C.

GMI custom front call basics

In order to extend the GMI with your own front calls, you must be familiar with Objective-C programming, and if you want to interface with iOS Apps, have a knowledge of the iOS API.

> **Important:** Before starting with GMI front call implementation, you need to get the GMI package and unzip the archive into the FGLDIR directory, as described in the prerequisites sections of Building iOS apps with Genero on page 2586.

The API for GMI front calls is based on the `FrontCall` class and the `FrontCallHelper` and `FunctionCall` protocols. You can find these in the file `frontcall.h` in the in the `FGLDIR/include/gmi` diretory.

To implement custom front calls, write a class which extends `FrontCall` and implement the "`moduleName`" and "`execute:retCount:params`" methods as well as the "`initWithFunctionModuleHelper:`" initializer.

To register your front calls with GMI, implement a function "`NSArray* frontCalls()`" in your extension project, which has to return an array of Objective-C strings with the names of the `FrontCall` classes you implemented.

Follow these steps to implement a custom front call module for the GMI:

1. Import the `frontcall.h` header file in your source.
2. Define an interface (`MyFrontCall`) which extends `FrontCall`.
3. Create the class (`MyFrontCall`) which implements this interface:
   a. Implement the `- (instancetype) initWithFunctionModuleHelper:(id)aHelper` initializer, calling `[superinitWithFunctionModuleHelper:aHelper]` to pass the `FrontCallHelper` to the base implementation.
   b. Implement the `- (NSString*) moduleName` method, returning the name of the front call module.

   c. Implement the `- (void)execute:(NSString)name retCount:(int)retCount params:(NSArray)params` method, defining the body of your front calls. See below for details about the `execute` method.
4. Implement the function `NSArray* frontCalls()` and return the class object of your class as the first element in the array (see below for code example).

API to implement custom front calls in GMI

To get parameters passed from the Genero program to the front call, and return values from the front call to the Genero program, use the following macros and methods of the `FrontCall` class:

Table 352: GMI custom front call API

Macro / Method	Description
`(void) FC_REQUIRED_PARAMS(`*`count`*`)`	Checks that the number of parameters passed by the Genero program equals *count*. This macro will raise an error in the Genero program if not enough parameters were passed.
`(NSString *) FC_PARAM(`*`index`*`)`	Get the string parameter passed to the front call, at the given position. If the parameters are of a different type, use the `doubleValue`, `floatValue` and `integerValue` methods on `NSString` or a `NSScanner`, to convert the parameter to the expected type.
`(int) FC_PARAM_INT(`*`index`*`)`	Get the int parameter passed to the front call, at the given position.
`(void) intResult:(int) intValue`	Ends the front call by returning one integer to Genero.
`(void) doubleResult:(double) doubleValue`	Ends the front call by returning one double to Genero.
`(void) stringResult:(NSString * ):stringValue*`	Ends the front call by returning one string to Genero.
`(void) startResult`	Initiate setting multiple result values. Must be followed by `add*` function calls and ended with `endResult`.
`(void) addIntResult:(int)intValue`	Add an integer to the list of results returned.

Macro / Method	Description
	To be used after a `startResult` call.
`(void) addDoubleResult:(double) doubleValue`	Add a double to the list of results returned. To be used after a `startResult` call.
`(void) addStringResult:(NSString * ) stringValue*`	Add a string to the list of results returned. To be used after a `startResult` call.
`(void) endResult`	Finalize the setting of multiple result values an return the results to the Genero program, with front call error code zero (i.e. success).
`(void) ok`	Ends the front call without returning any value to Genero, indicating that the front call execution was successful.
`(void) error(FCErrorCode):error`	Ends the front call with a specific front call error code defined in `FCErrorCode enum` in `frontcall.h`, to indicate that front call execution failed, typically because of invalid parameters or invalid function name.
`(void) errorWithMessage(NSString * )message*`	Ends the front call with front call return code -4 (maps to BDL error -6333), and a user-defined error message, that can be read with `ERR_GET()` in the Genero program.
`(void) willSetResultLater`	To be called at the end of the `execute` function, if result values are intended to be set after the `execute` function did return. If the `willSetResultLater` function is used, the current front call will not end until one of the result functions is called. For example, if your front call opens a message box, the `execute` function will return before one of the message box buttons are selected. Once a button is pressed, the front call result value is set.

Calling the custom front call from BDL

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as first parameter and the front call function name as second parameter.

The front call module name is defined by the string value returned from the `-(NSString * ) moduleName*` method of your front call implementation, and the front-call function name is passed to the `execute` method you implemented as first parameter (name).

For example, if you implement the following class:

```
#import <gmi/frontcall.h>
...
```

```
@interface MyFrontCall : FrontCall
   ...
@end

@class MyFrontCall

-(instancetype) initWithFunctionModuleHelper:(id)aHelper
{
   if (self = [superinitWithFunctionModuleHelper:aHelper]) {
      ...
   }
   return self;
}

-(NSString*) moduleName{
   return @"MyModule";
}

-(void)execute:(NSString)name
              retCount:(int)retCount
              params:(NSArray)params
{
   [super execute:name retCount:retCount params:params];
   if ([[name lowercaseString]isEqualToString:@"myfrontcall"]) {
      ...
```

The Genero program code must pass the module name "`MyModule`" as front call module name and the class name "`MyFrontCall`" as front call function name:

```
CALL ui.Interface.frontCall("MyModule", "MyFrontCall", ["John DOE"],[msg])
```

Custom front call implementation details (execute method)

First of all, call the execute method of the parent `FrontCall` class, right at the top of the `execute` method:

```
   [super execute:name retCount:retCount params:params];
```

The `execute` method must check the name of the front call function passed as parameter, to perform the expected code. This is the function name passed to the `ui.Interface.frontCall()` call in the Genero program:

```
   if([[name lowercaseString] isEqualToString:@"myfunction"]) {
```

Implement the body of the front call function in the `if()` block as follows:

Add an `assert()` line, to make sure that the number of return values match:

```
      assert(retCount == 2);
```

In order to get the parameters passed from the Genero program, use the FC_* macros in the body of your front call function.

First, check that the number of parameters passed is correct, with the `FC_REQUIRED_PARAMS(`*`count`*`)` macro:

```
      FC_REQUIRED_PARAMS(3);
      ...
```

Retrieve the parameters passed to the front call with the `FC_PARAM(index)` or `FC_PARAM_INT(index)` macros, which return a `NSString*` and an `int` respectively. If needed, use the `doubleValue`, `floatValue` and `integerValue` methods on `NSString` or a `NSScanner`, to convert the parameter to the expected type:

```
      NSString * info = FC_PARAM(0);
      int v1 = [FC_PARAM(1) integerValue];
      double v2 = [FC_PARAM(2) doubleValue];
```

Implement the actual code of the front call.

To return values to Genero, use one of the helper methods such as `intResult:value`, if a single value must be returned to the Genero program. If more than one value must be returned, build a return set with the `startResult`, `add*Result` and `endResult` methods:

```
    [self startResult];
    [self addIntResult:isIpad];
    [self addIntResult:canLocate];
    [self endResult];
```

If the front call displays a UI (e.g. an `UIAlertController` or displays a customer `UIViewController`), call the `willSetResultLater` method of the `FrontCall` class, to avoid that the control flow is returned to the Genero program upon exit of the `execute` method:

```
    [self willSetResultLater];
```

Additionally, if you call the `willSetResultLater` method, you need to call one of the result methods like `stringResult` at a later time.

Deploying the custom front call

The complied Objective-C classes and the `NSString frontCalls()` function must be included in the iOS app build process.

The same app building rules apply for custome front calls as for C extensions.

See Building iOS apps with Genero on page 2586 for more details.

Example

In this example, the `ExtensionFrontCall` class implements two front calls: "isipad" and "logindialog".

We start by defining the interface for the custom front call module:

```
@interface ExtensionFrontCall : FrontCall<UIAlertViewDelegate>
@end
```

The `ExtensionFrontCall` class extends `FrontCall`, and implements the `UIAlertViewDelegate` protocol which is used by the "logindialog" front call.

Next, we start the implementation of the interface:

```
@implementation ExtensionFrontCall

-(instancetype) initWithFunctionModuleHelper:(id)aHelper
{
   if (self = [superinitWithFunctionModuleHelper:aHelper]) {
   }
   return self;
}
```

```
-(NSString*) moduleName{
   return @"ExtensionFrontCall";
}

-(void)execute:(NSString)name retCount:(int)retCount params:(NSArray)params
 {
   [super execute:name retCount:retCount params:params];
   ...
}

...
@end
```

We use the standard initializer which will be called by GMI on startup and define "`ExtensionFrontCall`" as module name by returning it from the `moduleName` method.

We also start the implementation of the `execute` method by calling the super method.

Now we can implement the `frontCalls` function to notify GMI about the front call module we are adding:

```
NSArray* frontCalls()
{
   return @[ [ExtensionFrontCall class] ];
}
```

This function is added above the interface implementation in the example, but could be defined in any file, as long as it is included in the project. If more than one module has to be defined, add the class names of the other modules to the returned array (e.g. `return @[ [ExtensionFrontCall class] , [AnotherFrontCall class] ];`)

The `isipad` front call example

This front call simply returns the information on which device GMI is running. If it is an iPad the int 1 will be returned to the Genero program:

```
if ([[name lowercaseString] isEqualToString:@“isipad”]) {
    assert(retCount == 1);
    BOOL isIpad = UI_USER_INTERFACE_IDIOM() == UIUserInterfaceIdiomPad;
    [self startResult];
    [self addIntResult:isIpad];
    [self endResult];
}
```

After checking that only one return parameter was defined in Genero, the code identifies the platform with the `UI_USER_INTERFACE_IDIOM()` API and stores the result in the `isIpad` variable.

The next three lines return the result value to Genero, by starting a result block with `startResult`, adding an int to the return set with `addIntResult`, and finally calling `endResult` to send the result to the Genero progra,.

We could also have used the single line: `[self intResult:isIpad];` to achieve the same behavior, since we only return one result value.

The Genero program will call the `isIPad` front call as follows:

```
DEFINE res INTEGER
CALL ui.Interface.frontCall( "ExtensionFrontCall", "isipad", [ ], [res] )
```

The `logindialog` front call example

This front call will display a login dialog to the user. It expects two parameters (the title and the message for the login dialog), and will return the login name and the password entered by the end user:

```
if([[name lowercaseString] isEqualToString:@“logindialog”]) {
    assert(retCount == 2);
    FC_REQUIRED_PARAMS(2);
    NSString *title = FC_PARAM(0);
    NSString *message = FC_PARAM(1);
    UIAlertView *alert = [[UIAlertView alloc]
      initWithTitle:title
      message:message
      delegate:self
      cancelButtonTitle:NSLocalizedString(@"Cancel",@"Cancel")
      otherButtonTitles:NSLocalizedString(@"OK",@"OK"),nil];
    alert.alertViewStyle = UIAlertViewStyleLoginAndPasswordInput;
    [alert show];
    [self willSetResultLater];
}
```

We first check that two result values were set in Genero and that two parameters were supplied to the front call.

Then we use the `FC_PARAM` macro to fetch the parameters and assign them to `NSStrings`.

Then we allocate and initialize an `UIAlertView` with the given message and title and set the `alertViewStyle` to "`UIAlertViewStyleLoginAndPasswordInput`", so that one plain text field and one password field will be displayed on the alert.

In the `initWithTitle` call we also set "`self`" as the delegate of the alert so that we receive callbacks after user input (we had added the `UIAlertViewDelegate` protocol to our `ExtensionFrontCall` interface definition).

Finally, we call `willSetResultLater`, to keep the control flow in iOS. If we don’t call this function, GMI concludes the front call was not handled by the `execute` function (as none of the `xxxResult` functions was called inside), and the front call will fail with a “Frontcall not found” error message.

The `ExtensionFrontCall` class implements the `alertView:didDismissWithButtonIndex:` method from the `UIAlertViewDelegate` protocol:

```
pragma mark UIAlertViewDelegate(void)

alertView:(UIAlertView *)alertViewdidDismissWithButtonIndex:
(NSInteger)buttonIndex {
   [self startResult];
   if (buttonIndex != alertView.cancelButtonIndex) {
      [self addStringResult:[alertViewtextFieldAtIndex:0].text];
      [self addStringResult:[alertViewtextFieldAtIndex:1].text];
   } else {
      [self addStringResult:nil];
      [self addStringResult:nil];
   }
   [self endResult];
}
```

This method will be called after the user has tapped on one of the buttons and the view has been dismissed. Inside this method, we first call `startResult` to enable adding more than one return value.

If the tapped button was not the Cancel button, we add the values of the login and password fields as strings to the results and then call `endResult` to return the control flow to the Genero program.

The Genero program will call the login dialog front call as follows:

```
DEFINE ul, up STRING
CALL ui.Interface.frontCall( "ExtensionFrontCall", "logindialog",
                             ["MyApp","User login"],
                             [un, up] )
IF up IS NULL THEN
   ERROR "Login canceled"
   EXIT PROGRAM
END IF
```

> **Note:** The file `userextension.m` of the GMI Extension project contains a complete example on how to write custom front calls.

Implement front call modules for GWC - HTML5 theme

Custom front call modules for the GWC-HTML5 theme front-end are implemented by using JavaScript™.

GWC-HTML5 theme custom front call basics

When using the GWC-HTML5 theme, front-end calls are JavaScript™ functions executed locally on the workstation where the browser is running.

> **Note:** Executing front calls in the context of a web browser is limited to the OS functions a web browser can do. For example, it will not be possible to delete a file on the computer where the browser executes.

To implement custom front calls for GWC-HTML5 theme, you must edit the `csf.js` JavaScript file located in `$FGLASDIR/tpl/SetHtml5`. Genero built-in front calls and custom front calls are implemented in the `csf.js` file.

> **Important:** Custom front call module and function names must be registered in lowercase for the GWC-HTML5 theme front-end.

Follow these steps to implement a custom front call module for the GWC-HTML5 theme:

1. Edit the `$FGLASDIR/tpl/SetHtml5/csf.js` file.
2. Add a JavaScript object using the name of the front call module to the `gwc.frontCallModuleList` object:

   ```
   gwc.frontCallModuleList.mymodule = { ... }
   ```

3. Add your front call functions as JavaScript methods to the newly-created module object (with potential parameters):

   ```
   gwc.frontCallModuleList.mymodule = {
        myfunction : function ( param1, ... ) {
            ...
        }
   }
   ```

   The parameters of the JavaScript method must match the parameter list of the `ui.Interface.frontCall("mymodule", "myfunction", [`*`param-list`*`], [`*`return-list`*`])`.
4. If the front call must return values to the Genero program, add a `return` instruction in the JavaScript method:

   ```
       return ( [value1, ... ]);
   ```

The number of returned values must match the number of variables used in the return list of the Genero front call `ui.Interface.frontCall("mymodule", "myfunction", [`*`param-list`*`], [`*`return-list`*`])`.

If the front call does not return any value to the Genero program, the JavaScript method must return an empty list:

```
    return [];
```

Note:

- If the SetHtml5 directory contains compressed `.js` files, do not forget to compress the modified `csf.js` file, or remove the compressed version of the file (the GAS will use the non-compressed version).
- Keep in mind that the JavaScript modules can be cached in your browser. You may need to refresh the cache when doing modifications in the `csf.js` file.
- Make sure to save your custom front call definitions added to `csf.js` before installing a new version of the GAS; the existing `csf.js` will be overwritten by the new installation.
- Front call module and function names are case sensitive.

Example

Add the following lines in the `csf.js` file:

```
gwc.frontCallModuleList.mymodule = {
  myfunction1: function(param) {
    alert("param: " + param);
    return [];
  }
  myfunction2: function(param1,param2) {
    alert("param1: " + param1 + "\nparam2: " + param2);
    return [55,"aaa"];
  }
};
```

The above JavaScript code implements a front call module list with functions that can be called from the Genero programs as follows:

```
DEFINE r INTEGER, s STRING
CALL ui.Interface.frontCall("mymodule", "myfunction1", ["abc"], [] )
CALL ui.Interface.frontCall("mymodule", "myfunction2", [123,"abc"], [r,s] )
```

Implement front call modules for GWC - JavaScript

Custom front call modules for the GWC-JS front-end are implemented by using JavaScript™.

GWC-JS custom front call basics

In order to extend the GWC-JS with your own front calls, you must be familiar with JavaScript programming concepts.

> **Important:** Custom front call module and function names must be registered in lowercase for the GWC-JS front-end.

With GWC-JS, front-end calls are JavaScript functions executed locally on the workstation where the browser is running.

> **Note:** Executing front calls in the context of a web browser is limited to the OS functions a web browser can do. For example, it will not be possible to delete a file on the computer where the browser executes.

Customizing the GWC-JS front-end

In order to integrate your custom front calls in the GWC-JS front end, you need to setup the GWC-JS customization environment.

Basically, you will have to:

1. Setup GWC-JS customization (install Node.js).
2. Extract the GWC-JS front-end archive into a *project-dir* directory,
3. Copy your custom front calls JavaScript modules in the *`project-dir`*`/customization`,
4. Rebuild the GWC-JS front-end with the `grunt` utility.
5. Configure the GAS to use the customized GWC-JS front-end.

For more details, see GWS-JS customization chapter in the GAS documentation.

Structure of a custom front call JavaScript module

One JavaScript module will define a front call module implementing several front call fonctions.

The `.js` file must be copied into the *`project-dir`*`/customization` directory.

A custom front call JavaScript module must have the following structure:

```
"use strict";

modulum('FrontCallService.modules.module-name', ['FrontCallService'],
  /**
   * @param {gbc} context
   * @param {classes} cls
   */
  function(context, cls) {
    context.FrontCallService.modules.module-name = {

      function-name: function (param1, ...) {

           ... user code ...

      {
        return [ values ... ]
      |
          this.setReturnValues([ values ... ]);
      }

      },

      [...]   /* More functions can be defined for this module */

    };
  }
);
```

Where:

1. *module-name* is the name of the front call module, and corresponds to the first parameter of `ui.Interface.frontCall()`.
2. *function-name* is the name of the front call function, and corresponds to the second parameter of `ui.Interface.frontCall()`.
3. *param1*, *param2* ... are the input values provided as third parameter of `ui.Interface.frontCall()`.
4. *values* is a JavaScript array containaing the values to be returned in the last parameter of of `ui.Interface.frontCall()`.

GWC-JS custom front call API

The following JavaScript functions are provided to implement your custom front-calls:

Table 353: GWC-JS custom front call API

Method	Description
`this.parametersError( [ message ] )`	This function can be invoked when an invalid number of parameters is passed to the front call, in order to raise on exception in the BDL program. The *message* parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in ui.Interface.frontCall on page 395).
`this.runtimeError( [ message ] )`	This function can be used to raise an exception in the BDL program, when the front call needs to warn the program that an error occured. The *message* parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in ui.Interface.frontCall on page 395).
`this.setReturnValues( values )`	This function sets the values to be returned to the BDL program in the case of an asynchroneous front call. See Asynchroneous custom front calls on page 1634 for more details

Synchroneous custom front calls

Synchroneous front calls can directly return the front call values with a classic JavaScript `return` instruction, by specifying a JavaScript array.

The next code example returns a single value:

```
    return ["Hello " + name + " !"];
```

Following code example returns three values:

```
    return ["first", "second", "third"];
```

Asynchroneous custom front calls

JavaScript custom front calls sometimes require asynchroneous programming. In such case, the custom front call API provides the `setReturnValues()` function to register values that must be returned to the BDL program.

For example, to return value after a delay of 5 seconds:

```
        window.setTimeout(function () {
          this.setReturnValues(["After 5s, Hello " + name + " !"]);
        }.bind(this), 5000);
```

Example

The next JavaScript code example implements a synchroneous and an asynchroneous custom front call function:

```
"use strict";

modulum('FrontCallService.modules.mymodule',
 ['FrontCallService'],
  /**
   * @param {gbc} context
   * @param {classes} cls
   */
  function(context, cls) {
    context.FrontCallService.modules.mymodule = {

      add_hello_sync: function (name) {
        if (name === undefined) {
          this.parametersError();
          return;
        }
        if (name.length === 0) {
          this.runtimeError("name shouldn't be empty");
          return;
        }

        return ["Hello, " + name + " !"];
      },

      add_hello_async: function (name) {
        if (name === undefined) {
          this.parametersError();
          return;
        }
        if (name.length === 0) {
          this.runtimeError("name shouldn't be empty");
          return;
        }

        window.setTimeout(function () {
          this.setReturnValues(["After 5s, Hello, " + name +
 " !"]);
        }.bind(this), 5000);
      }
    };
  }
);
```

From the Genero BDL program:

```
DEFINE res INTEGER
CALL ui.Interface.frontcall("mymodule","add_hello_sync",
 ["world"] , [res])
CALL ui.Interface.frontcall("mymodule","add_hello_async",
 ["world"] , [res])
```

Web Components

Implement specialized form elements with Web Components.

For more details, see Web components on page 1416.

Library reference

Reference for classes and functions provided as built-in or extension packages.

- Built-in functions on page 1637
- Utility functions on page 1667
- Built-in packages on page 1687
- Extension packages on page 1947
- Built-in front calls on page 1881
- File extensions on page 2296
- Genero BDL errors on page 2297

Built-in functions

A *built-in function* is a predefined function that is part of the runtime system, or provided as a library function automatically loaded when a program starts. The built-in functions are part of the language.

Note that some operators such as `FIELD_TOUCHED(`*`field-spec`*`)` look like functions, but these are core language operators that are different in terms of semantics and order of precedence.

- Built-in functions on page 1637
- List of desupported built-in functions on page 1666
- The key code table on page 1666

Built-in functions

Table 354: Built-in functions

Function	Description

`arg_val(`
`  `*`position`* `INTEGER )`
`  RETURNING `*`result`* `STRING`
	Returns a command line argument by position.

`arr_count()` `  RETURNING `*`result`* `INTEGER`	Returns the number of rows entered during an `INPUT ARRAY` statement.
`arr_curr()` `  RETURNING `*`result`* `INTEGER`	Returns the current row in a `DISPLAY ARRAY` or `INPUT ARRAY`.

`downshift(`
`  `*`source`* `STRING )`
`  RETURNING `*`result`* `STRING`
	Converts a string to lowercase.

`err_get(` `  `*`errnum`* `INTEGER )`	Returns the text corresponding to an error number.

Function	Description
`  RETURNING result STRING`	
`err_print(` `  errnum INTEGER )`	Prints in the error line the text corresponding to an error number.
`err_quit(` `  errnum INTEGER )`	Prints in the error line the text corresponding to an error number and terminates the program.
`errorlog(` `  text STRING )`	Copies the string passed as parameter into the error log file.
`fgl_buffertouched()` `  RETURNING result INTEGER`	Returns TRUE if the input buffer was modified in the current field.
`fgl_db_driver_type()` `  RETURNING drvtype CHAR(3)`	Returns the 3-letter identifier/code of the current database driver.

`fgl_decimal_truncate(`
`  value DECIMAL,`
`  decimals INTEGER )`
`  RETURNING result DECIMAL`
	Returns a decimal truncated to the precision passed as parameter.

`fgl_decimal_sqrt(`
`  value DECIMAL )`
`  RETURNING result DECIMAL`
	Computes the square root of the decimal passed as parameter.

`fgl_decimal_exp(`
`  value DECIMAL )`
`  RETURNING result DECIMAL`
	Returns the value of Euler's constant (e) raised to the power of the decimal passed as parameter.

`fgl_decimal_logn(`
`  value DECIMAL )`
`  RETURNING result DECIMAL`
	Returns the natural logarithm of the decimal passed as parameter.

`fgl_decimal_power(`
`  base DECIMAL,`
`  exp DECIMAL )`
`  RETURNING result DECIMAL`
	Raises decimal to the power of the real exponent.

`fgl_dialog_getbuffer()` `  RETURNING result STRING`	Returns the text of the input buffer of the current field.
`fgl_dialog_getbufferlength()`	Returns the number of rows to feed a paged DISPLAY ARRAY.

Function	Description
RETURNING *result* INTEGER	
fgl_dialog_getbufferstart() RETURNING *result* INTEGER	Returns the row offset of the page to feed a paged display array.
fgl_dialog_getcursor() RETURNING *index* INTEGER	Returns the position of the edit cursor in the current field.
fgl_dialog_getfieldname() RETURNING *result* STRING	Returns the name of the current input field.
fgl_dialog_getkeylabel(*keyname* STRING) RETURNING *result* STRING	Returns the label associated to a key for the current interactive instruction.
fgl_dialog_getselectionend() RETURNING *position* INTEGER	Returns the position of the last selected character in the current field.
fgl_dialog_infield(*field-name* STRING) RETURNING *result* INTEGER	This function checks for the current input field.
fgl_dialog_setbuffer(*value* STRING)	Sets the input buffer of the current field.
fgl_dialog_setcurrline(*line* INTEGER, *row* INTEGER)	This function moves to a specific row in a record list.
fgl_dialog_setcursor(*position* INTEGER)	This function sets the position of the edit cursor in the current field.
fgl_dialog_setfieldorder(*active* INTEGER)	This function enables or disables field order constraint.
fgl_dialog_setkeylabel(*keyname* STRING, *label* STRING)	Sets the label associated to a key for the current interactive instruction.
fgl_dialog_setselection(*cursor* INTEGER, *end* INTEGER)	Selects the text in the current field.
fgl_drawbox(	Draws a rectangle in the current window.

Function	Description
height INTEGER, *width* INTEGER, *line* INTEGER, *column* INTEGER, *color* INTEGER)	
fgl_drawline(*column* INTEGER, *line* INTEGER, *width* INTEGER, *type* CHAR(1), *color* INTEGER)	Draws a line in the current window (TUI and traditional mode).
fgl_eventloop() RETURNING *status* BOOLEAN	Waits for a user interaction event.
fgl_dialog_getcursor() RETURNING *index* INTEGER	Returns the position of the edit cursor in the current field.
fgl_getenv(*variable* STRING) RETURNING *result* STRING	Returns the value of the environment variable.
fgl_getfile(*src* STRING, *dst* STRING)	Retrieves a file from the front-end context to the virtual machine context.
fgl_gethelp(*help-id* INTEGER) RETURNING *result* STRING	Returns the help text according to its identifier by reading the current help file.
fgl_getkey() RETURNING *keynum* INTEGER	Waits for a keystroke and returns the key number.
fgl_getkeylabel(*keyname* STRING) RETURNING *result* STRING	Returns the default label associated to a key.
fgl_getpid() RETURNING *result* INTEGER	Returns the system process identifier.
fgl_getresource(*name* STRING) RETURNING *result* STRING	Returns the value of an FGLPROFILE entry.
fgl_getversion()	Returns the product version number of Genero.

Function	Description
RETURNING *result* STRING	
fgl_getwin_height() RETURNING *result* INTEGER	Returns the number of rows of the current window.
fgl_getwin_width() RETURNING *result* INTEGER	Returns the width of the current window as a number of columns.
fgl_getwin_x() RETURNING *result* INTEGER	Returns the horizontal position of the current window.
fgl_getwin_y() RETURNING *result* INTEGER	Returns the vertical position of the current window.
fgl_keyval(*string* STRING) RETURNING *result* INTEGER	Returns the key code of a logical or physical key.
fgl_lastkey() RETURNING *result* INTEGER	Returns the key code corresponding to the logical key that the user most recently typed in the form.
fgl_putfile(*src* STRING, *dst* STRING)	Transfers a file from the virtual machine context to the front end context.
fgl_report_print_binary_file(*filename* STRING)	Prints a file containing binary data during a report.
fgl_report_set_document_handler(*handler* om.SaxDocumentHandler)	Redirects the next report to an XML document handler.
fgl_scr_size(*screen-array* STRING) RETURNING *result* INTEGER	Returns the size of the specified screen array in the current form.
fgl_set_arr_curr(*row* INTEGER)	Moves to a specific row in a record list.
fgl_setenv(*variable* STRING, *value* STRING)	Sets the value of an environment variable.
fgl_setkeylabel(*keyname* STRING,	Sets the default label associated to a key.

Function	Description
label STRING)	
fgl_setsize(*height* INTEGER, *width* INTEGER)	Sets the size of the main application window.
fgl_settitle(*label* STRING)	Sets the title of the current application window.
fgl_system(*command* STRING)	Runs a command on the application server.
fgl_width(*expression* STRING) RETURNING *result* INTEGER	Returns the number of columns needed to represent the printed version of the expression.
fgl_window_getoption(*attribute* STRING) RETURNING *result* STRING	Returns attributes of the current window.
length(*expression* STRING) RETURNING *result* INTEGER	Returns the number of the character string passed as parameter.
num_args() RETURNING *result* INTEGER	Returns the number of program arguments.
scr_line() RETURNING *result* INTEGER	Returns the index of the current row in the screen array.
set_count(*nbrows* INTEGER)	Defines the number of rows containing explicit data in a static array used by the next dialog.
showhelp(*helpnum* INTEGER)	Displays a runtime help text.
startlog(*filename* STRING)	Initializes error logging and opens the error log file passed as the parameter.
upshift(*source* STRING) RETURNING *result* STRING	Converts a string to uppercase.

arg_val()
Returns a command line argument by position.

Syntax

```
arg_val(
   position INTEGER )
  RETURNING result STRING
```

1. *position* is an integer defining the argument position.
2. *result* is a string containing the program argument.

Usage

This function provides a mechanism for passing values to the program through the command line that invokes the program. You can design a program to expect or allow arguments after the name of the program in the command line.

The *position* parameter defines the argument to be returned. 0 returns the name of the program, 1 returns the first argument.

Like all built-in functions, `arg_val()` can be invoked from any program block. You can use it to pass values to `MAIN`, which cannot have formal arguments, but you are not restricted to calling `arg_val()` from the `MAIN` statement.

Use the `arg_val()` function to retrieve individual arguments during program execution. Use the `num_args()` function to determine how many arguments follow the program name on the command line.

If *position* is greater than 0, `arg_val(`*`position`*`)` returns the command-line argument used at a given position. The value of *position* must be between 0 and the value returned by `num_args()`, the number of command-line arguments. The expression `arg_val(0)` returns the name of the application program.

If the argument position is negative or greater than `num_args()`, the method returns `NULL`.

arr_count()
Returns the number of rows entered during an `INPUT ARRAY` statement.

Syntax

```
arr_count()
  RETURNING result INTEGER
```

1. *result* is the current number of records that exist in the array.

Usage

Use `arr_count()` to determine the number of program records that are currently stored in a static program array used by the `INPUT ARRAY` instruction.

This function is typically called inside or after `INPUT ARRAY` or `DISPLAY ARRAY` statement.

`arr_count()` returns a positive integer, corresponding to the index of the furthest record within the static program array that the user accessed. Not all the rows counted by `arr_count()` necessarily contain data (for example, if the user presses the Down key more times than there are rows of data.

This function is not required when using dynamic arrays. In such case, the total number of rows in defined by the `array.getLength()` method after the dialog, or by the `ui.Dialog.getArrayLength()` method during the dialog execution.

arr_curr()
Returns the current row in a `DISPLAY ARRAY` or `INPUT ARRAY`.

Syntax

```
arr_curr()
  RETURNING result INTEGER
```

Usage

The `arr_curr()` function returns an integer value that identifies the current row of a list of rows in an `INPUT ARRAY` or `DISPLAY ARRAY` instruction. The first row is numbered 1.

Note that `arr_curr()` and `scr_line()` can return different values if the program array is larger than the screen array.

Consider using the `ui.Dialog.getCurrentRow()` method instead of `arr_curr()` when executing several list-handled instruction in parallel inside a `DIALOG` block.

downshift()
Converts a string to lowercase.

Syntax

```
downshift(
   source STRING )
  RETURNING result STRING
```

1. *source* is the character string to convert to lowercase letters.

Usage

The `downshift()` function returns a string value in which all uppercase characters in its argument are converted to lowercase.

The character conversion depends on locale settings (the LC_CTYPE environment variable). Non-alphabetic or lowercase characters are not altered.

scr_line()
Returns the index of the current row in the screen array.

Syntax

```
scr_line()
  RETURNING result INTEGER
```

Usage

The `scr_line()` function returns the index of the current row in the screen array. It is typically used inside a `DISPLAY ARRAY` or `INPUT ARRAY` statement.

> **Important:** When using new graphical objects such as TABLE containers, this function can return an invalid screen array line number, because the current row may not be visible if the user scrolls in the list with scrollbars.

Do not confuse `scr_line()` with `arr_curr()`, the first returns the index of the current row in the form screen array, and the second returns the index of the current row in the program variable.

num_args()
Returns the number of program arguments.

Syntax

```
num_args()
  RETURNING result INTEGER
```

Usage

Returns the number of arguments passed to the program.

The function returns 0 if no arguments are passed to the program.

err_get()
Returns the text corresponding to an error number.

Syntax

```
err_get(
   errnum INTEGER )
  RETURNING result STRING
```

1. *errnum* is a runtime error or an Informix® SQL error.

Usage

The `err_get()` function returns the error message corresponding to the number passed as parameter.

IBM® Informix® SQL error numbers can only be supported if the program is connected to an Informix database. Do not use this function in the context of SQL execution, when using different type of database servers.

err_print()
Prints in the error line the text corresponding to an error number.

Syntax

```
err_print(
   errnum INTEGER )
```

1. *errnum* is a runtime error or an Informix® SQL error.

Usage

The `err_print()` function displays to the screen the error message corresponding to the number passed as parameter. The message will be displayed in the error line defined by the program.

IBM® Informix® SQL error numbers can only be supported if the program is connected to an Informix database. Do not use this function when programming an application that must run with different type of database servers.

err_quit()
Prints in the error line the text corresponding to an error number and terminates the program.

Syntax

```
err_quit(
```

```
   errnum INTEGER )
```

1. *errnum* is a runtime error or an Informix® SQL error.

Usage

The `err_quit()` function prints the error message corresponding to the number passed as parameter. The message will be displayed in standard error stream and the program will terminate.

IBM® Informix® SQL error numbers can only be supported if the program is connected to an Informix database. Do not use this function when programming an application that must run with different type of database servers.

errorlog()
Copies the string passed as parameter into the error log file.

Syntax

```
errorlog(
   text STRING )
```

1. *text* is the character string to be inserted in the error log file.

Usage

The `errorlog()` function writes the passed string in the current error log file. The error log file is defined by a call to the `startlog()` function.

Use this function to identify errors in programs and to customize error handling. The error log functions can also be used to trace the way a program is used to improve it, record work habits or help to detect attempts to breach security.

fgl_buffertouched()
Returns TRUE if the input buffer was modified in the current field.

Syntax

```
fgl_buffertouched()
  RETURNING result INTEGER
```

Usage

The function returns TRUE if the input buffer has been modified after the current field was selected (i.e. got the focus).

Call this function in AFTER FIELD, AFTER INPUT, AFTER CONSTRUCT, ON KEY, ON ACTION blocks.

This function is not equivalent to FIELD_TOUCHED(): The modification status of `fgl_buffertouched()` is reset when entering a new field, while `FIELD_TOUCHED()` returns TRUE when a field was modified during the interactive instruction.

fgl_db_driver_type()
Returns the 3-letter identifier/code of the current database driver.

Syntax

```
fgl_db_driver_type()
  RETURNING drvtype CHAR(3)
```

Usage

This function can be called after connecting to a database server with the `CONNECT` or `DATABASE` instructions, in order to identify the type of the target database with the driver type.

Returned value is the 3-letter driver code, in lower case, such as "`ifx`", "`ora`", "`db2`", etc.

See the drivers table for more details about the list of database driver types.

The function returns `NULL` if there is no current database driver (i.e. if database connection is not yet established).

fgl_decimal_truncate()
Returns a decimal truncated to the precision passed as parameter.

Syntax

```
fgl_decimal_truncate(
   value DECIMAL,
   decimals INTEGER )
  RETURNING result DECIMAL
```

1. *value* is the decimal to be converted.
2. *decimals* defines the number of digits after the decimal point.

Usage

This function truncates the decimal to the number of decimal digits specified.

The value is not rounded, it is just truncated. For example, when truncating 12.345 to 2 decimal digits, the result will be 12.34, not 12.35.

fgl_decimal_sqrt()
Computes the square root of the decimal passed as parameter.

Syntax

```
fgl_decimal_sqrt(
   value DECIMAL )
  RETURNING result DECIMAL
```

1. *value* is the decimal to be computed.

fgl_decimal_exp()
Returns the value of Euler's constant (e) raised to the power of the decimal passed as parameter.

Syntax

```
fgl_decimal_exp(
   value DECIMAL )
  RETURNING result DECIMAL
```

1. *value* is the decimal to be computed.

fgl_decimal_logn()
Returns the natural logarithm of the decimal passed as parameter.

Syntax

```
fgl_decimal_logn(
```

```
    value DECIMAL )
  RETURNING result DECIMAL
```

1. *value* is the decimal to be computed.

fgl_decimal_power()
Raises decimal to the power of the real exponent.

Syntax

```
fgl_decimal_power(
      base DECIMAL,
      exp DECIMAL )
    RETURNING result DECIMAL
```

1. *base* is the decimal to be raise to the power of *exp*.
2. *exp* is the exponent.

Usage

Unlike the `**` operator, the `fgl_decimal_power()` function supports real numbers for the exponent.

fgl_dialog_getbuffer()
Returns the text of the input buffer of the current field.

Syntax

```
fgl_dialog_getbuffer()
  RETURNING result STRING
```

Usage

The `fgl_dialog_getbuffer()` function returns the content of the input buffer of the current field. It must be used in `INPUT`, `INPUT ARRAY` and `CONSTRUCT` blocks.

The function is especially useful in a `CONSTRUCT` instruction, because there is no variable associated to fields in this case.

Consider using the `ui.Dialog.getFieldBuffer()` method instead.

fgl_dialog_setbuffer()
Sets the input buffer of the current field.

Syntax

```
fgl_dialog_setbuffer(
   value STRING )
```

1. *value* is the text to set in the current input buffer.

Usage

In the default buffered input mode, this function modifies the input buffer of the current field; the corresponding input variable is not assigned. It makes no sense to call this function in `BEFORE FIELD` blocks of `INPUT` and `INPUT ARRAY`. However, if the statement is using the `UNBUFFERED` mode, the function will set both the field buffer and the program variable. If the string set by the function does not represent a valid value that can be stored by the program variable, the buffer and the variable will be set to `NULL`.

The `fgl_dialog_setbuffer()` function must be used in `INPUT`, `INPUT ARRAY` and `CONSTRUCT` blocks.

This function sets the modification flag for both `FIELD_TOUCHED()` and `fgl_buffertouched()` functions. There is a slight difference between both functions: The modification flag for `fgl_buffertouched()` is reset to `FALSE` when entering the field.

The function is especially useful in a `CONSTRUCT` instruction, because there is no variable associated to fields in this case.

fgl_dialog_getfieldname()
Returns the name of the current input field.

Syntax

```
fgl_dialog_getfieldname()
  RETURNING result STRING
```

Usage

This function returns the name of the current input field during a dialog execution. It must be use in `INPUT`, `INPUT ARRAY` or `CONSTRUCT` blocks.

Only the column part of the field name is returned (screen record name is omitted).

The `fgl_dialog_getfieldname()` is similar to the `INFIELD()` operator and `fgl_dialog_infield()` function.

fgl_dialog_infield()
This function checks for the current input field.

Syntax

```
fgl_dialog_infield(
   field-name STRING )
  RETURNING result INTEGER
```

1. *field-name* is the name if the form field.

Usage

The `fgl_dialog_infield()` function returns `TRUE` if the field name passed as the parameter is the current input field.

The function must be called in `INPUT`, `INPUT ARRAY` or `CONSTRUCT` blocks.

This function is the equivalent of the `INFIELD()` operator, except that the function takes a string expression as parameter, while the `INFIELD()` operator expects a hard-coded form field name.

fgl_dialog_setcursor()
This function sets the position of the edit cursor in the current field.

Syntax

```
fgl_dialog_setcursor(
   position INTEGER )
```

1. *position* is the edit cursor position in the text, using byte length semantics.

Usage

The `fgl_dialog_setcursor()` moves the edit cursor to the specified position in the current field. The function must be called in interactive instructions control blocks, when staying in the current field.

This function has only an effect when staying in the current field, it should not be called in an `AFTER FIELD` or `AFTER ROW` for example.

Note that you can use `FGL_DIALOG_SETSELECTION()` to select a piece of text in a field.

> **Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

fgl_dialog_setfieldorder()
This function enables or disables field order constraint.

Syntax

```
fgl_dialog_setfieldorder(
   active INTEGER )
```

1. When *active* is `TRUE`, the field order is constrained. When *active* is `FALSE`, the field order is not constrained.

Usage

Typical applications control user input with `BEFORE FIELD` and `AFTER FIELD` blocks. In many cases the field order and the sequential execution of `AFTER FIELD` blocks is important in order to validate the data entered by the user. But with graphical front ends you can use the mouse to move to a field. By default the runtime system executes all `BEFORE FIELD` and `AFTER FIELD` blocks of the fields used by the interactive instruction, from the origin field to the target field selected by mouse click. If needed, you can force the runtime system to ignore all intermediate field triggers, by calling this function with a `FALSE` attribute.

This function must be called outside interactive dialog blocks, typically at the beginning of the program.

Consider using the `Dialog.fieldOrder` parameter when all programs are affected. The FGLPROFILE profile entry is the default when the `fgl_dialog_setfieldorder()` function is not used.

Consider using `OPTIONS FIELD ORDER FORM` for new developments with graphical rendering.

fgl_dialog_setcurrline()
This function moves to a specific row in a record list.

Syntax

```
fgl_dialog_setcurrline(
  line INTEGER,
  row INTEGER )
```

1. *line* is the line number in the form screen array.
2. *row* is the row number in the program array variable.

Usage

Moves to the row / screen line specified. See fgl_set_arr_curr() for more details.

To be called during a `DISPLAY ARRAY` or `INPUT ARRAY` instruction, inside `BEFORE DISPLAY` / `BEFORE INPUT` or `ON ACTION` / `ON KEY` blocks only.

The *line* parameter is ignored in GUI mode.

fgl_dialog_getbufferstart()
Returns the row offset of the page to feed a paged display array.

Syntax

```
fgl_dialog_getbufferstart()
  RETURNING result INTEGER
```

Usage

The `FGL_DIALOG_GETBUFFERSTART()` function returns the record list offset to be used to fill a page of a `DISPLAY ARRAY` running in paged mode.

This function must be called in the context of the `ON FILL BUFFER` trigger. The returned value is undefined if the function is used outside this trigger.

fgl_dialog_getbufferlength()
Returns the number of rows to feed a paged DISPLAY ARRAY.

Syntax

```
fgl_dialog_getbufferlength()
  RETURNING result INTEGER
```

Usage

The `fgl_dialog_getbufferlength()` function returns the number of rows to be provided by the program to fill a page of a `DISPLAY ARRAY` running in paged mode.

This function must be called in the context of the `ON FILL BUFFER` trigger. The returned value is undefined if the function is used outside this trigger.

fgl_dialog_getcursor() / fgl_getcursor()
Returns the position of the edit cursor in the current field.

Syntax

```
fgl_dialog_getcursor()
  RETURNING index INTEGER
```

1. *index* is the edit cursor position in the text, using byte length semantics.

Usage

The `fgl_dialog_getcursor()` function can be used in conjunction with `fgl_dialog_getselectionend()` to get the position of the edit cursor and the piece of text that is selected in the current field.

> **Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

fgl_dialog_getkeylabel()
Returns the label associated to a key for the current interactive instruction.

Syntax

```
fgl_dialog_getkeylabel(
   keyname STRING )
  RETURNING result STRING
```

1. *keyname* is the logical name of a key such as `F11` or `DELETE`, `INSERT`, `CANCEL`.

Usage

The `fgl_dialog_getkeylabel()` function returns the label defined for the function or control key passed as parameter, for the current interactive instruction.

This function returns the key labels defined for the current dialog. There are different levels of key label definitions.

This function is provided for backward compatibility, use action defaults to define action view texts.

fgl_dialog_getselectionend()
Returns the position of the last selected character in the current field.

Syntax

```
fgl_dialog_getselectionend()
  RETURNING position INTEGER
```

1. *position* is the position of the last selected character in the current field text, using in byte length semantics.

Usage

The `fgl_dialog_getselectionend()` function returns the edit cursor position of the last selected character in the text of the current field.

> **Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

The function returns zero if the complete text is selected.

The edit cursor position returned by `fgl_dialog_getcursor()` will be lower as the position returned by `fgl_dialog_getselectionend()` if the text has been selected backwards.

fgl_dialog_setkeylabel()
Sets the label associated to a key for the current interactive instruction.

Syntax

```
fgl_dialog_setkeylabel(
   keyname STRING,
   label STRING )
```

1. *keyname* is the logical name of a key such as `F11` or `DELETE`,`INSERT`, `CANCEL`.
2. *label* is the text associated to the key.

Usage

The `fgl_dialog_setkeylabel()` associates a text to a function or control key. for the current dialog. Default action views (i.e. buttons that appears in the control frame of a window) will get the label displayed instead of the function or control key name.

This function defines the key labels for the current dialog. There are different levels of key label definitions.

> **Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

fgl_dialog_setselection()
Selects the text in the current field.

Syntax

```
fgl_dialog_setselection(
   cursor INTEGER,
   end INTEGER )
```

1. *cursor* defines the edit cursor position, using byte length semantics.
2. *end* defines the selection end position, using byte length semantics.

Usage

A call to `fgl_dialog_setselection(cursor, end)` sets the text selection in the current form field. The *cursor* parameter defines the character position of the edit cursor (equivalent to `fgl_dialog_getcursor()` position), while *end* defines the character position of the end of the text selection (equivalent to `fgl_dialog_getselectionend()` position).

> **Important:** When using byte length semantics, the positions are expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

cursor can be lower, greater or equal to *end*.

This function has only an effect when staying in the current field, it should not be called in an `AFTER FIELD` or `AFTER ROW` for example.

fgl_drawbox()
Draws a rectangle in the current window.

Syntax

```
fgl_drawbox(
   height INTEGER,
   width INTEGER,
   line INTEGER,
   column INTEGER,
   color INTEGER )
```

1. *height* is the height of the rectangle.
2. *width* is the width of the rectangle.
3. *line* is the horizontal coordinate of the upper side of the rectangle.
4. *column* is the vertical coordinate of the left side of the rectangle.
5. *color* is the color number (ignored).

Usage

The `fgl_drawbox()` function draws a rectangle based on the character terminal coordinates in the current open window.

Dimensions and coordinates are specified in grid cells unit (i.e. characters).

This function is provided for backward compatibility. A call to this function will be ignored if the current window is not SCREEN based. The function is supported to draw rectangles in text mode applications.

fgl_drawline()
Draws a line in the current window (TUI and traditional mode).

Syntax

```
fgl_drawline(
   column INTEGER,
   line INTEGER,
   width INTEGER,
   type CHAR(1),
   color INTEGER)
```

1. *line* is the horizontal coordinate of the upper side of the rectangle.
2. *column* is the vertical coordinate of the left side of the rectangle.
3. *width* is the width of the line.
4. *type* (ignored).
5. *color* is the color number (ignored).

Usage

The `fgl_drawline()` function draws a line based on the character terminal coordinates in the current open window.

Dimensions and coordinates are specified in grid cells unit (i.e. characters).

This function is provided for backward compatibility. A call to this function will be ignored if the current window is not SCREEN based. The function is supported to draw lines in text mode applications.

fgl_eventloop()
Waits for a user interaction event.

Syntax

```
fgl_eventloop()
   RETURNING status BOOLEAN
```

1. *status* is boolean indicating if the user event loop must continue.

Usage

The `fgl_eventloop()` function is used to implement the parallel dialog main event loop, in conjuction with `START DIALOG` / `TERMINATE DIALOG` instructions, used to register and end parallel dialogs.

The function waits until a user interaction event occurs and returns `TRUE` or `FALSE` to indicate if the event loop must continue or stop. It is typically used in a `WHILE` / `END WHILE` loop:

```
WHILE fgl_eventLoop()
END WHILE
```

Parallel dialogs are registrer with the `START DIALOG` instruction. As long as at least one parallel dialog is registered, the fgl_evenLoop() function returns `TRUE`. When the last parallel dialog is ended with a `TERMINATE DIALOG` instruction, the fgl_evenLoop() function returns `FALSE` and the even loop is stopped.

fgl_getenv()
Returns the value of the environment variable.

Syntax

```
fgl_getenv(
   variable STRING )
  RETURNING result STRING
```

1. *variable* is the name of the environment variable.

Usage

The argument of `fgl_getenv()` must be the name of an environment variable.

If the requested value exists in the current user environment, the function returns the value of that variable. If the specified environment variable is not defined, the function returns a `NULL` value. If the environment variable is defined but does not have a value assigned to it, the function returns blank spaces.

fgl_gethelp()
Returns the help text according to its identifier by reading the current help file.

Syntax

```
fgl_gethelp(
   help-id INTEGER )
  RETURNING result STRING
```

1. *help-id* is the help text identifier.

Usage

The `fgl_gethelp()` function returns the text corresponding to the help message number passed as parameter.

The text is read from the current help file. The current help file is defined by the `OPTIONS HELP FILE` instruction.

fgl_getpid()
Returns the system process identifier.

Syntax

```
fgl_getpid()
  RETURNING result INTEGER
```

Usage

The `fgl_getpid()` function returns the current process identifier. The process identifier is provided by the operating system.

fgl_getfile()
Retrieves a file from the front-end context to the virtual machine context.

Syntax

```
fgl_getfile(
   src STRING,
   dst STRING )
```

1. *src* is the path of the file to retrieve from the front-end context.
2. *dst* is the path of the file to write in the virtual machine context.

Usage

The `fgl_getfile()` function uploads a file from the front-end workstation disk to the application server disk where fglrun is executed.

> **Important:** Using this function can result in a security hole if you allow the end user to specify the file paths without control. There is not limitation on the file content or file paths: If the user executing the application on the server side is allowed to write critical server files, the program could transfer files from the client workstation and overwrite critical server files. On the other hand, critical files can be read from the client workstation and copied on the application server. It is in the hands of the programmer to implement file path and/or file content restrictions in the programs using `fgl_getfile()`.

When the front-end is located on a mobile device (GMA or GMI), the `fgl_getfile()` function can take an opaque file path as first argument, to identify a local device resource returned from a front call such as choosePhoto on page 1927, takeVideo on page 1939. This allows you to retrieve the media file into the virtual machine context, for persistent storage, and to share it with applications running on other devices. This `fgl_getfile()` feature can be used with a standalone app running on the device, or a client/server app executing on a server and displaying on the device. For more details, see Runtime images on page 787.

fgl_getkey()
Waits for a keystroke and returns the key number.

Syntax

```
fgl_getkey()
  RETURNING keynum INTEGER
```

1. *keynum* is the integer key code of the pressed key.

Usage

`fgl_getkey()` waits for a keystroke and returns the key code corresponding to the pressed physical key.

This function should only be used in text mode.

Unlike `fgl_lastkey()`, which can return a value indicating the logical effect of whatever key the user pressed,`fgl_getkey()` returns an integer representing the key code of the physical key that the user pressed. The `fgl_getkey()` function recognizes the same codes for keys that the `fgl_keyval()` function returns. Unlike `fgl_keyval()`, which can only return keystrokes that are entered during dialogs, `fgl_getkey()` can be called outside a dialog context.

fgl_getkeylabel()
Returns the default label associated to a key.

Syntax

```
fgl_getkeylabel(
   keyname STRING )
  RETURNING result STRING
```

1. *keyname* is the logical name of a key such as `F11` or `DELETE`, `INSERT`, `CANCEL`.

Usage

The `fgl_getkeylabel()` function returns the default label defined for the function or control key passed as parameter.

This function returns the default key labels defined for the all dialogs. There are different levels of key label definitions.

This function is provided for backward compatibility, use action defaults to define action view texts.

fgl_getresource()
Returns the value of an FGLPROFILE entry.

Syntax

```
fgl_getresource(
   name STRING )
  RETURNING result STRING
```

1. *name* is the FGLPROFILE entry name to be read.

Usage

The `fgl_getresource()` function reads the FGLPROFILE file(s) and returns the value defined for the entry passed as parameter.

If the entry does not exist in the configuration file, the function returns NULL.

Note that FGLPROFILE entry names are not case sensitive.

fgl_getversion()
Returns the product version number of Genero.

Syntax

```
fgl_getversion()
  RETURNING result STRING
```

Usage

The `fgl_getversion()` function returns the product version number the Genero Business Development Language runtime system.

> **Important:** This function is provided for debugging only; do not write business code dependent on the build number. The format of the returned value is subject of change in future versions.

fgl_getwin_height()
Returns the number of rows of the current window.

Syntax

```
fgl_getwin_height()
  RETURNING result INTEGER
```

Usage

The `fgl_getwin_height()` function returns the height of the current window, in character units.

This function is provided for text mode applications, in GUI mode, windows are re-sizeable and thus their height is variable.

fgl_getwin_width()
Returns the width of the current window as a number of columns.

Syntax

```
fgl_getwin_width()
  RETURNING result INTEGER
```

Usage

The `fgl_getwin_width()` function returns the width of the current window, in character units.

This function is provided for text mode applications, in GUI mode, windows are re-sizeable and thus their width is variable.

fgl_getwin_x()
Returns the horizontal position of the current window.

Syntax

```
fgl_getwin_x()
  RETURNING result INTEGER
```

Usage

The `fgl_getwin_x()` function returns the horizontal coordinate of the top/left corner of the current window.

This function is provided for text mode applications, in GUI mode, windows are movable and thus their position is variable.

fgl_getwin_y()
Returns the vertical position of the current window.

Syntax

```
fgl_getwin_y()
  RETURNING result INTEGER
```

Usage

The `fgl_getwin_y()` function returns the vertical coordinate of the top/left corner of the current window.

This function is provided for text mode applications, in GUI mode, windows are movable and thus their position is variable.

fgl_keyval()
Returns the key code of a logical or physical key.

Syntax

```
fgl_keyval(
   string STRING )
  RETURNING result INTEGER
```

1. *string* can be a single character, a digit, a printable symbol like @, #, $ or a special keyword such as ACCEPT.

Usage

`fgl_keyval()` can be used in form-related statements to examine a value returned by the `fgl_lastkey()` and `fgl_getkey()` functions.

Key names recognized by `fgl_keyval()` are: `ACCEPT`, `HELP`, `NEXT`, `RETURN`, `DELETE`, `INSERT`, `NEXTPAGE`, `RIGHT`, `DOWN`, `INTERRUPT`, `PREVIOUS`, `TAB`, `ESC`, `ESCAPE`, `LEFT`, `PREVPAGE`, `UP`, `F1` through `F64`, `CONTROL-`*`character`* (where *character* can be any letter except A, D, H, I, J, L, M, R, or X).

The function returns NULL if the parameter does not correspond to a valid key.

If you specify a single character, `fgl_keyval()` considers the case. In all other instances, the function ignores the case of its argument, which can be uppercase or lowercase letters.

To determine whether the user has performed an action, such as inserting a row, specify the logical name of the action (such as INSERT) rather than the name of the physical key (such as F1). For example, the logical name of the Accept action is ACCEPT, while the default physical key is ESCAPE. To test if the key most recently pressed by the user corresponds to the Accept action, specify `fgl_keyval("ACCEPT")` rather than `fgl_keyval("ESCAPE")` or `fgl_keyval("ESC")`. Otherwise, if a key other than ESCAPE is set as the Accept key and the user presses that key,`FGL_LASTKEY()` does not return a code equal to `fgl_keyval("ESCAPE")`.

This function is provided for backward compatibility especially for TUI mode applications. `fgl_keyval()` is well supported in text mode, but this function can only be emulated in GUI mode, because the front-ends communicate with the runtime system with other events as keystrokes.

fgl_lastkey()
Returns the key code corresponding to the logical key that the user most recently typed in the form.

Syntax

```
fgl_lastkey()
  RETURNING result INTEGER
```

Usage

The `fgl_lastkey()` function returns a numeric code corresponding to the user's last keystroke before the function was called. For example, if the last key that the user pressed was a lowercase *s*, the function returns the code 115 (i.e. the ASCII character set code).

The value of `fgl_lastkey()` is undefined in a `MENU` statement.

The function returns `NULL` if no key has been pressed.

It is not required to know the specific key codes returned by `fgl_lastkey()`: The `FGL_KEYVAL()` function can be used to compare the key code of the last key pressed. The `FGL_KEYVAL()` function lets you compare the last key pressed with a logical of physical key. For example, you do not need to know the physical key defined to validate a dialog, you can use the logical name "accept" instead. For a complete list of key codes and logical key names, see the Key code table.

Pay attention to the fact that this function is provided for backward compatibility. The abstract user interface protocol is based on logical events, not only key events. For example, in GUI mode, when selecting a new row with the mouse in a table, there is no key press as when moving in a static screen array in TUI mode. However, the runtime system tries to emulate as much as possible keystrokes from non-keystroke events.

fgl_putfile()
Transfers a file from the virtual machine context to the front end context.

Syntax

```
fgl_putfile(
   src STRING,
   dst STRING)
```

1. *src* is the path to the file to transmit from the virtual machine context.
2. *dst* is the path to the file to write in the front end context.

Usage

The `fgl_putfile()` function downloads a file from the application server disk where fglrun is executed to the front-end workstation disk.

> **Important:** Using this function can result in a security hole if you allow the end user to specify the file paths without control. There is not limitation on the file content or file paths: If the user executing the application on the server side is allowed to read critical server files, the program could transfer these files on the client workstation. On the other hand, critical files can be written on the client workstation. It is in the hands of the programmer to implement file path and/or file content restrictions in the programs using `fgl_putfile()`.

fgl_report_print_binary_file()
Prints a file containing binary data during a report.

Syntax

```
fgl_report_print_binary_file(
   filename STRING )
```

1. *filename* is the name of the binary file.

Usage

This function prints a file containing binary data during a report.

This function is provided for backward compatibility and must only be using inside a `REPORT` routine.

fgl_report_set_document_handler()
Redirects the next report to an XML document handler.

Syntax

```
fgl_report_set_document_handler(
```

```
   handler om.SaxDocumentHandler )
```

1. *handler* is the document handler variable.

Usage

This function attaches the specified XML document handler to the next executed report, it must be called before the execution of a report.

This function is provided for backward compatibility, you should use the `TO XML HANDLER` of `START REPORT` instead.

fgl_setkeylabel()
Sets the default label associated to a key.

Syntax

```
fgl_setkeylabel(
   keyname STRING,
   label STRING )
```

1. *keyname* is the logical name of a key such as `F11` or `DELETE`, `INSERT`, `CANCEL`.
2. *label* is the text associated to the key.

Usage

`fgl_setkeylabel()` associates a text to a function or control key. Default action views (i.e. buttons that appears in the control frame of a window) will get the label displayed instead of the function or control key name.

This function defines the default key labels for all dialogs. There are different levels of key label definitions.

> **Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

fgl_scr_size()
Returns the size of the specified screen array in the current form.

Syntax

```
fgl_scr_size(
   screen-array STRING )
  RETURNING result INTEGER
```

1. *screen-array* is the name of a screen-array in the current displayed form.

Usage

The `fgl_scr_size()` function takes the name of a screen array as parameter identifying an array in the currently opened form and returns an integer that corresponds to the number of screen records in that screen array.

This function is typically used with traditional text mode forms having screen arrays with a constant size, to display data in screen array rows with the `DISPLAY TO` instruction.

For modern GUI applications, consider using the UNBUFFERED mode in dialogs, to get automatic form field synchronization with program variables.

Error -1108 will be raised if the passed screen-array does not exits in the current form, and error -1114 is returned if no form is currently displayed.

fgl_setsize()
Sets the size of the main application window.

Syntax

```
fgl_setsize(
   height INTEGER,
   width INTEGER )
```

1. *height* is the number of lines of the window.
2. *width* is the number of columns of the window.

Usage

This function defines the size of the main window when using the traditional GUI mode.

fgl_settitle()
Sets the title of the current application window.

Syntax

```
fgl_settitle(
   label STRING )
```

1. *label* is the text of the title.

Usage

The `fgl_settitle()` function defines the title of the current window, as well as the default title for new created windows.

This function is provided for backward compatibility, the title of a window can be defined with the TEXT attribute of a `LAYOUT` section.

fgl_setenv()
Sets the value of an environment variable.

Syntax

```
fgl_setenv(
   variable STRING,
   value STRING )
```

1. *variable* is the name of the environment variable.
2. *value* is the value to be set.

Usage

The `fgl_setenv()` function sets or modifies the value of an environment variable.

There is a little difference between Windows™ and UNIX™ platforms when passing a NULL as the *value* parameter: On Windows platforms, the environment variable is removed, while on UNIX, the environment variable gets an empty value (i.e. it is not removed from the environment).

> **Important:** You may experience unexpected results if you change environment variables that are already used by the current program - for example, when you are connected to INFORMIX and you change the INFORMIXDIR environment variable.

fgl_set_arr_curr()
Moves to a specific row in a record list.

Syntax

```
fgl_set_arr_curr(
   row INTEGER )
```

1. *row* is the row number is the program array variable.

Usage

This function is typically used to control navigation in a `DISPLAY ARRAY` or `INPUT ARRAY`, within an `ON ACTION` or `ON KEY` block. The function can also be used inside `BEFORE DISPLAY` or `BEFORE INPUT` blocks, to jump to a specific row when the dialog starts. You should not use this function in an other context.

Control blocks like `BEFORE ROW` and field/row validation in `INPUT ARRAY` are performed, as if the user moved to another row, except when the function is called in `BEFORE DISPLAY` or `BEFORE INPUT`.

When a new row is reached by using with this function, the first editable field gets the focus.

An alternative to the `fgl_set_arr_curr()` function is the ui.Dialog.setCurrentRow() method; However, the dialog class method will be used in a different programming pattern, as it does not trigger the control blocks like the built-in function.

fgl_system()
Runs a command on the application server.

Syntax

```
fgl_system(
   command STRING )
```

1. *command* is the command line to be executed on the server.

Usage

The `fgl_system()` function suspends the execution of the program and executes the command passed as parameter on the application server where fglrun is executed. The command is executed in a new shell and the program is suspended until the command terminates.

When running the program in TUI mode, the terminal is switched to line mode before executing the command passed to the `fgl_system()` function.

This function is provided for backward compatibility. In older versions, the function could raise a terminal emulator on the front-end to show the command output on the workstation. This feature is no longer supported.

fgl_width()
Returns the number of columns needed to represent the printed version of the expression.

Syntax

```
fgl_width(
   expression STRING )
  RETURNING result INTEGER
```

1. *expression* is any valid string expression.

Usage

The `fgl_width()` function returns the number of columns that will be used if you display *expression* on a text terminal.

If the parameter is `NULL`, the function returns zero.

The number of columns used by a character depends on the glyph (i.e. the graphical symbol used to draw the character on the screen). For example, an ASCII character like A uses one column, while one Chinese ideogram uses 2 columns (i.e. on a text terminal, the size of one Chinese ideogram takes the same size as AB).

Trailing blanks are counted in the length of the string.

fgl_window_getoption()
Returns attributes of the current window.

Syntax

```
fgl_window_getoption(
   attribute STRING )
  RETURNING result STRING
```

1. *attribute* is the name of a window attribute.

Usage

The `fgl_window_getoption()` function returns the value of the window attribute passed as parameter.

Possible parameters are: `name`, `x`, `y`, `width`, `height`, `formline`, `messageline`.

This function is provided for backward compatibility, do not use this function in modern GUI applications.

length()
Returns the number of the character string passed as parameter.

Syntax

```
length(
   expression STRING )
  RETURNING result INTEGER
```

1. *expression* is any valid character string expression supported by the language.

Usage

The `length()` function counts the length of a character string.

If the parameter is `NULL`, the function returns zero.

> **Important:** When using byte length semantics, the length is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

set_count()
Defines the number of rows containing explicit data in a static array used by the next dialog.

Syntax

```
set_count(
   nbrows INTEGER )
```

1. *nbrows* defines the number of explicit rows in the static array.

Usage

When using a static array in an `INPUT ARRAY` (with `WITHOUT DEFAULTS` clause) or a `DISPLAY ARRAY` statement, you must specify the number of rows in the array which contain explicit data. In typical applications, these array elements contain the values fetched from a `SELECT` statement.

`set_count()` must be called before a `DISPLAY ARRAY` or `INPUT ARRAY` statement.

The number of rows can also specified with the `COUNT` attribute of `INPUT ARRAY` and `DISPLAY ARRAY` statements.

When using a dynamic array, the number of rows is implicitly defined by the array.

showhelp()
Displays a runtime help text.

Syntax

```
showhelp(
   helpnum INTEGER )
```

1. *helpnum* is the help message number in the current help file.

Usage

The `showhelp()` function displays a runtime help text, corresponding to its specified argument, from the current help file defined by the `OPTIONS HELP FILE` instruction.

In GUI mode, the help text will be displayed in a new popup window. In TUI mode, the help text is displayed in a the whole screen.

startlog()
Initializes error logging and opens the error log file passed as the parameter.

Syntax

```
startlog(
   filename STRING )
```

1. *filename* is the name of the error log file.

Usage

Call `startlog()` in the `MAIN` program block to open or create an error log file. After `startlog()` has been invoked, a record of every subsequent error that occurs during the program execution is written in the error log file.

The format of the error records appended to the error log file after each subsequent error is as follows:

```
Date: 03/06/99 Time: 12:20:20
Program error at "stock_one.4gl", line number 89.
SQL statement error number -239.
Could not insert new row - duplicate value in a UNIQUE INDEX column.
SYSTEM error number -100
ISAM error: duplicate value for a record with unique key.
```

To report specific application errors, use the `errorlog()` function to make an entry in the error log file.

If the argument of `startlog()` is not the name of an existing file, `startlog()` creates a new one. If the file already exists, `startlog()` opens it and positions the file pointer so that subsequent error messages can be appended to this file.

Example

```
CALL startlog("/var/myapp/logs/error-" || fgl_getpid() ||
 ".log")
...
CALL errorlog("The current user is not allowed to perform order
 validation")
```

upshift()
Converts a string to uppercase.

Syntax

```
upshift(
   source STRING )
  RETURNING result STRING
```

1. *source* is the character string to convert to uppercase letters.

Usage

The `upshift()` function returns a string value in which all lowercase characters in its argument are converted to uppercase.

The character conversion depends on locale settings (the LC_CTYPE environment variable). Non-alphabetic or uppercase characters are not altered.

List of desupported built-in functions

Table 355: Desupported built-in functions

Function	Description
`FGL_FORMFIELD_GETOPTION()`	Returns attributes of a specified form field.
`FGL_GETUITYPE()`	Returns the type of the front end.
`FGL_WINDOW_OPEN()`	Opens a new window with coordinates and size.
`FGL_WINDOW_OPENWITHFORM()`	Opens a new window with coordinates and form.
`FGL_WINDOW_CLEAR()`	Clears the window having the name that is passed as a parameter.
`FGL_WINDOW_CLOSE()`	Closes the window having the name that is passed as a parameter.
`FGL_WINDOW_CURRENT()`	Makes current the window having the name that is passed as a parameter.

The key code table

This table lists internal key codes. Avoid hard-coding these numbers in your sources; otherwise the source will not be compatible with future versions the language.

Always use the FGL_KEYVAL( ) function instead.

Table 356: Internal key codes

Value	Key name	Description
1 to 26	Control-*x*	Control key, where *x* is the any letter from A to Z. The key code corresponding to Control-A is 1, Control-B is 2, etc.
others < 256	ASCII chars	Other codes correspond to the ASCII characters set.
2000	up	The up-arrow logical key.
2001	down	The down-arrow logical key.
2002	left	The left-arrow logical key.
2003	right	The right-arrow logical key.
2005	nextpage	The next-page logical key.
2006	prevpage	The previous-page logical key.
2008	help	The help logical key.
2011	interrupt	The interrupt logical key.
2020	home	The home logical key.
2021	end	The end logical key.
2016	accept	The accept logical key.
2017	backspace	The backspace logical key.
3000 to 3255	F*x*	Function key, where *x* is the number of the function key. The key code corresponding to a function key F*x* is 3000+*x*-1, for example, 3011 corresponds to F12.

Utility functions

A utility function is a function provided in a separate library; it is not built in the runtime system.

To use a utility function, declare the module where the function is defined with the IMPORT FGL instruction:

```
IMPORT FGL fgldialog
...
   CALL fgl_winmessage( ... )
```

For backward compatibility, utility function are also grouped in a 42x library named libfgl4js.42x, which can be linked to your programs.

The 42x library file, 42m modules and 42f forms are located in FGLDIR/lib. The sources of the utility functions and form files are provided in the FGLDIR/src directory.

- Common dialog utility functions (IMPORT FGL fgldialog) on page 1668

- Database utility functions (IMPORT FGL fgldbutl) on page 1672
- Front-end dialog utility functions (IMPORT FGL fglwinexec) on page 1676

Common dialog utility functions (IMPORT FGL fgldialog)

Table 357: Common dialog utility functions (fgldialog.4gl)

Function	Description
`fgl_winbutton( title STRING, text STRING, default STRING, buttons STRING, icon STRING, danger SMALLINT ) RETURNING result STRING`	Displays an interactive message box containing multiple choices, in a popup window.
`fgl_winmessage( title STRING, text STRING, icon STRING )`	Displays an interactive message box containing text and OK button.
`fgl_winprompt( x INTEGER, y INTEGER, text STRING, default STRING, length INTEGER, type INTEGER ) RETURNING value STRING`	Displays a dialog box containing a field that accepts a value.
`fgl_winquestion( title STRING, text STRING, default STRING, buttons STRING, icon STRING, danger SMALLINT ) RETURNING value STRING`	Displays an interactive message box with configurable Ok/Yes/No/Cancel/Ignore/Abort/Retry buttons.
`fgl_winwait( text STRING )`	Displays an interactive message box and waits for user validation.

fgl_winbutton()
Displays an interactive message box containing multiple choices, in a popup window.

Syntax

```
fgl_winbutton(
   title STRING,
   text STRING,
   default STRING,
   buttons STRING,
```

```
   icon STRING,
   danger SMALLINT )
  RETURNING result STRING
```

1. title defines the title of the message window.
2. text specifies the string displayed in message window.
3. default indicates the default button to be pre-selected.
4. buttons defines a set of button labels separated by "|".
5. icon is the name of the icon to be displayed.
6. danger (for X11 only), number of the warnings item. Otherwise, this parameter is ignored.

Usage

Use the `fgl_winbutton()` function to open a message box and let the end user select an option in a set of buttons. The function returns the label of the button which has been selected by the user.

Use '\n' in *text* to separate lines (this does not work in TUI mode).

Supported names for the *icon* parameter are: `information`, `exclamation`, `question`, `stop`.

You can define up to 7 buttons that each have 10 characters.

If two buttons start with the same letter, the user will not be able to select one of them in the TUI mode.

The "&" before a letter for a button is displayed in TUI mode, or underlines the next letter in graphical front-ends.

This function is provided for backward compatibility, use a menu with "dialog" style instead.

Example

```
IMPORT FGL fgldialog
MAIN
  DEFINE answer STRING
  LET answer = fgl_winbutton( "Media selection", "What is your
 favorite media?",
      "Lynx", "Floppy Disk|CD-ROM|DVD-ROM|Other", "question", 0)
  DISPLAY "Selected media is: " || answer
END MAIN
```

fgl_winmessage()

Displays an interactive message box containing text and OK button.

Syntax

```
fgl_winmessage(
   title STRING,
   text STRING,
   icon STRING )
```

1. *title* defines message box title.
2. *text* is the text displayed in the message box. Use '\n' to separate lines.
3. *icon* is the name of the icon to be displayed.

Usage

The `fgl_winmessage()` function displays a message box to the end user.

Important: With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.

Supported names for the *icon* parameter are: `information`, `exclamation`, `question`, `stop`. Note that on some front-ends such as iOS devices, the native message popup window does not display an image.

On front-ends using a system dialog box API, the OK buttons will be automatically localized according to the operating system language settings. On other front-ends, the option buttons will be decorated according to action default settings.

Example

```
IMPORT FGL fgldialog
MAIN
  CALL fgl_winmessage( "Title", "This is a critical message.",
 "stop")
END MAIN
```

fgl_winprompt()
Displays a dialog box containing a field that accepts a value.

Syntax

```
fgl_winprompt(
   x INTEGER,
   y INTEGER,
   text STRING,
   default STRING,
   length INTEGER,
   type INTEGER )
  RETURNING value STRING
```

1. *x* is the column position in characters.
2. *y* is the line position in characters.
3. *text* is the message shown in the box.
4. *default* is the default value.
5. *length* is the maximum length of the input value.
6. *type* is the data type of the return value.
7. *value* is the value entered by the user.

Usage

The `fgl_winprompt()` function allows the end user to enter a value.

This function is provided for backward compatibility, you can also use your own input dialog with a customized form to get a value from the user. Or use the standard `PROMPT` instruction.

Possible values for the type parameter are: `0=CHAR, 1=SMALLINT, 2=INTEGER, 7=DATE, 255=invisible`

Avoid passing `NULL` values.

Example

```
IMPORT FGL fgldialog
MAIN
```

```
  DEFINE answer DATE
  LET answer = fgl_winprompt( 10, 10, "Today", DATE, 10, 7 )
  DISPLAY "Today is " || answer
END MAIN
```

fgl_winquestion()
Displays an interactive message box with configurable Ok/Yes/No/Cancel/Ignore/Abort/Retry buttons.

Syntax

```
fgl_winquestion(
   title STRING,
   text STRING,
   default STRING,
   buttons STRING,
   icon STRING,
   danger SMALLINT )
  RETURNING value STRING
```

1. *title* is the message box title.
2. *text* is the message displayed in the message box. Use '\n' to separate lines (does not work on ASCII client).
3. *default* defines the default button that is preselected.
4. *buttons* defines the options. Must be a pipe-separated list of 2 or three options : ok, yes, no, cancel, abort, retry, ignore.
5. *icon* is the name of the icon to be displayed.
6. *danger* is supported for backward compatibility. This parameter is ignored.

Usage

The `fgl_winquestion()` function shows a question message box to the end user and waits for an answer.

> **Important:** With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.

The function returns the label of the option which has been selected by the user.

Supported names for the *icon* parameter are: `information`, `exclamation`, `question`, `stop`. Note that on some front-ends such as iOS devices, the native message popup window does not display an image.

The *buttons* parameter defines the list of options that the user can select. Possible values are: `ok`, `yes`, `no`, `cancel`, `abort`, `retry`, `ignore`. You must specify a pipe-separated list of options, with a maximum of 3 options. For example: `"ok"`, `"yes|no"`, `"yes|no|cancel"`, `"abort|retry|ignore"`.

> **Important:** To display the popup window of this API, desktop and mobile front-ends use the platform specific message box API, with a predefined set of buttons. Some non-standard option combinations may not be supported, such as `"ok|yes|abort"`. Further, the order of the buttons depends also from platform standards. For example, with `"abort|retry|ignore"`, the buttons can appear in the following order: `[Retry] [Ignore] [Abort]`.

On front-ends using a system dialog box API, the option buttons will be automatically localized according to the operating system language settings. On other front-ends, the option buttons will be decorated according to action default settings.

Example

```
IMPORT FGL fgldialog
MAIN
  DEFINE answer STRING
  LET answer = "yes"
  WHILE answer = "yes"
    LET answer = fgl_winquestion(
        "Procedure", "Would you like to continue ? ",
        "cancel", "yes|no|cancel", "question", 0)
  END WHILE
  IF answer = "cancel" THEN
     DISPLAY "Canceled."
  END IF
END MAIN
```

fgl_winwait()
Displays an interactive message box and waits for user validation.

Syntax

```
fgl_winwait(
   text STRING )
```

1. *text* is the message displayed in the message box. Use '\n' to separate lines (not working on ASCII client).

Usage

The `fgl_winwait()` function displays a message to the end user and waits until the user presses the OK button.

> **Important:** With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.

Database utility functions (IMPORT FGL fgldbutl)

Table 358: Database utility functions (fgldbutl.4gl)

Function	Description
`db_get_database_type()` `  RETURNING result STRING`	Returns the database type for the current connection.

`db_get_sequence(`
`   id STRING )`
`  RETURNING result BIGINT`
	Generates a new sequence for a given identifier.

`db_start_transaction()` `  RETURNING result INTEGER`	Starts a nested transaction call.
`db_finish_transaction(`	Terminates a nested transaction call.

Function	Description
commit INTEGER) RETURNING *result* INTEGER	
db_is_transaction_started() RETURNING *result* INTEGER	Indicates whether a nested transaction call is started.

db_get_database_type()
Returns the database type for the current connection.

Syntax

```
db_get_database_type()
  RETURNING result STRING
```

Usage

After connecting to the database, you can get the type of the database server with this function.

Important: This function is deprecated, use the `fgl_dbdriver_type()` function instead.

Table 359: Codes returned by db_get_database_type() per database type

Code	Description
ASE	Sybase ASE
DB2	IBM® DB2®
IFX	IBM® Informix®
MYS	Oracle MySQL
MSV	Microsoft™ SQL Server
ORA	Oracle Database
PGS	PostgreSQL

db_get_sequence()
Generates a new sequence for a given identifier.

Syntax

```
db_get_sequence(
   id STRING )
  RETURNING result BIGINT
```

1. *id* is the identifier of the sequence.
2. *result* is the new generated sequence.

Usage

This function generates a new sequence from a register table created in the current database.

Important:

1. Needs a database table called SEQREG.

2. The function must be called inside a transaction block.

The table must be created as follows:

```
CREATE TABLE seqreg (
  sr_name VARCHAR(30) NOT NULL,
  sr_last BIGINT NOT NULL,
  PRIMARY KEY (sr_name)
)
```

Each time you call this function, the sequence is incremented in the database table and returned by the function.

It is mandatory to use this function inside a transaction block, in order to generate unique sequences.

Example

```
IMPORT FGL fgldbutl
MAIN
  DEFINE ns BIGINT, s INTEGER
  DATABASE mydb
  BEGIN WORK
  LET ns = db_get_sequence("mytable")
  INSERT INTO mytable VALUES ( ns, 'a new sequence' )
  COMMIT WORK
END MAIN
```

db_start_transaction()
Starts a nested transaction call.

Syntax

```
db_start_transaction()
  RETURNING result INTEGER
```

1. *result* is the SQL execution status or the transaction start. Zero indicates success.

Usage

On most database engines, you can only have a unique transaction, that is started with `BEGIN WORK` and ended with `COMMIT WORK` or `ROLLBACK WORK`. But in a some cases, you may need to do complex nested function calls, executing several SQL instruction that must all be grouped in a single transaction. The nested transaction utility functions help you to implement this.

With this nested transaction technique, you encapsulate transaction start and end withing the utility function. Custom functions doing SQL operations can then be reused in different parts of your application: If the caller does not start the transaction, the called function will automatically start and end the transaction.

The `db_start_transaction()` function encapsulates the `BEGIN WORK` instruction to start a transaction, in order to implement nested transactions.

> **Note:** These transaction encapsulation functions are provided for special cases, where the function call graph is complex. In general, you should simply use the standard `BEGIN WORK` / `COMMIT WORK` / `ROLLBACK WORK` instructions to implement transaction blocks.

These transaction management functions execute a real transaction instruction at the boundaries of the subsequent start/finish calls.

Example

```
IMPORT FGL fgldbutl

MAIN
  DEFINE s INTEGER
  DATABASE mydb
  LET s = db_start_transaction() -- real BEGIN WORK
  IF s != 0 THEN DISPLAY "error 1" END IF
  WHENEVER ERROR CONTINUE
  UPDATE customer SET cust_name = 'Undef'
  WHENEVER ERROR STOP
  LET s = SQLCA.SQLCODE
  IF s != 0 THEN
     DISPLAY "error 2"
  ELSE
     LET s = do_update()
     IF s != 0 THEN DISPLAY "error 3" END IF
  END IF
  LET s = db_finish_transaction(s==0) -- real COMMIT or ROLLBACK
 WORK
  IF s != 0 THEN DISPLAY "error 4" END IF
END MAIN

FUNCTION do_update()
  DEFINE s INTEGER
  LET s = db_start_transaction() -- no SQL command (nested)
  IF s != 0 THEN
     DISPLAY "error 1.1"
  ELSE
     WHENEVER ERROR CONTINUE
     UPDATE customer SET cust_status = 'X'
     WHENEVER ERROR STOP
     LET s = SQLCA.SQLCODE
     IF s != 0 THEN
        DISPLAY "error 1.2"
     END IF
  END IF
  LET s = db_finish_transaction(s==0) -- no SQL command (nested)
  IF s != 0 THEN DISPLAY "error 1.3" END IF
  RETURN s
END FUNCTION
```

db_finish_transaction()
Terminates a nested transaction call.

Syntax

```
db_finish_transaction(
   commit INTEGER )
  RETURNING result INTEGER
```

1. *commit* is a boolean that indicates whether the transaction must be committed.
2. *result* is the SQL execution status or the commit or rollback. Zero indicates success.

Usage

This function encapsulates the `COMMIT WORK` or `ROLLBACK WORK` instructions to end a transaction.

When the number of calls to `DB_START_TRANSACTION()` matches, this function executes a `COMMIT WORK` if the passed parameter is `TRUE`; if the passed parameter is `FALSE`, it executes a `ROLLBACK WORK`.

If the number of start/finish calls does not match, the function does nothing.

db_is_transaction_started()
Indicates whether a nested transaction call is started.

Syntax

```
db_is_transaction_started()
  RETURNING result INTEGER
```

- *result* is a boolean value that indicates if a nested transaction call sequence was started.

Usage

The function returns `TRUE` if a transaction was started with `db_start_transaction()`, and was not yet finished with a call to the `db_finish_transaction()` function.

Front-end dialog utility functions (IMPORT FGL fglwinexec)

Table 360: Front-end-side dialog functions (fglwinexec.4gl) (deprecated: use ui.Interface.frontCall() instead)

Function	Description
`winopendir( dirname STRING, caption STRING ) RETURNING result STRING`	Opens a dialog window to get a directory path on the front-end workstation.
`winopenfile( dirname STRING, typename STRING, extlist STRING, caption STRING ) RETURNING result STRING`	Opens a dialog window to get a file to be read on the front-end workstation.
`winsavefile( dirname STRING, typename STRING, extlist STRING, caption STRING ) RETURNING result STRING`	Opens a dialog window to get a file path to save data on the front-end workstation.
`winshellexec( filename STRING ) RETURNING result INTEGER`	Opens a document on the workstation where the Windows™ front end runs. Microsoft™ Windows™ only!
`winexecwait(`	Executes a program on the workstation where the Windows™ front-end runs and waits for termination.

Function	Description
command STRING) RETURNING *result* INTEGER	Microsoft™ Windows™ only!
winexec(*command* STRING) RETURNING *result* INTEGER	Executes a program on the workstation where the Windows™ front end runs and returns immediately. Microsoft™ Windows™ only!

winopendir()
Opens a dialog window to get a directory path on the front-end workstation.

Syntax

```
winopendir(
   dirname STRING,
   caption STRING )
  RETURNING result STRING
```

1. *dirname* is the default path to be displayed in the dialog window.
2. *caption* is the label to be displayed.

Usage

This function opens a dialog window to let the user select a directory path on the front end workstation file system.

The function returns the directory path on success.

The function returns NULL if a problem has occurred or if the user canceled the dialog.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

winopenfile()
Opens a dialog window to get a file to be read on the front-end workstation.

Syntax

```
winopenfile(
   dirname STRING,
   typename STRING,
   extlist STRING,
   caption STRING )
  RETURNING result STRING
```

1. *dirname* is the default path to be displayed in the dialog window.
2. *typename* is the name of the file type to be displayed.
3. *extlist* is a blank-separated list of file extensions defining the file type.
4. *caption* is the label to be displayed.

Usage

This function opens a dialog window to let the user select a file path on the front end workstation file system, in order to open the file.

The function returns the file path on success.

The function returns NULL if a problem has occurred or if the user canceled the dialog.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

winsavefile()
Opens a dialog window to get a file path to save data on the front-end workstation.

Syntax

```
winsavefile(
   dirname STRING,
   typename STRING,
   extlist STRING,
   caption STRING )
  RETURNING result STRING
```

1. *dirname* is the default path to be displayed in the dialog window.
2. *typename* is the name of the file type to be saved.
3. *extlist* is a blank separated list of file extensions defining the file type.
4. *caption* is the label to be saved.

Usage

This function opens a dialog window to let the user select a file path on the front end workstation file system, in order to save the file.

The function returns the file path on success.

The function returns NULL if a problem has occurred or if the user canceled the dialog.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

winexec() MS Windows™ FE Only!
Executes a program on the workstation where the Windows™ front end runs and returns immediately.

Syntax

```
winexec(
   command STRING )
  RETURNING result INTEGER
```

1. *command* is the command to be executed on the front end.

Usage

The function executes the program on the Windows™ front end and returns the control to the program without waiting.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

winexecwait() MS Windows™ FE Only!
Executes a program on the workstation where the Windows™ front-end runs and waits for termination.

Syntax

```
winexecwait(
   command STRING )
  RETURNING result INTEGER
```

1. *command* is the command to be executed on the front end.

Usage

The function executes the program on the Windows™ front end and waits for its termination.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

winshellexec() MS Windows™ FE Only!
Opens a document on the workstation where the Windows™ front end runs.

Syntax

```
winshellexec(
   filename STRING )
  RETURNING result INTEGER
```

1. *filename* is the file to be opened on the front end.

Usage

The function opens a document on the Windows™ front end without waiting.

> **Important:** This function is provided for backward compatibility and should be avoided to run your programs with different sort of front-ends. It must be called after the front-end connection was established.

vCard utility functions (IMPORT FGL VCard)

Table 361: vCard utility functions (VCard.4gl)

Function	Description

`PUBLIC TYPE VCAddress RECORD`
`  PostOfficeBox,`
`  ExtendedAddress, --  apartment or suite number`
`  Street,`
`  City,`
`  State,`
`  ZIP,`
`  Country STRING`
`  -- , CountryCode STRING -- X-ABADR:de`
	The VCAddress structured type to hold vCard address data.

Function	Description
`  END RECORD`	

`PUBLIC TYPE VCName RECORD`
`    FirstName,`
`    LastName,`
`    MiddleName,`
`    Prefix,`
`    Suffix STRING`
`    --, FormattedName STRING`
`  END RECORD`
	The VCName structured type to hold vCard data related to the person name.

`PUBLIC TYPE VCPerson RECORD`
`    FirstName STRING, -- N[1]`
`    LastName STRING, -- N[2]`
`    MiddleName STRING, -- N[3]`
`    Prefix STRING, -- N[4]`
`    Suffix STRING, -- N[5]`
`    formattedName STRING, -- FN`
`    nickname STRING, -- NICKNAME`
`    jobTitle STRING, -- TITLE`
`    organization STRING, --`
` ORG.value[1]`
`    department STRING, --`
` ORG.value[2]`
`    birthday STRING, -- BDAY`
`    note STRING, -- NOTE`
`    address DYNAMIC ARRAY OF RECORD`
`        type STRING,`
`        PostOfficeBox, -- ADR[1]`
`        ExtendedAddress, -- ADR[2]`
`        Street, -- ADR[3]`
`        City, -- ADR[4]`
`        State, -- ADR[5]`
`        ZIP, -- ADR[6]`
`        Country STRING   -- ADR[7]`
`    END RECORD,`
`    phone DYNAMIC ARRAY OF RECORD`
`        type STRING,`
`        number STRING -- TEL`
`    END RECORD,`
`    email DYNAMIC ARRAY OF RECORD`
`        type STRING,`
`        value STRING -- EMAIL`
`  END RECORD`
	The VCPerson structured type to hold vCard data.

`format_person(`
`   person VCPerson )`
`  RETURNING result STRING`
	Converts a VCPerson record to a vCard string representation vCard.

`scan_address(`
`   source STRING,`
`   type STRING )`
	Extracts an address from a string representing a vCard.

Function	Description
RETURNING *address* VCAddress	
scan_email(*source* STRING, *type* STRING) RETURNING *email* STRING	Extracts an email from a string representing a vCard.
scan_person(*source* STRING) RETURNING *person* VCPerson	Extracts person's data from a string representing a vCard.
scan_phone(*source* STRING, *type* STRING) RETURNING *phone* STRING	Extracts a phone number from a string representing a vCard.

VCAddress type
The VCAddress structured type to hold vCard address data.

Syntax

```
PUBLIC TYPE VCAddress RECORD
    PostOfficeBox,
    ExtendedAddress, --  apartment or suite number
    Street,
    City,
    State,
    ZIP,
    Country STRING
    -- , CountryCode STRING -- X-ABADR:de
  END RECORD
```

Usage

This type defines a record structure to hold vCard address information. It is used for values returned by the scan_address() function.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE a VCard.VCAddress
  LET a.Street = "Sunset Bld"
END MAIN
```

VCName type
The VCName structured type to hold vCard data related to the person name.

Syntax

```
PUBLIC TYPE VCName RECORD
    FirstName,
```

```
    LastName,
    MiddleName,
    Prefix,
    Suffix STRING
    --, FormattedName STRING
  END RECORD
```

Usage

This type defines a record structure to hold vCard information related to the person name. It is used for values returned by the scan_name() function.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE n VCard.VCName
  LET n.FirstName = "Hans"
  LET n.LastName = "Mustermann"
END MAIN
```

VCPerson type
The VCPerson structured type to hold vCard data.

Syntax

```
PUBLIC TYPE VCPerson RECORD
    FirstName STRING, -- N[1]
    LastName STRING, -- N[2]
    MiddleName STRING, -- N[3]
    Prefix STRING, -- N[4]
    Suffix STRING, -- N[5]
    formattedName STRING, -- FN
    nickname STRING, -- NICKNAME
    jobTitle STRING, -- TITLE
    organization STRING, -- ORG.value[1]
    department STRING, -- ORG.value[2]
    birthday STRING, -- BDAY
    note STRING, -- NOTE
    address DYNAMIC ARRAY OF RECORD
        type STRING,
        PostOfficeBox, -- ADR[1]
        ExtendedAddress, -- ADR[2]
        Street, -- ADR[3]
        City, -- ADR[4]
        State, -- ADR[5]
        ZIP, -- ADR[6]
        Country STRING   -- ADR[7]
    END RECORD,
    phone DYNAMIC ARRAY OF RECORD
        type STRING,
        number STRING -- TEL
    END RECORD,
    email DYNAMIC ARRAY OF RECORD
        type STRING,
        value STRING -- EMAIL
  END RECORD
```

Usage

This type defines a record structure to hold vCard information. It is used by VCard functions such as format_person().

Example

```
IMPORT FGL VCard
MAIN
  DEFINE p VCard.VCPerson
  LET p.FirstName = "Hans"
  LET p.LastName = "Mustermann"
END MAIN
```

format_person()
Converts a VCPerson record to a vCard string representation vCard.

Syntax

```
format_person(
   person VCPerson )
  RETURNING result STRING
```

1. *person* is a VCPerson record.
2. *result* is the resulting vCard string (version 3.0).

Usage

This function converts a record defined with the VCPerson type, to a string representing a vCard.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE p VCard.VCPerson
  LET p.FirstName = "Hans"
  LET p.LastName = "Mustermann"
  LET p.email[1].VALUE = "hans@nomail.com"
  LET p.phone[1].TYPE = "HOME"
  LET p.phone[1].number = "+49 123 4567 8901"
  LET p.phone[2].TYPE = "WORK"
  LET p.phone[2].number = "+49 123 9876 5431"
  DISPLAY VCard.format_person(p.*)
END MAIN
```

Output:

```
BEGIN:VCARD
VERSION:3.0
N:Hans;Mustermann;;;
FN:Hans Mustermann
TEL;TYPE=HOME:+49 123 4567 8901
TEL;TYPE=WORK:+49 123 9876 5431
EMAIL:hans@nomail.com
END:VCARD
```

scan_address()
Extracts an address from a string representing a vCard.

Syntax

```
scan_address(
   source STRING,
   type STRING )
  RETURNING address VCAddress
```

1. *source* is the vCard string (version 3.0).
2. *type* is the type of address (HOME, WORK, pref).
3. *address* is the address found, returned as VCAddress structure.

Usage

This function parses the vCard string passed as parameter to find address data according to a type, and returns address information in a record defined with the `VCAddress` type.

The function looks for lines starting with the "ADR" keyword.

The second parameter (*type*) defines is the value of the "TYPE" attribute in an "ADR" line. Values can for example be "HOME", "WORK", "pref". If this parameter is `NULL`, the address with TYPE=pref will be returned. If no preferred address exists, the first address will be returned.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE a VCard.VCAddress,
         f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_address(f,"WORK") RETURNING a.*
  DISPLAY a.*
END MAIN
```

scan_email()
Extracts an email from a string representing a vCard.

Syntax

```
scan_email(
   source STRING,
   type STRING )
  RETURNING email STRING
```

1. *source* is the vCard string (version 3.0).
2. *type* is the type of email (HOME, WORK, pref).
3. *email* is the email found.

Usage

This function parses the vCard string passed as parameter to find "EMAIL" data according to a type, and returns the email address as a string.

The function looks for lines starting with the "EMAIL" keyword.

The second parameter (*type*) defines is the value of the "TYPE" attribute in an "EMAIL" line. Values can for example be "HOME", "WORK", "pref". If this parameter is NULL, the email with TYPE=pref will be returned. If no preferred email exists, the first email will be returned.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE m STRING,
         f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_email(f,NULL) RETURNING m
  DISPLAY m
END MAIN
```

scan_name()
Extracts name information from a string representing a vCard.

Syntax

```
scan_name(
   source STRING)
  RETURNING name VCName
```

1. *source* is the vCard string (version 3.0).
2. *name* is the name found, returned as VCName structure.

Usage

This function parses the vCard string passed as parameter to find person name data, and returns name information in a record defined with the VCName type.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE n VCard.VCName,
         f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_name(f) RETURNING n.*
  DISPLAY n.*
END MAIN
```

scan_person()
Extracts person's data from a string representing a vCard.

Syntax

```
scan_person(
   source STRING )
  RETURNING person VCPerson
```

1. *source* is the vCard string (version 3.0).
2. *person* is the resulting VCPerson structure.

Usage

This function parses the vCard string passed as parameter, extracts all information, and returns a record defined with the VCPerson type.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE p VCard.VCPerson,
         f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_person(f) RETURNING p.*
  DISPLAY p.*
END MAIN
```

scan_phone()
Extracts a phone number from a string representing a vCard.

Syntax

```
scan_phone(
   source STRING,
   type STRING )
  RETURNING phone STRING
```

1. *source* is the vCard string (version 3.0).
2. *type* is the type of phone number (HOME, WORK, TEXT, VOICE, FAX, CELL, VIDEO, PAGER, TEXTPHONE, pref).
3. *phone* is the phone number found.

Usage

This function parses the vCard string passed as parameter to find phone data according to a type, and returns the phone number in a string.

The function looks for lines starting with the "TEL" keyword.

The second parameter (*type*) defines is the value of the "TYPE" attribute in an "TELs" line. Values can for example be "HOME", "WORK", "TEXT", "VOICE", "FAX", "CELL", "VIDEO", "PAGER", "TEXTPHONE", "pref". If this parameter is `NULL`, the phone number with TYPE=pref will be returned. If no preferred phone number exists, the first phone number will be returned.

Example

```
IMPORT FGL VCard
MAIN
  DEFINE n STRING,
         f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_phone(f,NULL) RETURNING n
  DISPLAY n
END MAIN
```

Built-in packages

These topics cover the built-in classes provided by the Genero Business Development Language.

- The BYTE data type as class on page 1687
- The STRING data type as class on page 1689
- The TEXT data type as class on page 1695
- DYNAMIC ARRAY as class on page 1697
- The Java Array type as class on page 1701
- The Application class on page 1703
- The Channel class on page 1707
- The StringBuffer class on page 1738
- The StringTokenizer class on page 1749
- The TypeInfo class on page 1752
- The MessageServer class on page 1754
- The Interface class on page 1755
- The Window class on page 1769
- The Form class on page 1774
- The Dialog class on page 1784
- The ComboBox class on page 1820
- The DragDrop class on page 1827
- The DomDocument class on page 1833
- The DomNode class on page 1839
- The NodeList class on page 1858
- The SaxAttributes class on page 1860
- The SaxDocumentHandler class on page 1865
- The XmlReader class on page 1871
- The XmlWriter class on page 1876

BDL data types package

These topics cover the built-in classes of BDL data types

- The BYTE data type as class on page 1687
- The STRING data type as class on page 1689
- The TEXT data type as class on page 1695
- DYNAMIC ARRAY as class on page 1697
- The Java Array type as class on page 1701

The BYTE data type as class

The BYTE built-in data type provides a set of utility methods to manipulate BYTE data.

BYTE methods can be invoked with the variable, for example:

```
DEFINE b BYTE
CALL t.writeFile("mydata")
```

BYTE data type methods

Table 362: Object methods

Name	Description
`readFile( filename STRING )`	Reads a file into a BYTE locator.
`writeFile( filename STRING )`	Writes the containt of a BYTE to a file.

BYTE.readFile
Reads a file into a BYTE locator.

Syntax

```
readFile( filename STRING )
```

1. *filename* is the path the file to be loaded.

Usage

This method reads a content from the specified file into the BYTE locator.

The bytes are loaded as is, without any conversion.

If the file is not found or if it cannot be read, the error -8087 is raised.

Example

```
MAIN
  DEFINE b BYTE
  LOCATE b IN MEMORY
  CALL b.readFile("mydata")
END MAIN
```

BYTE.writeFile
Writes the containt of a BYTE to a file.

Syntax

```
writeFile( filename STRING )
```

1. *filename* is the file to be written to.

Usage

This method writes the containt of the current BYTE locator to the specified file.

The bytes are written as is, without any conversion.

If the file cannot be written, the error -8087 is raised.

Example

```
MAIN
  DEFINE b BYTE
  LOCATE b IN MEMORY
```

```
  SELECT col_byte INTO b FROM ...
  CALL b.writeFile("mydata")
END MAIN
```

The STRING data type as class

The `STRING` built-in data type provides a set of utility methods to manipulate character strings.

`STRING` methods can be invoked with the variable, for example:

```
DEFINE s STRING
IF s.equalsIgnoreCase("pink") THEN
   ...
END IF
```

STRING data type methods

Table 363: Object methods

Name	Description
`append( string STRING ) RETURNING result STRING`	Concatenates a string.
`equals( string STRING ) RETURNING result BOOLEAN`	Compares a string to the content of the variable.
`equalsIgnoreCase( string STRING ) RETURNING result BOOLEAN`	Makes a case-insensitive string comparison.
`getCharAt( position INTEGER ) RETURNING result CHAR(1)`	Returns the character at the specified position.
`getIndexOf( string STRING, start INTEGER ) RETURNING result INTEGER`	Returns the position of a sub-string.
`getLength( ) RETURNING result INTEGER`	Returns the length of the current string.
`subString( start INTEGER, end INTEGER ) RETURNING result STRING`	Returns a sub-string according to start and end positions.
`toLowerCase( ) RETURNING result STRING`	Returns the string converted to lower case.
`toUpperCase( )`	Returns the string converted to upper case.

Name	Description
`RETURNING result STRING`	
`trim( )` `RETURNING result STRING`	Removes leading a trailing blanks.
`trimLeft( )` `RETURNING result STRING`	Removes leading blanks.
`trimRight( )` `RETURNING result STRING`	Removes trailing blanks.

STRING.append
Concatenates a string.

Syntax

```
append( string STRING )
       RETURNING result STRING
```

1. *string* is the string to be concatenated.

Usage

This method concatenates a string to the current `STRING` variable and returns the resulting string.

The original `STRING` variable is not modified.

Appending a `NULL` will have no effect: the original string is returned.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.append("... more text")
END MAIN
```

STRING.equals
Compares a string to the content of the variable.

Syntax

```
equals( string STRING )
       RETURNING result BOOLEAN
```

1. *string* is the string to compare with.

Usage

This method compares a string to the current `STRING` variable and returns `TRUE` if both strings match.

If the original `STRING` variable or the string passed as parameter is `NULL`, the result with be `FALSE`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "white"
  IF s.equals("white") THEN
     DISPLAY "Matches"
  END IF
END MAIN
```

STRING.equalsIgnoreCase
Makes a case-insensitive string comparison.

Syntax

```
equalsIgnoreCase( string STRING )
       RETURNING result BOOLEAN
```

1. *string* is the string to compare with.

Usage

This method compares a string to the current `STRING` variable by ignoring the character case, and returns `TRUE` if both strings match.

If the original `STRING` variable or the string passed as parameter is `NULL`, the result with be `FALSE`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "white"
  IF s.equalsIgnoreCase("WHITE") THEN
     DISPLAY "Matches"
  END IF
END MAIN
```

STRING.getCharAt
Returns the character at the specified position.

Syntax

```
getCharAt( position INTEGER )
       RETURNING result CHAR(1)
```

1. *position* is the position of the character int the string.

Usage

This method extracts the character at the specified position from the `STRING` variable.

If the `STRING` variable is `NULL`, or if the *position* is out of the bounds of the string, the result will be `NULL`.

> **Important:** When using byte length semantics, the position is expressed in bytes, and when using char length semantincs, position is specified in characters. In byte length semantics, the method returns `NULL` if the position does not match a valid character-byte index in the current string.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.getCharAt(4)
END MAIN
```

STRING.getIndexOf
Returns the position of a sub-string.

Syntax

```
getIndexOf( string STRING, start INTEGER )
       RETURNING result INTEGER
```

1. *string* is the sub-string to be searched.
2. *start* is the starting position for the search.

Usage

This method scans a `STRING` variable to find the sub-string passed as parameter, and returns the position of the sub-string.

The method starts to search the sub-string at the starting position specified as second parameter.

The method returns zero if:

- The substring was not found.
- The variable is `NULL`.
- The sub-string is `NULL`.
- The start position is out of bounds.

Important: When using byte length semantics, the position is expressed in bytes, and when using char length semantincs, it is specified in characters.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.getIndexOf("text",1)
END MAIN
```

STRING.getLength
Returns the length of the current string.

Syntax

```
getLength( )
       RETURNING result INTEGER
```

Usage

This method counts the number of bytes or characters in a `STRING` variable.

Note: Unlike the `LENGTH( )` function, the getLength() method counts the trailing blanks.

If the STRING variable is NULL, the method returns zero.

> **Important:** When using byte length semantics, the length is expressed in bytes, and when using char length semantincs, it is expressed in characters.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.getLength()
END MAIN
```

STRING.subString
Returns a sub-string according to start and end positions.

Syntax

```
subString( start INTEGER, end INTEGER )
       RETURNING result STRING
```

1. *start* is the starting position of the sub-string.
2. *end* is the ending position of the sub-string.

Usage

This method returns a sub-string of the current STRING variable according to a start and end position in the original string.

If the STRING variable is NULL, or when the positions are out of bounds, the method returns NULL.

> **Important:** When using byte length semantics, the positions are expressed in bytes, and when using char length semantincs, positions are expressed in characters.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.subString(6,9)
END MAIN
```

STRING.toLowerCase
Returns the string converted to lower case.

Syntax

```
toLowerCase( )
       RETURNING result STRING
```

Usage

This method converts the current STRING variable to lower case and returns the resulting string.

If the original STRING variable is NULL, the result is NULL.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.toLowerCase()
END MAIN
```

STRING.toUpperCase
Returns the string converted to upper case.

Syntax

```
toUpperCase( )
       RETURNING result STRING
```

Usage

This method converts the current `STRING` variable to upper case and returns the resulting string.

If the original `STRING` variable is `NULL`, the result is `NULL`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.toUpperCase()
END MAIN
```

STRING.trim
Removes leading a trailing blanks.

Syntax

```
trim( )
       RETURNING result STRING
```

Usage

This method deletes the white space characters before the first character and after the last character of the current `STRING` variable and returns the resulting string.

If the original `STRING` variable is `NULL`, the result will be `NULL`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "   Some text   "
  DISPLAY s.trim()
END MAIN
```

STRING.trimLeft
Removes leading blanks.

Syntax

```
trimLeft( )
       RETURNING result STRING
```

Usage

This method deletes the white space characters before the first character of the current `STRING` variable and returns the resulting string.

If the original `STRING` variable is `NULL`, the result will be `NULL`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "    Some text"
  DISPLAY s.trimLeft()
END MAIN
```

STRING.trimRight
Removes trailing blanks.

Syntax

```
trimRight( )
       RETURNING result STRING
```

Usage

This method deletes the white space characters after the last character of the current `STRING` variable and returns the resulting string.

If the original `STRING` variable is `NULL`, the result will be `NULL`.

Example

```
MAIN
  DEFINE s STRING
  LET s = "Some text     "
  DISPLAY s.trimRight()
END MAIN
```

The TEXT data type as class
The `TEXT` built-in data type provides a set of utility methods to manipulate TEXT data.

`TEXT` methods can be invoked with the variable, for example:

```
DEFINE t TEXT
CALL t.writeFile("mydata")
```

TEXT data type methods

Table 364: Object methods

Name	Description
`getLength( )` `RETURNING result INTEGER`	Returns the length of a TEXT content.
`readFile( filename STRING )`	Reads a file into a TEXT locator.
`writeFile( filename STRING )`	Writes the containt of a TEXT to a file.

TEXT.getLength
Returns the length of a TEXT content.

Syntax

```
getLength( )
   RETURNING result INTEGER
```

Usage

This method returns the number of bytes of the TEXT data.

> **Important:** This method returns always a number of bytes, even when using character length semantics.

Example

```
MAIN
  DEFINE t TEXT
  LOCATE t IN MEMORY
  DISPLAY t.getLength()
END MAIN
```

TEXT.readFile
Reads a file into a TEXT locator.

Syntax

```
readFile( filename STRING )
```

1. *filename* is the path the file to be loaded.

Usage

This method reads a content from the specified file into the TEXT locator.

If the file is not found or if it cannot be read, the error -8087 is raised.

> **Important:** The character set used in the file must match the current application locale.

Example

```
MAIN
  DEFINE t TEXT
  LOCATE t IN MEMORY
  CALL t.readFile("mydata")
END MAIN
```

TEXT.writeFile
Writes the containt of a TEXT to a file.

Syntax

```
writeFile( filename STRING )
```

1. *filename* is the file to be written to.

Usage

This method writes the containt of the current TEXT locator to the specified file.

If the file cannot be written, the error -8087 is raised.

Important: The character set used in the file must match the current application locale.

Example

```
MAIN
  DEFINE t TEXT
  LOCATE t IN MEMORY
  SELECT col_text INTO t FROM ...
  CALL t.writeFile("mydata")
END MAIN
```

DYNAMIC ARRAY as class

The DYNAMIC ARRAY (or static ARRAY) type provides a set of utility methods to manipulate the array elements.

DYNAMIC ARRAY methods can be invoked with the variable, for example:

```
DEFINE a DYNAMIC ARRAY OF STRING
CALL a.appendElement()
DISPLAY a.getLength()
```

DYNAMIC ARRAY methods

Table 365: Object methods

Name	Description
`appendElement( )`	Adds a new element to the end of the array.
`clear( )`	Removes all elements of the array.

Name	Description
`RETURNING result INTEGER`	
`deleteElement( index INTEGER )`	Removes an element from the array according to its index.
`getLength( )` `RETURNING result INTEGER`	Returns the length of the array.
`insertElement( index INTEGER )`	Inserts a new element at the given index.
`sort( key STRING, reverse BOOLEAN )`	Sorts the rows in the array.

DYNAMIC ARRAY.appendElement
Adds a new element to the end of the array.

Syntax

```
appendElement( )
```

Usage

This method creates a new element at the end of the array.

The element is initialized to `NULL`.

Example

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  ... (array has already 10 elements)
  CALL a.appendElement()
  LET a[a.getLength()] = a.getLength()
  DISPLAY a.getLength() -- shows 11
  DISPLAY a[10]  -- shows 10
  DISPLAY a[11]  -- shows 11
END MAIN
```

Since element allocation occurs automatically for dynamic arrays, you can omit the call the `appendElement()` method and assign directly the new element:

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  LET a[100] = 87234 -- Array gets a length of 100 automatically
  LET a[101] = 98562 -- New element at position 101
END MAIN
```

DYNAMIC ARRAY.clear
Removes all elements of the array.

Syntax

```
clear( )
```

```
    RETURNING result INTEGER
```

Usage

This method clears the array, by removing all its elements.

Use the `clear()` method just before filling the array with a new set of elements, if the array is potentially not empty.

Example

```
FUNCTION fill_array(arr)
    DEFINE arr DYNAMIC ARRAY OF STRING
    DEFINE i INTEGER
    CALL arr.clear()
    FOR i=1 TO 10
       LET arr[i] = "Item #"||i
    END FOR
END FUNCTION
```

DYNAMIC ARRAY.deleteElement
Removes an element from the array according to its index.

Syntax

```
deleteElement( index INTEGER )
```

Usage

This method removes the array element at the specified index.

No error is raised if the index is out of bounds.

Example

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  LET a[10] = 9
  CALL a.deleteElement(5)
  DISPLAY a.getLength() -- shows 9
  DISPLAY a[9]  -- shows 9
END MAIN
```

DYNAMIC ARRAY.getLength
Returns the length of the array.

Syntax

```
getLength( )
   RETURNING result INTEGER
```

Usage

This method returns the number of elements in the array.

Example

```
DEFINE arr DYNAMIC ARRAY OF STRING,
       i INTEGER
FOR i=1 TO arr.getLength()
    DISPLAY arr[i]
END FOR
```

DYNAMIC ARRAY.insertElement
Inserts a new element at the given index.

Syntax

```
insertElement( index INTEGER )
```

Usage

This method inserts a new element in the array, before the specified index.

No error is raised if the index is out of bounds.

Example

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  LET a[10] = 11
  CALL a.insertElement(10)
  LET a[10] = 10
  DISPLAY a.getLength() -- shows 11
  DISPLAY a[10]  -- shows 10
  DISPLAY a[11]  -- shows 11
END MAIN
```

DYNAMIC ARRAY.sort
Sorts the rows in the array.

Syntax

```
sort( key STRING, reverse BOOLEAN )
```

1. *key* is the name of a member of a structured array (`DYNAMIC ARRAY OF RECORD`), or `NULL` if the array is not structured.
2. *reverse* is `FALSE` for ascending order, `TRUE` for descending order.

Usage

This method sorts the array according to the name of the member passed as first parameter, for arrays defined with a structured type (`DYNAMIC ARRAY OF RECORD`). If the array is defined with a simple type, the first argument can be `NULL`.

The second parameter defines the sort order as ascending (FALSE) or descending (TRUE).

When doing subsequent calls to the sort() method using different record members of the array, the rows will be ordered by all of the record members specified for the cumulative sorts, with the most recent call defining the main sort field.

Another way to think of this is in terms of the `ORDER BY` clause of a SQL statement: If your dynamic array contained the variables A, B and C, and you included the following calls to the `sort()` method:

```
CALL a.sort("C",false)
CALL a.sort("B",false)
CALL a.sort("A",false)
```

This would be equivalent to writing an `ORDER BY` clause that states:

```
ORDER BY A, B, C
```

Note: Character string data is sorted according to the current application locale.

Example

```
MAIN
  DEFINE a DYNAMIC ARRAY OF RECORD
               key INTEGER,
               name VARCHAR(30)
         END RECORD
  LET a[1].key = 776236    LET a[1].name = "aaaaa"
  LET a[2].key = 273434    LET a[2].name = "cccccccc"
  LET a[3].key = 934092    LET a[3].name = "bbbbb"
  CALL a.sort("name",FALSE)
    -- Array is sorted by name (asc order)
  CALL a.sort("key",TRUE)
    -- Array is sorted by key (desc order), then by name (asc
 order)
    -- within each key;
    -- The current sort becomes the main sort field, the initial
 sort
    -- becomes the secondary sort field
END MAIN
```

The Java Array type as class

The Java Array type provides a set of utility methods array elements.

Java array methods can be invoked with a type reference or the array variable, for example:

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaaa"
    DISPLAY names.getLength()
END MAIN
```

Java Array type methods

Table 366: Class methods

Name	Description
java-array-type`.create(` *size* `INTEGER )` `RETURNING` *object java-array-type*	Creates a new Java array of the given type.

Table 367: Object methods

Name	Description
`getLength( )` `RETURNING result INTEGER`	Returns the length of the Java array.

java-array-type.create
Creates a new Java array of the given type.

Syntax

```
java-array-type.create( size INTEGER )
   RETURNING object java-array-type
```

1. *size* defines the actual number of elements of the array.

Usage

This class method creates a new instance of the Java array specified by the type used, with the size provided as parameter.

The type must be declared as a user defined type define with the `ARRAY [ ] OF` notation reserved for Java arrays.

Example

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaaa"
    DISPLAY names[1]
END MAIN
```

java-array.getLength
Returns the length of the Java array.

Syntax

```
getLength( )
   RETURNING result INTEGER
```

Usage

This method returns the number of elements in the Java array.

Example

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaaa"
    DISPLAY names.getLength()
```

```
END MAIN
```

The base package

These topics cover the built-in classes for the base class

- The Application class on page 1703
- The Channel class on page 1707
- The SqlHandle class on page 1725
- The StringBuffer class on page 1738
- The StringTokenizer class on page 1749
- The TypeInfo class on page 1752
- The MessageServer class on page 1754

The Application class

The `base.Application` class provides a set of utility functions related to the program environment.

Command line arguments, execution directory and FGLPROFILE resource entries are some of the elements you can query with this class.

This class is built-in and can be used directly in the source code.

This class does not have to be instantiated. It provides class methods for the current program.

base.Application methods

Table 368: Class methods

Name	Description
`base.Application.getArgument( index INTEGER ) RETURNING result STRING`	Returns the command line argument by position.
`base.Application.getArgumentCount() RETURNING result INTEGER`	Returns the total number of command line arguments.
`base.Application.getProgramDir() RETURNING result STRING`	Returns the directory path of the current program.
`base.Application.getProgramName() RETURNING result STRING`	Returns the name of the current program.
`base.Application.getFglDir() RETURNING result STRING`	Returns the path to the FGLDIR installation directory.
`base.Application.getResourceEntry( entry STRING ) RETURNING result STRING`	Returns the value of an FGLPROFILE entry.
`base.Application.getStackTrace()`	Returns the function call stack trace.

Name	Description
`RETURNING result STRING`	
`base.Application.isMobile()` `RETURNING result BOOLEAN`	Indicates if the application runs on a mobile device.

base.Application.getArgument
Returns the command line argument by position.

Syntax

```
base.Application.getArgument(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the index of the program argument.

Usage

The index is the program argument position. The first program argument is identified by the position 1. Argument number zero is the program name.

Returns `NULL` if there is no argument provided at the position.

Example

```
MAIN
  DEFINE i INTEGER
  FOR i=1 TO base.Application.getArgumentCount()
    DISPLAY base.Application.getArgument(i)
  END FOR
END MAIN
```

base.Application.getArgumentCount
Returns the total number of command line arguments.

Syntax

```
base.Application.getArgumentCount()
  RETURNING result INTEGER
```

Usage

Returns the total number of command line arguments, can be used to scan the argument values with `base.Application.getArgument()`.

base.Application.getFglDir
Returns the path to the FGLDIR installation directory.

Syntax

```
base.Application.getFglDir()
  RETURNING result STRING
```

Usage

The `getFglDir()` method returns the installation directory path defined by the FGLDIR environment variable. The directory path is system-dependent.

base.Application.getProgramDir
Returns the directory path of the current program.

Syntax

```
base.Application.getProgramDir()
  RETURNING result STRING
```

Usage

This method returns the directory path where the program file (42r) is located.

The directory path is system-dependent.

base.Application.getProgramName
Returns the name of the current program.

Syntax

```
base.Application.getProgramName()
  RETURNING result STRING
```

Usage

This method returns the name of the current program. This is the name of the 42m or 42r module passed to fglrun, without the file extension.

base.Application.getResourceEntry
Returns the value of an FGLPROFILE entry.

Syntax

```
base.Application.getResourceEntry(
   entry STRING )
  RETURNING result STRING
```

1. *entry* is the name of an FGLPROFILE entry.

Usage

This method returns the fglprofile value of the FGLPROFILE resource entry passed as parameter.

Example

```
MAIN
  DISPLAY
 base.Application.getResourceEntry("mycompany.params.logmode")
END MAIN
```

base.Application.getStackTrace
Returns the function call stack trace.

Syntax

```
base.Application.getStackTrace()
  RETURNING result STRING
```

Usage

Discover which functions have been called when a program raises an error. Use the `getStackTrace()` method to print the stack trace to a log file. This method returns a string containing a formatted list of the current function stack.

You typically use this function in a `WHENEVER ERROR CALL` handler.

```
MAIN
  WHENEVER ERROR CALL my_handler
  ...
END MAIN
...
FUNCTION my_handler()
  DISPLAY base.Application.getStackTrace()
END FUNCTION
```

Example of stack trace output:

```
#0 my_handler() at debug.4gl:173
#1 save_customer_data() at customer.4gl:1534
#2 edit_customer() at customer.4gl:542
#3 main at main.4gl:23
```

base.Application.isMobile
Indicates if the application runs on a mobile device.

Syntax

```
base.Application.isMobile()
  RETURNING result BOOLEAN
```

1. *result* is `TRUE` if the program runs on a mobile device.

Usage

This class method can be called to check if the program code is running on a smartphone or tablet device. The method will return `TRUE` if the program executes in standalone mode (i.e. the runtime system is on the mobile device).

Example

```
MAIN
  IF base.Application.isMobile() THEN
     MESSAGE "We are on a mobile device."
  END IF
END MAIN
```

The Channel class

The `base.Channel` class is a built-in class providing basic input/output functions.

base.Channel methods

Table 369: Class methods

Name	Description
`base.Channel.create()` `  RETURNING result base.Channel`	Create a new channel object.

Table 370: Object methods

Name	Description
`dataAvailable()` `  RETURNING result BOOLEAN`	Tests if some data can be read from the channel.
`close()`	Closes the channel.
`isEof()` `  RETURNING result BOOLEAN`	Detect the end of a file.

`openFile(`
`  path STRING,`
`  mode STRING )`
	Opening a file channel.

`openPipe(`
`  cmd STRING,`
`  mode STRING )`
	Opening a pipe channel to a sub-process.

`openClientSocket(`
`  host STRING,`
`  port INTEGER,`
`  mode STRING,`
`  timeout INTEGER )`
	Open a TCP client socket channel.

`openServerSocket(`
`  interface STRING, port INTEGER,`
`  mode STRING )`
	Open a TCP server socket channel.

`read(`
`  [ variable-list ] )`
`  RETURNING result INTEGER`
	Reads a list of data delimited by a separator from the channel.

`readLine()`	Read a complete line from the channel.

Name	Description
`RETURNING result STRING`	
`readOctets( bytes INTEGER) RETURNING result STRING`	Read a given number of bytes and return it as a character string.
`setDelimiter( delim STRING )`	Define the value delimiter for a channel.
`write( [ variable-list ] )`	Writes a list of data delimited by a separator to the channel.
`writeLine( line STRING )`	Write a complete line to the channel.
`writeNoNL( string STRING )`	Writes a string to the channel (without newline character).

base.Channel.create
Create a new channel object.

Syntax

```
base.Channel.create()
  RETURNING result base.Channel
```

Usage

Use the `base.Channel.create()` class method to create a channel object.

The new created object must be assigned to a program variable defined with the `base.Channel` type.

Example

```
DEFINE ch base.Channel
LET ch = base.Channel.create()
```

base.Channel.close
Closes the channel.

Syntax

```
close()
```

Usage

Call the `close()` method when you are done with the channel. The channel can be re-opened after it has been closed.

Note: A channel is automatically closed, when the channel object is destroyed.

Example

```
CALL ch.close()
```

base.Channel.dataAvailable
Tests if some data can be read from the channel.

Syntax

```
dataAvailable()
  RETURNING result BOOLEAN
```

Usage

The `dataAvailable()` method returns `TRUE` if some data can be read from the channel.

This method is only to be used in some rare cases. Use `dataAvailable()` if the protocol allows asynchronous messages from the peer. An example is an asynchronous error message from the peer, to stop sending more data.

`dataAvailable()` checks if at least one byte is available on the stream. A subsequent read will block, if the read operation can not be completed. This should not happen: the methods `read()` and `readLine()` and their counterparts `write()` and `writeLine()` read and write complete lines (a line is a sequence of characters terminated by the line separator).

The method opens up the possibility to read data asynchronously. One possible use for this method is to stop a data transfer to a remote site after receiving an error message from the remote site.

Example

The local site sends a huge amount of data to the remote site using `base.Channel.writeLine()`. An error may occur during the processing of data by the remote side. The remote site writes an error message causing the local site to stop the data transmission.

On the local site, the file is `parent.4gl`.

```
-- this file: parent.4gl
MAIN
  DEFINE i INT
  DEFINE c base.Channel

  LET c = base.Channel.create()
  CALL c.openPipe("fglrun child", "u")
  WHILE TRUE
    IF c.dataAvailable() THEN
      DISPLAY "message from child: ", c.readLine()
      EXIT WHILE
    END IF
    CALL c.writeLine("line " || i)
  END WHILE
END MAIN
```

On the remote site, the file is `child.4gl`.

```
-- this file: child.4gl
MAIN
```

```
  DEFINE c base.Channel
  DEFINE s STRING
  DEFINE n INT

  LET n = 0
  LET c = base.Channel.create()
  CALL c.openFile("", "u")
  WHILE NOT c.isEof()
    LET s = c.readLine()
    LET n = n + 1
    IF n == 3 THEN
      CALL c.writeLine("error: something happens")
      CALL readRemainingData(c)
      EXIT WHILE
    END IF
  END WHILE
END MAIN

FUNCTION readRemainingData(c)
  DEFINE c base.Channel
  DEFINE s STRING
  WHILE NOT c.isEof()
    LET s = c.readLine()
  END WHILE
END FUNCTION
```

base.Channel.isEof
Detect the end of a file.

Syntax

```
isEof()
  RETURNING result BOOLEAN
```

Usage

Use the `isEof()` method to detect the end of a file while reading from a channel.

The end of file is only detected after the last read. In other words, you first read, then check for the end of file and process if not end of file.

Example

```
DEFINE s STRING
WHILE TRUE
  LET s = ch.readLine()
  IF ch.isEof() THEN
     EXIT WHILE
  END IF
  DISPLAY s
END WHILE
```

base.Channel.openClientSocket
Open a TCP client socket channel.

Syntax

```
openClientSocket(
   host STRING,
```

```
   port INTEGER,
   mode STRING,
   timeout INTEGER )
```

1. *host* is the name of the host machine you want to connect to.
2. *port* is the port number of the service.
3. *mode* is the open mode. Can be `"r"`, `"w"` or `"u"` (combined with `"b"` if needed).
4. *timeout* is the timeout in seconds. -1 indicates no timeout (wait forever)

Usage

Use the `openClientSocket()` method to establish a TCP connection to a server.

Pay attention to character set used by the network protocol you want to use by opening a channel with this method: The protocol must be based on ASCII, or must use the same character set as the application.

The *host* parameter defines the host name of the server.

The *port* parameter defines the TCP port to connect to.

The opening *mode* can be one of the following:

- `r`: For read mode: only to read from the socket
- `w`: For write mode: only to write to the socket
- `u`: For read and write mode: To read and write from/to the socket

Any of these modes can be followed by `b`, to use binary mode and avoid CR/LF translation on Windows platforms.

> **Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening *mode* is not one of the above letters, the method will raise error -8085.

When the *timeout* parameter is -1, the connection waits forever.

The method raises error -8084 if the channel cannot be opened.

Example

```
CALL ch.openClientSocket( "localhost", 80, "u", 5 )
```

base.Channel.openFile
Opening a file channel.

Syntax

```
openFile(
   path STRING,
   mode STRING )
```

1. *path* is the path to the file to open, can be `NULL` for stdin/stdout.
2. *mode* is the open mode. Can be `"r"`, `"w"`, `"a"` or `"u"` (combined with `"b"` if needed).

Usage

The `openFile()` method can be used to open a file for reading, writing, or both.

When passing `NULL` as file name, the channel can be used to read and/or write to stdout or stdin, according to *mode*.

The opening *mode* can be one of the following:

- `r`: For read mode: reads from a file (standard input if path is `NULL`).
- `w`: For write mode: starts with an empty file (standard output if the path is `NULL`).
- `a`: For append mode: writes at the end of a file (standard output if the path is `NULL`).
- `u`: For read from standard input and write to standard output (path must be `NULL`).

Any of these modes can be followed by `b`, to use binary mode and avoid CR/LF translation on Windows platforms.

> **Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening *mode* is not one of the above letters, the method will raise error -8085

When you use the `w` or `a` modes, the file is created if it does not exist.

The method raises error -6340 sif the file cannot be opened.

Example

```
CALL ch.openFile( "file.txt", "w" )
```

base.Channel.openPipe
Opening a pipe channel to a sub-process.

Syntax

```
openPipe(
   cmd STRING,
   mode STRING )
```

1. *cmd* is the system command to be executed.
2. *mode* is the open mode. Can be `"r"`, `"w"`, `"a"` or `"u"` (combined with `"b"` if needed).

Usage

With the `openPipe()` method, you can read from the standard output of a subprocess, write to the standard input, or both.

> **Important:** This feature is not supported on mobile platforms.

The opening *mode* can be one of the following:

- `r`: For read only from standard output of the command.
- `w`: For write only to standard input of the command.
- `a`: For write only to standard input of the command.
- `u`: For read from standard output and write to standard input of the command.

Any of these modes can be followed by `b`, to use binary mode and avoid CR/LF translation on Windows platforms.

> **Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening *mode* is not one of the above letters, the method will raise error -8085.

Example

```
CALL ch.openPipe( "ls", "r" )
```

base.Channel.openServerSocket
Open a TCP server socket channel.

Syntax

```
openServerSocket(
   interface STRING, port INTEGER,
   mode STRING )
```

1. *interface* is the name of the network interface to be used.
2. *port* is the port number of the service.
3. *mode* is the open mode. Only `"u"` is allowed (combined with `"b"` if needed).

Usage

The `openServerSocket()` method initializes the channel object to listen to a given TCP interface and port.

The server socket accepts multiple client connects: After calling the `openServerSocket()` method, a call to `readLine()` waits until the first client connects and returns after reading a complete line. Only one client connection can be serviced at time: it's not possible to select a specific client connection. A client connection must be closed by writing the EOF character to the channel. The EOF character is ASCII 26. Do not call `base.Channel.close()` to close a client/server connection: This would close the sever socket and reject any pending client connection. The next call to `readLine()` after writing EOF will wait until the next client connects or select the next pending client.

Pay attention to character set used by the network protocol you want to use by opening a channel with this method: The protocol must be based on ASCII, or must use the same character set as the application.

The *interface* parameter defines the network interface to be used, in case if the server uses different network adapters. Use `NULL` to listen to all network interfaces, or when the server has only one network interface.

The *port* parameter defines the TCP port to listen to.

The opening *mode* must be `"u"`, to read and write from/to the socket. The method will raise error -8085 if the mode is different from `"u"`.

The `"u"` mode can be combined with the `"b"` binary mode, to avoid CR/LF translation on Windows platforms.

> **Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

The method raises error -8084 if the socket cannot be opened.

Example

```
MAIN
    DEFINE io base.Channel
    DEFINE s STRING
    LET io = base.Channel.create()
    CALL io.openServerSocket("127.0.0.1", 4711, "u")
    WHILE TRUE
        LET s = io.readLine()
        CALL io.writeLine(s)
        -- next line closes the current connection
        CALL io.writeLine(ASCII 26) -- EOF
    END WHILE
END MAIN
```

base.Channel.read
Reads a list of data delimited by a separator from the channel.

Syntax

```
read(
   [ variable-list ] )
  RETURNING result INTEGER
```

1. *variable-list* is a list of program variables separated by a comma, or record.*

Usage

After opening the channel object, use the `read()` method to read a record of data from the channel.

The `read()` method uses the field delimiter defined by `setDelimiter()`.

The `read()` method takes a modifiable list of variables as parameter, by using the `[ ]` square brace notation.

A call to `read()` is blocking until the read operation is complete.

If the `read()` method returns less data than expected, then the remaining variables will be initialized to NULL. If the `read()` method returns more data than expected, the data is silently ignored.

Any target variable must have a primitive type (`BOOLEAN`, `TINYINT`, `SMALLINT`, `INT`, `BIGINT`, `SMALLFLOAT`, `FLOAT`, `DECIMAL`, `DATE`, `DATETIME`, `INTERVAL`, `BYTE`, `TEXT`, `CHAR`, `VARCHAR`, `STRING`) or be a `RECORD` that contains only primitive members.

If data could be read, the `read()` method returns `TRUE`. Otherwise it returns `FALSE`, indicating the end of the file or stream.

Example

```
WHILE ch.read([cust_rec.*])
  ...
END WHILE
```

base.Channel.readLine
Read a complete line from the channel.

Syntax

```
readLine()
  RETURNING result STRING
```

Usage

After opening the channel object, use the `readLine()` method to read a complete line from the channel.

The `readLine()` method returns an empty string if the line is empty.

A call to `readLine()` is blocking until the read operation is complete.

The `readLine()` function returns `NULL` if end of file is reached. To distinguish empty lines from `NULL`, you must use the `STRING` data type. If you use a `CHAR` or `VARCHAR`, you will get `NULL` for empty lines. To detect the end of file, use the `isEof()` method.

Example

```
WHILE TRUE
```

```
  LET s = ch.readLine()
  IF ch.isEof() THEN EXIT WHILE END IF
  ...
END WHILE
```

base.Channel.readOctets
Read a given number of bytes and return it as a character string.

Syntax

```
readOctets(
   bytes INTEGER)
  RETURNING result STRING
```

1. *bytes* is the number of bytes to read, not the number of characters.

Usage

After opening the channel object, call the `readOctets()` method to read a given number of bytes from the channel. The bytes are returned as a character string. The bytes read must match the current encoding.

The `readOctets()` function returns `NULL` if end of file is reached. To distinguish empty lines from `NULL`, you must use the `STRING` data type. If you use a `CHAR` or `VARCHAR`, you will get `NULL` for empty lines. To properly detect end of file, use the `isEof()` method.

Before reading the actual bytes in a `readOctets()` call, you typically get the number of bytes to read from the sender, as shown in the example.

A valid use case of the method is the HTTP protocol. Reading HTML content with `readLine()` is not possible: The body consists of multiple lines, and the last line might not be terminated by a line-terminator, and the stream gets not EOF:

```
HTTP/1.0 200 OK
Date:  Wed, 16 Apr 2014 18:50:51 GMT
Content-Type: text/html
Content-Length: 1354

<html>
<body>
<h1>My title</h1>
  :
</body>
</html>
```

Example

```
WHILE TRUE
  ...
  -- Get the number of bytes to read.
  LET len = ch.readLine()
  -- Read the bytes as character string.
  LET s = ch.readOctets(len)
  IF ch.isEof() THEN EXIT WHILE END IF
  ...
END WHILE
```

base.Channel.setDelimiter
Define the value delimiter for a channel.

Syntax

```
setDelimiter(
   delim STRING )
```

1. *delim* is the value delimiter to be used.

Usage

After creating the channel object, define the field value delimiter with the `setDelimiter()` method.

```
CALL ch.setDelimiter("^")
```

The default delimiter is defined by the DBDELIMITER environment variable, or a pipe (`|`) if DBDELIMITER is not defined.

Specify `CSV` as the delimiter to read/write in Comma Separated Value format.

```
CALL ch.setDelimiter("CSV")
```

> **Important:** Setting a `NULL` delimiter is allowed for backward compatibility, but must be avoid: This was a workaround to read/write complete lines. If the delimiter is set to `NULL`, the `read()` and `write()` methods do not use the backslash (`\`) escape character. As a result, data with special characters like backslash, delimiter or line-feed will be written as is, and reading data will ignore escaped characters in the source stream. If you need to read or write non-formatted data, you should use the `readLine()`/`writeLine()` methods instead. These methods do not use a delimiter, nor do they use the backslash escape character.

base.Channel.write
Writes a list of data delimited by a separator to the channel.

Syntax

```
write(
   [ variable-list ] )
```

1. *variable-list* is a list of program variables separated by a comma, or record.*

Usage

After opening a channel, use the `write()` method to write a record of data to the channel.

The `write()` method uses the field delimiter defined by `setDelimiter()`.

The `write()` method takes a modifiable list of variables as the parameter, using the `[ ]` square brace notation.

The method raises error -6345 if the channel fails to write data.

Example

```
CALL ch.write([cust_rec.*])
```

base.Channel.writeLine
Write a complete line to the channel.

Syntax

```
writeLine(
   line STRING )
```

1. *line* is the string expression to be written to the channel.

Usage

After opening a channel, use the `writeLine()` method to write a line of text to the channel.

The `writeLine()` method does not use the field delimiter, it write the text data to the stream, with an ending newline character.

To write a string with no ending newline character, use the `writeNoNL()` method.

The method raises error -6345 if the channel fails to write data.

Example

```
CALL ch.writeLine("Customer number: "|| custno)
```

base.Channel.writeNoNL
Writes a string to the channel (without newline character).

Syntax

```
writeNoNL(
     string STRING )
```

1. *string* is the character string to be written to the channel.

Usage

After opening a channel, use the `writeNoNL()` method to write a string to the channel, without a trailing newline character.

> **Important:** Do not confuse the `writeNoNL()` method with the `write()` method. The first is provided to write raw character strings to the stream, while the second is designed to write records with formatted data and field delimiters. Note also that the Channel class provides the `writeLine()` method to write a string with a ending newline character.

The method raises error -6345 if the channel fails to write data.

Example

```
CALL ch.writeNoNL("Some text ...")
```

Usage

The `base.Channel` class is a built-in class providing basic input/output functionality for:

- text file reading/writing
- subprocess communication (through pipes)
- basic network communication (through TCP sockets)

> **Important:** No character set conversion is done when reading or writing data with channel objects. The character set used in the data file must correspond to the locale of the runtime system, for both input and output.

Steps to use a channel object:

- Define a variable with the `base.Channel` type.
- Create a channel object with `base.Channel.create()` and assign it to the variable.
- Open the channel for a file, piped process or socket (as a client).
- Read or write data in formatted mode or in line mode.
- Close the channel.

Channel methods may raise exceptions. Exceptions can be trapped with the `WHENEVER ERROR` or `TRY/CATCH` instructions.

When reading or writing strings, the escape character is the backslash (\).

The are three modes to read and write data with Channels:

1. Reading/writing formatted data as a set of fields in a line (i.e. records), with the `read()` and `write()` methods, needing a value separator defined by `setDelimiter()`. This mode follows the same formatting rules as the `LOAD/UNLOAD` instructions, and can also be used to read/write CSV (Comma Separated Value) formatted data.
2. Reading/writing complete lines with the `readLine()` and `writeLine()` methods. This mode is typically used to read/write simple data files.
3. Handling raw character string data by reading/writing pieces of strings, with the readOctets() and writeNoNL() methods.

Read and write formatted data

When the channel is open, use the `read()`/`write()` methods to read and write data records where field values are separated by a delimiter defined by `setDelimiter()`.

> **Note:** The `LOAD`/ `UNLOAD` SQL instructions follow the same formatting rules as the `read()`/`write()` channel methods.

The input or output stream is text data where each line contains the string representation of a record. Field values are separated by the delimiter character defined.

For example, a formatted text file can look like this, when using a default pipe (`|`) delimiter:

```
8712|David|Cosneski|24-12-1978|
3422|Frank|Zapinetti|13-04-1968|
323|Mark|Kelson|03-10-1988|
```

In the serialized data, empty fields (`||`) have a length of zero and are considered as `NULL`.

To read the above formatted data, the code could be:

```
MAIN
  DEFINE ch base.Channel
  DEFINE custinfo RECORD
            cust_num INTEGER,
            cust_fname VARCHAR(40),
            cust_lname VARCHAR(40),
            cust_bdate DATE
          END RECORD
  LET ch = base.Channel.create()
  CALL ch.setDelimiter("|")
  CALL ch.openFile("custinfo.txt","r")
  WHILE ch.read([custinfo.*])
    DISPLAY custinfo.*
  END WHILE
```

```
  CALL ch.close()
END MAIN
```

The backslash \ is the escape character: When writing data with `write()`, special characters like the backslash, line-feed or the delimiter character will be escaped. When reading data with `read()`, any escaped *char* character will be converted to *char*.

The next code writes a single field value where the character string contains a backslash, the pipe delimiter and a line-feed character. The backslash is also the escape character for string literals, therefore we need to double the backslash to get a backslash in the string, while the line-feed character (<lf>) is represented by backslash-n (\n) in string literals:

```
CALL ch.setDelimiter("|")
CALL ch.write("aaa\\bbb|ccc\nddd")   -- [aaa<bs>bbb|ccc<lf>ddd]
```

This code will produce the following text file:

```
aaa\\bbb\|ccc\
ddd|
```

When reading such a line back into memory with the `read()` method, all escaped characters are converted back to the single character. In this example, \\ becomes \, \| becomes | and \<lf> becomes <lf>.

When using the `read()`/`write()` methods, the escaped line-feed (LF, \n) characters are written as BS + LF to the output, and when reading with `read()`, BS + LF are detected and interpreted, to be restored as if the value was assigned by a `LET` instruction, with the same string used in the `write()` function.

If you want to write a LF as part of a value, the string must contain the backslash and line-feed as two independent characters. You need to escape the backslash when you write the string constant in the .4gl source file.

```
CALL ch.setDelimiter("|")
CALL ch.write("aaa\\\nbbb")  -- [aaa<bs><lf>bbb]
CALL ch.write("ccc\nddd")    -- [aaa<lf>bbb]
```

would generate the following output:

```
aaa\
bbb|
ccc|
ddd|
```

where the first two lines contain data for the same line, in the meaning of a Channel record.

When you read these lines back with a `read()` call, you get the following strings in memory:

```
Read 1: aaa<bs><lf>bbb
Read 2: ccc
Read 3: ddd
```

These reads would correspond to the following assignments when using string constants:

```
LET s = "aaa\\\nbbb"
LET s = "ccc"
LET s = "ddd"
```

Data can also be formatted as CVS (Comma Separated Values), when defining `"CVS"` as delimiter value:

```
CALL ch.setDelimiter("CVS")
```

This CVS format is similar to the standard channel format, with the following differences:

- Values in the file might be surrounded with double quotes (").
- If a value contains a comma or a NEWLINE, it is not escaped; the value must be quoted in the file.
- Double-quote characters in values are doubled in the output file and the output value must be quoted.
- Backslash characters are not escaped and are read as is; the value must be quoted.
- Leading and trailing blanks are kept (no truncation).
- No ending delimiter is expected at the end of the record line.

Read and write simple lines

When the channel is open, use the `readLine()`/`writeLine()` methods to read and write simple lines of data terminated by a line terminator.

When using the `readLine()` and `writeLine()` functions, a LF character represents the end of a line.

For example, a simple text file can look like this:

```
first line
second line
third line
```

To read the above text file, the code could be:

```
MAIN
  DEFINE i INTEGER
  DEFINE s STRING
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL ch.openFile("file.txt","r")
  LET i = 1
  WHILE TRUE
    LET s = ch.readLine()
    IF ch.isEof() THEN EXIT WHILE END IF
    DISPLAY i, " ", s
    LET i = i + 1
  END WHILE
  CALL ch.close()
END MAIN
```

LF characters escaped by a backslash are **not** interpreted as part of the line during a `readLine()` call.

When a line is written, any LF characters in the string will be written as is to the output. When a line is read, the LF escaped by a backslash is **not** interpreted as part of the line.

For example, this code:

```
CALL ch.writeLine("aaa\\\nbbb")  -- [aaa<bs><lf>bbb]
CALL ch.writeLine("ccc\nddd")    -- [aaa<lf>bbb]
```

would generate this output:

```
aaa\
bbb
ccc
ddd
```

and the subsequent `readLine()` will read four different lines, where the first line is ended by a backslash:

```
Read 1 aaa<bs>
Read 2 bbb
Read 3 ccc
```

```
Read 4 ddd
```

Line terminators on Windows™ and UNIX™

On Windows™ platforms, DOS formatted text files use CR/LF as line terminators. You can manage these type of files with the `base.Channel` class.

By default, on both Windows™ and UNIX™ platforms, when records are read from a DOS file with the `base.Channel` class, the CR/LF line terminator is removed. When a record is written to a file on Windows™, the lines are terminated with CR/LF in the file; on UNIX™, the lines are terminated with LF only.

To avoid the automatic translation of CR/LF on Windows™, you can use the `b` option of the `openFile()` and `openPipe()` methods. You can combine the `b` option with `r` or `w`, based on the read or write operations that you want to do.

```
CALL ch.openFile( "mytext.txt", "rb" )
```

On Windows™, when lines are read with the `b` option, only LF is removed from CR/LF line terminators; CR will be copied as a character part of the last field. In contrast, when lines are written with the `b` option, LF characters will not be converted to CR/LF.

On UNIX™, writing lines with or without the binary mode option does not matter.

Handle channel exceptions

Channel errors can be trapped with the `WHENEVER ERROR` exception handler:

```
WHENEVER ERROR CONTINUE
CALL ch.write([num,label])
IF STATUS THEN
  ERROR "An error occurred while reading from Channel"
  CALL ch.close()
  RETURN -1
END IF
WHENEVER ERROR STOP
```

Or with a `TRY/CATCH` block:

```
TRY
  CALL ch.write([num,label])
CATCH
  ERROR "An error occurred while reading from Channel"
  CALL ch.close()
  RETURN -1
END TRY
```

Implementing a TCP socket channel

The `base.Channel` class provides methods to implement basic TCP client and server programs. Consider character set encodings when designing such programs: No implicit character set conversion is done by the runtime system. Both client and server must use the same character set and length semantics.

The following code example implements a client program connecting to a TCP port, using the `openClientSocket()` method:

```
MAIN
  DEFINE ch base.Channel,
         time DATETIME HOUR TO SECOND,
         data STRING
  LET ch = base.Channel.create()
  CALL ch.openClientSocket("localhost",99999,"u",3)
  CALL ch.writeLine("get_time")
  LET time = ch.readLine()
```

```
  DISPLAY "client 1: ", time
  CALL ch.writeLine("get_string")
  LET data = ch.readLine()
  DISPLAY "client 2: ", data
  CALL ch.writeLine("disconnect")
  CALL ch.close()
END MAIN
```

The next code example implements the server program that can be used with the above client program. The server program uses the `openServerSocket()` and `readLine()` methods to listen to a given TCP interface/port. Note that the connection with a client must be ended by sending an EOF character (ASCII 26) to the client, the next `readLine()` call will wait for a new client connection, or select a pending client connection:

```
MAIN
  DEFINE ch base.Channel,
         cmd, data STRING
  LET ch = base.Channel.create()
  DISPLAY "starting server..."
  CALL ch.openServerSocket(null, 99999, "u")
  WHILE TRUE
      LET cmd = ch.readLine()
      IF ch.isEof() THEN
        DISPLAY "Connection ended by client..."
        EXIT WHILE
      END IF
      DISPLAY "cmd: ", cmd
      IF cmd == "get_time" THEN
        CALL ch.writeLine(CURRENT HOUR TO SECOND)
      END IF
      IF cmd == "get_string" THEN
        LET data = "This is a string..."
        CALL ch.writeLine(data)
      END IF
      IF cmd == "disconnect" THEN
         CALL ch.writeLine(ASCII 26) -- EOF
      END IF
  END WHILE
  DISPLAY "end of server..."
END MAIN
```

Examples

Example 1: Reading formatted data from a file

This program reads data from `file.txt`, which contains two columns separated by a pipe (`|`) character. It writes this data to the end of `fileout.txt`, using a percent sign (`%`) as the delimiter.

```
MAIN
  DEFINE custinfo RECORD
            cust_num INTEGER,
            cust_name VARCHAR(40)
         END RECORD
  DEFINE ch_in, ch_out base.Channel
  LET ch_in = base.Channel.create()
  CALL ch_in.setDelimiter("|")
  LET ch_out = base.Channel.create()
  CALL ch_out.setDelimiter("%")
  CALL ch_in.openFile("file.txt","r")
  CALL ch_out.openFile("fileout.txt","w")
  WHILE ch_in.read([custinfo.*])
    CALL ch_out.write([custinfo.*])
  END WHILE
```

```
  CALL ch_in.close()
  CALL ch_out.close()
END MAIN
```

Example 2: Executing the ls UNIX™ command

This program executes the `ls` command and displays the filenames and extensions separately.

```
MAIN
  DEFINE fn CHAR(40)
  DEFINE ex CHAR(10)
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL ch.setDelimiter(".")
  CALL ch.openPipe("ls -l","r")
  WHILE ch.read([fn,ex])
    DISPLAY fn, "   ", ex
  END WHILE
  CALL ch.close()
END MAIN
```

Example 3: Reading lines from a file

```
MAIN
  DEFINE i INTEGER
  DEFINE s STRING
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL ch.openFile("file.txt","r")
  LET i = 1
  WHILE TRUE
    LET s = ch.readLine()
    IF ch.isEof() THEN EXIT WHILE END IF
    DISPLAY i, " ", s
    LET i = i + 1
  END WHILE
  CALL ch.close()
END MAIN
```

Example 4: Communicating with an HTTP server

```
MAIN
  DEFINE ch base.Channel, eof INTEGER
  LET ch = base.Channel.create()
  -- HTTP protocol forces every line to be terminate by \r\n
  -- So we use channel binary mode to avoid CR+LF translation on Windows.
  -- In text mode, each line would be terminated by \r\r\n on Windows.
  WHENEVER ERROR CONTINUE
  CALL ch.openClientSocket("localhost", 80, "ub", 30)
  IF STATUS != 0 THEN
    DISPLAY "Could not open socket: error ", STATUS
    EXIT PROGRAM 1
  END IF
  WHENEVER ERROR STOP
  -- HTTP expects CR+LF: Note that LF is added by writeLine()!
  CALL ch.writeLine("GET / HTTP/1.0\r")
  -- No HTTP headers...
  -- Empty line = end of headers
  CALL ch.writeLine("\r")
  WHILE NOT eof
    DISPLAY ch.readLine()
    LET eof = ch.isEof()
  END WHILE
```

```
  CALL ch.close()
END MAIN
```

Example 5: Sending mails through an SMTP server

```
MAIN
    DEFINE mc base.Channel
    DEFINE i, res INTEGER
    DEFINE subject, emFrom, emRcpt, msg STRING
    DEFINE mailbody DYNAMIC ARRAY OF STRING
    LET subject = "Hello..."
    LET emFrom = "ted.fisher@4js.com"
    LET emRcpt = "ted.fisher@4js.com"
    LET mailbody[1] = "Hello,"
    LET mailbody[2] = "What's new?"
    LET mc = base.Channel.create()
    -- We use channel binary mode to avoid CR+LF translation on Windows.
    -- In text mode, each line would be terminated by \r\r\n on Windows.
    CALL mc.openClientSocket("mail.strasbourg.4js.com", 25, "ub", 5)
    CALL readSmtpAnswer(mc) RETURNING res, msg
    CALL smtpSend(mc, "HELO xxx\r") RETURNING res, msg
    CALL smtpSend(mc, SFMT("MAIL FROM: %1\r", emFrom)) RETURNING res, msg
    CALL smtpSend(mc, SFMT("RCPT TO: %1\r", emRcpt)) RETURNING res, msg
    CALL smtpSend(mc, "DATA\r") RETURNING res, msg
    DISPLAY "Sending mail body:"
    CALL mc.writeLine(SFMT("Subject: %1\r", subject))
    FOR i = 1 TO mailbody.getLength()
        CALL mc.writeLine(mailbody[i])
    END FOR
    CALL mc.writeLine(".")
    CALL readSmtpAnswer(mc) RETURNING res, msg
    DISPLAY "  Result: ", res
    CALL smtpSend(mc, "QUIT\r") RETURNING res, msg
    CALL mc.close()
END MAIN

FUNCTION smtpSend(ch, command)
    DEFINE ch base.Channel
    DEFINE command, msg STRING
    DEFINE res INTEGER
    DISPLAY "Sending command: ", command
    CALL ch.writeLine(command)
    CALL readSmtpAnswer(ch) RETURNING res, msg
    DISPLAY "  Result: ", res
    RETURN res, msg
END FUNCTION

FUNCTION readSmtpAnswer(ch)
    DEFINE ch base.Channel
    DEFINE line, msg STRING
    DEFINE res INTEGER
    LET msg = ""
    WHILE TRUE
        LET line = ch.readLine() -- Note: /r/n is already removed!
        IF line IS NULL THEN
            RETURN -1, "COULD NOT READ SMTP ANSWER"
        END IF
        IF line MATCHES "[0-9][0-9][0-9] *" THEN
            IF msg.getLength() != 0 THEN
                LET msg=msg || "\n"
            END IF
            LET msg=msg.append(line.subString(4, line.getLength()))
            LET res = line.subString(1,3)
```

```
            RETURN res, msg
        END IF
        IF line MATCHES "[0-9][0-9][0-9]-*" THEN
            IF msg.getLength() != 0 THEN
                LET msg=msg || "\n"
            END IF
            LET msg=msg.append(line.subString(4, line.getLength()))
        END IF
    END WHILE
END FUNCTION
```

The SqlHandle class

The `base.SqlHandle` class is a built-in class providing an API to execute parameterized SQL statements, with or without result sets.

base.SqlHandle methods

Table 371: Class methods

Name	Description
`create()` `RETURNING` *`handle`* `base.SqlHandle`	Create a new base.SqlHandle object.

Table 372: Object methods

Name	Description
`close()`	Closes the SQL handle (cursor).
`execute()`	Executes a simple SQL statement (without result set).
`fetch()`	Fetches a new row from the SQL result set.
`fetchAbsolute(`*`position`* `INTEGER)`	Fetches to a specified row in a scrollable SQL result set.
`fetchFirst()`	Fetches the first row in a scrollable SQL result set.
`fetchLast()`	Fetches the last row in a scrollable SQL result set.
`fetchPrevious()`	Fetches the previous row in a scrollable SQL result set.
`fetchRelative(`*`offset`* `INTEGER)`	Fetches a row relative to the current row in a scrollable SQL result set.
`flush()`	Flushes the rows from the insert cursor buffer.
`getResultCount()`	Returns the number of result set columns produced by the SQL statement.

Name	Description
`RETURNING count INTEGER`	
`getResultName( index INTEGER ) RETURNING name STRING`	Returns the name of a column in the result set produced by the SQL statement.
`getResultType( index INTEGER ) RETURNING type STRING`	Returns the Genero type name of a column in the result set produced by the SQL statement.
`getResultValue( index INTEGER ) RETURNING value fgl-type`	Returns the value of a column in the result set produced by the SQL statement.
`open()`	Opens the SQL handle (SELECT or INSERT cursor).
`openScrollCursor()`	Opens the SQL handle (with scrollable option).
`prepare( sql-text STRING )`	Prepares an SQL statement for the SQL handle.
`put()`	Put a new row in the insert cursor buffer.
`setParameter( index INTEGER, value fgl-type )`	Sets the value of an SQL parameter for this SQL handle.

base.SqlHandle.create
Create a new base.SqlHandle object.

Syntax

```
create()
 RETURNING handle base.SqlHandle
```

Usage

Use the `create()` method to create a base.SqlHandle object to execute SQL statements.

The value returned by this method must be assigned to a variable defined with the base.SqlHandle type.

As with other built-in classes, the SqlHandle object will be automatically destroyed if no longer referenced.

Example

```
DEFINE sh base.SqlHandle
LET sh = base.SqlHandle.create()
...
```

base.SqlHandle.close
Closes the SQL handle (cursor).

Syntax

```
close()
```

Usage

Call the `close()` method when you are done with the SQL handle.

The statement can be re-opened after it has been closed.

> **Note:** An SqlHandle object is automatically closed when the object is destroyed.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.close()
```

base.SqlHandle.execute
Executes a simple SQL statement (without result set).

Syntax

```
execute()
```

Usage

Call the `execute()` method to execute the prepared SQL statement, without producing a result set (INSERT, UPDATE, DELETE, CREATE TABLE, ...).

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains ? parameter place holders, issue a `setParameter()` call for each parameter before executing the SQL statement.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.execute()
```

base.SqlHandle.fetch
Fetches a new row from the SQL result set.

Syntax

```
fetch()
```

Usage

Call the `fetch()` method to fetch a new row from the SQL result set.

The SQL statement must have been opened with a `open()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(`*`index`*`)`, `getResultType(`*`index`*`)` and `getResultValue(`*`index`*`)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetch()
```

base.SqlHandle.fetchAbsolute
Fetches to a specified row in a scrollable SQL result set.

Syntax

```
fetchAbsolute(position INTEGER)
```

1. *position* is the absolute row position in the result set (starts at 1).

Usage

Call the `fetchAbsolute()` method to fetch to the specified row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(`*`index`*`)`, `getResultType(`*`index`*`)` and `getResultValue(`*`index`*`)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the specified position does not correspond to a row position in the result set, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetchAbsolute(10)
```

base.SqlHandle.fetchFirst
Fetches the first row in a scrollable SQL result set.

Syntax

```
fetchFirst()
```

Usage

Call the `fetchFirst()` method to fetch the first row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(`*`index`*`)`, `getResultType(`*`index`*`)` and `getResultValue(`*`index`*`)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetchFirst()
```

base.SqlHandle.fetchLast
Fetches the last row in a scrollable SQL result set.

Syntax

```
fetchLast()
```

Usage

Call the `fetchLast()` method to fetch the last row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(`*`index`*`)`, `getResultType(`*`index`*`)` and `getResultValue(`*`index`*`)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetchLast()
```

base.SqlHandle.fetchPrevious
Fetches the previous row in a scrollable SQL result set.

Syntax

```
fetchPrevious()
```

Usage

Call the `fetchPrevious()` method to fetch to the previous row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(`*`index`*`)`, `getResultType(`*`index`*`)` and `getResultValue(`*`index`*`)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, or if the current row is already the first row, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetchPrevious()
```

base.SqlHandle.fetchRelative
Fetches a row relative to the current row in a scrollable SQL result set.

Syntax

```
fetchRelative(offset INTEGER)
```

1. *offset* is the row offset in the result set. The offset can be negative, to fetch backwards.

Usage

Call the `fetchRelative()` method to fetch the row at the specified offset, relative to the current row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, or if no row exists at the specified offset relative to the current row position, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.fetchRelative(-3)
```

base.SqlHandle.flush
Flushes the rows from the insert cursor buffer.

Syntax

```
flush()
```

Usage

With an insert cursor, call the `flush()` method to force the buffered rows to the database server.

The SQL statement must have been opened with a `open()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.flush()
```

base.SqlHandle.getResultCount
Returns the number of result set columns produced by the SQL statement.

Syntax

```
getResultCount()
 RETURNING count INTEGER
```

Usage

Call the `getResultCount()` method to query the number of columns in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

Example

```
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultName(i)
END FOR
```

base.SqlHandle.getResultName
Returns the name of a column in the result set produced by the SQL statement.

Syntax

```
getResultName( index INTEGER )
 RETURNING name STRING
```

1. *index* is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultName()` method to query the name of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

Example

```
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultName(i)
END FOR
```

base.SqlHandle.getResultType
Returns the Genero type name of a column in the result set produced by the SQL statement.

Syntax

```
getResultType( index INTEGER )
 RETURNING type STRING
```

1. *index* is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultType()` method to query the type of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

The type name is a string that represents a Genero type. For example, "INTEGER", "DECIMAL(10,2)", "DATE", "DATETIME YEAR TO SECOND".

> **Important:** The type returned can differ, depending on the brand of database server used. The database driver provides the column type according to the described API of the client database software, which in turn queries the database server for the native type of the column. For example, if you create a table in the Genero program with a DATE type in a Oracle database, the resulting DATE native type in Oracle will correspond to a Genero type of DATETIME YEAR TO SECOND.

Example

```
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultType(i)
END FOR
```

base.SqlHandle.getResultValue
Returns the value of a column in the result set produced by the SQL statement.

Syntax

```
getResultValue( index INTEGER )
 RETURNING value fgl-type
```

1. *index* is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultValue()` method to get the value of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

The value returned can be assigned to a program variable of the type corresponding to the type name returned by `getResultType()`.

> **Important:** TEXT and BYTE values are returned by reference. In order to get the value of a TEXT or BYTE column, define a variable of this type and assign the `getResultValue()` return. The returned TEXT or BYTE variable is already located in memory, there is no need to LOCATE the variable before calling `getResultValue()`.

```
DEFINE p_text TEXT
...
LET p_text = h.getResultValue(3)
...
```

Example

```
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultValue(i)
END FOR
```

base.SqlHandle.open
Opens the SQL handle (SELECT or INSERT cursor).

Syntax

```
open()
```

Usage

Call the `open()` method to execute the prepared SQL statement, and open the result set cursor or insert cursor.

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains ? parameters:

- For a statement with a result set (SELECT), values must be provided for each parameter before the `open()` call.
- For an insert cursor, values must be provided after the `open()` call, before each `put()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.open()
```

base.SqlHandle.openScrollCursor
Opens the SQL handle (with scrollable option).

Syntax

```
openScrollCursor()
```

Usage

Call the `openScrollCursor()` method to execute a prepared SQL statement, and open the result set for use with a scrollable SQL cursor.

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains ? parameters, values must be provided for each parameter before the `openScrollCursor()` call.

After opening the scrollable cursor, use methods such as `fetchFirst()`, `fetchPrevious()` and `fetchAbsolute(n)` to move forwards and backwards in the SQL result set.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.openScrollCursor()
```

base.SqlHandle.prepare
Prepares an SQL statement for the SQL handle.

Syntax

```
prepare( sql-text STRING )
```

Usage

Call the `prepare()` method to prepare the SQL statement that will be executed with either `execute()` or `open()`.

The SQL statement can contain ? parameter place holders, to be filled with the `setParameter()` method before executing the statement.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.prepare("INSERT INTO mytable VALUES (?,?)")
```

base.SqlHandle.put
Put a new row in the insert cursor buffer.

Syntax

```
put()
```

Usage

Call the `put()` method to create a new row for the insert cursor.

The SQL statement must have been prepared with a `prepare()` call.

All SQL parameter values must be provided before doing the `put()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
CALL sh.put()
```

base.SqlHandle.setParameter
Sets the value of an SQL parameter for this SQL handle.

Syntax

```
setParameter(
   index INTEGER,
   value fgl-type )
```

1. *index* is the ordinal position of the ? SQL parameter (starts at 1).
2. *value* is the variable containing the parameter value.

Usage

Call the `setParameter()` method to define the value of an SQL parameter specified with a ? place holder in the string passed to the `prepare()` method.

The SQL statement must have been prepared with a `prepare()` call.

It is possible to pass numeric and string constants directly to the method, but type conversion cannot be done without a program variable.

Example

```
DEFINE v_pk INT, v_crea DATETIME YEAR TO SECOND
...
CALL sh.setParameter(1,v_pk)
CALL sh.setParameter(2,v_crea)
```

Usage

The `base.SqlHandle` class is a built-in class providing dynamic SQL support with a 3GL API.

Compared to regular SQL cursor instructions, the main purpose of the `base.SqlHandle` class is to provide column name and SQL data type information with the `getResultName()` and `getResultType()` methods. It is also possible to write generic code for parameterized queries with the `setParameter()` method.

Important: A database connection must exist in order to use SqlHandle objects.

Unlike regular Genero cursors, SQL handle objects are created dynamically, and can be passed as parameter or returned from functions:

```
MAIN
   DEFINE h base.SqlHandle
   CONNECT TO "mydb"
   LET h = base.SqlHandle.create()
   CALL my_prepare(h)
   CALL my_execute(h)
END MAIN

FUNCTION my_prepare(h)
   DEFINE h base.SqlHandle
   CALL h.prepare("INSERT INTO cust VALUES ( ...
END FUNCTION

FUNCTION my_execute(h)
   DEFINE h base.SqlHandle
   CALL h.execute()
END FUNCTION
```

Executing a simple SQL statement without a result set

Perform the following steps, to execute an SQL statement without a result set:

1. Define the SQL handle variable as `base.SqlHandle`
2. Create an SQL handle object `base.SqlHandle.create()`
3. `prepare(`*`sql-text`*`)`
4. For each SQL parameter:
   a. `setParameter(`*`index, value`*`)`
5. `execute()` -- test for `SQLCA.SQLCODE`
6. Repeat from (5), (4), or (3)

Executing a SQL statement returning a result set

Perform the following steps, to execute an SQL statement with a result set:

1. Define the SQL handle variable as `base.SqlHandle`
2. Create an SQL handle object `base.SqlHandle.create()`
3. `prepare(`*`sql-text`*`)`
4. For each SQL parameter:
   a. `setParameter(`*`index, value`*`)`
5. `open()`
6. `fetch()` -- test for `SQLCA.SQLCODE == 100`
7. `getResultCount()` -- for each column index:
   a. `getResultName(`*`index`*`)`
   b. `getResultType(`*`index`*`)`
   c. `getResultValue(`*`index`*`)`
8. `close()`
9. Repeat from (6), (4), (5), or (3)

Executing a SQL statement returning a result set, as scrollable cursor

Perform the following steps, to execute an SQL statement with a result set and scroll forwards and backwards in the rows:

1. Define the SQL handle variable as `base.SqlHandle`
2. Create an SQL handle object `base.SqlHandle.create()`
3. `prepare(`*`sql-text`*`)`
4. For each SQL parameter:
   a. `setParameter(`*`index, value`*`)`
5. `openScrollCursor()`
6. `fetch()` (next row), `fetchLast()`, `fetchFirst()`, `fetchPrevious()`, `fetchRelative(n)` or `fetchAbsolute(n)` -- test for `SQLCA.SQLCODE == 100`
7. `getResultCount()` -- for each column index:
   a. `getResultName(`*`index`*`)`
   b. `getResultType(`*`index`*`)`
   c. `getResultValue(`*`index`*`)`
8. `close()`
9. Repeat from (6), (4), (5), or (3)

Creating rows with an insert cursor

Perform the following steps, to insert many rows with an SQL handle insert cursor:

1. Define the SQL handle variable as `base.SqlHandle`
2. Create an SQL handle object `base.SqlHandle.create()`
3. `prepare(`*`insert-stmt-with-params`*`)`
4. `BEGIN WORK`
5. `open()`
6. For each row to insert:
   a. For each SQL parameter:
      a. `setParameter(`*`index, value`*`)`
   b. `put()`
7. `close()`

8. `COMMIT WORK`
9. Repeat from (4) or (3)

SQL error handling with SqlHandle

Handling SQL error and status information (such as `NOTFOUND`) can be done with SqlHandle objects as with regular SQL instruction, by testing the `SQLCA.SQLCODE` register, and by using `TRY/CATCH` blocks or `WHENEVER ERROR`.

```
MAIN
   DEFINE h base.SqlHandle
   CONNECT TO "mydb"
   LET h = base.SqlHandle.create()
   TRY
       CALL h.prepare("SELECT * FROM mytab")
       CALL h.open()
       CALL h.fetch()
       DISPLAY h.getResultValue(1)
       CALL h.close()
   CATCH
       DISPLAY "SQL ERROR:", SQLCA.SQLCODE
   END TRY
END MAIN
```

Examples

Example 1: SQL statement without a result set

The following code executes a simple UPDATE statement with the base.SqlHandle API:

```
MAIN
    DEFINE h base.SqlHandle

    CONNECT TO "mydb"

    LET h = base.SqlHandle.create()

    CALL h.prepare("UPDATE t1 SET name = ? WHERE pk = ?")

    CALL h.setParameter(1, "Scott")
    CALL h.setParameter(2, "8723")

    TRY
         CALL h.execute()
    CATCH
         DISPLAY "Error detected: ", SQLCA.SQLCODE
    END TRY

END MAIN
```

Example 2: SQL statement with a result set

The following code executes a simple SELECT statement with the base.SqlHandle API:

```
MAIN
    DEFINE h base.SqlHandle,
           d DATE,
           i INTEGER

    CONNECT TO "mydb"

    LET h = base.SqlHandle.create()
```

```
    CALL h.prepare("SELECT * FROM t1 WHERE created > ?")

    LET d = TODAY
    CALL h.setParameter(1, d)

    CALL h.open()

    WHILE TRUE
        CALL h.fetch()
        IF SQLCA.SQLCODE==NOTFOUND THEN EXIT WHILE END IF
        DISPLAY "-----------------"
        FOR i=1 TO h.getResultCount()
            DISPLAY i, ":", h.getResultName(i),
                    " / ", h.getResultType(i),
                    " = ", h.getResultValue(i)
        END FOR
    END WHILE

    CALL h.close()

END MAIN
```

The StringBuffer class

The `base.StringBuffer` class is a built-in class designed to manipulate character strings.

This class is optimized for string operations such as scanning, replacements, concatenation.

Use the `base.StringBuffer` class instead of `STRING` variables to implement heavy string manipulations. When you use a `base.StringBuffer` object, you work directly on the internal string buffer. When you use the `STRING` data type and modify a string, the runtime system creates a new buffer. While this does not impact the performance of programs with a user interface or even batch programs doing SQL, it can impact performance when you need to rapidly process large character strings. For example, if you need to process 500 KB of text (such as when you are performing a global search-and-replace of specific words), you get much better performance with a `base.StringBuffer` object than you would with a `STRING` variable.

When you pass a `base.StringBuffer` object as a function parameter, the function receives a variable that references the object. Passing the object by reference is much more efficient than using a `STRING` that is passed by value, because `STRING` data is copied on the stack. The function manipulates the original string, not a copy of the string.

> **Important:** The methods of this class use character positions and string length. When using byte length semantics, the length is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

base.StringBuffer methods

Table 373: Class methods

Name	Description
`base.StringBuffer.create()` `  RETURNING` *result* `base.StringBuffer`	Create a string buffer object.

Table 374: Object methods

Name	Description
`append(`	Append a string at the end of the current string.

Name	Description
part STRING)	
clear()	Clear the string buffer.
equals(*reference* STRING) RETURNING *result* BOOLEAN	Compare strings (case sensitive).
equalsIgnoreCase(*reference* STRING) RETURNING *result* BOOLEAN	Compare strings (case insensitive)
getCharAt(*position* INTEGER) RETURNING *result* STRING	Return the character at a specified position.
getIndexOf(*substr* STRING, *start* INTEGER) RETURNING *result* INTEGER	Return the position of a substring.
getLength() RETURNING *result* INTEGER	Return the length of a string.
insertAt(*part* STRING, *pos* INTEGER)	Insert a string at a given position.
replace(*old* STRING, *new* STRING, *occ* INTEGER)	Replace one string with another.
replaceAt(*start* INTEGER, *length* INTEGER, *new* STRING)	Replace part of a string with another string.
subString(*start* INTEGER, *end* INTEGER)	Return the substring at the specified position.

Name	Description
RETURNING *result* STRING	
toLowerCase()	Converts the string in the buffer to lower case.
toUpperCase()	Converts the string in the buffer to upper case.
toString() RETURNING *result* STRING	Create a STRING from the string buffer.
trim()	Remove leading and trailing blanks.
trimLeft()	Removes leading blanks.
trimRight()	Removes trailing blanks.

base.StringBuffer.create
Create a string buffer object.

Syntax

```
base.StringBuffer.create()
  RETURNING result base.StringBuffer
```

Usage

Use the `base.StringBuffer.create()` class method to create a string buffer object.

The new created object must be assigned to a program variable defined with the `base.StringBuffer` type.

Example

```
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
```

base.StringBuffer.append
Append a string at the end of the current string.

Syntax

```
append(
   part STRING )
```

1. *part* is the string to append to the string buffer.

Usage

The `append()` method appends a string to the internal string buffer.

Example

```
LET buf = base.StringBuffer.create()
CALL buf.append("abc")
```

base.StringBuffer.clear
Clear the string buffer.

Syntax

```
clear()
```

Usage

Use the `clear()` method to clear the string buffer.

After clearing, the string buffer is empty and the length is zero.

Example

```
CALL buf.clear()
```

base.StringBuffer.equals
Compare strings (case sensitive).

Syntax

```
equals(
   reference STRING )
  RETURNING result BOOLEAN
```

1. *reference* is the string to compare with.

Usage

Use the `equals()` method to determine whether the value of a `base.StringBuffer` object is identical to a specified string.

This method is case-sensitive.

Since the parameter for the method must be a string, you can use the `toString()` method to convert a `base.StringBuffer` object in order to compare it.

The method returns `TRUE` if the strings are identical, otherwise it returns `FALSE`.

Example

```
DEFINE buf, buf2 base.StringBuffer,
       mystring STRING
LET buf = base.StringBuffer.create()
CALL buf.append("there")

-- compare to a STRING
IF buf.equals("there") THEN
   DISPLAY "buf matches there"
END IF

-- compare to a STRING variable
```

```
LET mystring = "there"
IF buf.equals(mystring) THEN
   DISPLAY "buf matches mystring"
END IF

-- compare to another StringBuffer object
LET buf2 = base.StringBuffer.create()
CALL buf2.append("there")
IF buf.equals(buf2.toString()) THEN
   DISPLAY "buf matches buf2"
END IF
```

Output:

```
buf matches there
buf matches mystring
buf matches buf2
```

base.StringBuffer.equalsIgnoreCase
Compare strings (case insensitive)

Syntax

```
equalsIgnoreCase(
   reference STRING )
  RETURNING result BOOLEAN
```

1. *reference* is the string to compare with.

Usage

The `equalsIgnoreCase()` method compares the current string buffer with the passed string, ignoring the character case.

Since the parameter for the method must be a string, you can use the `toString()` method to convert a `base.StringBuffer` object in order to compare it.

The method returns `TRUE` if the strings are identical, otherwise it returns `FALSE`.

Example

```
DEFINE buf3 base.StringBuffer
LET buf3 = base.StringBuffer.create()
CALL buf3.append("there")
IF buf3.equalsIgnoreCase("There") THEN
   DISPLAY "buf matches There ignoring case"
END IF
```

Output:

```
buf matches There ignoring case
```

base.StringBuffer.getCharAt
Return the character at a specified position.

Syntax

```
getCharAt(
   position INTEGER )
```

```
   RETURNING result STRING
```

1. *position* is the character position in the string.

Usage

The `getCharAt()` method returns the character from the string buffer at the position that you specify.

The first character position is 1.

The method returns `NULL` if the position is lower as 1 or greater as the length of the string.

> **Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
CALL buf.append("abcdef")
DISPLAY buf.getCharAt(3)  -- Shows c
```

base.StringBuffer.getIndexOf
Return the position of a substring.

Syntax

```
getIndexOf(
   substr STRING,
   start INTEGER )
  RETURNING result INTEGER
```

1. *substr* is the substring to be found.
2. *start* is the starting position.

Usage

The `getIndexOf()` method returns the position of a substring in the string buffer. Specify the substring and an integer specifying the position at which the search should begin. Use 1 if you want to start at the beginning of the string buffer.

The method returns zero if the substring is not found.

```
CALL buf.append("abcdef")
DISPLAY buf.getIndexOf("def",1) -- Shows 4
```

> **Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

This example iterates through the complete string to display the position of multiple occurrences of the same substring.

```
MAIN
  DEFINE b base.StringBuffer
  DEFINE pos INTEGER
  DEFINE s STRING
```

```
  LET b = base.StringBuffer.create()
  CALL b.append("---abc-----abc--abc----")
  LET pos = 1
  LET s = "abc"
  WHILE TRUE
    LET pos = b.getIndexOf(s,pos)
    IF pos == 0 THEN
      EXIT WHILE
    END IF
    DISPLAY "Pos: ", pos
    LET pos = pos + length(s)
  END WHILE
END MAIN
```

base.StringBuffer.getLength
Return the length of a string.

Syntax

```
getLength()
  RETURNING result INTEGER
```

Usage

Use the `getLength()` method to return the number of characters in the current string buffer, including trailing spaces.

The length of an empty string buffer is 0.

> **Important:** When using byte length semantics, the string length is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
CALL buf.append("abc")
DISPLAY buf.getLength() -- Shows 3
-- append three spaces to the end of the string
CALL buf.append("   ")
DISPLAY buf.getLength() -- Shows 6
```

base.StringBuffer.insertAt
Insert a string at a given position.

Syntax

```
insertAt(
   part STRING,
   pos INTEGER )
```

1. *part* is the string part to be inserted.
2. *pos* is the position where the string must be inserted.

Usage

The `insertAt()` method inserts a string before the specified position in the string buffer.

Important: When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
CALL buf.append("abcdef")
CALL buf.insertAt(3, "xx")
DISPLAY buf.toString() -- Shows abcxxdef
```

base.StringBuffer.replace
Replace one string with another.

Syntax

```
replace(
   old STRING,
   new STRING,
   occ INTEGER )
```

1. *old* is the string to be replaced.
2. *new* is the new string replacing the old string.
3. *occ* is the number of replacements to do.

Usage

The `replace()` method replaces a string within the current string buffer with a different string. Specify the original string, replacement string, and the number of occurrences to replace. Use 0 to replace all occurrences.

Example

```
CALL buf.append("aaxxbbxxcc")
CALL buf.replace("xx", "zz", 1)
DISPLAY buf.toString() -- Shows aazzbbxxcc
```

base.StringBuffer.replaceAt
Replace part of a string with another string.

Syntax

```
replaceAt(
   start INTEGER,
   length INTEGER,
   new STRING )
```

1. *start* is position where the replacement starts.
2. *length* is the number of characters to be replaced.
3. *new* is the replacement string.

Usage

The `replaceAt()` method replaces part of the current string with another string.

The parameters are integers indicating the position at which the replacement should start, the number of characters to be replaced, and the replacement string.

The first position in the string is 1.

> **Important:** When using byte length semantics, the position and length are expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
CALL buf.append("abxxxxef")
CALL buf.replaceAt(3,4,"cd")
DISPLAY buf.toString() -- Shows abcdef
```

base.StringBuffer.subString
Return the substring at the specified position.

Syntax

```
subString(
   start INTEGER,
   end INTEGER )
  RETURNING result STRING
```

1. *start* is the substring to be found.
2. *end* is the ending position.

Usage

The `subString()` method returns the substring defined by the start and end positions passed as parameter.

The first character is at position 1.

> **Important:** When using byte length semantics, the positions are expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
CALL buf.append("abcdefg")
DISPLAY buf.subString(2,5) -- Shows bcde
```

base.StringBuffer.toLowerCase
Converts the string in the buffer to lower case.

Syntax

```
toLowerCase()
```

Usage

The `toLowerCase()` method converts the current string to lower case.

Example

```
CALL buf.append("AbC")
CALL buf.toLowerCase()
```

```
DISPLAY buf.toString() -- Shows abc
```

base.StringBuffer.toString
Create a `STRING` from the string buffer.

Syntax

```
toString()
  RETURNING result STRING
```

Usage

The `toString()` method creates a `STRING` value from the current string buffer.

Use this method if you need to pass the string to another method or instruction that expects a `STRING` as parameter.

Example

```
CALL buf.append("abc")
DISPLAY buf.toString() -- Shows abc
```

base.StringBuffer.toUpperCase
Converts the string in the buffer to upper case.

Syntax

```
toUpperCase()
```

Usage

The `toUpperCase()` method converts the current string to upper case.

Example

```
CALL buf.append("AbC")
CALL buf.toUpperCase()
DISPLAY buf.toString() -- Shows ABC
```

base.StringBuffer.trim
Remove leading and trailing blanks.

Syntax

```
trim()
```

Usage

The `trim()` method removes the leading and trailing blanks in the string buffer.

Example

```
CALL buf.append("  abc  ")
CALL buf.trim()
```

```
DISPLAY "["||buf.toString()||"]" -- Shows [abc]
```

base.StringBuffer.trimLeft
Removes leading blanks.

Syntax

```
trimLeft()
```

Usage

The `trimLeft()` method removes the leading blanks in the string buffer.

Example

```
CALL buf.append("  abc  ")
CALL buf.trimLeft()
DISPLAY "["||buf.toString()||"]" -- Shows [abc  ]
```

base.StringBuffer.trimRight
Removes trailing blanks.

Syntax

```
trimRight()
```

Usage

The `trimRight()` method removes the trailing blanks in the string buffer.

```
CALL buf.append("  abc  ")
CALL buf.trimRight()
DISPLAY "["||buf.toString()||"]" -- Shows [  abc]
```

Examples
Example 1: Add strings to a StringBuffer

```
MAIN
  DEFINE buf base.StringBuffer
  LET buf = base.StringBuffer.create()
  CALL buf.append("abc")
  DISPLAY buf.toString()
  CALL buf.append("def")
  DISPLAY buf.toString()
  CALL buf.append(123456)
  DISPLAY buf.toString()
END MAIN
```

Output:

```
abc
abcdef
abcdef123456
```

Example 2: Modify a StringBuffer with a function

```
MAIN
  DEFINE buf base.StringBuffer
  LET buf = base.StringBuffer.create()
  CALL modify(buf)
  DISPLAY "buf is ", buf.toString()
END MAIN

FUNCTION modify(sb)
  DEFINE sb base.StringBuffer
  CALL sb.append("more")
  DISPLAY "sb is ", sb.toString()
END FUNCTION
```

Output:

```
sb is more
buf is more
```

The StringTokenizer class

The `base.StringTokenizer` class is designed to parse a string to extract tokens according to delimiters.

The steps to use a string tokenizer are:

1. Define a variable with the `base.StringTokenizer` type.
2. Create the string tokenizer object with one of the create methods, passing the string to be parsed as parameter.
3. Optionally, count the number of tokens with `countTokens()` before processing.
4. Use a `WHILE` loop to process the different tokens, by using `hasMoreTokens()` as loop condition and `nextToken()` inside the loop body to get the next token.

base.StringTokenizer methods

Table 375: Class methods

Name	Description
`base.StringTokenizer.create( source STRING, delims STRING ) RETURNING result base.StringTokenizer`	Create a string tokenizer object.
`base.StringTokenizer.createExt( source STRING, delims STRING, escape STRING, nulls BOOLEAN ) RETURNING result base.StringTokenizer`	Create a string tokenizer object with escape char and null handling.

Table 376: Object methods

Name	Description
`countTokens()`	Returns the number of tokens left to be returned.

Name	Description
`RETURNING result INTEGER`	
`hasMoreTokens()` `RETURNING result BOOLEAN`	Returns TRUE if there are more tokens to return.
`nextToken()` `RETURNING result STRING`	Returns the next token found in the source string.

base.StringTokenizer.create
Create a string tokenizer object.

Syntax

```
base.StringTokenizer.create(
   source STRING,
   delims STRING )
  RETURNING result base.StringTokenizer
```

1. *source* is the character string to be parsed.
2. *delims* defines the delimiters to be used.

Usage

Use the `base.StringTokenizer.create()` class method to create a string tokenizer object.

The new created object must be assigned to a program variable defined with the `base.StringTokenizer` type.

The method can take a unique or multiple delimiters into account. A delimiter is always one character long.

The empty tokens are not taken into account, and no escape character is defined for the delimiters. The `nextToken()` method will never return `NULL` strings.

> **Note:** To specify a backslash as a delimiter, you must use double backslashes in both the source string and as the delimiter, as shown in Example 3: Specify a backslash as a delimiter on page 1752

Example

```
DEFINE tok base.StringTokenizer
-- Using a single pipe delimiter
LET tok = base.StringTokenizer.create("aaa|bbb|ccc","|")
-- Using several delimiters
LET tok = base.StringTokenizer.create("aaa|bbb;ccc+ddd","|+;")
```

base.StringTokenizer.createExt
Create a string tokenizer object with escape char and null handling.

Syntax

```
base.StringTokenizer.createExt(
   source STRING, delims STRING,
   escape STRING, nulls BOOLEAN )
  RETURNING result base.StringTokenizer
```

1. *source* is the character string to be parsed.
2. *delims* defines the delimiters to be used.
3. *escape* defines the escape character.
4. *nulls* indicates if empty tokens must be returned.

Usage

Use the `base.StringTokenizer.createExt()` class method to create a string tokenizer object, with escape character and null token handling.

The new created object must be assigned to a program variable defined with the `base.StringTokenizer` type.

The method can take a unique or multiple delimiters into account. A delimiter is always one character long.

When defining an escape character with the third parameter, the delimiters can be escaped in the source string.

When passing `TRUE` to the last parameter, the empty tokens are taken into account. The `nextToken()` method might return `NULL` strings. In the source string, leading and trailing delimiters or the amount of delimiters between two tokens affects the number of tokens.

> **Note:** To specify a backslash as a delimiter, you must use double backslashes in both the source string and as the delimiter, as shown in Example 3: Specify a backslash as a delimiter on page 1752

Example

```
DEFINE tok base.StringTokenizer
LET tok = base.StringTokenizer.createExt("|aaa||b\\|bb|
ccc","|","\\",TRUE)
```

base.StringTokenizer.countTokens
Returns the number of tokens left to be returned.

Syntax

```
countTokens()
  RETURNING result INTEGER
```

Usage

Use the `countTokens()` method to count the number of tokens left to be returned by the string tokenizer.

This method can be used to know the number of tokens before processing the source string with the `hasMoreTokens()` and `nextToken()` methods.

base.StringTokenizer.hasMoreTokens
Returns `TRUE` if there are more tokens to return.

Syntax

```
hasMoreTokens()
  RETURNING result BOOLEAN
```

Usage

The `hasMoreTokens()` method indicates if there are other tokens in the source string that are not yet processed.

Use the `hasMoreTokens()` method typically as the expression of a `WHILE` block.

base.StringTokenizer.nextToken
Returns the next token found in the source string.

Syntax

```
nextToken()
  RETURNING result STRING
```

Usage

The `nextToken()` method parses the source string for tokens, according to the creation method used, and returns the next token if found.

The method returns `NULL` if no token is found, or if an empty token was found and the nulls parameter of the createExt() method was set to `TRUE`.

Use the `hasMoreTokens`() method to check if more tokens are to be read.

Examples

Example 1: Split a UNIX™ directory path

```
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.create("/home/tomy","/")
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```

Example 2: Escaped delimiters and NULL tokens

```
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.createExt("||\\|aaa||bbc|","|","\\",TRUE)
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```

Example 3: Specify a backslash as a delimiter

```
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.create("C:\\My Documents\\My Pictures","\
\")
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```

The TypeInfo class

The `base.TypeInfo` class creates a DOM node from a structured program variable.

This class does not have to be instantiated.

Steps to use the class:

- Define a variable with the `om.DomNode` type.

- Create a channel object with `base.TypoInfo.create( var )` and assign it to the DOM node variable.
- Use the new created DOM node.

For example. to convert a list of database records to XML, fetch rows from a database table in a structured array, specify the array as the input parameter for the `base.TypeInfo.create()` method to create a new `base.DomNode` object, and serialize the resulting DOM node to a file by using the `node.writeXml()` method. You can then pass the resulting file to any application that is able to read XML for input.

> **Note:** Consider using the JSON interface to serialize and de-serialize program variables.

base.TypeInfo methods

Table 377: Class methods

Name	Description
`base.TypeInfo.create()` `  RETURNING result om.DomNode`	Create a DomNode from a structured program variable.

base.TypeInfo.create()
Create a DomNode from a structured program variable.

Syntax

```
base.TypeInfo.create()
  RETURNING result om.DomNode
```

Usage

Use the `base.TypeInfo.create()` class method to create a `om.DomNode` object from a program variable.

The program variable is typically a `RECORD`, but it can be any sort of structured variable, including arrays.

The `om.DomNode` is created with type information and values.

The data is formatted according to current environment settings (DBDATE, DBFORMAT, and DBMONEY).

Example

```
MAIN
  DEFINE n om.DomNode
  DEFINE r RECORD
      key INTEGER,
      lastname CHAR(20),
      birthdate DATE
  END RECORD
  LET r.key = 234
  LET r.lastname = "Johnson"
  LET r.birthdate = MDY(12,24,1962)
  LET n = base.TypeInfo.create( r )
  CALL n.writeXml( "r.xml" )
END MAIN
```

The generated node contains variable values and data type information. The example creates this file:

```
<?xml version="1.0"? encoding="ISO-8859-1">
<Record>
  <Field type="INTEGER" value="234" name="key"/>
  <Field type="CHAR(20)" value="Johnson" name="lastname"/>
  <Field type="DATE" value="12/24/1962" name="birthdate"/>
</Record>
```

The MessageServer class

The `base.MessageServer` class allows a program to send a key action over the network to other programs using this service.

This class can be used to join a group of programs to be notified by simple messages (i.e. key events). The programs can run on different machines connected together in a network.

> **Important:** This feature is experimental and subject to change.

The `base.MessageServer` uses network API capabilities with Sockets and the UDP protocol. The computers must be configured with a network. The UDP protocol does not guarantee the transmission of datagrams, therefore messages sent with the MessageServer can arrive out of order, duplicated, or go missing without notice.

The UDP port is `6600` and the IP address group is `224.0.1.1`. These cannot be changed.

> **Important:** This feature is only supported in direct connection with the GDC front-end. It is not supported when using other front-ends or when using the GAS.

base.MessageServer methods

Table 378: Class methods

Name	Description
`base.MessageServer.connect()`	Connects to the group of programs to be notified by a message.
`base.MessageServer.send(` `  keyname STRING )`	Sends a key event to the group of programs connected together.

base.MessageServer.connect

Connects to the group of programs to be notified by a message.

Syntax

```
base.MessageServer.connect()
```

Usage

Use the `connect()` method to join the group of programs that can be notified by a key event message.

base.MessageServer.send
Sends a key event to the group of programs connected together.

Syntax

```
base.MessageServer.send(
   keyname STRING )
```

1. *keyname* is a string expression defining the key event to be sent over the network.

Usage

Once connected to the message server group with `base.MessageServer.connect()`, a program calls the `base.MessageServer.send()` class method to notify other programs registered to the group.

```
CALL base.MessageServer.send("f1")
```

All programs registered to the message server group are notified, including the program which has sent the message. The messages can be treated by the current dialog with a simple `ON KEY()` interaction block.

Examples

Example 1: Simple MessageServer usage

```
MAIN
  CALL base.MessageServer.connect()
  MENU "test"
    COMMAND "send F1" CALL base.MessageServer.send("f1")
    ON KEY (F1) DISPLAY "Key F1 received..."
    COMMAND "quit" EXIT MENU
  END MENU
END MAIN
```

The ui package

These topics cover the built-in classes for the ui class

- The Interface class on page 1755
- The Window class on page 1769
- The Form class on page 1774
- The Dialog class on page 1784
- The ComboBox class on page 1820
- The DragDrop class on page 1827

The Interface class

The `ui.Interface` class provides methods to manipulate the user interface.

This class does not have to be instantiated.

ui.Interface methods

Methods of the `ui.Interface` class

Table 379: Class methods

Name	Description

`ui.Interface.frontCall(`
`  module STRING,`
`  function STRING,`
`  [ parameter-list ],`
	`ui.Interface.frontCall` performs a function call to the current front-end.

Name	Description
`[ returning-list ] )`	
`ui.Interface.filenameToURI( filename STRING ) RETURNING uri INTEGER`	Converts a file name to an URI to be used as a web component image resource.
`ui.Interface.getChildCount() RETURNING result INTEGER`	Get the number of children in a parent container.
`ui.Interface.getChildInstances( name STRING ) RETURNING result INTEGER`	Get the number of child instances for a given program name.
`ui.Interface.getContainer() RETURNING result STRING`	Get the parent container of the curren program.
`ui.Interface.getDocument() RETURNING result om.DomDocument`	Returns the DOM document of the abstract user interface tree.
`ui.Interface.getFrontEndName() RETURNING result STRING`	Returns the type of the front-end currently in use.
`ui.Interface.getFrontEndVersion() RETURNING result STRING`	Returns the version of the front-end currently in use.
`ui.Interface.getName() RETURNING result STRING`	`ui.Interface.frontCall` performs a function call to the current front-end.
`ui.Interface.getImage() RETURNING result STRING`	`ui.Interface.frontCall` performs a function call to the current front-end.
`ui.Interface.getText() RETURNING result STRING`	Returns the title of the program.
`ui.Interface.getType() RETURNING result STRING`	Returns the type of the program.
`ui.Interface.getRootNode() RETURNING result om.DomNode`	Get the root DOM node of the abstract user interface.
`ui.Interface.loadActionDefaults(`	Load the default action defaults file.

Name	Description
filename STRING)	
ui.Interface.loadStartMenu(*filename* STRING)	Load the start menu file.
ui.Interface.loadToolBar(*filename* STRING)	Load a default toolbar file.
ui.Interface.loadTopMenu(*filename* STRING)	Load a default topmenu file.
ui.Interface.loadStyles(*filename* STRING)	Load the presentation styles file.
ui.Interface.setImage(*icon* STRING)	Defines the icon image of the program.
ui.Interface.setName(*name* STRING)	Define the name of the current program for the front-end.
ui.Interface.setText(*title* STRING)	Defines the title for the program.
ui.Interface.setType(*type* STRING)	Defines the type of the program for the front-end.
ui.Interface.setSize(*height* INTEGER, *width* INTEGER)	Specify the initial size of the parent container window.
ui.Interface.setContainer(*name* STRING)	Define the parent container for the current program.
ui.Interface.refresh()	Synchronize the user interface with the front-end.

ui.Interface.frontCall
`ui.Interface.frontCall` performs a function call to the current front-end.

Syntax

```
ui.Interface.frontCall(
   module STRING,
   function STRING,
   [ parameter-list ],
```

```
    [ returning-list ] )
```

1. *module* defines the shared library or classpath where the function is implemented.
2. *function* defines the name of the function to be called.
3. *parameter-list* is a list of input parameters.
4. *returning-list* is a list of output parameters.

> **Important:** The *returning-list* variables are passed by reference to the `frontCall()` method.

Usage

The `ui.Interface.frontCall()` class method can be used to execute a procedure on the front-end workstation through the front-end software component. You can for example launch a front-end specific application like a browser or a text editor, or manage the clipboard content.

The method takes four parameters:

1. The module, identifying the shared library (.so or .DLL) or the Java class (GMA) implementing the front call function.
2. The function of the module the be executed.
3. The list of input parameters, using the square brace notation.
4. The list of output parameters, using the square brace notation.

Input and output parameters are provided as a variable list of parameters, by using the square braces notation (`[param1,param2,...]`). Input parameters can be an expression supported by the language; output parameters must be variables only, to receive the returning values. An empty list is specified with `[]`. Output parameters are optional: If the front call returns values, they will be ignored by the runtime system.

Simple front call example:

```
FUNCTION call()
  DEFINE info STRING
  CALL ui.Interface.frontCall( "standard", "feInfo", ["feName"], [info] )
END FUNCTION
```

Some front calls need a file path as parameter. File paths must follow the syntax of the front end workstation file system. You may need to escape backslash characters in such parameters. The next example shows how to pass a file path with a space in a directory name to a front-end running on a Microsoft™ Windows™ workstation:

```
FUNCTION call()
   DEFINE path STRING, res INTEGER
   LET path = "\"c:\\work dir\\my report.doc\""
   -- This is: "c:\work dir\my report.doc"
   CALL ui.Interface.frontCall( "standard", "shellExec", [path], [res] )
END FUNCTION
```

Front call error handling

Exception handling instructions can be used to check the execution status of a front call. Both `WHENEVER ERROR` directives or `TRY/CATCH` block can surround the front call to avoid program stop in case of error, and check the error number returned in the STATUS variable.

> **Note:** There is not need to surround front calls with exception handlers such as `TRY/CATCH`, if the front call is always supposed to execute without error. For example, the feInfo front call will never produce an exception.

Example of front call error handling with a `TRY/CATCH` block:

```
FUNCTION takePhoto()
```

```
   DEFINE path STRING
   TRY -- This front call may fail if the front-end is not a mobile device:
       CALL ui.Interface.frontCall( "mobile", "takePhoto", [], [path] )
   CATCH
       MESSAGE "Cannot take photo: ", STATUS, " ", err_get(STATUS)
       LET path = NULL
   END TRY
   RETURN path
END FUNCTION
```

If the front call module name or the function name is invalid, the errors -6331 or -6332 will be raised, respectively.

If the front call execution failed for some reason, the error -6333 will be raised. The description of the problem can be found in the second part of the error message, returned by a call to the ERR_GET() function.

The error -6334 can be raised in case of input or output parameter mismatch. The control of the number of input and output parameters is in the hands of the front-end. Most of the standard front calls have optional returning parameters and will not raise error -6334, if the output parameter list is left empty. However, front-end specific extensions or user-defined front-end functions may return an invalid execution status in case of input or output parameter mismatch, raising error -6334. If the front-end sends an call execution status of zero (OK), and the number of returned values does not match the number of program variables, the runtime system will set unmatched program variables to `NULL`. As a general rule, the program should provide the expected input and output parameters as specified in the documentation.

ui.Interface.filenameToURI
Converts a file name to an URI to be used as a web component image resource.

Syntax

```
ui.Interface.filenameToURI(
   filename STRING )
  RETURNING uri INTEGER
```

1. *filename* is the local file name to be converted to a URI.
2. *uri* is the resulting URI.

Usage

The `ui.Interface.filenameToURI()` class method converts a local (VM context / server) file name to an URI that can be accessed by the front ends to get the resource. This method is typically used to provide application image files in Web Components.

> **Note:** The runtime system uses the same mechanism to provide the front-end with images referenced in form elements: Thus, there is no need to call this method except when using application images in web components.

This method is typically used when executing applications behind a GAS, but it can also be used with direct connection to the front-end (typical GDC desktop connection), or when running apps on a mobile device.

The VM context file name to URI mapping is done as follows:

- If the *filename* parameter is already an URI (i.e. has a scheme like `http:`, `https:`, `file:`), the file name is returned as is.
- If the *filename* parameter is an absolute, relative file path, or a simple file name:
  - When the program is executing behind a GAS, user agents can access files via HTTP. In this architecture, the method will produce an URI that can be referenced in HTML elements of a web component: The image resource will be available from this location.

- When using a direct connection to the (GDC) front-end without using the GAS, the method returns the file name as is, and the image resources will be transmitted to the GDC through the FGLIMAGEPATH mechanism.
- When executing an app on a mobile device, both front-end and runtime system cohexist on the same platform and can access to the same file system. In this architecture, the method builds the complete local path to the file, following the list of directories defined in the FGLIMAGEPATH environment variable.

  Note: The URI or file path returned by the `filenameToURI()` method are only valid during the program live time: Do not stores these values in a persistent way.

For more details, see Providing the image resource on page 784 and Using image resources with the gICAPI web component on page 1430

Example

```
LET uri = ui.Interface.filenameToURI("myimage.png")
```

ui.Interface.getChildCount
Get the number of children in a parent container.

Syntax

```
ui.Interface.getChildCount()
  RETURNING result INTEGER
```

Usage

The `ui.Interface.getChildCount()` class method returns the number of child programs attached to the current parent WCI program.

WCI child programs are attached to a given container by using the `ui.Interface.setContainer()` method. Container and child program identifiers/names are defined by the `ui.Interface.setName()` method.

ui.Interface.getChildInstances
Get the number of child instances for a given program name.

Syntax

```
ui.Interface.getChildInstances(
   name STRING )
  RETURNING result INTEGER
```

1. *name* is the name of a child program attached to the container of the current program.

Usage

The `ui.Interface.getChildInstances()` class method returnes the number of child instances of a program attached to the current parent WCI program, according to the name of the child program passed as parameter.

The name of a child program is defined by the `ui.Interface.setName()` method.

The `getChildInstances()` method is typically used to check if a give child program is already started, to avoid multiple instances of the same program in a given WCI container.

ui.Interface.getContainer
Get the parent container of the curren program.

Syntax

```
ui.Interface.getContainer()
  RETURNING result STRING
```

Usage

The `ui.Interface.getContainer()` class method returns the name of the parent WCI container defined with `ui.Interface.setContainer()`.

ui.Interface.getDocument
Returns the DOM document of the abstract user interface tree.

Syntax

```
ui.Interface.getDocument()
  RETURNING result  om.DomDocument
```

Usage

The `ui.Interface.getDocument()` method returns the DOM document of the abstract user interface tree.

Define a variable with the type `om.DomDocument` to receive the result of this method.

Consider using the `getRootNode()` method instead to get directely the root DOM node of the AUI tree.

ui.Interface.getFrontEndName
Returns the type of the front-end currently in use.

Syntax

```
ui.Interface.getFrontEndName()
  RETURNING result STRING
```

Usage

The `ui.Interface.getFrontEndName()` class method returns the type of the front end used by the program.

Table 380: Front-end names

Front-end name	Description
`GDC`	Desktop front-end
`GMA`	Mobile front-end for Android™
`GMI`	Mobile front-end for iOS
`GWC`	Web browser front-end
`Console`	Text front-end (dumb terminal)

ui.Interface.getFrontEndVersion
Returns the version of the front-end currently in use.

Syntax

```
ui.Interface.getFrontEndVersion()
  RETURNING result STRING
```

Usage

The `ui.Interface.getFrontEndVersion()` class method returns the version number of the front end used by the program.

> **Note:** This method is primarily used for debugging purposes.

ui.Interface.getImage
Returns the icon image of the program.

Syntax

```
ui.Interface.getImage()
  RETURNING result STRING
```

Usage

Use the `ui.Interface.getImage()` class method to get the icon image name of the program previously set by `setImage()`.

ui.Interface.getName
Returns the name of the program.

Syntax

```
ui.Interface.getName()
  RETURNING result STRING
```

Usage

The `ui.Interface.getName()` class method returns the name of the program that was defined with the `setName()` method.

ui.Interface.getRootNode
Get the root DOM node of the abstract user interface.

Syntax

```
ui.Interface.getRootNode()
  RETURNING result om.DomNode
```

Usage

The `ui.Interface.getRootNode()` method returns the root DOM node of the abstract user interface tree.

Define a variable with the type `om.DomNode` to receive the result of this method.

```
DEFINE rn om.DomNode
```

```
LET rn = ui.Interface.getRootNode()
-- use d to inspect/change the AUI tree
```

ui.Interface.getText
Returns the title of the program.

Syntax

```
ui.Interface.getText()
  RETURNING result STRING
```

Usage

Use the `ui.Interface.getText()` class method to get the title of the program previously set by `setText()`.

ui.Interface.getType
Returns the type of the program.

Syntax

```
ui.Interface.getType()
  RETURNING result STRING
```

Usage

Use the `ui.Interface.getType()` class method to get the type of the program previously set by `setType()`.

ui.Interface.loadActionDefaults
Load the default action defaults file.

Syntax

```
ui.Interface.loadActionDefaults(
   filename STRING )
```

1. *filename* is the name of action defaults file, without the extension.

Usage

Use the `ui.Interface.loadActionDefaults()` class method to load a .4ad file defining action defaults for all program forms.

Specify the filename without the "4ad" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH/FGLRESOURCEPATH environment variable.

Example

```
CALL ui.Interface.loadActionDefaults("mydefaults")
```

ui.Interface.loadStartMenu
Load the start menu file.

Syntax

```
ui.Interface.loadStartMenu(
   filename STRING )
```

1. *filename* is the name of a start menu file, without the extension.

Usage

Use the `ui.Interface.loadStartMenu()` class method to load a .4sm file defining a start menu.

Specify the filename without the "`4sm`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH/FGLRESOURCEPATH environment variable.

Example

```
CALL ui.Interface.loadStartMenu("mystartmenu")
```

ui.Interface.loadStyles
Load the presentation styles file.

Syntax

```
ui.Interface.loadStyles(
   filename STRING )
```

1. *filename* is the name of presentation styles file, without the extension.

Usage

Use the `ui.Interface.loadStyles()` class method to load a .4st file defining presentation styles for all program forms.

Specify the filename without the "`4st`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH/FGLRESOURCEPATH environment variable.

Example

```
CALL ui.Interface.loadStyles("mystyles")
```

ui.Interface.loadToolBar
Load a default toolbar file.

Syntax

```
ui.Interface.loadToolBar(
   filename STRING )
```

1. *filename* is the name of a toolbar file, without the extension.

Usage

Use the `ui.Interface.loadToolBar()` class method to load a .4tb file defining a default global toolbar for all forms.

Specify the filename without the "`4tb`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH/FGLRESOURCEPATH environment variable.

The default toolbar loaded by this method is also used for the WCI container.

Example

```
CALL ui.Interface.loadToolBar("mytoolbar")
```

ui.Interface.loadTopMenu
Load a default topmenu file.

Syntax

```
ui.Interface.loadTopMenu(
   filename STRING )
```

1. *filename* is the name of a topmenu file, without the extension.

Usage

Use the `ui.Interface.loadTopMenu()` class method to load a .4tm file defining a default topmenu for all forms.

Specify the filename without the "`4tm`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH/FGLRESOURCEPATH environment variable.

The default topmenu loaded by this method is also used for the WCI container.

Example

```
CALL ui.Interface.loadTopMenu("mytopmenu")
```

ui.Interface.setContainer
Define the parent container for the current program.

Syntax

```
ui.Interface.setContainer(
   name STRING )
```

1. *name* is the name of the parent container.

Usage

The `ui.Interface.setContainer(name)` class method to specify the name of the parent WCI container where the current program windows must be displayed. This creates a WCI relation between two independent programs running with distinct fglrun processes.

Each WCI program must be identified by a name, to be set with the `ui.Interface.setName()` class method.

ui.Interface.setImage
Defines the icon image of the program.

Syntax

```
ui.Interface.setImage(
   icon STRING )
```

1. *icon* is the image file name to be used as program icon.

Usage

Use the `ui.Interface.setImage()` class method to define the icon image for the program to be used by the front-ends.This icon will be used in task bars, for example.

Call the method at the beginning of the program, before any interactive instruction.

ui.Interface.setName
Define the name of the current program for the front-end.

Syntax

```
ui.Interface.setName(
   name STRING )
```

1. *name* is the identifier of the program.

Usage

Use the `ui.Interface.setName()` class method to define the identifier for the program to be used by the front-ends, for example in case of window container usage.

The name passed to this method will be passed to the front-end in order to identify the program.

Call the method at the beginning of the program, before any interactive instruction.

By default, it is the program name (without .42m or .42r extension).

ui.Interface.setSize
Specify the initial size of the parent container window.

Syntax

```
ui.Interface.setSize(
   height INTEGER,
   width INTEGER )
```

1. *height* is the initial height of the main window.
2. *width* is the initial width of the main window.

Usage

Use the `ui.Interface.setSize(height,width)` class method to define the initial size of the parent container window of an window container application. The parameters can be integer or string values.

By default, the unit is the character grid cells, but you can add the **px** unit to specify the height and width in pixels.

The `setSize()` method can also be used to configure the size of the main window when using traditional mode, as a replacement of `fgl_setsize()` built-in function.

Call the method at the beginning of the program, before any interactive instruction.

ui.Interface.setText
Defines the title for the program.

Syntax

```
ui.Interface.setText(
   title STRING )
```

1. *title* is the text to be used as program title.

Usage

Use the `ui.Interface.setText()` class method to define the title for the program to be used by the front-ends, for example in case of window container usage (as title for the main window), or for the text to be displayed in the task bars.

Call the method at the beginning of the program, before any interactive instruction.

ui.Interface.setType
Defines the type of the program for the front-end.

Syntax

```
ui.Interface.setType(
   type STRING )
```

1. *type* is the identifier of the program.

Usage

Use the `ui.Interface.setType()` class method to define the type for the program to be used by the front-ends, for example in case of window container usage.

Possible values are: `normal`, `container`, `child`.

The type passed to this method will be passed to the front-end in order to define the rendering and behavior of the program.

Call the method at the beginning of the program, before any interactive instruction.

ui.Interface.refresh
Synchronize the user interface with the front-end.

Syntax

```
ui.Interface.refresh()
```

Usage

The `ui.Interface.refresh()` class method forces a synchronization of the abstract user interface tree with front-end .

By default, during an interactive instruction like `DIALOG`, the AUI tree is refreshed automatically when the runtime system gets the control back after user code execution. There is no need to call the refresh method in regular code.

> **Important:** This method should be used with care; It is only provided to synchronize with the front-end in specific cases. For example, when you need to display batch processing information to the user. Calling this method too frequently will produce a lot of network traffic.

Example

```
FOR i=1 TO 10
   DISPLAY i TO step_num
   CALL ui.Interface.refresh()
   SLEEP 1
END FOR
```

Examples

Example 1: Get the type and version of the front end

```
MAIN
  MENU "Test"
    COMMAND "Get"
      DISPLAY "Name = " || ui.Interface.getFrontEndName()
      DISPLAY "Version = " || ui.Interface.getFrontEndVersion()
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

Example 2: Get the AUI root node and save it to a file in XML format

```
MAIN
  DEFINE n om.DomNode
  MENU "Test"
    COMMAND "SaveUI"
      LET n = ui.Interface.getRootNode()
      CALL n.writeXml("auitree.xml")
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

Example 3: Using the Window Container Interface

The WCI parent program:

```
MAIN
  CALL ui.Interface.setName("main1")
  CALL ui.Interface.setText("This is the parent container")
  CALL ui.Interface.setType("container")
  CALL ui.Interface.setSize("600px","600px")
  CALL ui.Interface.loadStartMenu("appmenu")
  MENU "Main"
    COMMAND "Help" CALL help()
    COMMAND "About" CALL aboutbox()
    COMMAND "Exit"
      IF ui.Interface.getChildCount()>0 THEN
        ERROR "You must first exit the child programs."
      ELSE
        EXIT MENU
      END IF
  END MENU
END MAIN
```

The WCI child program:

```
MAIN
  CALL ui.Interface.setName("prog1")
  CALL ui.Interface.setText("This is module 1")
```

```
  CALL ui.Interface.setType("child")
  CALL ui.Interface.setContainer("main1")
  MENU "Test"
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

Example 4: Synchronizing the AUI tree with the front end

```
MAIN
  DEFINE cnt INTEGER
  OPEN WINDOW w WITH FORM "myform"
  FOR cnt=1 TO 10
    DISPLAY BY NAME cnt
    CALL ui.Interface.refresh()
    SLEEP 1
  END FOR
END MAIN
```

The Window class
The `ui.Window` class provides an interface to the window objects create with the `OPEN WINDOW` instruction.

A windows is typically created with a form with the `OPEN WINDOW WITH FORM` instruction. If the window contains a form, consider using the `ui.Form` class instead of `ui.Window`.

ui.Window methods
Methods of the `ui.Window` class.

Table 381: Class methods

Name	Description
`ui.Window.forName( name STRING ) RETURNING result ui.Window`	Get a window object by name.
`ui.Window.getCurrent() RETURNING result ui.Window`	Get the current window object.

Table 382: Object methods

Name	Description
`createForm( name STRING ) RETURNING result ui.Form`	Create a new empty form in a window.
`findNode( type STRING, name STRING ) RETURNING result om.DomNode`	Search for a specific element in the window.
`getForm()`	Get the current form of a window.

Name	Description
RETURNING *result* ui.Form	
getNode() RETURNING *result* om.DomNode	Get the DOM node of a window.
getImage() RETURNING *result* STRING	Get the window icon.
getText() RETURNING *result* STRING	Get the window title.
setImage(*image* STRING)	Set the window icon.
setText(*text* STRING)	Set the window title.

ui.Window.forName
Get a window object by name.

Syntax

```
ui.Window.forName(
   name STRING )
  RETURNING result ui.Window
```

1. *name* defines the name of the window.

Usage

The `ui.Window.forName()` class method returns the `ui.Window` object corresponding to an identifier used to create the window with the `OPEN WINDOW` instruction.

Declare a variable of type `ui.Window` to hold the window object reference.

Example

```
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.forName("w1")
```

ui.Window.createForm
Create a new empty form in a window.

Syntax

```
createForm(
   name STRING )
  RETURNING result ui.Form
```

1. *name* is the name for the form.

Usage

The `createForm()` method can be used to create a new empty form in the window object. This is typically used to build forms dynamically, by creating the elements with the OM API.

> **Important:** It is mandatory to create a form in a window with the `createForm()` method, otherwise it is not usable.

The method returns a new `ui.Form` instance or `NULL` if the form name passed as the parameter identifies an existing form used by the window.

Example

```
DEFINE w ui.Window,
       f ui.Form,
       n, g om.DomNode
OPEN WINDOW w1 WITH 10 ROWS, 20 COLUMNS
LET w = ui.Window.getCurrent()
LET f = w.createForm("myform")
LET n = f.getNode()
LET g = f.createChild("Grid")
```

ui.Window.getCurrent
Get the current window object.

Syntax

```
ui.Window.getCurrent()
  RETURNING result ui.Window
```

Usage

The `ui.Window.getCurrent()` class method returns the `ui.Window` object corresponding to the current window.

Declare a variable of type `ui.Window` to hold the window object reference.

Example

```
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
```

ui.Window.getForm
Get the current form of a window.

Syntax

```
getForm()
  RETURNING result ui.Form
```

Usage

The `getForm()` method returns the `ui.Form` object corresponding to the current form used by the window object.

Declare a variable of type `ui.Form` to hold the form object reference.

Consider using the `ui.Dialog.getForm()` method to get the form used by the current dialog.

Example

```
DEFINE f ui.Form
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
LET f = w.getForm()
```

ui.Window.getNode
Get the DOM node of a window.

Syntax

```
getNode()
  RETURNING result om.DomNode
```

Usage

The `getNode()` method returns the `om.DomNode` object corresponding to the window object.

Declare a variable of type `om.DomNode` to hold the DOM node object reference.

Consider using the `ui.Dialog.getForm()` method to get the form used by the current dialog.

Example

```
DEFINE w ui.Window, n om.DomNode
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
LET n = w.getNode()
```

ui.Window.findNode
Search for a specific element in the window.

Syntax

```
findNode(
   type STRING,
   name STRING )
  RETURNING result om.DomNode
```

1. *type* defines the type of the node.
2. *name* defines the name of the node.

Usage

The `findNode()` method allows you to search for a specific DOM node in the abstract representation of the window. You search for a child node by giving its type and the name of the element (i.e. the tagname and the value of the 'name' attribute).

The method returns the first element found matching the specified type (tagname) and node name. Window element names must be unique for the same type of nodes, if you want to distinguish all elements.

The `findNode()` method is provided for `ui.Window` class for specific cases when the window does not contain a form. For windows containing a form, use the `ui.Form.findNode()` method instead.

ui.Window.getImage
Get the window icon.

Syntax

```
getImage()
  RETURNING result STRING
```

Usage

Use the `getImage()` method to get the current icon of a window.

ui.Window.getText
Get the window title.

Syntax

```
getText()
  RETURNING result STRING
```

Usage

Use the `getText()` method to get the current title of a window.

ui.Window.setImage
Set the window icon.

Syntax

```
setImage(
   image STRING )
```

1. *image* is the image name for the icon of the window.

Usage

The `setImage()` method defines the icon of the window.

By default, the icon of a window is defined by the `IMAGE` attribute of the `LAYOUT` definition in form files.

ui.Window.setText
Set the window title.

Syntax

```
setText(
   text STRING )
```

1. *text* is the title of the window.

Usage

The `setText()` method defines the title of the window.

By default, the title of a window is defined by the `TEXT` attribute of the `LAYOUT` definition in form files.

Examples
Example 1: Get a window by name and change the title

```
MAIN
  DEFINE w ui.Window
  OPEN WINDOW w1 WITH FORM "customer" ATTRIBUTES(TEXT="Unknown")
  LET w = ui.Window.forName("w1")
  IF w IS NULL THEN
    EXIT PROGRAM
  END IF
  CALL w.setText("Customer")
  MENU "Test"
     COMMAND "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

Example 2: Get a the current form and hide a groupbox

```
MAIN
  DEFINE w ui.Window
  DEFINE f ui.Form
  OPEN WINDOW w1 WITH FORM "customer"
  LET w = ui.Window.getCurrent()
  IF w IS NULL THEN
    EXIT PROGRAM
  END IF
  LET f = w.getForm()
  MENU "Test"
    COMMAND "hide" CALL f.setElementHidden("gb1",1)
    COMMAND "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

The Form class
The `ui.Form` class provides an interface to form objects created by an `OPEN WINDOW WITH FORM` or `DISPLAY FORM` instruction.

A form object allows you to manipulate form elements by program. For example, you can hide parts of a form with the `setElementHidden()` method. The runtime system is able to handle hidden fields during a dialog instruction. You can, for example, hide a `GROUP` containing fields and labels.

Outside dialogs, get a `ui.Form` instance of the current form with the `ui.Window.getForm()` method. When executing a dialog, use the `ui.Dialog.getForm()` method.

Note that the `OPEN FORM` instruction does not load a form; it simply declares a handle. The form will be created in the AUI tree when executing the `DISPLAY FORM` instruction. Therefore, the corresponding `ui.Form` object is only available after `DISPLAY FORM` is executed.

ui.Form methods
Methods of the `ui.Form` class.

Table 383: Class methods

Name	Description
`ui.Form.setDefaultInitializer(` `  funcname STRING )`	Define the default initializer for all forms.

Table 384: Object methods

Name	Description
`findNode( type STRING, name STRING ) RETURNING result om.DomNode`	Search for a child node in the form.
`getNode() RETURNING result om.DomNode`	Get the DOM node of the form.
`loadActionDefaults( filename STRING )`	Load form action defaults.
`loadToolBar( filename STRING )`	Load the form toolbar.
`loadTopMenu( filename STRING )`	Load the form topmenu.
`setElementHidden( name STRING, hide INTEGER )`	Show or hide form elements.
`setElementImage( name STRING, text STRING )`	Change the image of form elements.
`setElementStyle( name STRING, style STRING )`	Change the style of form elements.
`setElementText( name STRING, text STRING )`	Change the text of form elements.
`setFieldHidden( name STRING, hide INTEGER )`	Show or hide a form field.
`setFieldStyle( name STRING, style STRING )`	Change the style of a form field.
`ensureElementVisible(`	Ensure the visibility of a form element.

Name	Description
name STRING)	
ensureFieldVisible(*name* STRING)	Ensure visibility of a form field.

ui.Form.setDefaultInitializer
Define the default initializer for all forms.

Syntax

```
ui.Form.setDefaultInitializer(
   funcname STRING )
```

1. *funcname* is the name of a function in the program.

Usage

Specify a default initialization function with the `ui.Form.setDefaultInitializer()` method, to implement global processing when a form is opened.

The method takes the name of the initialization function as a parameter.

> **Important:** The initialization function name must be in lowercase letters. The language syntax allows case-insensitive functions names, but the runtime system must reference functions in lowercase letters internally.

When a form is loaded with `OPEN FORM / DISPLAY FORM` or with `OPEN WINDOW ... WITH FORM`, the initialization function will be called with a `ui.Form` object as a parameter.

Example

```
MAIN
    ...
    CALL ui.Form.setDefaultInitializer("form_init")
    ...
    OPEN FORM f1 FROM "customers"
    DISPLAY FORM f1 -- initialization function is called
    ...
END MAIN

FUNCTION form_init(f)
    DEFINE f ui.Form
    CALL f.loadToolBar("common_toolbar")
END FUNCTION
```

ui.Form.ensureElementVisible
Ensure the visibility of a form element.

Syntax

```
ensureElementVisible(
   name STRING )
```

1. *name* defines the name of the form element.

Usage

Use the `ensureElementVisible()` method to make sure that the given form element (not form field) is visible to the user. This method can for example be used to show a folder page by passing a field that is located in the folder page, even if the field is not used in a dialog.

This method must be used for static form elements, to make form fields visible, use the `ensureFieldVisible()` method instead.

The form element is identified by its name. If several form elements can have the same name, the first form element found is selected.

Note that the `ensureElementVisible()` method can only show the specified element if it's possible, according to the focus handling in the current active dialog. For more details, see the `ensureFieldVisible()` instead.
ui.Form.ensureFieldVisible
Ensure visibility of a form field.

Syntax

```
ensureFieldVisible(
   name STRING )
```

1. *name* defines the name of the form field.

Usage

The `ensureFieldVisible()` method makes the given form field visible to the user. This method can for example be used to show a folder page by passing a field that is located in the folder page, even if the field is not used in a dialog.

The form field is identified by name, with an optional prefix (`table.column` or `column`).

This method does not give the focus to the field passed as parameter: The folder page or screen area shown by this method call is temporarily visible and can disappear at the next user interaction, according to focus management.

For example, consider a folder having two pages. The focus is in a field on the first page. A call to the `ensureFieldVisible()` method makes the second folder page visible, passing a field located in the second page. When the user presses the TAB key, the focus goes to the next field on the first page, bringing the first page to the top. If you want to show a folder page and give the focus to a specific field in that page, you must explicitly give the focus to a field of the page, with `NEXT FIELD`.

The `ensureFieldVisible()` method is used for form fields, to show static form elements such as labels or images, use the `ensureElementVisible()` method instead.

ui.Form.getNode
Get the DOM node of the form.

Syntax

```
getNode()
  RETURNING result om.DomNode
```

Usage

The `getNode()` method returns the DOM node containing the abstract representation of the window/form.

After loading and displaying a form with `OPEN FORM / DISPLAY FORM` or with `OPEN WINDOW ... WITH FORM`, get the form object for example with `ui.Dialog.getForm()` and use the `getNode()` method to query the DOM node corresponding to the form.

Example

```
DEFINE n om.DomNode,
       f ui.Form

INPUT BY NAME ...
   ...
   LET f = DIALOG.getForm()
   LET n = f.getNode()
   ...
```

ui.Form.findNode
Search for a child node in the form.

Syntax

```
findNode(
   type STRING,
   name STRING )
  RETURNING result om.DomNode
```

1. *type* defines the type of the node.
2. *name* defines the name of the node.

Usage

The `findNode()` method allows you to search for a specific DOM node in the abstract representation of the form. You search for a child node by giving its type and the name of the element (i.e. the tagname and the value of the 'name' attribute).

The method returns the first element found matching the specified type (tagname) and node name. Form element names must be unique for the same type of nodes, if you want to distinguish all elements.

Example

```
DEFINE n om.DomNode,
       f ui.Form

INPUT BY NAME ...
   ...
   LET f = DIALOG.getForm()
   LET n = f.findNode("Label", "lb_name")
   ...
```

ui.Form.loadActionDefaults
Load form action defaults.

Syntax

```
loadActionDefaults(
   filename STRING )
```

1. *filename* is the name of the action defaults file without extension.

Usage

Load form specific action defaults at runtime with the `loadActionDefaults()` method.

The `loadActionDefaults()` method is commonly used in the form initialization function.

Specify the filename without the "`4ad`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH / FGLRESOURCEPATH environment variable.

If a form contains already action defaults, it will be replaced by the new action defaults loaded by this method.

ui.Form.loadToolBar
Load the form toolbar.

Syntax

```
loadToolBar(
   filename STRING )
```

1. *filename* is the name of the toolbar file without extension.

Usage

Load a toolbar XML definition file into the form with the `loadToolBar()` method.

The `loadToolBar()` method is commonly used in the form initialization function.

Specify the filename without the "`4tb`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH / FGLRESOURCEPATH environment variable.

If the form already contains a toolbar, it will be replaced by the new toolbar loaded from this method.

ui.Form.loadTopMenu
Load the form topmenu.

Syntax

```
loadTopMenu(
   filename STRING )
```

1. *filename* is the name of the topmenu file without extension.

Usage

Load a topmenu XML definition file into the form with the `loadTopMenu()` method.

The `loadTopMenu()` method is commonly used in the form initialization function.

Specify the filename without the "`4tm`" extension.

If the file does not exist in the current directory, it is searched in the directories defined in the DBPATH / FGLRESOURCEPATH environment variable.

If the form already contains a topmenu, it will be replaced by the new topmenu loaded by this method.

ui.Form.setElementHidden
Show or hide form elements.

Syntax

```
setElementHidden(
   name STRING,
```

```
   hide INTEGER )
```

1. *name* defines the name of the node.
2. *hide* the integer value to show or hide the element.

Usage

Change the visibility of a form element with the `setElementHidden()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

The `setElementHidden()` method changes the hidden attribute of all form elements identified by the name.

The value passed to hide/show the element can be 0, 1 or 2:

Table 385: Hidden attribute integer values

Hidden value	Description
`0`	Makes the element visible.
`1`	The element is hidden and the user cannot make it visible. Typically used to hide information the user is not allowed to see.
`2`	The element is hidden and the user can make it visible.

> **Note:** Do not hide all fields of a dialog, otherwise the dialog execution stops. At least one field must get the focus during a dialog execution.

ui.Form.setElementImage
Change the image of form elements.

Syntax

```
setElementImage(
   name STRING,
   text STRING )
```

1. *name* defines the name of the node.
2. *image* is the image to be set.

Usage

Change the image/icon of a form element with the `setElementImage()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

ui.Form.setElementStyle
Change the style of form elements.

Syntax

```
setElementStyle(
   name STRING,
   style STRING )
```

1. *name* defines the name of the node.
2. *style* is the style name to be set.

Usage

Change the style of a form element with the `setElementStyle()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

ui.Form.setElementText
Change the text of form elements.

Syntax

```
setElementText(
   name STRING,
   text STRING )
```

1. *name* defines the name of the node.
2. *text* is the text to be set.

Usage

Change the text of a form element with the `setElementText()` method, for example to modify the text of a static label or group box during program execution. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition file (per) or the name attribute for the element as defined in the form file.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

ui.Form.setFieldHidden
Show or hide a form field.

Syntax

```
setFieldHidden(
   name STRING,
   hide INTEGER )
```

1. *name* defines the name of the form field.
2. *hide* the integer value to show or hide the element.

Usage

Change the visibility of a form field with the `setFieldHidden()` method. You must pass the identifier of the form field, as defined in the .per form definition. The form field is identified by column name, with an optional prefix (`table.column` or `column`). The form field can be a regular field or a column of a list container such as a TABLE.

The value passed to hide/show the element can be 0, 1 or 2:

Table 386: Hidden attribute integer values

Hidden value	Description
`0`	Makes the field visible.

Hidden value	Description
1	The field is hidden and the user cannot make it visible. Typically used to hide information the user is not allowed to see.
2	The element is hidden and the user can make it visible.

Note: Do not hide all fields of a dialog, otherwise the dialog execution stops. At least one field must get the focus during a dialog execution.

ui.Form.setFieldStyle
Change the style of a form field.

Syntax

```
setFieldStyle(
   name STRING,
   style STRING )
```

1. *name* defines the name of the form field.
2. *style* is the style name to be set.

Usage

Change the style of a form field with the `setFieldStyle()` method. You must pass the identifier of the form field, as defined in the .per form definition. The form field is identified by column name, with an optional prefix (`table.column` or `column`). The form field can be a regular field or a column of a list container such as a `TABLE`.

Examples

Example 1: Implement a global form initialization function

```
MAIN
  CALL ui.Form.setDefaultInitializer("init")
  OPEN FORM f1 FROM "items"
  DISPLAY FORM f1 -- Form appears in the default SCREEN window
  OPEN WINDOW w1 WITH FORM "customer"
  OPEN WINDOW w2 WITH FORM "orders"
  DISPLAY FORM f1 -- Form appears in w2 window
  MENU "Test"
    COMMAND "exit" EXIT MENU
  END MENU
END MAIN

FUNCTION init(f)
  DEFINE f ui.Form
  DEFINE n om.DomNode
  CALL f.loadTopMenu("mymenu")
  LET n = f.getNode()
  DISPLAY "Init: ", n.getAttribute("name")
END FUNCTION
```

Example 2: Hide form elements dynamically

```
MAIN
  DEFINE w ui.Window
  DEFINE f ui.Form
  DEFINE custid INTEGER
```

```
  DEFINE custname CHAR(10)
  OPEN WINDOW w1 WITH FORM "customer"
  LET w = ui.Window.getCurrent()
  LET f = w.getForm()
  INPUT BY NAME custid, custname
    ON ACTION hide
      CALL f.setFieldHidden("customer.custid",1)
      CALL f.setElementHidden("label_custid",1)
    ON ACTION show
      CALL f.setFieldHidden("customer.custid",0)
      CALL f.setElementHidden("label_custid",0)
  END INPUT
END MAIN
```

Example 3: Change the title of table column headers

The form file (coltitle.per):

```
LAYOUT
GRID
{
<TABLE t1             >
 Id      Name
[c1     |c2           ]
[c1     |c2           ]
[c1     |c2           ]
[c1     |c2           ]
[c1     |c2           ]
}
END
END
ATTRIBUTES
c1 = FORMONLY.col1;
c2 = FORMONLY.col2;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

The program file:

```
MAIN
    DEFINE f ui.Form, i INT
    DEFINE arr DYNAMIC ARRAY OF RECORD
                   id INT,
                   name VARCHAR(40)
               END RECORD
    OPEN FORM f1 FROM "coltitle"
    DISPLAY FORM f1
    FOR i=1 TO 10
        LET arr[i].id = i
        LET arr[i].name = "aaa"||i
    END FOR
    DISPLAY ARRAY arr TO sr.* ATTRIBUTES(UNBUFFERED)
        BEFORE DISPLAY
           let f = dialog.getForm()
        ON ACTION change_title
           CALL f.setElementText("formonly.col1","ID")
           CALL f.setElementText("formonly.col2","NAME")
    END DISPLAY
END MAIN
```

The Dialog class

The `ui.Dialog` class provides a set of methods to configure, query and control the current interactive instruction.

A `ui.Dialog` object can for example be used to enable or disable actions and form fields dynamically during the dialog execution.

A dialog object is typically available inside a dialog block, with the predefined `DIALOG` keyword, and can only be referenced during the execution of that interactive instruction. After the interactive instruction, the dialog object is destroyed and its reference becomes invalid.

Dialog objects can also be created dynamically to handle forms created at runtime. This feature is only provided for specific needs.

ui.Dialog methods

Methods of the `ui.Dialog` class.

Table 387: Class methods

Name	Description

`ui.Dialog.createConstructByName(`
`  fields DYNAMIC ARRAY OF RECORD`
`  name STRING,`
`  type STRING`
`  END RECORD`
`  )`
	Creates a new ui.Dialog object to handle a CONSTRUCT BY NAME.

`ui.Dialog.createDisplayArrayTo(`
`  fields DYNAMIC ARRAY OF RECORD`
`  name STRING,`
`  type STRING`
`  END RECORD,`
`  tabname STRING )`
	Creates a new ui.Dialog object to handle a DISPLAY ARRAY.

`ui.Dialog.createInputByName(`
`  fields DYNAMIC ARRAY OF RECORD`
`  name STRING,`
`  type STRING`
`  END RECORD`
`  )`
	Creates a new ui.Dialog object to handle an INPUT BY NAME.

`ui.Dialog.getCurrent()` `  RETURNING result ui.Dialog`	Returns the current dialog object.
`ui.Dialog.setDefaultUnbuffered(` `  value BOOLEAN )`	Set the default unbuffered mode for all dialogs.

Table 388: Object methods

Name	Description
`accept()`	Validates and terminates the dialog.
`addTrigger(` `  name STRING )`	Adds an event trigger to the dynamic dialog

`appendNode(`
`  name STRING,`
`  index INTEGER )`
	Appends a new node in the specified tree-view.

`appendRow(` `  name STRING )`	Appends a new row in the specified list.
`deleteAllRows(` `  name STRING )`	Deletes all rows from the specified list.

`arrayToVisualIndex(`
`  name STRING,`
`  index INTEGER )`
	Converts the program array index to the visual index for a given screen array.

`deleteNode(`
`  name STRING,`
`  index INTEGER )`
	Deletes a node from the specified tree-view.

`deleteRow(`
`  name STRING,`
`  index INTEGER )`
	Deletes a row from the specified list.

`getArrayLength(`
`  name STRING )`
`  RETURNING result INTEGER`
	Returns the total number of rows in the specified list.

`getCurrentItem()` `  RETURNING result STRING`	Returns the current item having focus.

`getCurrentRow(`
`  name STRING )`
`  RETURNING result INTEGER`
	Returns the current row of the specified list.

`getFieldBuffer(` `  field STRING )`	Returns the input buffer of the specified field.

Name	Description
RETURNING *result* STRING	
getFieldTouched(*field-list* STRING) RETURNING *result* BOOLEAN	Returns the modification flag for a field.
getFieldValue(*name* STRING)	Returns the value of a field controlled by a dynamic dialog.
getForm() RETURNING *result* ui.Form	Returns the current form used by the dialog.
getSortKey(*screen-array* STRING) RETURNING *field-name* STRING	Returns the name of the sort field selected by the user.
getSortReverse(*screen-array* STRING) RETURNING *result* BOOLEAN	Indicates the sort order direction (FALSE=ascending, TRUE=descending)
insertNode(*name* STRING, *index* INTEGER)	Inserts a new node in the specified tree.
insertRow(*name* STRING, *index* INTEGER)	Inserts a new row in the specified list.
isRowSelected(*name* STRING, *index* INTEGER) RETURNING *result* BOOLEAN	Queries row selection for a give list and row.
nextField(*name* STRING)	Registering the next field to jump to.
nextEvent() RETURNING event STRING	Waits for a dialog event.
selectionToString(*name* STRING) RETURNING *result* STRING	Serializes data of the selected rows.
setActionActive(*name* STRING,	Enabling and disabling dialog actions.

Name	Description
active BOOLEAN)	
setActionHidden(*name* STRING, *hide* INTEGER)	Handling default action view visibility.
setArrayAttributes(*name* STRING, *attributes* ARRAY)	Define cell decoration attributes array for the specified list (singular or multiple dialogs).
setArrayLength(*name* STRING, *len* INTEGER)	Sets the total number of rows in the specified list.
setCellAttributes(*attributes* ARRAY)	Define cell decoration attributes array for the specified list (singular dialog only).
setCompleterItems(*items-array* DYNAMIC ARRAY OF STRING)	Define autocompletion items for the a field defined with COMPLETER attribute.
setCurrentRow(*name* STRING, *row* INTEGER)	Sets the current row in the specified list.
setFieldActive(*field-list* STRING, *active* BOOLEAN)	Enable and disable form fields.
setFieldTouched(*field-list* STRING, *touched* BOOLEAN)	Sets the modification flag of the specified field.
setFieldValue(*name* STRING, *value fgl-type*)	Sets the value of a field controlled by the dialog object.
setSelectionMode(*name* STRING, *mode* INTEGER)	Defines the row selection mode for the specified list.
setSelectionRange(*name* STRING, *start* INTEGER, *end* INTEGER,	Sets the row selection flags for a range of rows.

Name	Description
value BOOLEAN)	
validate(*field-list* STRING) RETURNING *result* INTEGER	Check form level validation rules.
visualToArrayIndex(*name* STRING, *index* INTEGER)	Converts the visual index to the program array index for a given screen array.

ui.Dialog.createConstructByName
Creates a new ui.Dialog object to handle a CONSTRUCT BY NAME.

Syntax

```
ui.Dialog.createConstructByName(
   fields DYNAMIC ARRAY OF RECORD
                          name STRING,
                          type STRING
                       END RECORD
   )
```

1. *fields* is the list of form fields controlled by the dialog. This must be a `DYNAMIC ARRAY` of `RECORD` structure, with a `name` and `type` member of type `STRING`.

Usage

The `ui.Dialog.createConstructByName()` class method creates a new dialog object to implement the equivalent of a static `CONSTRUCT` block.

> **Note:** The current form will be attached to the new created dialog.

The method takes a list of field definitions as parameter. The parameter must be defined as a `DYNAMIC ARRAY OF RECORD`, with `name` and `type` members:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                          name STRING,
                          type STRING
                 END RECORD
```

These names provided in the field definition list must identify form fields defined in the current form. For example, if the current form file defines the following fields:

```
LAYOUT
...
END
TABLES
customer
END
ATTRIBUTES
EDIT f1 = customer.cust_id;
EDIT f2 = customer.cust_name;
...
END
```

The field names provided to the `createConstructByName()` method must be defined as follows:

```
LET fields[1].name = "customer.cust_id"
LET fields[2].name = "customer.cust_name"
...
```

The types provided in the field definition list will identify the data type to be used for data input and display.

Possible values for types are the string equivalents of the Genero BDL built-in types. For example:

- `"INTEGER"`
- `"VARCHAR(50)"`
- `"DATE"`
- `"DECIMAL(10,2)"`
- `"DATETIME YEAR TO FRACTION(5)"`

Note: The type used to define form fields can be the returning value of a `base.SqlHandle.getResultType()` method.

Example

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                        name STRING,
                        type STRING
              END RECORD
DEFINE d ui.Dialog

OPEN FORM f1 FROM "custform"
DISPLAY FORM f1

LET fields[1].name = "customer.cust_id"
LET fields[1].type = "INTEGER"

LET fields[2].name = "customer.cust_name"
LET fields[2].type = "VARCHAR(50)"
...
LET d = ui.Dialog.createConstructByName(fields)
...
```

ui.Dialog.createInputByName
Creates a new ui.Dialog object to handle an INPUT BY NAME.

Syntax

```
ui.Dialog.createInputByName(
   fields DYNAMIC ARRAY OF RECORD
                       name STRING,
                       type STRING
                  END RECORD
   )
```

1. *fields* is the list of form fields controlled by the dialog. This must be a `DYNAMIC ARRAY` of a `RECORD` structure, with a `name` and `type` member of type `STRING`.

Usage

The `ui.Dialog.createInputByName()` class method creates a new dialog object to implement the equivalent of a static `INPUT BY NAME` block.

Note: The current form will be attached to the new created dialog.

The method takes a list of field definitions as parameter. The parameter must be defined as a `DYNAMIC ARRAY OF RECORD`, with `name` and `type` members:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                        name STRING,
                        type STRING
              END RECORD
```

These names provided in the field definition list must identify form fields defined in the current form. For example, if the current form file defines the following fields:

```
LAYOUT
...
END
TABLES
customer
END
ATTRIBUTES
EDIT f1 = customer.cust_id;
EDIT f2 = customer.cust_name;
...
END
```

The field names provided to the `createInputByName()` method must be defined as follows:

```
LET fields[1].name = "customer.cust_id"
LET fields[2].name = "customer.cust_name"
...
```

The types provided in the field definition list will identify the data type to be used for data input and display.

Possible values for types are the string equivalents of the Genero BDL built-in types, for example:

- `"INTEGER"`
- `"VARCHAR(50)"`
- `"DATE"`
- `"DECIMAL(10,2)"`
- `"DATETIME YEAR TO FRACTION(5)"`

Note: The type used to define form fields can be the returning value of a `base.SqlHandle.getResultType()` method.

Example

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                        name STRING,
                        type STRING
              END RECORD
DEFINE d ui.Dialog

OPEN FORM f1 FROM "custform"
DISPLAY FORM f1

LET fields[1].name = "customer.cust_id"
LET fields[1].type = "INTEGER"

LET fields[2].name = "customer.cust_name"
LET fields[2].type = "VARCHAR(50)"
...
```

```
LET d = ui.Dialog.createInputByName(fields)
...
```

ui.Dialog.createDisplayArrayTo
Creates a new ui.Dialog object to handle a DISPLAY ARRAY.

Syntax

```
ui.Dialog.createDisplayArrayTo(
   fields DYNAMIC ARRAY OF RECORD
                          name STRING,
                          type STRING
                       END RECORD,
   tabname STRING )
```

1. *fields* is the list of form fields controlled by the dialog. This must be a `DYNAMIC ARRAY` of a `RECORD` structure, with a `name` and `type` member of type `STRING`.
2. *tabname* is the name of the screen array (defined with the `SCREEN RECORD` instruction in form files).

Usage

The `ui.Dialog.createDisplayArrayTo()` class method creates a new dialog object to implement the equivalent of a static `DISPLAY ARRAY TO` block.

> **Note:** The current form will be attached to the new created dialog.

The method takes a list of field definitions as first parameter. This parameter must be defined as a `DYNAMIC ARRAY OF RECORD`, with `name` and `type` members:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                          name STRING,
                          type STRING
                END RECORD
```

These names provided in the field definition list must identify form fields defined in the current form. For example, if the current form file defines the following fields:

```
LAYOUT
...
END
TABLES
customer
END
ATTRIBUTES
EDIT f1 = customer.cust_id;
EDIT f2 = customer.cust_name;
...
END
```

The field names provided to the `createDisplayArrayTo()` method must be defined as follows:

```
LET fields[1].name = "customer.cust_id"
LET fields[2].name = "customer.cust_name"
...
```

The types provided in the field definition list will identify the data type to be used for data input and display.

Possible values for types are the string equivalents of the Genero BDL built-in types, for example:

- `"INTEGER"`

- "VARCHAR(50)"
- "DATE"
- "DECIMAL(10,2)"
- "DATETIME YEAR TO FRACTION(5)"

Note: The type used to define form fields can be the returning value of a `base.SqlHandle.getResultType()` method.

The second parameter passed to the `createDisplayArrayTo()` method is the name of the screen record which groups the fields together, for the list view of the form. For example, in the next form definition, the screen record name is "`sr_custlist`":

```
...
INSTRUCTIONS
SCREEN RECORD sr_custlist
(
 customer.cust_id,
 customer.cust_name,
 ...
);
END
```

For more details, see Screen records on page 866.

Example

```
DEFINE fields DYNAMIC ARRAY OF RECORD
                        name STRING,
                        type STRING
              END RECORD
DEFINE d ui.Dialog

OPEN FORM f1 FROM "custform"
DISPLAY FORM f1

LET fields[1].name = "customer.cust_id"
LET fields[1].type = "INTEGER"

LET fields[2].name = "customer.cust_name"
LET fields[2].type = "VARCHAR(50)"
...
LET d = ui.Dialog.createDisplayArrayTo(fields, "sr_custlist")
...
```

ui.Dialog.getCurrent
Returns the current dialog object.

Syntax

```
ui.Dialog.getCurrent()
  RETURNING result ui.Dialog
```

Usage

To get the current active dialog object, use the `ui.Dialog.getCurrent()` class method.

The method returns NULL if there is no current active dialog.

Example

```
FUNCTION field_disable(name)
  DEFINE name STRING
  DEFINE d ui.Dialog
  LET d = ui.Dialog.getCurrent()
  IF d IS NOT NULL THEN
    CALL d.setFieldActive(name, FALSE)
  END IF
END FUNCTION
```

ui.Dialog.setDefaultUnbuffered
Set the default unbuffered mode for all dialogs.

Syntax

```
ui.Dialog.setDefaultUnbuffered(
   value BOOLEAN )
```

1. *value* is a boolean to enable the unbuffered mode.

Usage

By default, modal dialogs are not sensitive to variable changes. To make a dialog sensitive, use the `UNBUFFERED` attribute in the dialog instruction definition.

To defined the default for all subsequent dialogs, use the `setDefaultUnbuffered()` class method:

```
CALL ui.Dialog.setDefaultUnbuffered(TRUE)
```

> **Note:** Only singular and multiple dialogs are sensitive to this API, parallel dialogs are implicitely using the unbuffered mode.

ui.Dialog.accept
Validates and terminates the dialog.

Syntax

```
accept()
```

Usage

Use the `accept()` method to validate field input and terminate the dialog. This method is equivalent to the `ACCEPT INPUT` / `ACCEPT DISPLAY` / `ACCEPT DIALOG` instructions.

The method is provided as a 3GL alternative to the `ACCEPT` control instructions, for example to terminate the dialog in a function, outside the context of a dialog block, where control instructions cannot be used.

Typical dialog validation rules are performed when calling this method. See `ACCEPT DIALOG` for more details.

ui.Dialog.addTrigger
Adds an event trigger to the dynamic dialog

Syntax

```
addTrigger(
   name STRING )
```

1. *name* is the name of the dialog.

Usage

When implementing a dynamic dialog, the `addTrigger()` method must be used to register the triggers, that need to be handled with user code:

```
CALL d.addTrigger("ON ACTION print")
```

Registered dialog triggers are then typically managed in a `WHILE` loop using the nextEvent() method, to wait for dialog events.

The following triggers are accepted by the `addTrigger()` method:

> **Note:** More predefined triggers such as "`BEFORE ROW`" are existing for dynamic dialogs, but these triggers do not have to be added with the `addTrigger()` method, since they are implicit.

Table 389: User-defined triggers for dynamic dialogs

Trigger name	Description	Dialog block equivalent
`ON ACTION` *`action-name`*	Action handler for the action identified by *action-name*.	`ON ACTION` block
`ON APPEND`	Row addition action handler for a display array dynamic dialog.	`ON APPEND` block
`ON DELETE`	Row deletion action handler for a display array dynamic dialog.	`ON DELETE` block
`ON INSERT`	Row insertion action handler for a display array dynamic dialog.	`ON INSERT` block
`ON UPDATE`	Row modification action handler for a display array dynamic dialog.	`ON UPDATE` block

ui.Dialog.appendRow
Appends a new row in the specified list.

Syntax

```
appendRow(
   name STRING )
```

1. *name* is the screen array name.

Usage

The `appendRow()` method appends a row to the end of the array controlled by the dialog.

> **Important:** This method is designed to be used in an `ON ACTION` block. It must not be called in control blocks such as `BEFORE ROW`, `AFTER ROW`, `BEFORE INSERT`, `AFTER INSERT`, `BEFORE DELETE`, or `AFTER DELETE`.

The method is similar to appending a new element to the program array, except the internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection flags of existing rows are kept. The new row is inserted at the end of the list with the selection flag set to zero.

> **Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a `DISPLAY ARRAY` dialog. Avoid using this method in `INPUT ARRAY`. To allow the end user to append, modify or delete rows in a `DISPLAY ARRAY`, use list modification interaction blocks.

After the method is called, a new row is created in the program array. You can assign values to the variables before the control goes back to the user. The `getArrayLength()` method will return the new row count.

The method does not set the current row and does not give the focus to the list; you need to call `setCurrentRow()` and execute `NEXT FIELD` to give the focus.

This method does not execute any `BEFORE ROW`, `BEFORE INSERT`, `AFTER INSERT` or `AFTER ROW` control blocks.

The `appendRow()` method does not create a temporary row as the implicit append action of `INPUT ARRAY`; The row is considered permanent once it is added.

Example

This example implements a user-defined action to append ten rows at the end of the list.

```
ON ACTION append_some_rows
  FOR i = 1 TO 10
    CALL DIALOG.appendRow("sa")
    LET r = DIALOG.getArrayLength("sa")
    LET p_items[r].item_quantity = 1.00
  END FOR
```

ui.Dialog.appendNode
Appends a new node in the specified tree-view.

Syntax

```
appendNode(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the parent node in the program array (starts at 1).

Usage

The `appendNode()` method adds a new node under a given parent, when the dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with `ON EXPAND` / `ON COLLAPSE` triggers. Before the execution of the dialog, you can fill the program array directly. This includes the context of `BEFORE DISPLAY` or `BEFORE DIALOG` control blocks.

When adding rows for a tree view, the id of the parent node and new node matters because that information is used to build the internal tree structure. When calling `appendNode()`, you pass the index of the parent node under which the new node will be appended. In the program array, the parent-id member of the new node will automatically be initialized with the value of the id of the parent node identifier by the index passed as parameter, then the internal tree structure is rebuilt.

If the parent index is zero, a new root node will be appended.

The method returns the index of the new inserted node.

In the program array, the parent-id member of the new node will automatically be initialized with the value of the id member of the parent node identified by the index.

```
DISPLAY ARRAY mytree TO sr.*
    ...
    ON EXPAND(id)
       CALL DIALOG.appendNode("sr", id)
       ...
    ...
```

ui.Dialog.arrayToVisualIndex
Converts the program array index to the visual index for a given screen array.

Syntax

```
arrayToVisualIndex(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the program array row.

Usage

When the end user sorts rows in a table, the program array index may differ from the visual row index.

Use this method to convert a program array row index (`arr_curr()`) to a row index as seen by the end user. For example, if you want to display a typical message with (*current-row* / *total-rows*), convert the current program array row to a visual row index before displaying the value:

```
MESSAGE SFMT( "Row: %1/%2",
   DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr") ),
   DIALOG.getArrayLength( "sr" )
 )
```

ui.Dialog.deleteAllRows
Deletes all rows from the specified list.

Syntax

```
deleteAllRows(
   name STRING )
```

1. *name* is the screen array name.

Usage

The `deleteAllRows()` method removes all the rows of a list driven by a `DISPLAY ARRAY` or `INPUT ARRAY`. This is equivalent to a `deleteRow()` call, but instead of deleting one particular row, it removes all rows of the specified list.

This method must not be called in control blocks such as `BEFORE ROW`, `AFTER ROW`, `BEFORE INSERT`, `AFTER INSERT`, `BEFORE DELETE`, `AFTER DELETE`, it is designed to be used in an `ON ACTION` block.

After the method is called, all rows are deleted from the program array, and the `getArrayLength()` method will return zero.

The method takes the name of the screen-array as parameter.

If the `deleteAllRows()` method is called during an `INPUT ARRAY`, the dialog will automatically append a new temporary row if the focus is in the list, to let the user enter new data. When using `AUTO APPEND = FALSE` attribute, no temporary row will be created and the current row register will be automatically changed to make sure that it will not be greater than the total number of rows.

If `deleteAllRows()` method is called during an `INPUT ARRAY` or `DISPLAY ARRAY` that has the focus, the `BEFORE ROW` control block will be executed if you delete the current row. This is required to reset the internal state of the dialog.

If the list was decorated with cell attributes, the program array defining the attributes will be cleared. If multi-row selection is enabled, selection flags are cleared.

ui.Dialog.deleteNode
Deletes a node from the specified tree-view.

Syntax

```
deleteNode(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the node in the program array that has to be deleted (starts at 1).

Usage

The `deleteNode()` method is similar to `deleteRow()`, except that it has to be used when the dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with `ON EXPAND` / `ON COLLAPSE` triggers. Before the execution of the dialog, you can fill the program array directly. This includes the context of `BEFORE DISPLAY` or `BEFORE DIALOG` control blocks.

The main difference with `deleteRow()` is that `deleteNode()` will remove recursively all child nodes before removing the node identified by index.

If the index is zero, all root nodes will be deleted from the tree.

ui.Dialog.deleteRow
Deletes a row from the specified list.

Syntax

```
deleteRow(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the row to be deleted (starts a 1).

Usage

The `deleteRow()` method deletes the row in the array controlled by the dialog.

> **Important:** This method is designed to be used in an `ON ACTION` block. It must not be called in control blocks such as `BEFORE ROW`, `AFTER ROW`, `BEFORE INSERT`, `AFTER INSERT`, `BEFORE DELETE`, or `AFTER DELETE`.

The method is similar to deleting an element to the program array, except that internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is

decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection information is synchronized (i.e., selection flags are shifted up) for all rows after the deleted row.

> **Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a `DISPLAY ARRAY` dialog. Avoid using this method in `INPUT ARRAY`. To allow the end user to append, modify or delete rows in a `DISPLAY ARRAY`, use list modification interaction blocks.

After the method is called, the row no longer exists in the program array, and the `getArrayLength()` method will return the new row count.

If the `deleteRow()` method is called during an `INPUT ARRAY` that has the focus, control blocks such as `BEFORE ROW` and `BEFORE FIELD` will be executed, if you delete the current row. This is required to reset the internal state of the dialog. However, the method does not execute any `BEFORE ROW` or `AFTER ROW` control blocks in a `DISPLAY ARRAY` dialog.

If the `deleteRow()` method is called during an `INPUT ARRAY`, and if no more rows are in the list after the call, the dialog will automatically append a new temporary row if the focus is in the list, to let the user enter new data. When using `AUTO APPEND = FALSE` attribute, no temporary row will be created and the current row register will be automatically changed to make sure that it will not be greater than the total number of rows.

If you pass zero as row index, the method does nothing (if no rows are in the list, `getCurrentRow()` returns zero).

Example

This example implements a user-defined action to remove rows that have a specific property:

```
ON ACTION delete_invalid_rows
  FOR r = 1 TO DIALOG.getArrayLength("sa")
    IF NOT s_orders[t].is_valid THEN
      CALL DIALOG.deleteRow("sa",r)
      LET r = r - 1
    END IF
  END FOR
```

ui.Dialog.getArrayLength
Returns the total number of rows in the specified list.

Syntax

```
getArrayLength(
   name STRING )
  RETURNING result INTEGER
```

1. *name* is the screen array name.

Usage

The `getArrayLength()` method returns the total number of rows of an `INPUT ARRAY` or `DISPLAY ARRAY` list. The name of the screen array is passed as parameter to identify the list.

Example

```
DIALOG
  DISPLAY ARRAY custlist TO sa_custlist.*
    BEFORE ROW
```

```
      MESSAGE "Row count: " ||
  DIALOG.getArrayLength("sa_custlist")
    ...
  END DISPLAY
  INPUT ARRAY ordlist TO sa_ordlist.*
    BEFORE ROW
      MESSAGE "Row count: " ||
  DIALOG.getArrayLength("sa_ordlist")
    ...
  END INPUT
  ...
```

ui.Dialog.getCurrentItem
Returns the current item having focus.

Syntax

```
getCurrentItem()
  RETURNING result STRING
```

Usage

The `getCurrentItem()` method returns the name of the current form item having the focus.

- If the focus is on an action view (typically, a `BUTTON` in the form layout), `getCurrentItem()` returns the name of the corresponding action. If several action views a bound to the same action handler with a unique name, there is no way to distinguish which action view has the focus.
- If the focus is in a simple field controlled by an `INPUT` or `CONSTRUCT` sub-dialog, `getCurrentItem()` returns the *[tab-name.]field-name* of that current field. The *tab-name.* prefix is added if a `FROM` clause is used with an explicit list of fields. No prefix is added if `FROM screen-record.*` is used or if `BY NAME` clause is used.
- If the focus is in a list controlled by a `DISPLAY ARRAY` sub-dialog, `getCurrentItem()` returns the *screen-array* name identifying the list.
- If the focus is in a field of a list controlled by an `INPUT ARRAY` sub-dialog, `getCurrentItem()` returns *screen-array.field-name*, identifying both the list and the current field. In some context, the current field is undefined. For example when entering the `INPUT ARRAY` sub-dialog, `getCurrentItem()` will return the *screen-array* only when in the `BEFORE INPUT` control block.

ui.Dialog.getCurrentRow
Returns the current row of the specified list.

Syntax

```
getCurrentRow(
   name STRING )
  RETURNING result INTEGER
```

1. *name* is the screen array name.

Usage

Use the `getCurrentRow()` method to retrieve the current row of an `INPUT ARRAY` or `DISPLAY ARRAY` list.

You must pass the name of the screen array to identify the list.

```
DIALOG
  DISPLAY ARRAY custlist TO sa_custlist.*
```

```
    BEFORE ROW
      MESSAGE "Current row: " || DIALOG.getCurrentRow("sa_custlist")
    ...
  END DISPLAY
  INPUT ARRAY ordlist TO sa_ordlist.*
    BEFORE ROW
      MESSAGE "Current row: " || DIALOG.getCurrentRow("sa_ordlist")
    ...
  END INPUT
  ...
```

ui.Dialog.getFieldBuffer
Returns the input buffer of the specified field.

Syntax

```
getFieldBuffer(
   field STRING )
  RETURNING result STRING
```

1. *field* is the field specification.

Usage

The `getFieldBuffer()` method returns the current input buffer of the specified field. The input buffer is used by the dialog to synchronize form fields and program variables. In some situations, especially when using the buffered mode or in a `CONSTRUCT`, you may want to access the field input buffer.

> **Note:** This method should only be used in dialogs allowing field input (`INPUT`, `INPUT ARRAY`, `CONSTRUCT`). The behavior is undefined when used in `DISPLAY ARRAY`.

The parameter is a field specification, a string containing the field qualifier, with an optional prefix ("`[table.]column`").

```
LET buff = DIALOG.getFieldBuffer("customer.cust_name")
```

The input buffer can be set with:

- A `DISPLAY TO` or `DISPLAY BY NAME` instruction
- The `FGL_DIALOG_SETBUFFER()` function (only for the current field)

For more details about field name specification, see Identifying fields in dialog methods on page 1818.

ui.Dialog.getFieldTouched
Returns the modification flag for a field.

Syntax

```
getFieldTouched(
   field-list STRING )
  RETURNING result BOOLEAN
```

1. *field-list* is the string with the list of field specification.

Usage

The `getFieldTouched()` method returns `TRUE` if the modification flag of the specified field(s) is set.

The *field-list* is a string containing the field qualifier, with an optional prefix ("`[table.]column`"), a table prefix followed by a dot and an asterisk ("`table.*`"), or a simple asterisk ("`*`").

This code checks if a specific field has been touched:

```
AFTER FIELD cust_name
  IF DIALOG.getFieldTouched("customer.cust_address") THEN
     ...
```

If the parameter is a screen record following by dot-asterisk, the method checks the touched flags of all the fields that belong to the screen record:

```
ON ACTION quit
  IF DIALOG.getFieldTouched("customer.*") THEN
    ...
```

When passing a simple asterisk (*) to the method, the runtime system will check all fields used by the dialog:

```
ON ACTION quit
  IF DIALOG.getFieldTouched("*") THEN
    ...
```

For more details about field name specification, see Identifying fields in dialog methods on page 1818.

ui.Dialog.getFieldValue
Returns the value of a field controlled by a dynamic dialog.

Syntax

```
getFieldValue(
   name STRING )
```

1. *name* is the name of the dialog.

Usage

The `getFieldValue()` method can be used when implementing a dynamic dialog, to return the value of a field:

```
DISPLAY d.getFieldValue( "customer.cust_addr" )
```

The first parameter defines the field to be set. For more details about field name specification, see Identifying fields in dialog methods on page 1818.

When used in a dynamic dialog controlling a list of records, this methods returns the value for a field in the current row. The current row can be set with the `setCurrentRow()` method.

ui.Dialog.getForm
Returns the current form used by the dialog.

Syntax

```
getForm()
  RETURNING result ui.Form
```

Usage

The `getForm()` method returns a `ui.Form` object as a handle to the current form used by the dialog.

Use this form object to modify elements of the current form. For example, you can hide some parts of the form with the `ui.Form.setElementHidden()` method.

ui.Dialog.getQueryFromField
Returns the SQL condition of a field used in a query by example dialog.

Syntax

```
getQueryFromField(
   field-name STRING )
  RETURNING sql-condition STRING
```

1. *field-name* is the name of the form field.

Usage

The `getQueryFromField()` method generates the SQL condition from the value entered in the field specified by the *field-name* parameter.

This method is used in the context of a construct dynamic dialog.

The result of this method can be used to build the `WHERE` part of a `SELECT` statement to find rows in a database.

Collect and concatenate field conditions returned from `getQueryFromField()`, then add `AND` or `OR` boolean operators to create an executable SQL query.

> **Note:** The SQL condition is generated according to the current type of database. The SQL syntax may vary according to the target database. Therefore you should not reuse the generated SQL conditions. However, the user input of a query by example dialog can be reused for different type of databases (see ui.Dialog.setFieldValue on page 1813 and ui.Dialog.getFieldValue on page 1801)

ui.Dialog.getSortKey
Returns the name of the sort field selected by the user.

Syntax

```
getSortKey(
   screen-array STRING )
  RETURNING field-name STRING
```

1. *screen-array* is the name of the screen array.

Usage

The `getSortKey()` method returns the form field name selected by the user to sort rows.

This method is used in the context of the `ON SORT` trigger.

> **Note:** If the sort is reset, the `getSortKey()` method returns `NULL`.

ui.Dialog.getSortReverse
Indicates the sort order direction (FALSE=ascending, TRUE=descending)

Syntax

```
getSortReverse(
   screen-array STRING )
  RETURNING result BOOLEAN
```

1. *screen-array* is the name of the screen array.

Usage

The `getSortReverse()` method returns `FALSE` if the sort order is ascending, and `TRUE` if the sort is in descending order.

This method is used in the context of the `ON SORT` trigger.

ui.Dialog.insertNode
Inserts a new node in the specified tree.

Syntax

```
insertNode(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the next sibling node in the program array (starts at 1).

Usage

The `insertNode()` method is similar to `insertRow()`, except that it has to be used when the list dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with `ON EXPAND` / `ON COLLAPSE` triggers. Before the execution of the dialog, you can fill the program array directly. This includes the context of `BEFORE DISPLAY` or `BEFORE DIALOG` control blocks.

When adding rows for a tree view, the id of the parent node and new node matters because that information is used to build the internal tree structure. When calling `insertNode()`, you pass the index of the next sibling node. In the program array, the parent-id member of the new node will automatically be initialized with the value of the parent-id of the next sibling node, then the internal tree structure is rebuilt.

ui.Dialog.insertRow
Inserts a new row in the specified list.

Syntax

```
insertRow(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index where the row must be inserted (starts at 1).

Usage

The `insertRow()` method inserts a row in the list, at a given position.

> **Important:** This method is designed to be used in an `ON ACTION` block. It must not be called in control blocks such as `BEFORE ROW`, `AFTER ROW`, `BEFORE INSERT`, `AFTER INSERT`, `BEFORE DELETE`, or `AFTER DELETE`.

The method is similar to inserting a new element in the program array, except the internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection flags of existing rows are kept. Selection information is synchronized (i.e., flags are shifted down) for all rows after the new inserted row.

> **Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a `DISPLAY ARRAY` dialog. Avoid using this method in `INPUT ARRAY`. To allow the end user to append, modify or delete rows in a `DISPLAY ARRAY`, use list modification interaction blocks.

After the method is called, a new row is created in the program array, so you can assign values to the variables before the control goes back to the user. The `getArrayLength()` method will return the new row count.

The method does not set the current row and does not give the focus to the list; you need to call `setCurrentRow()` and execute `NEXT FIELD` to give the focus.

The `insertRow()` method must not be used when controlling a tree view. Use the `insertNode()` method instead.

This method does not execute any `BEFORE ROW`, `BEFORE INSERT`, `AFTER INSERT` or `AFTER ROW` control blocks.

If the index is greater than the number of rows, a new row is appended at the end or the list. This is the equivalent of calling the `appendRow()` method.

If the list is empty, `getCurrentRow()` returns zero. If zero is returned, use 1 to reference the first row, otherwise you can get a -1326 error when using the program array.

Example

This example shows a user-defined action to insert ten rows in the list at the current position:

```
ON ACTION insert_some_rows
  LET r = DIALOG.getCurrentRow("sa")
  IF r == 0 THEN LET r = 1 END IF
  FOR i = 10 TO 1 STEP -1
    CALL DIALOG.insertRow("sa", r)
    LET p_items[r].item_quantity = 1.00
  END FOR
```

ui.Dialog.isRowSelected
Queries row selection for a give list and row.

Syntax

```
isRowSelected(
   name STRING,
   index INTEGER )
  RETURNING result BOOLEAN
```

1. *name* is the screen array name.
2. *index* is a row index.

Usage

If multi-row selection is enabled with `setSelectionMode()`, you can check whether a row is selected with the `isRowSelected()` method:

```
ON ACTION check_current_row_selected
  IF DIALOG.isRowSelected( "sr", DIALOG.getCurrentRow("sr") ) THEN
    MESSAGE "Current row is selected."
  END IF
```

If multi-row selection is off, the method returns `TRUE` for the current row and `FALSE` for other rows.

ui.Dialog.nextEvent
Waits for a dialog event.

Syntax

```
nextEvent()
   RETURNING event STRING
```

1. *event* is the name of the dialog event that raised.

Usage

The `nextEvent()` waits for a dialog event to occur, and returns a string that identifies the dialog event that has raised.

This method is typically used in a `WHILE` loop, to implement a dynamic dialog.

A dialog event can be a user-defined trigger such as `"ON ACTION print"`, or an implicit trigger such as `"BEFORE ROW"`, corresponding to the control blocks that can be defined in static dialog instructions such as `DISPLAY ARRAY`.

User-defined triggers are added to the dynamic dialog with the `addTrigger()` method:

Table 390: User-defined triggers for dynamic dialogs

Trigger name	Description	Dialog block equivalent
`ON ACTION` *action-name*	Action handler for the action identified by *action-name*.	`ON ACTION` block
`ON APPEND`	Row addition action handler for a display array dynamic dialog.	`ON APPEND` block
`ON DELETE`	Row deletion action handler for a display array dynamic dialog.	`ON DELETE` block
`ON INSERT`	Row insertion action handler for a display array dynamic dialog.	`ON INSERT` block
`ON UPDATE`	Row modification action handler for a display array dynamic dialog.	`ON UPDATE` block

Implicit dialog triggers are predefined and can be detected and handled in the dialog `WHILE` loop if needed:

Table 391: Implicit triggers for dynamic dialogs

Trigger name	Description	Dialog block equivalent
`BEFORE DISPLAY`	Initialization of the display array dynamic dialog.	`BEFORE DISPLAY` block
`BEFORE INPUT`	Initialization of the input by name dynamic dialog.	`BEFORE INPUT` block
`AFTER DISPLAY`	End of the display array dynamic dialog.	`AFTER DISPLAY` block
`AFTER INPUT`	End of the input by name dynamic dialog.	`AFTER INPUT` block
`BEFORE ROW`	Moving to a new row in a display array dynamic dialog.	`BEFORE ROW` block
`AFTER ROW`	Leaving the current row in a display array dynamic dialog.	`AFTER ROW` block

Trigger name	Description	Dialog block equivalent
`BEFORE FIELD field-name`	Entering the field *field-name* in an input dynamic dialog.	`BEFORE FIELD` block
`AFTER FIELD field-name`	Leaving the field *field-name* in an input dynamic dialog.	`AFTER FIELD` block

ui.Dialog.nextField
Registering the next field to jump to.

Syntax

```
nextField(
   name STRING )
```

1. *name* is the form field name.

Usage

The `nextField()` method registers the name of the next field that must get the focus when control goes back to the dialog.

The first parameter identifies the form field, see Identifying fields in dialog methods for more details.

This method is similar to the `NEXT FIELD` instruction, except that it does not implicitly break the program flow. If you want to get the same behavior as `NEXT FIELD`, the method call must be followed by a `CONTINUE DIALOG` instruction, or an equivalent instruction, in case of singular dialog.

Since this method takes an expression as parameter, you can write generic code, when the name of the target field is not known at compile time. In the next example, the `check_value()` function returns a field name where the value does not satisfy the validation rules.

```
DEFINE fn STRING
...
ON ACTION save
  IF ( fn:= check_values() ) IS NOT NULL THEN
    CALL DIALOG.nextField(fn)
    CONTINUE DIALOG
  END IF
  CALL save_data()
  ...
```

ui.Dialog.selectionToString
Serializes data of the selected rows.

Syntax

```
selectionToString(
   name STRING )
  RETURNING result STRING
```

1. *name* is the screen array name.

Usage

The `selectionToString()` method can be used to get a tab-separated value list of the selected rows.

When multi-row selection is disabled, the method serializes the current row.

You typically use this method in conjunction with drag & drop to fill the buffer, by using a text/plain MIME type, to export data to external applications.

```
ON ACTION serialize
  LET buff = DIALOG.selectionToString( "sr" )
```

Numeric and date data will be formatted according to current locale settings (DBMONEY, DBDATE).

The visual presentation of data is respected: The dialog will copy the rows in the sort order specified by the user, moved columns will appear in the same positions as in the table and hidden columns will be ignored. Note that phantom columns are not copied.

Items in the tab-separated record will be surrounded by double-quotes if the value contains special characters such as a newline, a double-quote, or controls characters with ASCII code < 0x20. Double-quotes in the value will be doubled.

ui.Dialog.setActionActive
Enabling and disabling dialog actions.

Syntax

```
setActionActive(
  name STRING,
  active BOOLEAN )
```

1. *name* is the name of the action.
2. *active* is a boolean value.

Usage

Use the `setActionActive()` method to enable or disable an action.

```
CALL DIALOG.setActionActive("zoom", FALSE)
```

The second parameter of the method must be a boolean expression that evaluates to 0 (FALSE) or 1 (TRUE).

For more details about action names, see Identifying actions in dialog methods on page 1817.

ui.Dialog.setActionHidden
Handling default action view visibility.

Syntax

```
setActionHidden(
   name STRING,
   hide INTEGER )
```

1. *name* is the name of the action.
2. *hide* is 1 to hide, 0 to show.

Usage

Use the `setActionHidden()` method to hide the default view (and context menu option) of an action.

```
CALL DIALOG.setActionHidden( "confirm", 1 )
```

The first parameter identifies the action object of the dialog

For more details about action names, see Identifying actions in dialog methods.

ui.Dialog.setArrayAttributes
Define cell decoration attributes array for the specified list (singular or multiple dialogs).

Syntax

```
setArrayAttributes(
   name STRING,
   attributes ARRAY )
```

1. *name* is the screen array name.
2. *attributes* is a program array defining the cell attributes.

Usage

In an `INPUT ARRAY` or `DISPLAY ARRAY` dialog, the `setArrayAttributes()` method can be used to specify display attributes for each cell.

The `setArrayAttributes()` when several screen arrays are defined, to be able to idenfify the list by the name of the screen array. An equivalent method called `setCellAttributes()` can be used, for dialogs where only one screen array is defined.

Possible values for cell attributes are a combination of the following:

- The TTY attribute `reverse`
- The TTY attribute `blink`
- The TTY attribute `underline`
- One of the TTY colors: `white, yellow, magenta, red, cyan, green, blue, black`

Define an array with the same number of record elements as the data array used by the `INPUT ARRAY` or `DISPLAY ARRAY`. Each element must have the same name as in the data array, and must be defined with a character data type (typically: `STRING`):

```
DEFINE data DYNAMIC ARRAY OF RECORD
         pkey INTEGER,
         name VARCHAR(50)
       END RECORD
DEIFNE attributes DYNAMIC ARRAY OF RECORD
         pkey STRING,
         name STRING
       END RECORD
```

Fill the display attributes array with color and video attributes. These must be specified in lowercase characters and separated by a blank (ex: "`red reverse`"):

```
FOR i=1 TO data.getLength()  -- length from data array!
    LET attributes[i].name = "blue reverse"
END FOR
```

Then, attach the array to the dialog with the `setArrayAttributes()` method, in a `BEFORE DIALOG`, `BEFORE INPUT` or `BEFORE DISPLAY` block:

```
BEFORE DIALOG
   CALL DIALOG.setArrayAttributes( "sr", attributes )
```

Like data values, if you change the cell attributes during the dialog, these are not displayed automatically unless the `UNBUFFERED` mode is used.

```
ON ACTION modify_cell_attribute
   LET attributes[arr_curr()].name = "red reverse"
```

If you set NULL to a element, the default TTY attributes will be reset:

```
ON ACTION clean_cell_attribute
   LET attributes[arr_curr()].name = NULL
```

ui.Dialog.setArrayLength
Sets the total number of rows in the specified list.

Syntax

```
setArrayLength(
   name STRING,
   len INTEGER )
```

1. *name* is the screen array name.
2. *len* is the new size of the array.

Usage

The `setArrayLength()` method is used to specify the total number of rows when using the `DISPLAY ARRAY` paged mode. The name of the screen array is passed to identify the list, followed by an integer expression defining the number of rows.

When using a dynamic array without paged mode (i.e. without the `ON FILL BUFFER` clause), you don't need to specify the total number of rows to the `DIALOG` instruction: It is defined by the number of elements in the array. However, when using the paged mode in a `DISPLAY ARRAY`, the total number of rows does not correspond to the elements in the program array, because the program array holds only a page of the whole list. In any other cases, a call to this method is just ignored.

A call to `setArrayLength()` will not trigger the execution of the `ON FILL BUFFER` clause immediately. The trigger to fill a page of rows will be executed when all the user code has been execute and the control goes back to the dialog instruction.

The `setArrayLength()` method is also be used to fix the final number of rows when using `COUNT=-1` attribute, to implement a paged list without knowing the total number of rows when the dialog starts.

ui.Dialog.setCellAttributes
Define cell decoration attributes array for the specified list (singular dialog only).

Syntax

```
setCellAttributes(
   attributes ARRAY )
```

1. *attributes* is a program array defining the cell attributes.

Usage

In an `INPUT ARRAY` or `DISPLAY ARRAY` dialog, the `setCellAttributes()` method can be used to specify display attributes for each cell.

The `setCellAttributes()` method is designed for dialog programming, where only one screen array is used (for example, in a singular `DISPLAY ARRAY` dialog). An equivalent method called `setArrayAttributes()` can be used, when several screen arrays are defined in a multiple dialog, to be able to idenfify the list by the name of the screen array.

Possible values for cell attributes are a combination of the following:

- The TTY attribute `reverse`
- The TTY attribute `blink`

- The TTY attribute `underline`
- One of the TTY colors: `white, yellow, magenta, red, cyan, green, blue, black`

Define an array with the same number of record elements as the data array used by the `INPUT ARRAY` or `DISPLAY ARRAY`. Each element must have the same name as in the data array, and must be defined with a character data type (typically: `STRING`):

```
DEFINE data DYNAMIC ARRAY OF RECORD
         pkey INTEGER,
         name VARCHAR(50)
       END RECORD
DEIFNE attributes DYNAMIC ARRAY OF RECORD
         pkey STRING,
         name STRING
       END RECORD
```

Fill the display attributes array with color and video attributes. These must be specified in lowercase characters and separated by a blank (ex: "`red reverse`"):

```
FOR i=1 TO data.getLength()  -- length from data array!
    LET attributes[i].name = "blue reverse"
END FOR
```

Then, attach the array to the dialog with the `setCellAttributes()` method, in a `BEFORE INPUT` or `BEFORE DISPLAY` block:

```
BEFORE DISPLAY
   CALL DIALOG.setCellAttributes( attributes )
```

Like data values, if you change the cell attributes during the dialog, these are not displayed automatically unless the `UNBUFFERED` mode is used.

```
ON ACTION modify_cell_attribute
   LET attributes[arr_curr()].name = "red reverse"
```

If you set `NULL` to a element, the default TTY attributes will be reset:

```
ON ACTION clean_cell_attribute
   LET attributes[arr_curr()].name = NULL
```

ui.Dialog.setCompleterItems
Define autocompletion items for the a field defined with `COMPLETER` attribute.

Syntax

```
setCompleterItems(
   items-array DYNAMIC ARRAY OF STRING )
```

1. *items-array* defines the list of proposals to be passed to the front-end.

Usage

The `setCompleterItems(`*`items-array`*`)` dialog method defines the list of proposals for the current field, to implement autocompletion.

The field must be defined in the form with the `COMPLETER` attribute.

The list of proposal items is passed as a dynamic array of strings:

```
DEFINE items DYNAMIC ARRAY OF STRING
```

To cleanup the proposal list for a give field, pass `NULL` as second parameter to the function.

> **Important:** The method will raise error -8114, if the list of items contains more than 50 elements. Note that this error is not trappable with exception handlers like `TRY/CATCH`, the code must avoid to reach the limit.

See Enabling autocompletion on page 1274 for more details.

Example

```
DEFINE items DYNAMIC ARRAY OF STRING
...
   ON CHANGE firstname
      -- fill the array with items
      LET items[1] = "Ann"
      LET items[2] = "Anna"
      LET items[3] = "Annabel"
      CALL DIALOG.setCompleterItems(items)
```

ui.Dialog.setCurrentRow
Sets the current row in the specified list.

Syntax

```
setCurrentRow(
   name STRING,
   row INTEGER )
```

1. *name* is the screen array name.
2. *row* is the new row in the array.

Usage

Use the `setCurrentRow()` method to change the current row in an `INPUT ARRAY` or `DISPLAY ARRAY` list. You must pass the name of the screen array to identify the list, and the new row number.

```
DEFINE x INTEGER
DIALOG
  DISPLAY ARRAY custlist TO sa_custlist.*
    ...
  END DISPLAY
  ON ACTION goto_x
    CALL DIALOG.setCurrentRow("sa_custlist", x)
    ...
```

Moving to a different row with `setCurrentRow()` will not trigger control blocks such as `BEFORE ROW` / `AFTER ROW`, as the `fgl_set_arr_curr()` built-in function does.

The `setCurrentRow()` method will not set the focus; You need to use `NEXT FIELD` to set the focus to a list. (This works with `DISPLAY ARRAY` as well as with `INPUT ARRAY`.)

If the passed row index is lower than 1, the first row will be selected. If the row index is greater than the total number of rows, the last row will be selected.

If the new current row is out of the current page of rows, the dialog will adapt the list offset to make the new current row visible.

If multi-row selection is enabled, all selection flags of rows are cleared, and the new current row gets automatically selected.

ui.Dialog.setFieldActive
Enable and disable form fields.

Syntax

```
setFieldActive(
   field-list STRING,
   active BOOLEAN )
```

1. *field-list* is the string with the list of field specification.
2. *active* is a boolean value.

Usage

The `setFieldActive()` method can be used to enable / disable form fields.

The *field-list* is a string containing the field qualifier, with an optional prefix ("`[table.]column`"), or a table prefix followed by a dot and an asterisk ("`table.*`").

```
CALL DIALOG.setFieldActive( "customer.cust_addr",
            (rec.cust_name IS NOT NULL) )
```

Do not disable all fields of a dialog, otherwise the dialog execution stops (at least one field must get the focus during a dialog execution).

For more details about field name specification, see Identifying fields in dialog methods on page 1818.

ui.Dialog.setFieldTouched
Sets the modification flag of the specified field.

Syntax

```
setFieldTouched(
   field-list STRING,
   touched BOOLEAN )
```

1. *field-list* is the string with the list of field specification.
2. *touched* is the boolean value to set the modification flag.

Usage

The `setFieldTouched()` method can be used to change the modification flag of the specified field(s).

The *field-list* is a string containing the field qualifier, with an optional prefix ("`[table.]column`"), or a table prefix followed by a dot and an asterisk ("`table.*`").

You typically use this method to set the touched flag when assigning a variable, to emulate a user input. Remember when using the `UNBUFFERED` mode, you don't need to display the value to the fields. The `setFieldTouched()` method is provided as a 3GL replacement for the `DISPLAY BY NAME / TO` instructions to set the modification flags.

```
ON ACTION zoom_city
  LET p_cust.cust_city = zoom_city()
  CALL DIALOG.setFieldTouched("customer.cust_city", TRUE)
    ...
```

If the parameter is a screen record following by dot-asterisk, the method checks the modification flags of all the fields that belong to the screen record. You typically use this to reset the touched flags of a group of fields, after modifications have been saved to the database, to get back to the initial state of the dialog:

```
ON ACTION save
  CALL save_cust_record()
  CALL DIALOG.setFieldTouched("customer.*", FALSE)
    ...
```

The modification flags are reset to false when using an `INPUT ARRAY` list, every time you leave the modified row.

For more details about field name specification, see Identifying fields in dialog methods on page 1818.

ui.Dialog.setFieldValue
Sets the value of a field controlled by the dialog object.

Syntax

```
setFieldValue(
   name STRING,
   value fgl-type )
```

1. *name* is the name of the field.
2. *value* is the value to be set.

Usage

The `setFieldValue()` method can be used when implementing a dynamic dialog, to set the value of a field:

```
DEFINE default_address STRING,
       default_creadate DATE
...
CALL d.setFieldValue( "customer.cust_addr", default_address )
CALL d.setFieldValue( "customer.cust_creadate", default_creadate )
```

The first parameter defines the field to be set. For more details about field name specification, see Identifying fields in dialog methods on page 1818.

When used in a dynamic dialog controlling a list of records, this methods sets the value for a field in the current row. The current row can be set with the `setCurrentRow()` method. This is also true when filling the dynamic dialog with rows: You must first set the current row with `setCurrentRow()`, then set field (i.e. cell values) with `setFieldValue()`.

Example

The following code example implements a `FOR` loop to copy values of all fields of the `d_disparr` dialog to the field of the `d_recinp` dialog:

```
DEFINE row, i INTEGER,
       h base.SqlHandle,
       fields DYNAMIC ARRAY OF RECORD
                  name STRING,
                  type STRING
              END RECORD
       d_rec ui.Dialog,
       d_list ui.Dialog
...
    -- Fill the array with rows from an SqlHandle object
    CALL h.open()
```

```
    LET row = 0
    WHILE status == 0
        -- must set the current row before setting values
        CALL d_list.setCurrentRow("sr_custlist", row:=row+1 )
        FOR i = 1 TO h.getResultCount()
            CALL d_list.setFieldValue( h.getResultName(i),
 h.getResultValue(i) )
        END FOR
        CALL h.fetch()
    END WHILE
    CALL d_list.setCurrentRow("sr_custlist", 1)
...
    -- Copy field values from d_list to d_rec dialog
    FOR i=1 TO fields.getLength()
        CALL d_rec.setFieldValue( fields[i].name,
               d_list.getFieldValue( fields[i].name )
             )
    END FOR
```

ui.Dialog.setSelectionMode
Defines the row selection mode for the specified list.

Syntax

```
setSelectionMode(
   name STRING,
   mode INTEGER )
```

1. *name* is the screen array name.
2. *mode* defines the selection mode (0, 1).

Usage

In `DISPLAY ARRAY` instructions, the `setSelectionMode()` method can be used to enable/disable multi-row selection.

Possible values of the *mode* parameter are 0 (single row selection) or 1 (multi-range selection). Other values are reserved for future use.

If multi-row selection is switched off, selected rows get deselected.

For more details about multi-row selection, see Multiple row selection on page 1381.

ui.Dialog.setSelectionRange
Sets the row selection flags for a range of rows.

Syntax

```
setSelectionRange(
   name STRING,
   start INTEGER,
   end INTEGER,
   value BOOLEAN )
```

1. *name* is the screen array name.
2. *start* is the starting row index.
3. *end* is the ending row index.
4. *value* is the selection flag to set.

Usage

If multi-row selection is enabled with *setSelectionMode()*, you can set the selection flags for a range of rows with the `setSelectionRange()` method.

```
ON ACTION select_all
  CALL DIALOG.setSelectionRange( "sr", 1, -1, TRUE)
```

The start and end index must be in the range of possible row indexes (from 1 to `DIALOG.getArrayLength()`).

If you specify an end index of -1, it will set the flags from start index to the end of the list.

ui.Dialog.validate
Check form level validation rules.

Syntax

```
validate(
   field-list STRING )
  RETURNING result INTEGER
```

1. *field-list* is the string with the list of field specification.

Usage

Use the `validate()` method in order to execute `NOT NULL`, `REQUIRED` and `INCLUDE` validation rules defined in the form specification files.

Can the method by passing a list of fields or screen records as parameter.

The method returns zero if success and the input error code of the first field which does not satisfy the validation rules.

The current field is always checked, even if it is not part of the validation field list. This is mandatory, otherwise the current field may be left with invalid data.

If an error occurs, the `validate()` method automatically displays the corresponding error message, and registers the next field to jump to when the interactive instruction gets the control back.

The `validate()` method does not stop code execution if an error is detected. You must execute a `CONTINUE DIALOG` or `CONTINUE INPUT` instruction to cancel the code execution.

A typical usage is for a "save" action:

```
ON ACTION save
   IF DIALOG.validate("cust.*") < 0 THEN
      CONTINUE DIALOG
   END IF
   CALL customer_save()
```

For more details about field name specification, see Identifying fields in dialog methods on page 1818.

ui.Dialog.visualToArrayIndex
Converts the visual index to the program array index for a given screen array.

Syntax

```
visualToArrayIndex(
   name STRING,
   index INTEGER )
```

1. *name* is the screen array name.
2. *index* is the index of the row as seen by the end user.

Usage

When the end user sorts rows in a table, the visual row index may differ from the program array index.

Use this method to convert a row index as seen by the end user, to the program array index. For example, if the application implements a feature that allows the user to enter a row index to jump to that row, it will be entered as a visual row index. You must convert this index to the program array index, for example to make a `setCurrentRow()`.

```
CALL DIALOG.setCurrentRow("sr", DIALOG.visualToArrayIndex("sr", user_index))
```

Usage
Referencing the current dialog

In order to reference the current dialog, you can define a variable with the `ui.Dialog` type, and get the current dialog object with the `ui.Dialog.getCurrent()` method:

```
DEFINE d ui.Dialog

INPUT BY NAME ...
   BEFORE DIALOG
      LET d = ui.Dialog.getCurrent()
      CALL d.setActionActive("zoom", FALSE)
   ...
```

As an alternative and to simplify programming, you should use the `DIALOG` keyword in the context of the interactive instruction block. the `DIALOG` keyword is a predefined object variable referencing the current dialog. The `DIALOG` variable can only be used inside the interactive instruction block:

```
INPUT BY NAME custid, custname
  ON ACTION disable
    CALL DIALOG.setFieldActive("custid", FALSE)
END INPUT
```

Passing a dialog reference to functions

Using the `DIALOG` keyword outside a dialog instruction block results in a compilation error. However, you can pass the object to a function that defines the dialog parameter with the `ui.Dialog` type.

The next example passes the `DIALOG` object reference to the `setupDialog()` function, which implements action activation rules that must be applied after different events, during the dialog execution:

```
INPUT BY NAME custid, custname, custaddr
  BEFORE INPUT
    CALL setupDialog(DIALOG)
  ...
  ON ACTION check_address
    ...
    CALL setupDialog(DIALOG)
  ...
END INPUT

FUNCTION setupDialog(d)
  DEFINE d ui.Dialog
  DEFINE isAdmin BOOLEAN
  LET isAdmin = (global_params.user_group == "admin")
  CALL d.setActionActive("delete", isAdmin)
  CALL d.setActionActive("convert", isAmdin)
  CALL d.setActionActive("check_address",
```

```
           isAdmin AND rec.custaddr IS NOT NULL)
END FUNCTION
```

Identifying actions in dialog methods

In `ui.Dialog` methods such as `setActionActive()`, the first parameter identifies the action object to be modified. This parameter can be full-qualified or partly-qualified. If you don't specify a full-qualified name, the action object will be identified according to the focus context.

The action name specification can be any of the following:

- *action-name*
- *dialog-name.action-name*
- *dialog-name.field-name.action-name*
- *field-name.action-name* (singular dialogs only)

Here *action-name* identifies the name of the action specified in `ON ACTION` *`action-name`* or `COMMAND` "*`action-name`*" handlers, while *dialog-name* identifies the singular dialog or sub-dialog and *field-name* defines the field bound to the action `INFIELD` clause of `ON ACTION`.

The action name must be passed in lowercase letters.

The runtime system will raise the error **-8089** if the action specified by *[dialog-name.][field-name.]action-name* can not be found within the current dialog.

> **Note:** As a general rule, assign unique action names for each specific dialog action, to avoid the usage of dialog and/or field identifiers.

In the `DIALOG` instruction, actions can be prefixed with the sub-dialog identifier. However, if methods like `setActionActive()` are called in the context of the sub-dialog, the prefix can be omitted. When using a field-specific action defined with the `INFIELD` clause of `ON ACTION`, you can identify the action with the full-qualified name *dialog-name.field-name.action-name*. Like sub-dialog actions, if you specify only *action-name*, the runtime system will search for the action object according to the focus context.

Note that an `INPUT` or `CONSTRUCT` sub-dialogs have no identifier by default. The dialog name can be defined with the `NAME` attribute. For more details, see Identifying sub-dialogs in procedural DIALOG on page 1152.

When using a singular dialog like `INPUT`, you can identify field-specific actions by *field-name.action-name*, if the dialog was defined without a `NAME` attribute.

Example

```
DIALOG ...
   ...
   INPUT BY NAME cust_rec.* ATTRIBUTES(NAME="cust")
      ON ACTION compare
         ...
      ON ACTION check INFIELD cust_city
         ...
   END INPUT
   ...
   DISPLAY ARRAY orders TO sr_ord.*
      ...
      ON ACTION archive
         ...
   END DISPLAY
   ...
   ON ACTION print
      ...
   ON ACTION disable_all
      CALL DIALOG.setActionActive("cust.compare", FALSE)
      CALL DIALOG.setActionActive("cust.cust_city.check", FALSE)
```

```
      CALL DIALOG.setActionActive("sr_ord.archive", FALSE)
      CALL DIALOG.setActionActive("print", FALSE)
END DIALOG
```

Identifying fields in dialog methods

In `ui.Dialog` methods such as `setFieldActive()`, the first parameter identifies the form field (or, for some methods, a list of fields) to be modified. The form field names can be full-qualified or partly-qualified.

Fields are identified by the form field name specification, not the program variable name used by the dialog. Remember form fields are bound to program variables with the binding clause of dialog instruction (`INPUT` *`variable-list`* `FROM` *`field-list`*, `INPUT BY NAME` *`variable-list`*, `CONSTRUCT BY NAME` *`sql`* `ON` *`column-list`*,`CONSTRUCT` *`sql`* `ON` *`column-list`* `FROM` *`field-list`*, `INPUT ARRAY` *`array-name`* `FROM` *`screen-array.*`*).

The field name specification can be any of the following:

- *field-name*
- *table-name.field-name*
- *screen-record-name.field-name*
- FORMONLY.*field-name*

Here are some examples:

- `"cust_name"`,
- `"customer.cust_name"`,
- `"cust_screen_record.cust_name"`,
- `"item_screen_array.item_label"`,
- `"formonly.total"`,
- `"customer.*"` (only some methods accept the "dot asterisk" notation)

When no field name prefix is used, the first form field matching that field name will be used. If the field specification is invalid (i.e. no field in the current dialog matches the field specification), the method will throw the error -1373.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog according to the field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using `INPUT BY NAME` *`variable-list`*,) the field prefix must be the database table name (or `FORMONLY`) used in the form file, or any valid screen-record using that field. But when the `FROM` clause of the dialog specifies an explicit screen-record (for example, in `INPUT` *`variable-list`* `FROM` *`screen-record.* /field-list-with-screen-record-prefix`* or `INPUT ARRAY` *`array-name`* `FROM` *`screen-array.*`*) the field prefix must be the screen-record name used in the `FROM` clause.

The methods `validate()`, `setFieldActive()`, `setFieldTouched()`, `getFieldTouched()` can take a list of fields as parameter, by using the "dot-asterisk " notation (screen-record.*). This way you can check, query or change a complete list of fields in one method call:

```
ON ACTION save
  CALL save_cust_record()
  CALL DIALOG.setFieldTouched("customer.*", FALSE)
    ...
```

Examples

Example 1: Disable fields dynamically

```
FUNCTION input_customer()
  DEFINE custid INTEGER
  DEFINE custname CHAR(10)
  INPUT BY NAME custid, custname
```

```
    ON ACTION enable
      CALL DIALOG.setFieldActive("custid",1)
    ON ACTION disable
      CALL DIALOG.setFieldActive("custid",0)
  END INPUT
END FUNCTION
```

Example 2: Get the form and hide fields

```
FUNCTION input_customer()
  DEFINE f ui.Form
  DEFINE custid INTEGER
  DEFINE custname CHAR(10)
  INPUT BY NAME custid, custname
    BEFORE INPUT
      LET f = DIALOG.getForm()
      CALL f.setElementHidden("customer.custid",1)
  END INPUT
END FUNCTION
```

Example 3: Pass a dialog object to a function

```
 FUNCTION input_customer()
   DEFINE custid INTEGER
   DEFINE custname CHAR(10)
   INPUT BY NAME custid, custname
     BEFORE INPUT
       CALL setup_dialog(DIALOG)
   END INPUT
 END FUNCTION

 FUNCTION setup_dialog(d)
   DEFINE d ui.Dialog
   CALL d.setActionActive("print",user.can_print)
   CALL d.setActionActive("query",user.can_query)
 END FUNCTION
```

Example 4: Set display attributes for cells

```
FUNCTION display_items()
   DEFINE i INTEGER
   DEFINE items DYNAMIC ARRAY OF RECORD
                key INTEGER,
                name CHAR(10)
              END RECORD
   DEFINE attributes DYNAMIC ARRAY OF RECORD
                key STRING,
                name STRING
              END RECORD

   FOR i=1 TO 10
     CALL items.appendElement()
     LET items[i].key = i
     LET items[i].name = "name " || i
     CALL attributes.appendElement()
     IF i MOD 2 = 0 THEN
       LET attributes[i].key = "red"
       LET attributes[i].name = "blue reverse"
     ELSE
       LET attributes[i].key = "green"
       LET attributes[i].name = "magenta reverse"
     END IF
```

```
   END FOR

   DISPLAY ARRAY items TO sr.* ATTRIBUTES(UNBUFFERED)
       BEFORE DISPLAY
         CALL DIALOG.setCellAttributes(attributes)
       ON ACTION att_modify_cell
         LET attributes[2].key = "red reverse"
       ON ACTION att_clear_cell
         LET attributes[2].key = NULL
   END DISPLAY

END FUNCTION
```

The ComboBox class
The `ui.ComboBox` class provides an interface to the `COMBOBOX` form field view in the abstract user interface tree.

In .per form specification files, a `COMBOBOX` form field defines both a form field and a view for that model. The `ui.ComboBox` class is an interface to the view of a `COMBOBOX` form field. It is typically used to configure the widget dynamically in programs, for example to create the list of items shown in the drop down box.

ui.ComboBox methods
Methods of the `ui.ComboBox` class.

Table 392: Class methods

Name	Description
`ui.ComboBox.forName( name STRING ) RETURNING result ui.ComboBox`	Search for a combobox in the current form.
`ui.ComboBox.setDefaultInitializer( funcname STRING )`	Define the default initializer for combobox form items.

Table 393: Object methods

Name	Description
`addItem( value STRING, label STRING )`	Add an element to the item list.
`clear()`	Clear the item list of a combobox.
`getColumnName() RETURNING result STRING`	Get the column name of the form field.
`getIndexOf( name STRING )`	Get an item position by name.

Name	Description
`RETURNING result INTEGER`	
`getItemCount()` `RETURNING result INTEGER`	Get the number of items.

`getItemName(`
`position INTEGER )`
`RETURNING result STRING`
	Get an item name by position.

`getItemText(`
`position INTEGER )`
`RETURNING result STRING`
	Get the item text by position.

`getTableName()` `RETURNING result STRING`	Get the table prefix of the form field.
`getTag()` `RETURNING result STRING`	Get the combobox tag value.

`getTextOf(`
`name STRING )`
`RETURNING result STRING`
	Get the item text by name.

`removeItem(` `name STRING )`	Remove an item by name.

ui.ComboBox.setDefaultInitializer
Define the default initializer for combobox form items.

Syntax

```
ui.ComboBox.setDefaultInitializer(
   funcname STRING )
```

1. *funcname* is the name of the initialization function.

Usage

The `ui.ComboBox.setDefaultInitializer()` class method defines the default initialization function to be called each time a `COMBOBOX` form field is created when loading forms. Use this method if you want to define a global/default initialization function for all comboboxes of the program. For individual comboboxes, consider using the `INITIALIZER` form field attribute instead.

> **Tip:** Consider defining the initialization function name in lowercase letters. The language syntax allows case-insensitive functions names, but to avoid mistakes, it is recommended to use a common naming convention with lowercase letters.

The function is called with the `ui.ComboBox` object as the parameter.

The combobox initialization functions are typically used to fill the drop down list with items.

Example

```
MAIN
    ...
    CALL ui.ComboBox.setDefaultInitializer("cb_init")
    ...
    OPEN FORM f1 FROM "customers"
    DISPLAY FORM f1 -- initialization function is called
    ...
END MAIN

FUNCTION cb_init(cb)
  DEFINE cb ui.ComboBox
  CALL cb.clear()
  CALL cb.addItem(0,"Undefined")
  ...
END FUNCTION
```

ui.ComboBox.forName
Search for a combobox in the current form.

Syntax

```
ui.ComboBox.forName(
   name STRING )
  RETURNING result ui.ComboBox
```

1. *name* is the name of `COMBOBOX` form item.

Usage

The `ui.ComboBox.forName()` class method searches for a `ui.ComboBox` object by form field name in the current form.

> **Important:** The form field name must be in lower-case letters: The language syntax allows case-insensitive form field names, and the runtime system must reference fields in lowercase letters internally. Since the form compiler converts field names to lowercase in the 42f file, the name must be lowercase in this method call.

After loading a form with `OPEN WINDOW WITH FORM`, use the class method to retrieve a `ui.ComboBox` object into a variable defined as a `ui.ComboBox`.

```
DEFINE cb ui.ComboBox
LET cb = ui.ComboBox.forName("formonly.airport")
```

Verify the function has returned an object, as the form field may not exist.

```
IF cb IS NULL THEN
  ERROR "Form field not found in current form"
  EXIT PROGRAM
END IF
```

Once instantiated, the `ui.ComboBox` object can be used, for example to fill the items of the drop down list.

```
CALL cb.clear()
CALL cb.addItem(1,"Paris")
CALL cb.addItem(2,"London")
CALL cb.addItem(3,"Madrid")
```

ui.ComboBox.addItem
Add an element to the item list.

Syntax

```
addItem(
   value STRING,
   label STRING )
```

1. *value* is the unique key that identifies the item.
2. *label* is the text to be displayed in the drop down list.

Usage

The `addItem()` method adds an item to the end of the drop down list of the `COMBOBOX`.

The first parameter is the value that can be set in the form field. The second parameter is the label to be displayed in the drop down list. If the second parameter is `NULL`,the runtime system automatically uses the first parameter as the display value.

Uniqueness is not checked by the runtime system. Make sure that the items created are unique, regarding the value key and the display label.

Trailing spaces should be avoided when populating the first parameter because values get truncated when field validation occurs, and the resulting value (without trailing spaces) will no longer match the `COMBOBOX` item name. Additionally, trailing spaces in the second parameter may cause the `COMBOBOX` to be much wider than expected. To avoid such problems, use `VARCHAR` or `STRING` variables, or use the `CLIPPED` operator with `CHAR` variables.

ui.ComboBox.clear
Clear the item list of a combobox.

Syntax

```
clear()
```

Usage

The `clear()` method clears the item list of the combobox.

If the item list is empty, the `COMBOBOX` drop-down button shows an empty list on the client side.

ui.ComboBox.getColumnName
Get the column name of the form field.

Syntax

```
getColumnName()
  RETURNING result STRING
```

Usage

The `getColumnName()` method returns the form field column name. The form field column name can be `NULL` if not defined at the form field level.

Use the `getTableName()` and `getColumnName()` methods together in order to identify the form field associated with the `COMBOBOX`. This allows to identify the combobox field in your program, for example to fill the drop down list with the appropriate items.

```
IF cb.getTableName()||"."||cb.getColumnName()
   == "customer.cust_city" THEN
      CALL cb.clear()
      CALL cb.addItem(1, "Paris" )
      CALL cb.addItem(2, "London" )
      CALL cb.addItem(3, "Madrid" )
END IF
```

ui.ComboBox.getIndexOf
Get an item position by name.

Syntax

```
getIndexOf(
   name STRING )
  RETURNING result INTEGER
```

1. *name* is the name of a combobox item.

Usage

The `getIndexOf()` method takes an item name as parameter and returns the position of the item in the drop down list.

The first item is at position 1. The method returns 0 (zero) if the item name does not exist.

The next example checks for item existence, before adding the item.

```
IF cb.getIndexOf("SFO") == 0 THEN
  CALL cb.addItem("SFO", "San Francisco International Airport, CA" )
END IF
```

ui.ComboBox.getItemCount
Get the number of items.

Syntax

```
getItemCount()
  RETURNING result INTEGER
```

Usage

The `getItemCount()` method returns the current number of items defined for the `COMBOBOX` form field.

The method returns 0 (zero) if no items are defined.

ui.ComboBox.getItemName
Get an item name by position.

Syntax

```
getItemName(
   position INTEGER )
  RETURNING result STRING
```

1. *position* is the index of the combobox item.

Usage

The `getItemName()` method returns the name of an item at the give position.

The first item starts at position 1.

ui.ComboBox.getItemText
Get the item text by position.

Syntax

```
getItemText(
   position INTEGER )
  RETURNING result STRING
```

1. *position* is the index of the combobox item.

Usage

The `getItemText()` method returns the display label of an item at the give position.

The first item starts at position 1.

ui.ComboBox.getTableName
Get the table prefix of the form field.

Syntax

```
getTableName()
  RETURNING result STRING
```

Usage

The `getTableName()` method returns the name of the form field table prefix. The form field table prefix can be `NULL` if not defined at the form field level.

This allows to identify a `COMBOBOX` field in your program, for example to fill the drop down list with the appropriate items.

ui.ComboBox.getTag
Get the combobox tag value.

Syntax

```
getTag()
  RETURNING result STRING
```

Usage

The `getTag()` method returns the value define by the `TAG` attribute.

Use the tag to mark `COMBOBOX` form items with your own flags, in order to adapt the configuration of the combobox dynamically by program. For example, if `TAG` contains the token "short", fill the drop down list with short names, otherwise fill with long names. The same code can then be used for different `COMBOBOX` form fields.

ui.ComboBox.getTextOf
Get the item text by name.

Syntax

```
getTextOf(
   name STRING )
  RETURNING result STRING
```

1. *name* is the name of a combobox item.

Usage

The `getTextOf()` method returns the display label of the item identified by the name passed as parameter.

The method returns `NULL` if the item name does not exist.

ui.ComboBox.removeItem
Remove an item by name.

Syntax

```
removeItem(
   name STRING )
```

1. *name* is the name of a combobox item.

Usage

The `removeItem()` method deletes an item from the list. The item to be removed is identified by the name passed as a parameter. If the item does not exist, the method returns without error.

Examples
Example Get a ComboBox form field view and fill the item list

Form Specification File:

```
DATABASE FORMONLY
LAYOUT
GRID
{
  Airport:  [cb01                ]
}
END
END
ATTRIBUTES
COMBOBOX cb01 = FORMONLY.airport TYPE CHAR;
END
```

Program File:

```
MAIN
  DEFINE cb ui.ComboBox
  DEFINE airport CHAR(3)
  OPEN FORM f1 FROM "combobox"
  DISPLAY FORM f1
  LET cb = ui.ComboBox.forName("formonly.airport")
  IF cb IS NULL THEN
     ERROR "Form field not found in current form"
     EXIT PROGRAM
```

```
  END IF
  CALL cb.clear()
  CALL cb.addItem("CDG", "Paris-Charles de Gaulle, France")
  CALL cb.addItem("LCY", "London-City Airport, UK")
  CALL cb.addItem("LHR", "London-Heathrow, UK")
  CALL cb.addItem("FRA", "Frankfurt Airport, Germany")
  IF cb.getIndexOf("SFO") == 0 THEN
     CALL cb.addItem("SFO", "San Francisco International Airport, CA" )
  END IF
  INPUT BY NAME airport
END MAIN
```

Example Using the INITIALIZER attribute in the form file

Form Specification File:

```
DATABASE FORMONLY
LAYOUT
GRID
{
  Airport:  [cb01                ]
}
END
END
ATTRIBUTES
COMBOBOX cb01 = FORMONLY.airport TYPE CHAR, INITIALIZER=initcombobox;
END
```

Initialization function:

```
FUNCTION initcombobox(cb)
  DEFINE cb ui.ComboBox
  CALL cb.clear()
  CALL cb.addItem("CDG", "Paris-Charles de Gaulle, France")
  CALL cb.addItem("LCY", "London-City Airport, UK")
  CALL cb.addItem("LHR", "London-Heathrow, UK")
  CALL cb.addItem("FRA", "Frankfurt Airport, Germany")
  CALL cb.addItem("SFO", "San Francisco International Airport, CA" )
END FUNCTION
```

The DragDrop class

The `ui.DragDrop` class is used to control the events related to drag & drop events.

When implementing drag & drop in a dialog, the `ON DRAG*` / `ON DROP` dialog control blocks take a `ui.DragDrop` variable as a parameter to let you configure and control the drag & drop events. The `ui.DragDrop` variable must be declared in the scope of the dialog implementing drag & drop.

ui.DragDrop methods

Methods of the `ui.DragDrop` class.

Table 394: Object methods

Name	Description
`addPossibleOperation(`	Add a possible operation.

Name	Description
oper STRING)	
dropInternal()	Perform built-in row drop in trees.
getBuffer() RETURNING *result* STRING	Get drag & drop data from the buffer.
getLocationParent() RETURNING *result* INTEGER	Get the index of the parent node where the object was dropped.
getLocationRow() RETURNING *result* INTEGER	Get the index of the target row where the object was dropped.
getOperation() RETURNING *result* STRING	Identify the type of operation on drop.
getSelectedMimeType() RETURNING *result* STRING	Get the previously selected MIME type.
selectMimeType(*type* STRING)	Select the MIME type before getting the data.
setBuffer(*data* STRING)	Set the text data of the dragged object.
setFeedback(*type* STRING)	Define the appearance of the target during Drag & Drop.
setMimeType(*type* STRING)	Define the MIME type of the dragged object.
setOperation(*oper* STRING)	Define the type of Drag & Drop operation.

ui.DragDrop.addPossibleOperation
Add a possible operation.

Syntax

```
addPossibleOperation(
   oper STRING )
```

1. *oper* is the name of a drag & drop operation.

Usage

Drag & drop actions can be of different kinds; you can do a copy of the dragged object, or move the dragged object from the source to the destination.

The default drag & drop operation is defined by a call to `setOperation()` method in `ON DRAG_START`. Use the `addPossibleOperation()` method to define additional operations that are allowed.

See setOperation() for possible values.

ui.DragDrop.dropInternal
Perform built-in row drop in trees.

Syntax

```
dropInternal()
```

Usage

In order to simplify drag & drop programming in the same list, the `ui.DragDrop` class provides the `dropInternal()` utility method, to be called in the `ON DROP` block. This method will perform all the row changes in the array and move row selection as well as cell attributes.

When implementing drag & drop on a tree-view, dropping an element on the tree requires complex code in order to handle parent-child relationships. Nodes can be inserted under a parent between two children, appended at the end of the children list, and at different levels in the tree hierarchy. However, the `dropInternal()` method can also be used simple lists displayed in a regular `TABLE`.

A call to `dropInternal()` will silently be ignored, if the drag source is not the drop target, or if the method is called in a different context as `ON DROP`.

For more details about dropping elements in tree-views, see Drag & drop on page 1411.

ui.DragDrop.getBuffer
Get drag & drop data from the buffer.

Syntax

```
getBuffer()
  RETURNING result STRING
```

Usage

After identifying the MIME type of a dropped object with `getSelectedMimeType()`, you can call the `getBuffer()` method to get text data from the drag & drop buffer.

Drag & drop data is only available at `ON DROP` time, therefore, the `getBuffer()` method must be called in `ON DROP` only.

ui.DragDrop.getLocationParent
Get the index of the parent node where the object was dropped.

Syntax

```
getLocationParent()
  RETURNING result INTEGER
```

Usage

When using a tree view, a node can be dropped as a sibling or as a child node to another node. In order to distinguish between the cases, you must use the `getLocationParent()` method, which returns the index of the parent node of the drop target node returned by `getLocationRow()`.

If both methods return the same row index, you must append the dropped row as a child of the target node. Otherwise, `getLocationParent()` identifies the parent node where the dropped row has to be added as a child, and `getLocationRow()` is the index of a sibling node. In the last case the dropped node must be inserted before the node identified by `getLocationRow()`.

These methods are typically used in the `ON DROP` block, but can also be used in `ON DRAG_OVER` to deny the drop according to the indexes returned; for example, the program might only allow the drop of objects as new children for a given parent node.

ui.DragDrop.getLocationRow
Get the index of the target row where the object was dropped.

Syntax

```
getLocationRow()
  RETURNING result INTEGER
```

Usage

The `getLocationRow()` method returns the index of the row in the drop target list pointed to by the mouse cursor.

This method is typically used in the `ON DROP` block to get the index of the target row to be modified or replaced by the dragged object.

The method can also be used in `ON DRAG_OVER` to deny the drop according to the current target row returned by `getLocationRow()`

ui.DragDrop.getSelectedMimeType
Get the previously selected MIME type.

Syntax

```
getSelectedMimeType()
  RETURNING result STRING
```

Usage

Before retrieving data from the drag & drop buffer with `getBuffer()`, first call the `getSelectedMimeType()` method to identify the data format that was previously selected by a `selectMimeType()` call.

The `getSelectedMimeType()` method is typically called in `ON DROP` to identity the format of the dropped object.

ui.DragDrop.getOperation
Identify the type of operation on drop.

Syntax

```
getOperation()
  RETURNING result STRING
```

Usage

The `getOperation()` method returns the type of the current drag & drop operation ("`copy`", "`move`", or "`none`").

According to the value returned by this method, the program can make the appropriate changes in the data model. For example, after a row has been dropped into another list, the source list can remove the original row if the operation was a "`move`", but keeps the original row if the operation was a "`copy`".

The `getOperation()` method is typically called in the `ON DRAG_FINISHED` block.

ui.DragDrop.selectMimeType
Select the MIME type before getting the data.

Syntax

```
selectMimeType(
   type STRING )
```

1. *type* defines the MIME type for dragged objects.

Usage

Call the `selectMimeType()` method to check that data is available in a format identified by the MIME type passed as parameter.

If this type of data is available in the buffer, the method returns `TRUE` and you can later get the data with `getBuffer()`.

The `selectMimeType()` method is typically used in `ON DRAG_ENTER`, `ON DRAG_OVER` to deny the drag & drop operation if none of the supported MIME types is available in the buffer.

ui.DragDrop.setBuffer
Set the text data of the dragged object.

Syntax

```
setBuffer(
   data STRING )
```

1. *data* is a string expression containing drag & drop data.

Usage

Use the `setBuffer()` method to provide the text data of objects dragged from the program to an external application.

The `setBuffer()` method is typically used in an `ON DRAG_START` block in conjunction with `setMimeType()`.

By default, the dialog will serialize the data of the selected rows as a tab-separated list of values.

The text/plain MIME type is the default.

ui.DragDrop.setFeedback
Define the appearance of the target during Drag & Drop.

Syntax

```
setFeedback(
   type STRING )
```

1. *type* is the type of feedback to display during the drag & drop operation.

Usage

The `setFeedback()` method defines the appearance the target object must have during the drag & drop process.

For example, in a table or tree view, when the mouse is flying over rows in the drop target, a different visual indicator will appear according to the value that was passed to `setFeedback()`.

Possible values for the `setFeedback()` method are:

Table 395: Values for the `setFeedback()` method

Parameter Values	Description
`all`	Dragged object will be dropped somewhere on the target widget, the exact location does not matter.
`insert`	In lists, dragged object will be inserted in between existing rows.
`select`	In lists, dragged object will replace the current row under the mouse.

ui.DragDrop.setMimeType
Define the MIME type of the dragged object.

Syntax

```
setMimeType(
   type STRING )
```

1. *type* defines the MIME type for the drag & drop buffer.

Usage

Objects dragged from the program to an external application need to be identified with a MIME type and the program must provide the data. The MIME type can be specified with the `setMimeType()` method.

The `setMimeType()` method is typically used in an `ON DRAG_START` block in conjunction with `setBuffer()`.

By default, the source target will use the text/plain MIME type and copy the data of the selected rows into the Drag & Drop buffer.

ui.DragDrop.setOperation
Define the type of Drag & Drop operation.

Syntax

```
setOperation(
   oper STRING )
```

1. *oper* is the name of a drag & drop operation.

Usage

Drag & drop actions can be of different kinds; you can do a copy of the dragged object, or move the dragged object from the source to the destination.

Use the `setOperation()` method to define/force the type of drag & drop operation or to deny/cancel the drag & drop process.

Table 396: Parameters for the `setOperation()` method

Parameter Value	Description
`NULL`	To deny/cancel the drag & drop process.
`copy`	To allow drag & drop as a copy of the source object.
`move`	To allow drag & drop as a move of the source object.

The `setOperation()` method can be called in different drag & drop triggers.

A common usage is to deny drag & drop by passing `NULL` in the `ON DRAG_ENTER` and/or `ON DRAG_OVER` blocks because the dragged object does not correspond to the type of objects the target can receive.

This method is also used in `ON DRAG_START` to force a specific type of drag & drop operation (copy or move), or to deny drag start if the context does not allow a drag & drop action.

When called in the `ON DRAG_ENTER` block, the method forces a specific drag & drop operation.

The om package

These topics cover the built-in classes for the om class

- The DomDocument class on page 1833
- The DomNode class on page 1839
- The NodeList class on page 1858
- The SaxAttributes class on page 1860
- The SaxDocumentHandler class on page 1865
- The XmlReader class on page 1871
- The XmlWriter class on page 1876

The DomDocument class

The `om.DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

A `om.DomDocument` object holds a DOM tree of `om.DomNode` objects.

A unique root `om.DomNode` object is owned by a `om.DomDocument` object.

om.DomDocument methods

Methods of the `om.DomDocument` class.

Table 397: Class methods

Name	Description

`om.DomDocument.create(`
`  tag STRING )`
`  RETURNING result om.DomDocument`
	Create a new empty `om.DomDocument` object.

`om.DomDocument.createFromString(` `  string STRING )`	Create a new `om.DomDocument` object from an XML string.

Name	Description
`RETURNING result om.DomDocument`	
`om.DomDocument.createFromXmlFile( filename STRING ) RETURNING result om.DomDocument`	Create a new `om.DomDocument` object from an XML file.

Table 398: Object methods

Name	Description
`createChars( string STRING ) RETURNING result om.DomNode`	Create a new text node in the DOM document.
`createElement( tag STRING ) RETURNING result om.DomNode`	Create a new element node in the DOM document.
`createEntity( name STRING ) RETURNING result om.DomNode`	Create a new entity node in the DOM document.
`copy( source om.DomNode, deep INTEGER ) RETURNING result om.DomNode`	Create a new element node by copying an existing node.
`getDocumentById( id INTEGER ) RETURNING result om.DomNode`	Returns a node element according to the internal AUI tree id.
`getDocumentElement() RETURNING result om.DomNode`	Returns the root node element of the DOM document.
`removeElement( element om.DomNode )`	Remove a DomNode object and all its descendants.

om.DomDocument.create
Create a new empty `om.DomDocument` object.

Syntax

```
om.DomDocument.create(
   tag STRING )
  RETURNING result om.DomDocument
```

1. *tag* defines the tag name of the root element.

Usage

Use the class method `om.DomDocument.create()` to instantiate a new, empty DOM document object.

To hold the reference to a DOM document object, define a variable with the type `om.DomDocument` type.

Example

```
DEFINE d  om.DomDocument
LET d = om.DomDocument.create("Vehicles")
```

om.DomDocument.createFromString
Create a new `om.DomDocument` object from an XML string.

Syntax

```
om.DomDocument.createFromString(
   string STRING )
  RETURNING result om.DomDocument
```

1. *string* is the string expression containing XML data.

Usage

Use the class method `om.DomDocument.createFromString()` to instantiate a new DomDocument object that is filled with the content of the specified XML formatted string.

To hold the reference to a DOM document object, define a variable with the type `om.DomDocument` type.

Example

```
DEFINE d  om.DomDocument
LET d = om.DomDocument.createFromString("<Vehicles/>")
```

om.DomDocument.createFromXmlFile
Create a new `om.DomDocument` object from an XML file.

Syntax

```
om.DomDocument.createFromXmlFile(
   filename STRING )
  RETURNING result om.DomDocument
```

1. *filename* is the path to the file containing XML data.

Usage

Use the class method `om.DomDocument.createFromXmlFile()` to instantiate a new DomDocument object that is filled with the content of the specified XML file.

To hold the reference to a DOM document object, define a variable with the type `om.DomDocument` type.

Example

```
DEFINE d  om.DomDocument
LET d = om.DomDocument.createFromXmlFile("vehicles.xml")
```

om.DomDocument.getDocumentElement
Returns the root node element of the DOM document.

Syntax

```
getDocumentElement()
  RETURNING result om.DomNode
```

Usage

The method `getDocumentElement()` returns the root `om.DomNode` element node of the DOM document.

To hold the reference to the root node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE n om.DomNode
LET n = mydoc.getDocumentElement()
```

om.DomDocument.getElementById
Returns a node element according to the internal AUI tree id.

Syntax

```
getDocumentById(
   id INTEGER )
  RETURNING result om.DomNode
```

Usage

The method `getElementById()` returns the `om.DomNode` element of the DOM document according to the internal id number passed as parameter.

Each DOM node gets an internal integer id when it is created in the abstract user interface tree, and can be referenced by this unique id. The node id is typically used in other nodes, to reference a node in the DOM document.

To hold the reference to the root node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE n om.DomNode
LET n = mydoc.getElementById()
```

om.DomDocument.createChars
Create a new text node in the DOM document.

Syntax

```
createChars(
   string STRING )
  RETURNING result om.DomNode
```

1. *string* defines the content of the text node.

Usage

Use the method `createChars()` to create a new `om.DomNode` text node. The content of the text node must be passed as parameter.

The new created node will have the reserved tagName "`@chars`", and a single attribute named "`@chars`" storing the character data.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```
MAIN
  DEFINE mydoc  om.DomDocument
  DEFINE root, text om.DomNode
  LET mydoc = om.DomDocument.create("Test")
  LET root = mydoc.getDocumentElement()
  LET text = mydoc.createChars("Hello, world!")
  DISPLAY text.getAttribute("@chars")
  CALL root.appendChild(text)
  CALL root.writeXML("output.xml")
END MAIN
```

om.DomDocument.createElement
Create a new element node in the DOM document.

Syntax

```
createElement(
   tag STRING )
  RETURNING result om.DomNode
```

1. *tag* defines the tag name of the node.

Usage

Use the method `createElement()` to create a new `om.DomNode` element node. The tag name of the element must be passed as parameter.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE n om.DomNode
LET n = mydoc.createElement("Car")
```

om.DomDocument.createEntity
Create a new entity node in the DOM document.

Syntax

```
createEntity(
   name STRING )
  RETURNING result om.DomNode
```

1. *name* defines the name of the entity node.

Usage

Use the method `createEntity()` to create a new `om.DomNode` entity node. The entity name must be passed as parameter.

The text representation of a entity node is *&name;*.

The new created node will have the reserved tagName "`@entity`" , with a single attribute named "`@entity`" containing the text of the entity.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE n om.DomNode
LET n = mydoc.createEntity("quot")
```

om.DomDocument.copy
Create a new element node by copying an existing node.

Syntax

```
copy(
   source om.DomNode,
   deep INTEGER )
  RETURNING result om.DomNode
```

1. *source* references the source node to copy.
2. *deep* is a boolean to control the recursive node copy.

Usage

Use the method `copy()` to create a new `om.DomNode` element node from an existing node.

Pass `TRUE` as second parameter to clone a complete tree of nodes.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE n, s om.DomNode
LET s = mydoc.createElement("Car")
LET n = mydoc.copy(s, TRUE)
```

om.DomDocument.removeElement
Remove a DomNode object and all its descendants.

Syntax

```
removeElement(
   element om.DomNode )
```

1. *element* is the DOM node to be removed.

Usage

Use the `removeElement()` method to remove an element and all its descendants from DOM document.

Any reference to the removed `om.DomNode` objects becomes invalid.

Examples
Example 1: Creating a DOM document

```
MAIN
  DEFINE d  om.DomDocument
  DEFINE r om.DomNode
  LET d = om.DomDocument.create("MyDocument")
  LET r = d.getDocumentElement()
END MAIN
```

The DomNode class
The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

This class follows the DOM standards.

A DomNode object is a node (or element) of a DomDocument.

Tag and attribute names of DOM nodes are case sensitive; "Wheel" is not the same as "wheel".

Text nodes cannot have attributes, but they have plain text. In text nodes, the characters can be accessed with the `@chars` attribute name. In XML representation, a text node is the text itself. Do not confuse it with the parent node. For example, `<Item id="32">Red shoes</Item>` represents 2 nodes: The parent 'Item' node and a text node with string 'Red shoes'.

If you need to identify an element, use a common attribute like "name". If you need to label an element, use a common attribute like "text".

om.DomNode methods
Methods of the `om.DomNode` class.

Table 399: Object methods: Node creation

Name	Description
`appendChild( node om.DomNode )`	Adds an existing node at the end of the list of children in the current node.
`createChild( tag STRING ) RETURNING result om.DomNode`	Creates and adds an node at the end of the list of children in the current node.
`insertBefore( new om.DomNode, existing om.DomNode)`	Inserts an existing node before the existing node specified.
`removeChild( node om.DomNode )`	Deletes the specified child node from the current node.
`replaceChild( new om.DomNode, old om.DomNode)`	Replaces a node by another in the children nodes of the current node.

Table 400: Object methods: In/Out

Name	Description
`loadXml( filename STRING ) RETURNING result om.DomNode`	Load an XML file into the current node.
`parse( string STRING ) RETURNING result om.DomNode`	Parses an XML formatted string and creates the DOM structure in the current node.
`toString() RETURNING result STRING`	Serializes the current node into an XML formatted string.
`write( sdh om.SaxDocumentHandler )`	Processes a DOM document with a SAX document handler.
`writeXml( filename STRING )`	Creates an XML file from the current DOM node.

Table 401: Object methods: Node identification

Name	Description
`getId() RETURNING result INTEGER`	Returns the internal AUI tree id of a DOM node.
`getTagName() RETURNING result STRING`	Returns the XML tag name of a DOM node.

Table 402: Object methods: Attributes management

Name	Description
`getAttribute( name STRING ) RETURNING result STRING`	Returns the value of a DOM node attribute.
`getAttributesCount() RETURNING result INTEGER`	Returns the number of attributes in the DOM node.
`getAttributeInteger( name STRING, def STRING )`	Returns the value of a DOM node attribute, with default integer value.

Name	Description
`RETURNING result INTEGER`	
`getAttributeString( name STRING, def STRING ) RETURNING result STRING`	Returns the value of a DOM node attribute, with default string value.
`getAttributeName( index INTEGER ) RETURNING result STRING`	Returns the name of a DOM node attribute by position.
`getAttributeValue( index INTEGER ) RETURNING result STRING`	Returns the value of a DOM node attribute by position.
`setAttribute( name STRING, value STRING )`	Sets the value of a DOM node attribute.
`removeAttribute( name STRING ) RETURNING result STRING`	Delete the specified attribute from the DOM node.

Table 403: Object methods: Tree navigation

Name	Description
`getChildByIndex( index INTEGER ) RETURNING result om.DomNode`	Returns a child DOM node by position.
`getChildCount() RETURNING result INTEGER`	Returns the number of children nodes.
`getFirstChild() RETURNING result om.DomNode`	Returns the first child DOM node.
`getLastChild() RETURNING result om.DomNode`	Returns the last child DOM node.
`getNext() RETURNING result om.DomNode`	Returns the next sibling DOM node of this node.
`getParent()`	Returns the parent DOM node.

Name	Description
RETURNING *result* om.DomNode	
getPrevious() RETURNING *result* om.DomNode	Returns previous sibling DOM node of this node.
selectByPath(*xpath* STRING) RETURNING *result* om.NodeList	Finds descendant DOM nodes according to an XPath-like pattern.
selectByTagName(*tagname* STRING) RETURNING *result* om.NodeList	Finds descendant DOM nodes according to a tag name.

om.DomNode.appendChild
Adds an existing node at the end of the list of children in the current node.

Syntax

```
appendChild(
   node om.DomNode )
```

1. *node* is a reference to a node.

Usage

The `appendChild()` method takes an existing `om.DomNode` element node and adds it at the end of the children of the object node calling the method.

The child node passed to the `appendChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

If the node passed to the `appendChild()` method is already attached to another parent node, it will be detached from that parent node before being attached to the new parent node.

Example

```
MAIN
    DEFINE doc  om.DomDocument,
           r om.DomNode,
           p1, p2 om.DomNode,
           c1, c2 om.DomNode

    LET doc = om.DomDocument.create("Items")

    LET r = doc.createElement("Zoo")

    LET p1 = doc.createElement("DodoList")

    -- appends p1 under r
    CALL r.appendChild(p1)

    LET c1 = doc.createElement("Dodo")
    CALL c1.setAttribute("name", "momo")
    CALL c1.setAttribute("gender", "male")
    CALL p1.appendChild(c1)
```

```
    LET p2 = doc.createElement("DodoList")
    CALL r.appendChild(p2)
    LET c2 = doc.createElement("Dodo")
    CALL c2.setAttribute("name", "kiki")
    CALL c2.setAttribute("gender", "female")
    CALL p2.appendChild(c2)

    CALL r.writeXml("file1.xml")

    -- moves c1 under p2
    CALL p2.appendChild(c1)

    CALL r.writeXml("file2.xml")
END MAIN
```

The above program will produce the following XML files:

`file.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList>
    <Dodo name="momo" gender="male"/>
  </DodoList>
  <DodoList>
    <Dodo name="kiki" gender="female"/>
  </DodoList>
</Zoo>
```

`file2.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList/>
  <DodoList>
    <Dodo name="kiki" gender="female"/>
    <Dodo name="momo" gender="male"/>
  </DodoList>
</Zoo>
```

om.DomNode.createChild
Creates and adds an node at the end of the list of children in the current node.

Syntax

```
createChild(
   tag STRING )
  RETURNING result om.DomNode
```

1. *tag* is the tag name of the new node.

Usage

The `createChild()` method creates a new `om.DomNode` element with the tag name passed as parameter, and adds it at the end of the children of the object node calling the method.

The method returns the reference to the new created object.

Example

```
DEFINE parent, child om.DomNode
...
LET child = parent.createChild("Item")
```

om.DomNode.insertBefore
Inserts an existing node before the existing node specified.

Syntax

```
insertBefore(
   new om.DomNode,
   existing om.DomNode)
```

1. *new* is a reference to a new created node.
2. *existing* is a reference to a child node existing in the current node.

Usage

The `insertBefore()` method takes an existing `om.DomNode` element node and adds it before the child node passed as second parameter, in the list of children of the object node calling the method.

The child node passed to the `insertChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

Example

```
DEFINE parent, other, child om.DomNode
...
LET child = mydoc.createElement("Item")
CALL parent.insertBefore(child, other)
```

om.DomNode.loadXml
Load an XML file into the current node.

Syntax

```
loadXml(
   filename STRING )
  RETURNING result om.DomNode
```

1. *filename* is the path to the XML file.

Usage

The `loadXml()` method takes a file path as parameter and loads the XML content into the current node, by creating a new DOM structure in memory. The method then returns the new created child DOM node.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```
DEFINE parent, new om.DomNode
...
LET new = parent.loadXml("myfile.xml")
```

om.DomNode.parse
Parses an XML formatted string and creates the DOM structure in the current node.

Syntax

```
parse(
   string STRING )
  RETURNING result om.DomNode
```

1. *string* is an XML formatted string.

Usage

The `parse()` method scans the XML formatted string passed as parameter and creates the corresponding DOM nodes into the current node. The method then returns the new created child DOM node.

The node must be created before it is passed as parameter to this method, typically, with `om.DomDocument.createElement()`.

Example

```
DEFINE parent, child om.DomNode
...
LET child = parent.parse("<Item/>")
```

om.DomNode.getAttribute
Returns the value of a DOM node attribute.

Syntax

```
getAttribute(
   name STRING )
  RETURNING result STRING
```

1. *name* is the name of the attribute.

Usage

The `getAttribute()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist for this node type, or if the attribute is not set, the method returns `NULL`.

For character nodes (created for example with the `createChars()` of a `DomDocument` object), you can get the text value by passing the `@chars` attribute name to the method.

Example

```
DEFINE node om.DomNode
...
DISPLAY node.getAttribute("color")
```

om.DomNode.getAttributeInteger
Returns the value of a DOM node attribute, with default integer value.

Syntax

```
getAttributeInteger(
   name STRING,
   def STRING )
  RETURNING result INTEGER
```

1. *name* is the name of the attribute.
2. *def* is the default value.

Usage

The `getAttributeInteger()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

om.DomNode.getAttributesCount
Returns the number of attributes in the DOM node.

Syntax

```
getAttributesCount()
  RETURNING result INTEGER
```

Usage

The `getAttributesCount()` method returns the number of attributes defined in the current node.

This method is typically used to scan all the attributes of a node by position, with the `getAttributeName()` and `getAttributeValue()` methods.

Example

```
DEFINE node om.DomNode,
       index INTEGER
...
FOR index = 1 TO node.getAttributesCount()
    DISPLAY node.getAttributeName(index)
END FOR
```

om.DomNode.getAttributeString
Returns the value of a DOM node attribute, with default string value.

Syntax

```
getAttributeString(
   name STRING,
   def STRING )
  RETURNING result STRING
```

1. *name* is the name of the attribute.
2. *def* is the default value.

Usage

The `getAttributeString()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

om.DomNode.getAttributeName
Returns the name of a DOM node attribute by position.

Syntax

```
getAttributeName(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the index of the attribute, starts at 1.

Usage

The `getAttributeName()` method returns the name of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.

Example

```
DEFINE node om.DomNode
...
DISPLAY node.getAttributeName(12)
```

om.DomNode.getAttributeValue
Returns the value of a DOM node attribute by position.

Syntax

```
getAttributeValue(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the index of the attribute, starts at 1.

Usage

The `getAttributeValue()` method returns the value of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.

Example

```
DEFINE node om.DomNode
...
DISPLAY node.getAttributeValue(12)
```

om.DomNode.getChildByIndex
Returns a child DOM node by position.

Syntax

```
getChildByIndex(
   index INTEGER )
  RETURNING result om.DomNode
```

1. *index* is the index of the child node, starts at 1.

Usage

The `getChildByIndex()` method returns the child DOM node by position in the current node.

If there is no child node at the give position, the method returns `NULL`.

om.DomNode.getChildCount
Returns the number of children nodes.

Syntax

```
getChildCount()
  RETURNING result INTEGER
```

Usage

The `getChildCount()` method returns the number of children nodes in the current node.

This method is typically used to scan the children nodes of a DOM node, with the `getChildByIndex()` method.

Example

```
DEFINE parent, child om.DomNode,
       index INTEGER
...
FOR index=1 TO node.getChildCount()
    LET child = parent.getChildByIndex(index)
    ...
END FOR
```

om.DomNode.getFirstChild
Returns the first child DOM node.

Syntax

```
getFirstChild()
  RETURNING result om.DomNode
```

Usage

The `getFirstChild()` method returns the first child DOM node in the current node.

This method is typically used to scan children nodes with the `getNext()` method, until `getNext()` returns `NULL`.

Example

```
DEFINE parent, child om.DomNode
...
LET child = parent.getFirstChild()
WHILE child IS NOT NULL
    ...
    LET child = child.getNext()
END WHILE
```

om.DomNode.getId
Returns the internal AUI tree id of a DOM node.

Syntax

```
getId()
  RETURNING result INTEGER
```

Usage

The `getId()` method returns to internal integer identifier generated automatically for any `om.DomNode` object created in the abstract user interface tree.

The internal id is typically used to reference a DOM node in an attribute of another node, to link logically nodes together.

If the DOM node does not belong to the AUI tree, the method returns zero.

om.DomNode.getLastChild
Returns the last child DOM node.

Syntax

```
getLastChild()
  RETURNING result om.DomNode
```

Usage

The `getLastChild()` method returns the last child DOM node in the current node.

This method is typically used to scan children nodes with the `getPrevious()` method, until `getPrevious()` returns `NULL`.

Example

```
DEFINE parent, child om.DomNode
...
LET child = parent.getLastChild()
WHILE child IS NOT NULL
    ...
    LET child = child.getPrevious()
END WHILE
```

om.DomNode.getNext
Returns the next sibling DOM node of this node.

Syntax

```
getNext()
  RETURNING result om.DomNode
```

Usage

The `getNext()` method returns the next sibling DOM node following the current node, withing the children list of the parent node.

om.DomNode.getParent
Returns the parent DOM node.

Syntax

```
getParent()
  RETURNING result om.DomNode
```

Usage

The `getParent()` method returns the parent DOM node of the current node.

If the current node is the root node, the method returns `NULL`.

Example

```
DEFINE parent, current om.DomNode
...
LET parent = current.getParent()
```

om.DomNode.getPrevious
Returns previous sibling DOM node of this node.

Syntax

```
getPrevious()
  RETURNING result om.DomNode
```

Usage

The `getPrevious()` method returns the previous sibling DOM node preceding the current node, withing the children list of the parent node.

om.DomNode.getTagName
Returns the XML tag name of a DOM node.

Syntax

```
getTagName()
  RETURNING result STRING
```

Usage

The `getTagName()` method returns the XML tag name of the node.

Use this method to identity the type of the node.

om.DomNode.removeAttribute
Delete the specified attribute from the DOM node.

Syntax

```
removeAttribute(
   name STRING )
  RETURNING result STRING
```

1. *name* is the name of the attribute.

Usage

The `removeAttribute()` method deletes the attribute identified by the name passed as parameter.

DOM node attribute names are case-sensitive.

If the attribute does not exist for this node the method returns silently.

Example

```
DEFINE node om.DomNode
...
CALL node.removeAttribute("comments")
```

om.DomNode.removeChild
Deletes the specified child node from the current node.

Syntax

```
removeChild(
   node om.DomNode )
```

1. *node* is a reference to a node.

Usage

The `removeChild()` method detaches a `om.DomNode` element node from the current node.

The removed node is not destroyed, if it is still referenced by a variable: The `removeChild()` method will only break the link between the parent node and the child node. The child node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

Example

```
MAIN
    DEFINE doc  om.DomDocument,
           r om.DomNode,
           p om.DomNode,
           c om.DomNode

    LET doc = om.DomDocument.create("Items")

    LET r = doc.createElement("Zoo")
```

```
    LET p = doc.createElement("DodoList")
    CALL r.appendChild(p)

    LET c = doc.createElement("Dodo")
    CALL c.setAttribute("name", "momo")
    CALL c.setAttribute("gender", "male")
    CALL p.appendChild(c)

    CALL r.writeXml("file1.xml")

    CALL p.removeChild(c)

    -- c is orphan but still exists
    CALL c.writeXml("file2.xml")
    LET c = NULL -- unref/destroy the node

    CALL r.writeXml("file3.xml")
END MAIN
```

The above program will produce the following files:

`file1.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList>
    <Dodo name="momo" gender="male"/>
  </DodoList>
</Zoo>
```

`file2.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Dodo name="momo" gender="male"/>
```

`file3.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList/>
</Zoo>
```

om.DomNode.replaceChild
Replaces a node by another in the children nodes of the current node.

Syntax

```
replaceChild(
   new om.DomNode,
   old om.DomNode)
```

1. *new* is a reference to the new node.
2. *old* is the the node to be replaced.

Usage

The `replaceChild()` nethod puts the `om.DomNode` element passed as first parameter at the place of the node referenced by the second parameter, in the children list of the object node calling the method.

The new child node passed to the `replaceChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

The old node is not destroyed, if it is still referenced by a variable. The old node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

Example

```
MAIN
    DEFINE doc  om.DomDocument,
           r om.DomNode,
           p om.DomNode,
           o om.DomNode,
           n om.DomNode

    LET doc = om.DomDocument.create("Items")

    LET r = doc.createElement("Zoo")

    LET p = doc.createElement("DodoList")
    CALL r.appendChild(p)

    LET o = doc.createElement("Dodo")
    CALL o.setAttribute("name", "momo")
    CALL o.setAttribute("gender", "male")
    CALL p.appendChild(o)

    CALL r.writeXml("file1.xml")

    LET n = doc.createElement("Dodo")
    CALL n.setAttribute("name", "kiki")
    CALL n.setAttribute("gender", "female")

    CALL p.replaceChild(n, o)

    -- o is orphan but still exists
    CALL o.writeXml("file2.xml")
    LET o = NULL -- unref/destroy the node

    CALL r.writeXml("file3.xml")
END MAIN
```

The above program will produce following files:

`file1.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList>
    <Dodo name="momo" gender="male"/>
  </DodoList>
</Zoo>
```

`file2.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Dodo name="momo" gender="male"/>
```

`file3.xml`

```
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
```

```
  <DodoList>
    <Dodo name="kiki" gender="female"/>
  </DodoList>
</Zoo>
```

om.DomNode.setAttribute
Sets the value of a DOM node attribute.

Syntax

```
setAttribute(
   name STRING,
   value STRING )
```

1. *name* is the name of the attribute.
2. *value* is the attribute value.

Usage

The `setAttribute()` method sets the value of an attribute in the current node.

DOM node attribute names are case-sensitive.

> **Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

Example

```
DEFINE node om.DomNode
...
CALL node.setAttribute("name", "tiger")
```

om.DomNode.toString
Serializes the current node into an XML formatted string.

Syntax

```
toString()
  RETURNING result STRING
```

Usage

The `toString()` method builds an XML formatted string with the DOM structure of the current node and returns the string.

Example

```
DEFINE node om.DomNode, s STRING
...
LET s = node.toString()
```

om.DomNode.write
Processes a DOM document with a SAX document handler.

Syntax

```
write(
   sdh om.SaxDocumentHandler )
```

1. *sdh* references a SAX document handler.

Usage

The `write()` method processes the current DOM node content with the SAX document handler passed as parameter.

See the SAX document handler class for more details.

om.DomNode.writeXml
Creates an XML file from the current DOM node.

Syntax

```
writeXml(
   filename STRING )
```

1. *filename* is the path to the XML file.

Usage

The `writeXml()` method writes the content of the current DOM node to the file passed as parameter.

Example

```
DEFINE node om.DomNode
...
CALL noe.writeXml("output.xml")
```

om.DomNode.selectByPath
Finds descendant DOM nodes according to an XPath-like pattern.

Syntax

```
selectByPath(
   xpath STRING )
  RETURNING result om.NodeList
```

1. *xpath* is an XPath-like pattern, using .

Usage

The `selectByPath()` method scans the DOM tree for descendant nodes according to the specified XPath-like pattern.

The pattern supported is limited to the following syntax:

```
{ / | // } TagName [ [@AttributeName="Value"] ] [...]
```

DOM node tag names and attributes names are case-sensitive.

The method creates a list of nodes as a `om.NodeList` object. This list object is then used to process the nodes found.

Example

```
DEFINE node om.DomNode,
       nodelist om.NodeList
...
LET nodelist = node.selectByPath("//Grid/Table[@tabName=
\"t1\"]")
```

om.DomNode.selectByTagName
Finds descendant DOM nodes according to a tag name.

Syntax

```
selectByTagName(
   tagname STRING )
  RETURNING result om.NodeList
```

1. *tagname* is a tag name for the search.

Usage

The `selectByTagName()` method scans the DOM tree for descendant nodes defined with the tag name specified as parameter.

DOM node tag names are case-sensitive.

The method creates a list of nodes as a `om.NodeList` object. This list object is then used to process the nodes found.

Example

```
DEFINE node om.DomNode,
       nodelist om.NodeList
...
LET nodelist = node.selectByTagName("Car")
```

Examples
Example 1: Creating a DOM tree

To create a DOM tree with the following structure (represented in XML format):

```
<Vehicles>
   <Car name="Corolla" color="Blue" weight="1546">Nice car!</Car>
   <Bus name="Maxibus" color="Yellow" weight="5278">
      <Wheel width="315" diameter="925" />
      <Wheel width="315" diameter="925" />
      <Wheel width="315" diameter="925" />
      <Wheel width="315" diameter="925" />
   </Bus>
</Vehicles>
```

You write the following:

```
MAIN
  DEFINE d  om.DomDocument
  DEFINE r, n, t, w om.DomNode
```

```
  DEFINE i INTEGER

  LET d = om.DomDocument.create("Vehicles")
  LET r = d.getDocumentElement()

  LET n = r.createChild("Car")
  CALL n.setAttribute("name","Corolla")
  CALL n.setAttribute("color","Blue")
  CALL n.setAttribute("weight","1546")

  LET t = d.createChars("Nice car!")
  CALL n.appendChild(t)
  LET t = d.createEntity("nbsp")
  CALL n.appendChild(t)
  LET t = d.createChars("Yes, very nice!")
  CALL n.appendChild(t)

  LET n = r.createChild("Bus")
  CALL n.setAttribute("name","Maxibus")
  CALL n.setAttribute("color","yellow")
  CALL n.setAttribute("weight","5278")
  FOR i=1 TO 4
    LET w = n.createChild("Wheel")
    CALL w.setAttribute("width","315")
    CALL w.setAttribute("diameter","925")
  END FOR

  CALL r.writeXml("Vehicles.xml")

END MAIN
```

Example 2: Displaying a DOM tree recursively

The following example displays a DOM tree content recursively:

```
FUNCTION displayDomNode(n,e)
  DEFINE n om.DomNode
  DEFINE e, i, s INTEGER

  LET s = e*2
  DISPLAY s SPACES || "Tag: " || n.getTagName()

  DISPLAY s SPACES || "Attributes:"
  FOR i=1 TO n.getAttributesCount()
     DISPLAY s SPACES || "  " || n.getAttributeName(i) ||
                     "=[" || n.getAttributeValue(i) ||"]"
  END FOR
  LET n = n.getFirstChild()

  DISPLAY s SPACES || "Child Nodes:"
  WHILE n IS NOT NULL
    CALL displayDomNode(n,e+1)
    LET n = n.getNext()
  END WHILE

END FUNCTION
```

Example 3: Writing a DOM tree to a SAX handler

The following example outputs a Dom tree without indentation.

```
MAIN
  DEFINE d  om.DomDocument
```

```
  DEFINE r, n, t, w om.DomNode
  DEFINE dh om.SaxDocumentHandler

  DEFINE i INTEGER

  LET dh = om.XmlWriter.createPipeWriter("cat")
  CALL dh.setIndent(FALSE)

  LET d = om.DomDocument.create("Vehicles")
  LET r = d.getDocumentElement()

  LET n = r.createChild("Car")
  CALL n.setAttribute("name","Corolla")
  CALL n.setAttribute("color","Blue")
  CALL n.setAttribute("weight","1546")

  LET t = d.createChars("Nice car!")
  CALL n.appendChild(t)

  LET n = r.createChild("Bus")
  CALL n.setAttribute("name","Maxibus")
  CALL n.setAttribute("color","yellow")
  CALL n.setAttribute("weight","5278")
  FOR i=1 TO 4
    LET w = n.createChild("Wheel")
    CALL w.setAttribute("width","315")
    CALL w.setAttribute("diameter","925")
  END FOR

  CALL r.write(dh)

END MAIN
```

The NodeList class
A `om.NodeList` object hold a list of DOM nodes.

The list is created from a `om.DomNode.selectByTagName()` or `om.DomNode.selectByPath()` method.

After creating the node list, you can process the nodes withe the `getLength()` and `item()` methods of the om.NodeList object.

om.NodeList methods
Methods of the `om.NodeList` class.

Table 404: Object methods

Name	Description
`getLength()` `  RETURNING` *`result`* `INTEGER`	Returns the number of elements in the node list.
`item(` *`index`* `INTEGER )` `  RETURNING` *`result`* `om.DomNode`	Returns a DOM node element by position in the node list.

om.NodeList.getLength
Returns the number of elements in the node list.

Syntax

```
getLength()
  RETURNING result INTEGER
```

1. *node* is a reference to a node.

Usage

The `getLength()` method returns the size of the node list.

Query for node list for elements with the `item()` method, in the range 1 to `getLength()`.

Example

```
DEFINE list om.NodeList
...
DISPLAY list.getLength()
```

om.NodeList.item
Returns a DOM node element by position in the node list.

Syntax

```
item( index INTEGER )
  RETURNING result om.DomNode
```

1. *index* is the ordinal position of the node in the list.

Usage

The `item()` method returns the `om.DomNode` object at the position specified.

First element is at position 1.

If there is no element at the specified index, the method returns `NULL`.

Example

```
DEFINE list om.NodeList,
       node om.DomNode
...
LET node = list.item(12)
```

Examples
Example 1: Search for child nodes by tag name

```
MAIN
  DEFINE nl om.NodeList
  DEFINE r, n om.DomNode
  DEFINE i INTEGER

  LET r = ui.Interface.getRootNode()
  LET nl = r.selectByTagName("Form")

  FOR i=1 to nl.getLength()
```

```
    LET n = nl.item(i)
    DISPLAY n.getAttribute("name")
  END FOR

END MAIN
```

Example 2: Search for child nodes by XPath

```
MAIN
  DEFINE nl om.NodeList
  DEFINE r, n om.DomNode
  DEFINE i INTEGER

  LET r = ui.Interface.getRootNode()
  LET nl = r.selectByPath("//Window[@name=\"screen\"]")

  FOR i=1 to nl.getLength()
    LET n = nl.item(i)
    DISPLAY n.getAttribute("name")
  END FOR

END MAIN
```

The SaxAttributes class
The `om.SaxAttributes` class holds a set of attributes to process with a SAX reader or writer.

To process SAX attributes, create a `om.SaxAttributes` object with a SAX reader or SAX writer SAX writer object.

Get an instance of SaxAttributes with the `om.XmlReader.getAttributes()` method.

om.SaxAttributes methods
Methods of the `om.SaxAttributes` class.

Table 405: Class methods

Name	Description
`copy( attrs om.SaxAttributes ) RETURNING result om.SaxAttributes`	Clones an existing SAX attributes object.
`create() RETURNING result om.SaxAttributes`	Create a new SAX attributes object.

Table 406: Object methods

Name	Description
`addAttribute( name STRING, value STRING )`	Appends a new attribute to the end of the list.
`clear()`	Clears the SAX attribute list.
`getLength()`	Returns the number of attributes in the list.

Name	Description
`RETURNING result INTEGER`	
`getName( index INTEGER ) RETURNING result STRING`	Returns the name of an attribute by position.
`getValue( name STRING ) RETURNING result STRING`	Returns the value of an attribute by name.
`getValueByIndex( index INTEGER ) RETURNING result STRING`	Returns an attribute value by position.
`removeAttribute( index INTEGER )`	Delete an attribute by position.
`setAttributes( attrs om.SaxAttributes )`	Clears the list and copies the attributes passed.

om.SaxAttributes.addAttribute
Appends a new attribute to the end of the list.

Syntax

```
addAttribute(
   name STRING,
   value STRING )
```

1. *name* is the name of the attribute.
2. *value* is the value of the attribute.

Usage

The `addAttribute()` method appends a new attribute with name and value at the end of the list.

Attribute names are case-sensitive.

> **Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

Example

```
DEFINE attrs om.SaxAttributes
...
CALL attrs.addAttribute("name","jo")
```

om.SaxAttributes.copy
Clones an existing SAX attributes object.

Syntax

```
copy(
   attrs om.SaxAttributes )
  RETURNING result om.SaxAttributes
```

1. *attrs* is a set of SAX attributes to clone.

Usage

The `om.SaxAttributes.copy()` class method makes a clone of the `om.SaxAttributes` object passed as reference and returns the new created object.

Example

```
DEFINE copy, orig om.SaxAttributes
...
LET copy = om.SaxAttributes.copy(orig)
```

om.SaxAttributes.create
Create a new SAX attributes object.

Syntax

```
create()
  RETURNING result om.SaxAttributes
```

Usage

The `om.SaxAttributes.create()` class method create a new `om.SaxAttributes` object returns it.

To hold the reference to a SAX attributes object, define a variable with the type `om.SaxAttributes` type.

Example

```
DEFINE attrs om.SaxAttributes
...
LET attrs = om.SaxAttributes.create()
```

om.SaxAttributes.clear
Clears the SAX attribute list.

Syntax

```
clear()
```

Usage

Use the `clear()` method the clean the SAX attribute list.

om.SaxAttributes.getLength
Returns the number of attributes in the list.

Syntax

```
getLength()
  RETURNING result INTEGER
```

Usage

The `getLength()` method returns the number of attributes in the current SAX attribute list.

Use this method with `getName()` and `getValueByIndex()` to retrieve attributes by position.

Example

```
DEFINE attrs om.SaxAttributes,
       index INTEGER
...
FOR index = 1 TO attrs.getLength()
    DISPLAY attrs.getName(index), " = ",
 attrs.getValueByIndex(index)
END FOR
```

om.SaxAttributes.getName
Returns the name of an attribute by position.

Syntax

```
getName(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the position of the attribute in the list.

Usage

The `getName()` method returns the name of the attribute at the specified ordinal position in the list.

If the attribute does not exist at the given position, the method returns `NULL`.

om.SaxAttributes.getValue
Returns the value of an attribute by name.

Syntax

```
getValue(
   name STRING )
  RETURNING result STRING
```

1. *name* is the name of an attribute.

Usage

The `getValue()` method returns the value of the attribute identified by the name passed as parameter.

If the attribute does not exist, the method returns `NULL`.

Example

```
DEFINE attrs om.SaxAttributes
...
DISPLAY attrs.getValue("name")
```

om.SaxAttributes.getValueByIndex
Returns an attribute value by position.

Syntax

```
getValueByIndex(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the position of the attribute in the list.

Usage

The `getValueByIndex()` method returns the value of the attribute at the specified ordinal position in the list.

If the attribute does not exist at the given position, the method returns `NULL`.

om.SaxAttributes.removeAttribute
Delete an attribute by position.

Syntax

```
removeAttribute(
   index INTEGER )
```

1. *index* is the position of the attribute in the list.

Usage

The `removeAttribute()` method removes the attribute at the given ordinal position.

If the attribute does not exist at the given position, the method returns silently.

Example

```
DEFINE attrs om.SaxAttributes
...
CALL attrs.removeAttribute( attrs.getLength() )
```

om.SaxAttributes.setAttributes
Clears the list and copies the attributes passed.

Syntax

```
setAttributes(
   attrs om.SaxAttributes )
```

1. *attrs* is a reference to list of attributes.

Usage

The `setAttributes()` method takes an existing `om.SaxAttributes` object reference and makes a copy of all attributes into the current attribute list.

Example

```
DEFINE curr, orig om.SaxAttributes
...
CALL curr.setAttributes(orig)
```

Examples

Example 1: Displaying SAX attributes of an XML node

```
FUNCTION displayAttributes( a )
   DEFINE a om.SaxAttributes
   DEFINE i INTEGER
   FOR i=1 to a.getLength()
      DISPLAY a.getName(i) || "=[" || a.getValueByIndex(i) || "]"
   END FOR
END FUNCTION
```

The SaxDocumentHandler class

The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

This class follows the SAX standards.

A `om.SaxDocumentHandler` object can be used in two different ways:

1. To implement an XML SAX filter, based of functions defined in a `.4gl` module, by using the `createForName()` class method.
2. To write an XML document to a file, process or socket output, by using `om.XmlWriter` creation methods, and the `om.SaxDocumentHandler` processing methods.

The `om.SaxDocumentHandler` class also provides methods to process all SAX events by hand. This is useful if you want to chain SAX filters.

om.SaxDocumentHandler methods

Methods of the `om.SaxDocumentHandler` class.

Table 407: Class methods

Name	Description

`om.SaxDocumentHandler.createForName( module STRING )`
 	
`RETURNING result om.SaxDocumentHandler`
	Creates a new SAX document handler object for the given .4gl module.

Table 408: Object methods

Name	Description
`characters(`	Processes a text node.

Name	Description
data STRING)	
endDocument()	Processes the end of the document.
endElement(*tagname* STRING)	Processes the end of an element.
processingInstruction(*name* STRING, *data* STRING)	Processes a processing instruction.
readXmlFile(*filename* STRING)	Reads and processes an XML file with the SAX document handler.
setIndent(*on* BOOLEAN)	Controls indentation in XML output.
startDocument()	Processes the beginning of the document.
startElement(*tagname* STRING, *attrs* om.SaxAttributes)	Processes the beginning of an element.
skippedEntity(*name* STRING)	Processes an unresolved entity.

om.SaxDocumentHandler.createForName
Creates a new SAX document handler object for the given .4gl module.

Syntax

```
om.SaxDocumentHandler.createForName(
   module STRING )
  RETURNING result om.SaxDocumentHandler
```

1. *module* is the name of the .4gl module defining the document handler events.

Usage

The `om.SaxDocumentHandler.createForName()` method creates a `om.SaxDocumentHandler` instance and binds the .4gl module passed as argument to the object.

To hold the reference to a SAX document handler object, define a variable with the type `om.SaxDocumentHandler` type.

The .4gl module must be available as a compiled 42m file, loadable according to environment settings (FGLLDPATH).

The .4gl module must implement the following functions to process the SAX filter events:

Table 409: Functions of the SAX document handler module

Function	Description
`startDocument()`	Called once at the beginning of the document processing.
`endDocument()`	Called once at the end of the document processing.

`startElement(`
` tagname STRING,`
` attrs om.SaxAttributes )`
1. *tagname* is the tag name of element.
2. *attrs* is list of attributes.
	Called when an XML element is reached. Use the `om.SaxAttributes` methods to handle the attributes of the processed element.

`endElement( tagname STRING )` **1.** *tagname* is the tag name of element.	Called when the end of an XML element is reached.

`processingInstruction(`
` piname STRING,`
` data STRING )`
1. *piname* is the name of the processing instruction.
2. *data* is the content of the processing instruction.
	Called when a processing instruction is reached.

`characters( data STRING )` **1.** *data* is the text data.	Called when a text node is reached.
`skippedEntity( name STRING )` **1.** *name* is the name of the unknown entity.	Called when an unknown entity node is reached (like &xxx; for example).

Example

```
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
```

om.SaxDocumentHandler.characters
Processes a text node.

Syntax

```
characters(
   data STRING )
```

1. *data* is the content of the text node.

Usage

The `characters()` method processes a text node with the SAX interface.

> **Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

om.SaxDocumentHandler.endDocument
Processes the end of the document.

Syntax

```
endDocument()
```

Usage

The `endDocument()` method ends the document processing with the SAX interface.

om.SaxDocumentHandler.endElement
Processes the end of an element.

Syntax

```
endElement(
   tagname STRING )
```

1. *tagname* is the tag name of element.

Usage

The `endElement()` method processes the end of an element with the SAX interface.

om.SaxDocumentHandler.processingInstruction
Processes a processing instruction.

Syntax

```
processingInstruction(
   name STRING,
   data STRING )
```

1. *name* is the name of the processing instruction (token after <?).
2. *data* is the string in the processing instruction tag.

Usage

The `processingInstruction()` method processes a processing instruction with the SAX interface.

A processing instruction appears in an XML formatted text as:

```
<?name data ?>
```

om.SaxDocumentHandler.readXmlFile
Reads and processes an XML file with the SAX document handler.

Syntax

```
readXmlFile(
```

```
    filename STRING )
```

1. *filename* is the path to an XML formatted file.

Usage

Use the `readXmlFile()` method after creating the `om.SaxDocumentHandler` object, to process the XML data from a file input stream.

Example

```
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
CALL f.readXmlFile("cars.xml")
```

om.SaxDocumentHandler.setIndent
Controls indentation in XML output.

Syntax

```
setIndent(
   on BOOLEAN )
```

1. *on* is a boolean: `TRUE` enables identation; `FALSE` disables indentation.

Usage

By default, the `om.SaxDocumentHandler` object outputs XML with indentation.

In order to disable indentation, use the `setIndent(FALSE)` method.

om.SaxDocumentHandler.startDocument
Processes the beginning of the document.

Syntax

```
startDocument()
```

Usage

The `startDocument()` method begins the document processing with the SAX interface.

om.SaxDocumentHandler.startElement
Processes the beginning of an element.

Syntax

```
startElement(
   tagname STRING,
   attrs om.SaxAttributes )
```

1. *tagname* is the tag name of element.
2. *attrs* is the list of attributes of the element.

Usage

The `startElement()` method processes the beginning of an element with the SAX interface.

Use the `om.SaxAttributes` methods to handle the attributes of an element.

Example

```
DEFINE out om.SaxDocumentHandler
       attrs om.SaxAttributes,
       node om.DomNode,
       x INTEGER
...
CALL attrs.clear()
FOR x=1 TO r.getAttributesCount()
    CALL attrs.addAttribute( node.getAttributeName(x),
 node.getAttributeValue(x) )
END FOR
CALL out.startElement( node.getTagName(), attrs )
```

om.SaxDocumentHandler.skippedEntity
Processes an unresolved entity.

Syntax

```
skippedEntity(
   name STRING )
```

1. *name* is the name of the unknown entity.

Usage

The `skippedEntity()` method processes an entity that is not known by the XML parser.

Examples
Example 1: Extracting phone numbers from a directory.

This example shows how to write a SAX filter to extract phone numbers from a directory file written in XML.

```
MAIN
  DEFINE f om.SaxDocumentHandler
  LET f = om.SaxDocumentHandler.createForName("module1")
  CALL f.readXmlFile("customers")
END MAIN
```

Note:

1. The parameter of the createForName() method specifies the name of a source file that has been compiled into a .42m file ("module1.42m" in our example).

The module "module1.4gl":

```
FUNCTION startDocument()
END FUNCTION

FUNCTION processingInstruction(name,data)
  DEFINE name,data STRING
END FUNCTION

FUNCTION startElement(name,attr)
  DEFINE name STRING
  DEFINE attr om.SaxAttributes
  DEFINE i INTEGER
  IF name="Customer" THEN
     DISPLAY attr.getValue("lname")," ",
```

```
            attr.getValue("fname"),":",
            COLUMN 60, attr.getValue("phone")
  END IF
END FUNCTION

FUNCTION endElement(name)
  DEFINE name STRING
END FUNCTION

FUNCTION endDocument()
END FUNCTION

FUNCTION characters(chars)
  DEFINE chars STRING
END FUNCTION

FUNCTION skippedEntity(chars)
  DEFINE chars STRING
END FUNCTION
```

The XML file "customers":

```
<Customers>
  <Customer customer_num="101" fname="Ludwig" lname="Pauli"
    company="All Sports Supplies" address1="213 Erstwild Court"
    address2="" city="Sunnyvale" state="CA" zip-code="94086"
    phone="408-789-8075" />
  <Customer customer_num="102" fname="Carole" lname="Sadler"
    company="Sports Spot" address1="785 Geary St"
    address2="" city="San Francisco" state="CA" zip-code="94117"
    phone="415-822-1289" />
  <Customer customer_num="103" fname="Philip" lname="Currie"
    company="Phil&apos;s Sports" address1="654 Poplar"
    address2="P. O. Box 3498" city="Palo Alto" state="CA"
    zip-code="94303" phone="415-328-4543" />
</Customers>
```

The XmlReader class

The `om.XmlReader` class provides methods to read and process a file written in XML format.

The processing of the XML file is streamed-data based; the file is loaded and processed sequentially with events. To process XML element attributes, an `om.XmlReader` object must cooperate with a `om.SaxAttributes` object. The XmlReader class can only read from a file. To write to a file, use the `om.XmlWriter` class.

Steps to use a XML reader:

1. Declare a variable with the `om.XmlReader` type.
2. Create the reader object with the `createFileReader()` method and assign the reference to the variable.
3. Process SAX events in a `WHILE` loop, by reading document fragments with the `read()` method.
4. Inside the loop, according to the SAX event, process element attributes with getAttributes() or get the element data with the getCharacters() methods.

om.XmlReader methods

Methods of the `om.XmlReader` class.

Table 410: Class methods

Name	Description
`createFileReader( filename STRING ) RETURNING result om.XmlReader`	Creates an XML reader object from a file.

Table 411: Object methods

Name	Description
`getCharacters() RETURNING result STRING`	Returns the character data of the current processed element.
`getAttributes() RETURNING result om.SaxAttributes`	Builds an attribute list for the current processed element.
`getTagName() RETURNING result STRING`	Returns the tag name of the current processed element.
`read() RETURNING result STRING`	Reads the next SAX event to process.
`skippedEntity() RETURNING result STRING`	Returns the name of an unresolved entity.

om.XmlReader.createFileReader

Creates an XML reader object from a file.

Syntax

```
createFileReader(
   filename STRING )
  RETURNING result om.XmlReader
```

1. *filename* is the path to an XML formatted file.

Usage

Use the `om.XmlReader.createFileReader()` method to create a new `om.XmlReader` object, to process the XML data from a file input stream.

To hold the reference to an XmlReader object, define a variable with the type `om.XmlReader` type.

Example

```
DEFINE r om.XmlReader
```

```
LET r = om.XmlReader.createFileReader("cars.xml")
```

om.XmlReader.getAttributes
Builds an attribute list for the current processed element.

Syntax

```
getAttributes()
  RETURNING result om.SaxAttributes
```

Usage

Use the `getAttributes()` method create a list of attributes as a `om.SaxAttributes` object, from the current processed element, in the `StartElement` or `EndElement` event context.

Declare a variable with the `om.SaxAttributes` type to reference the attribute list.

Note that once created with the `getAttributes()` method, the `om.SaxAttributes` object is automatically updated based on the element currently processed by the `om.XmlReader`.

Example

```
DEFINE r om.XmlReader,
       e STRING, i INT
       a om.SaxAttributes
   ...
   LET e = r.read()
   WHILE e IS NOT NULL
     CASE e
       ...
       WHEN "StartElement"
         LET a = r.getAttributes()
         FOR i=1 to a.getLength()
             ...
```

om.XmlReader.getCharacters
Returns the character data of the current processed element.

Syntax

```
getCharacters()
  RETURNING result STRING
```

Usage

Use the `getCharacters()` method to get the character data of the current processed element, in the `Characters` event context.

Example

```
DEFINE r om.XmlReader,
       e STRING
   ...
   LET e = r.read()
   WHILE e IS NOT NULL
     CASE e
       ...
       WHEN "Characters"
```

```
          DISPLAY "Characters:'",r.getCharacters(),"'"
      ...
```

om.XmlReader.getTagName
Returns the tag name of the current processed element.

Syntax

```
getTagName()
  RETURNING result STRING
```

Usage

Use the `readXmlFile()` method to get the tag name of the current processed element, in the `StartElement` or `EndElement` event context.

Example

```
DEFINE r om.XmlReader,
       e STRING
   ...
   LET e = r.read()
   WHILE e IS NOT NULL
     CASE e
       ...
       WHEN "StartElement"
         DISPLAY "TagName = ", r.getTagName()
             ...
```

om.XmlReader.read
Reads the next SAX event to process.

Syntax

```
read()
  RETURNING result STRING
```

Usage

The `read()` method reads the next XML fragment and returns the name of the SAX event to process.

Table 412: Events that can be returned by the `read()`method

Event name	Description	Action
`StartDocument`	Beginning of the document	Prepare processing (allocate resources)
`StartElement`	Beginning of a node	Get current element's tag name or attributes with `getTagName()` `getAttributes()`
`Characters`	Value of the current element	Get current text element's value with `getCharacters()`
`SkippedEntity`	Reached skipped entity	Get current skipped entity element's value with `skippedEntity()`
`EndElement`	Ending of a node	Get current element's tagname with `getTagName()`
`EndDocument`	Ending of the document	Finish processing (release resources)

Example

```
DEFINE r om.XmlReader,
       e STRING
   ...
   LET e = r.read()
   WHILE e IS NOT NULL
     CASE e
       ...
     END CASE
     LET e = r.read()
   END WHILE
```

om.XmlReader.skippedEntity
Returns the name of an unresolved entity.

Syntax

```
skippedEntity()
  RETURNING result STRING
```

Usage

The `skippedEntity()` method returns the name of the unresolved entity, in the `SkippedEntity` event context.

The parser identifies well know character entities such as `&` / `&apos;` / `<` / `>` / `&quot;`, other character entities are treated as skipped entities and can be processed in the `SkippedEntity` event.

Example

```
DEFINE r om.XmlReader,
       e STRING
   ...
```

```
    LET e = r.read()
    WHILE e IS NOT NULL
      CASE e
        ...
        WHEN "SkippedEntity"
          DISPLAY "Entity:'",r.skippedEntity(),"'"
      ...
```

Examples

Example 1: Parsing an XML file

```
MAIN
   DEFINE i, l INTEGER
   DEFINE r om.XmlReader
   DEFINE e String
   DEFINE a om.SaxAttributes
   LET r = om.XmlReader.createFileReader("myfile.xml")
   LET l = 0
   LET e = r.read()
   WHILE e IS NOT NULL
     CASE e
       WHEN "StartDocument"
         DISPLAY "StartDocument:"
       WHEN "StartElement"
         LET l=l+1
         DISPLAY l SPACES, "StartElement:", r.getTagName()
         LET a = r.getAttributes()
         FOR i=1 to a.getLength()
           DISPLAY l SPACES,"  ",
             a.getName(i)," = ",
             a.getValueByIndex(i)
         END FOR
       WHEN "Characters"
         DISPLAY l SPACES, "  Characters:'",r.getCharacters(),"'"
       WHEN "EndElement"
         DISPLAY l SPACES, "EndElement:", r.getTagName()
         LET l=l-1
       WHEN "EndDocument"
         DISPLAY "EndDocument:"
       OTHERWISE
         DISPLAY "Invalid event: ",e
     END CASE
     LET e=r.read()
   END WHILE
END MAIN
```

The XmlWriter class

The `om.XmlWriter` class implements methods to write XML to a stream.

The `om.XmlWriter` class implements methods to create a `om.SaxDocumentHandler` object.

Steps to use a XML writer:

1. Declare a variable with the `om.SaxDocumentHandler` type.
2. Create the writer object with one of the class methods of `om.XmlWriter` and assign the reference to the variable.
   - `om.XmlWriter.createFileWriter(`*`filename`*`)` creates an object writing to a file.
   - `om.XmlWriter.createPipeWriter(`*`command`*`)` creates an object writing to a pipe opened by a sub-process.
   - `om.XmlWriter.createSocketWriter(`*`hostname`*`,`*`portnum`*`)` creates an object writing to the TCP socket.

3. Output XML data with the methods of the `om.SaxDocumentHandler` object:
   a. Use the method `startDocument()` to start writing to the output.
   b. From this point, the order of method calls defines the structure of the XML document. To write an element, fill an `om.SaxAttributes` object with attributes.
   c. Then, initiate the element output with the method `startElement()`.
   d. Write element data with the `characters()` method.
   e. Entity nodes are created with the `skippedEntity()` method.
   f. Finish element output with a call to the `endElement()` method.
   g. Repeat these steps as many times as you have elements to write.
   h. Instead of using the `startElement()` method, you can generate processing instruction elements with `processingInstruction()`.
   i. Finally, you must finish the document output with a `endDocument()` call.

om.XmlWriter methods
Methods of the `om.XmlWriter` class.

Table 413: Class methods

Name	Description
`om.XmlWriter.createChannelWriter( channel base.Channel ) RETURNING result om.SaxDocumentHandler`	Creates an `om.SaxDocumentHandler` object writing to a channel object.
`om.XmlWriter.createFileWriter( filename STRING ) RETURNING result om.SaxDocumentHandler`	Creates an `om.SaxDocumentHandler` object writing to a file.
`om.XmlWriter.createPipeWriter( command STRING ) RETURNING result om.SaxDocumentHandler`	Creates an `om.SaxDocumentHandler` object writing to a pipe created for a process.
`om.XmlWriter.createSocketWriter( host STRING, port INTEGER ) RETURNING result om.SaxDocumentHandler`	Creates an `om.SaxDocumentHandler` object writing to a socket.

om.XmlWriter.createChannelWriter
Creates an `om.SaxDocumentHandler` object writing to a channel object.

Syntax

```
om.XmlWriter.createChannelWriter(
   channel base.Channel )
  RETURNING result om.SaxDocumentHandler
```

1. *channel* is a `base.Channel` object reference.

Usage

The `om.XmlWriter.createChannelWriter()` class method creates an `om.SaxDocumentHandler` object that will write to the specified channel object, when using the `om.SaxDocumentHandler` methods.

The `base.Channel` object must exist and be open to receive data from the SAX document handler.

Example

The next example uses the channel to write to stdout, passing `NULL` as file name to the `base.Channel.openFile()` method:

```
DEFINE w om.SaxDocumentHandler
DEFINE ch base.Channel
...
LET ch = base.Channel.create()
CALL ch.openFile(NULL,"w")
LET w = om.XmlWriter.createChannelWriter(ch)
...
```

om.XmlWriter.createFileWriter
Creates an `om.SaxDocumentHandler` object writing to a file.

Syntax

```
om.XmlWriter.createFileWriter(
   filename STRING )
  RETURNING result om.SaxDocumentHandler
```

1. *filename* is the path to the file.

Usage

The `om.XmlWriter.createFileWriter()` class method creates an `om.SaxDocumentHandler` object that will write to the specified file when using the `om.SaxDocumentHandler` methods.

The file is created if it does not exist. If the file cannot be created, the method returns `NULL`.

When passing `NULL` as file name, the XmlWriter can be used to write to stdout.

Example

```
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createFileWriter("mydata.xml")
IF w IS NULL THEN
   ERROR "Could not create file."
   EXIT PROGRAM 1
END IF
...

-- Create an XmlWriter object to write to stdout:
LET w = om.XmlWriter.createFileWriter(NULL)
...
```

om.XmlWriter.createPipeWriter
Creates an `om.SaxDocumentHandler` object writing to a pipe created for a process.

Syntax

```
om.XmlWriter.createPipeWriter(
   command STRING )
  RETURNING result om.SaxDocumentHandler
```

1. *command* is the command to be executed.

Usage

The `om.XmlWriter.createPipeWriter()` class method creates an `om.SaxDocumentHandler` object that will write to a pipe created for the specified command. XML data will be send through the pipe when using the `om.SaxDocumentHandler` methods.

If the process or pipe cannot be created, the method returns `NULL`.

Example

```
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createPipeWriter("sort -u")
IF w IS NULL THEN
   ERROR "Could not create process."
   EXIT PROGRAM 1
END IF
```

om.XmlWriter.createSocketWriter
Creates an `om.SaxDocumentHandler` object writing to a socket.

Syntax

```
om.XmlWriter.createSocketWriter(
   host STRING,
   port INTEGER )
  RETURNING result om.SaxDocumentHandler
```

1. *host* is the name of the host computer listening to the TCP port.
2. *port* is the port number to connect to.

Usage

The `om.XmlWriter.createSocketWriter()` class method creates an `om.SaxDocumentHandler` object that will write to a socket identified by the host and port number passed as parameters. XML data will be send through the socket when using the `om.SaxDocumentHandler` methods.

If the socket cannot be opened, the method returns `NULL`. No timeout is used.

Example

```
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createSocketWriter("myhost",8012)
IF w IS NULL THEN
   ERROR "Could not open socket."
   EXIT PROGRAM 1
```

```
  END IF
```

Examples

Example 1: Writing XML to a file

```
MAIN
  DEFINE w om.SaxDocumentHandler
  DEFINE a,n om.SaxAttributes

  LET w = om.XmlWriter.createFileWriter("sample.html")
  LET a = om.SaxAttributes.create()
  LET n = om.SaxAttributes.create()

  CALL n.clear()

  CALL w.startDocument()

    CALL w.startElement("HTML",n)

      CALL w.startElement("HEAD",n)

        CALL w.startElement("TITLE",n)
        CALL w.characters("HTML page generated with XmlWriter")
        CALL w.endElement("TITLE")

        CALL a.clear()
        CALL a.addAttribute("type","text/css")
        CALL w.startElement("STYLE",a)
        CALL w.characters("\nBODY { background-color:#c0c0c0; }\n")
        CALL w.endElement("STYLE")

      CALL w.endElement("HEAD")

      CALL w.startElement("BODY",n)

        CALL addHLine(w)
        CALL addTitle(w,"What is XML?",1,"55ff55")
        CALL addParagraph(w,"XML = eXtensible Markup Language ...")

        CALL addHLine(w)
        CALL addTitle(w,"What is SAX?",1,"55ff55")
        CALL addParagraph(w,"SAX = Simple Api for XML ...")

      CALL w.endElement("BODY")

    CALL w.endElement("HTML")

  CALL w.endDocument()

END MAIN

FUNCTION addHLine(w)
  DEFINE w om.SaxDocumentHandler
  DEFINE a om.SaxAttributes
  LET a = om.SaxAttributes.create()
  CALL a.clear()
  CALL a.addAttribute("width","100%")
  CALL w.startElement("HR",a)
  CALL w.endElement("HR")
END FUNCTION

FUNCTION addTitle(w,t,x,c)
```

```
  DEFINE w om.SaxDocumentHandler
  DEFINE t VARCHAR(100)
  DEFINE x INTEGER DEFINE c VARCHAR(20)
  DEFINE a om.SaxAttributes
  DEFINE n varchar(10)
  LET a = om.SaxAttributes.create()
  LET n = "h" || x
  CALL a.clear()
  CALL w.startElement(n,a)
  IF c IS NOT NULL THEN CALL a.addAttribute("color",c)
  END IF CALL w.startElement("FONT",a)
  CALL w.characters(t)
  CALL w.endElement("FONT")
  CALL w.endElement(n)
END FUNCTION

FUNCTION addParagraph(w,t)
  DEFINE w om.SaxDocumentHandler
  DEFINE t VARCHAR(2000)
  DEFINE a om.SaxAttributes
  LET a = om.SaxAttributes.create()
  CALL a.clear()
  CALL w.startElement("P",a)
  CALL w.characters("Text is:")
  CALL w.skippedEntity("nbsp") # Add a non breaking space:  
  CALL w.characters("is")
  CALL w.characters(t)
  CALL w.endElement("P")
END FUNCTION
```

Built-in front calls

This section contains the description of all built-in front calls.

- Built-in front calls on page 1881
  - Standard front calls on page 1889
  - Webcomponent front calls on page 1902
  - Genero Desktop Client front calls on page 1904
  - Genero Application Server front calls on page 1924
  - Genero Mobile common front calls on page 1925
  - Genero Mobile Android front calls on page 1940
  - Genero Mobile iOS front calls on page 1945

Built-in front calls

Various front-end functions are implemented within Genero front-ends.

This section describes the front-end functions available for all type of front-ends. Note that several front-end functions are specific to the type of front-end.

Table 414: Standard front-end functions

Function Name	Description	GDC	GWC-JS	GMA	GMI
`ui.Interface.frontCall("standard", "cbAdd",`	Adds to the content of the clipboard.	Yes	No	No	No

Function Name	Description	GDC	GWC-JS	GMA	GMI
`[text], [result])`					
`ui.Interface.frontCall("standard", "cbClear", [], [result])`	Clears the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbGet", [], [text])`	Gets the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbPaste", [], [result])`	Pastes the content of the clipboard to the current field.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbSet", [text], [result])`	Set the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "execute", [cmd,wait], [result])`	Executes a command on the front-end platform, with or without waiting.	Yes	No	No	No
`ui.Interface.frontCall("standard", "feInfo", [name], [result])`	Queries general front-end properties.	Yes	Yes	Yes	Yes
`ui.Interface.frontCall("standard", "getEnv", [name], [value])`	Returns an environment variable set in the user session on the front end platform.	Yes	No	No	No
`ui.Interface.frontCall("standard", "getWindowId", [aui-win-id], [loc-win-id])`	Returns the local window manager identifier of the window corresponding to the AUI window id passed as parameter.	Yes	No	No	No
`ui.Interface.frontCall("standard", "hardCopy", [pgsize], [result])`	Prints a screen shot of the current window	Yes	No	No	No
`ui.Interface.frontCall("standard", "launchURL", [ url [, mode ] ], [] )`	Opens an URL with the default URL handler of the front-end.	Yes	Yes	Yes	Yes
`ui.Interface.frontCall("standard", "mdClose",`	Unloads a DLL or shared library front call module.	Yes	No	No	No

Function Name	Description	GDC	GWC-JS	GMA	GMI
[*name*], [*result*])					
ui.Interface.frontCall("standard", "openDir", [*path*,*caption*], [*result*])	Displays a file dialog window to get a directory path on the local file system.	Yes	No	No	No
ui.Interface.frontCall("standard", "openFile", [*path*,*name*,*wildcards*,*caption*], [*result*])	Displays a file dialog window to get a path to open a file on the local file system.	Yes	Yes	No	No
ui.Interface.frontCall("standard", "playSound", [*filename*], [])	Plays the sound file passed as parameter on the front-end platform.	Yes	Yes	Yes	Yes
ui.Interface.frontCall("standard", "saveFile", [*path*,*name*,*filetype*,*caption*], [*result*])	Displays a file dialog window to get a path to save a file on the local file system.	Yes	No	No	No
ui.Interface.frontCall("standard", "setReportFont", [*font*], [*result*])	Override the font used for report generation for the current application.	Yes	No	No	No
ui.Interface.frontCall("standard", "setReportPrinter", [*printer*], [*result*])	Override the printer configuration used for report generation for the current application.	Yes	No	No	No
ui.Interface.frontCall("standard", "setWebComponentPath", [*path*], [])	Defines the base path where web components are located.	Yes	N/A	Yes	Yes
ui.Interface.frontCall("standard", "shellExec", [*document*, *action*], [*result*])	Opens a file on the front-end platform with the program associated to the file extension.	Yes	No	No	No

Table 415: Webcomponent module front-end functions

Function Name	Description
ui.Interface.frontCall("webcomponent", "call", [*aui-name*, *function-name*, [*param1*, *param2*, ...]], [*result*]	Calls a JavaScript function through the web component.

Function Name	Description
)	
ui.Interface.frontCall("webcomponent", "frontCallAPIVersion", [],[*result*])	Returns the API version of web component front-end calls.
ui.Interface.frontCall("webcomponent", "getTitle", [*aui-name*], [*result*])	Returns the title of the HTML doc rendered by a web component.

Table 416: Windows DDE front-end functions

Function name	Description
CALL ui.Interface.frontCall("WINDDE","DDEConnect", [*program*, *document*, *encoding*], [*result*])	DDEConnect opens a DDE connection.
CALL ui.Interface.frontCall("WINDDE","DDEExecute", [*program*, *document*, *command*, *encoding*], [*result*])	DDEExecute executes a DDE command.
CALL ui.Interface.frontCall("WINDDE","DDEFinish", [*program*, *document*], [*result*])	DDEFinish closes a DDE connection.
CALL ui.Interface.frontCall("WINDDE","DDEFinishAll", [], [*result*])	DDEFinishAll closes all DDE connections.
CALL ui.Interface.frontCall("WINDDE","DDEError", [], [*errmsg*])	DDEError returns error information about the last DDE operation.
CALL ui.Interface.frontCall("WINDDE","DDEPeek", [*program*, *container*, *cells*, *encoding*], [*result*, *value*])	DDEPeek retrieves data from the specified program and document using the DDE channel.
CALL ui.Interface.frontCall("WINDDE","DDEPoke", [*program*, *container*, *cells*, *values*, *encoding*], [*result*])	DDEPoke sends data to the specified program and document using the DDE channel.

Table 417: Windows COM front-end functions

Function name	Description
`CALL ui.Interface.frontCall("WinCOM","CreateInstance", [ program ], [handle] )`	The `CreateInstance` function creates an instance of a registered COM object.
`CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method, arg1, ... ], [result] )` `CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method(arg1, ...) ], [result] )`	The `CallMethod` function calls a method on a specified object.
`CALL ui.Interface.frontCall("WINCOM","GetProperty", [ handle, member ], [result] )`	The `GetProperty` function gets a property of an object.
`CALL ui.Interface.frontCall("WINCOM","SetProperty", [handle, member, value], [result] )`	The `SetProperty` function sets a property of an object.
`CALL ui.Interface.frontCall("WINCOM","GetError", [], [result] )`	The `GetError` function gets a description of the last error which occurred.
`CALL ui.Interface.frontCall("WINCOM","ReleaseInstance", [handle], [result] )`	The `ReleaseInstance` function releases an instance of a COM object.

Table 418: WinMail front-end functions: General

Function name	Description
`CALL ui.Interface.frontCall("WinMail","Init", [], [id ] )`	The `Init` function initializes the module.
`CALL ui.Interface.frontCall("WinMail","Close", [id], [ result ] )`	The `Close` function clears all information corresponding to a message, and frees the memory occupied by the message.
`CALL ui.Interface.frontCall("WinMail","SetBody",`	The `SetBody` function sets the body of the mail.

Function name	Description
[*id*, *body*], [*result*])	
CALL ui.Interface.frontCall("WinMail","SetSubject", [*id*, *subject*], [*result*])	The SetSubject function sets the subject of the mail.
CALL ui.Interface.frontCall("WinMail","AddTo", [id, *name*, *address*], [*result*])	The AddTo function adds a "To" addressee to the mail.
CALL ui.Interface.frontCall("WinMail","AddCC", [id, *name*, *address*], [*result*])	The AddCC function adds a "CC" addressee to the mail.
CALL ui.Interface.frontCall("WinMail","AddBCC", [*id*, *name*, *address*], [*result*])	The AddBCC function adds a "BCC" addressee to the mail.
CALL ui.Interface.frontCall("WinMail","AddAttachment", [*id*, *fileName*], [*result*])	The AddAttachment function adds a file as an attachment to the mail.
CALL ui.Interface.frontCall("WinMail","SendMailSMTP", [*id*], [*result*])	The SendMailSMTP function sends the mail with the SMTP protocol.
CALL ui.Interface.frontCall("WinMail","SendMailMAPI", [*id*], [*result*])	The SendMailMAPI function sends the mail with the MAPI protocol.
CALL ui.Interface.frontCall("WinMail","GetError", [*id*], [*result*])	The GetError function gets a description of the last error that occurred.

Table 419: WinMail front-end functions: SMTP-specific

Function name	Description
CALL ui.Interface.frontCall("WinMail","SetSmtp", [*id*, *smtp:port*], [*result*])	The SetSmtp function sets the SMTP server to be used.
CALL ui.Interface.frontCall("WinMail","SetFrom",	The SetFrom function sets sender information.

Function name	Description
`[ id, name, address ], [ result ] )`	

Table 420: Session module front-end functions

Function name	Description
`ui.Interface.frontCall("session", "getVar", [name], [result])`	Returns the value of a session variable.
`ui.Interface.frontCall("session", "setVar", [name,value], [result])`	Sets a value of a session variable.

Table 421: Common mobile module front-end functions

Function Name	Description
`ui.Interface.frontCall("mobile", "chooseContact", [], [result])`	Lets the user choose a contact from the mobile device contact list and returns the vCard.
`ui.Interface.frontCall("mobile", "choosePhoto", [], [path])`	Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.
`ui.Interface.frontCall("mobile", "chooseVideo", [], [path])`	Lets the user select a video from the mobile device's video gallery and returns a video identifier.
`ui.Interface.frontCall("mobile", "composeMail", [to, subject, content, cc, bcc, attachments ...], [result])`	Invokes the user's default mail application for a new mail to send.
`ui.Interface.frontCall("mobile", "composeSMS", [ recipients, content ], [ result ] )`	Sends an SMS text to one or more phone numbers.
`ui.Interface.frontCall("mobile", "connectivity", [], [result] )`	Returns the type of network available for the mobile device.
`ui.Interface.frontCall("mobile", "getGeolocation", [], [status, latitude, longitude] )`	Returns the Global Positioning System (GPS) location of a mobile device.
`ui.Interface.frontCall("mobile","getRemoteNotifications",`	This front call retrieves push notification messages.

Function Name	Description
`[sender_id], [data] )`	
`ui.Interface.frontCall("mobile", "importContact", [vcard], [result] )`	Creates a new, or merges to an existing entry, the contact details passed in vCard string.
`ui.Interface.frontCall("mobile","registerForRemoteNotifications", [sender_id], [registration_token] )`	This front call registers a mobile device for push notifications.
`ui.Interface.frontCall("mobile", "runOnServer", [ appurl, timeout ], [] )`	Run an application from the Genero Application Server according to the specified URL.
`ui.Interface.frontCall("mobile", "scanBarCode", [], [code, type] )`	Allow the user to scan a barcode with a mobile device
`ui.Interface.frontCall("mobile", "takePhoto", [], [path] )`	Lets the user take a picture with the mobile device and returns the corresponding picture identifier.
`ui.Interface.frontCall("mobile", "takeVideo", [], [path])`	Lets the user take a video with the mobile device and returns the corresponding video identifier.
`ui.Interface.frontCall("mobile","unregisterFromRemoteNotifications", [ sender_id ], [] )`	This front call unregisters the mobile device from push notifications.

Table 422: Android module front-end functions

Function Name	Description
`ui.Interface.frontCall("android", "askForPermission", [permission], [result])`	Ask the user to enable a dangerous feature on the Android device.
`ui.Interface.frontCall("android", "showAbout", [],[])`	Shows the GMA about box displaying version information.
`ui.Interface.frontCall("android", "showSettings", [], [])`	Shows the GMA settings box controlling debug options.
`ui.Interface.frontCall("android", "startActivity", [action, data, category, type, component, extras],`	Starts an external Android application (activity), and returns to the GMA application immediately.

Function Name	Description
`[])`	
`ui.Interface.frontCall("android", "startActivityForResult", [action, data, category, type, component, extras], [outdata, outextras])`	Starts an external application (Android activity) and waits until the activity is closed.

Table 423: iOS module front-end functions

Function Name	Description
`ui.Interface.frontCall("ios", "getBadgeNumber", [],[value])`	Returns the current badge number associated to the app.
`ui.Interface.frontCall("ios", "newContact", [defaults],[vcard])`	Lets the user input contact information to create a new entry in the contact database of the mobile device.
`ui.Interface.frontCall("ios", "setBadgeNumber", [value], [])`	Sets the current badge number associated to the app.

Standard front calls

Standard front call functions provide common utility APIs to control the front-end.

This table shows the functions implemented by the front-ends in the "`standard`" module, available on all front-ends.

Table 424: Standard front-end functions

Function Name	Description	GDC	GWC-JS	GMA	GMI
`ui.Interface.frontCall("standard", "cbAdd", [text], [result])`	Adds to the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbClear", [], [result])`	Clears the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbGet", [], [text])`	Gets the content of the clipboard.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbPaste", [], [result])`	Pastes the content of the clipboard to the current field.	Yes	No	No	No
`ui.Interface.frontCall("standard", "cbSet",`	Set the content of the clipboard.	Yes	No	No	No

Function Name	Description	GDC	GWC-JS	GMA	GMI
`[text], [result])`					
`ui.Interface.frontCall("standard", "execute", [cmd,wait], [result])`	Executes a command on the front-end platform, with or without waiting.	Yes	No	No	No
`ui.Interface.frontCall("standard", "feInfo", [name], [result])`	Queries general front-end properties.	Yes	Yes	Yes	Yes
`ui.Interface.frontCall("standard", "getEnv", [name], [value])`	Returns an environment variable set in the user session on the front end platform.	Yes	No	No	No
`ui.Interface.frontCall("standard", "getWindowId", [aui-win-id], [loc-win-id])`	Returns the local window manager identifier of the window corresponding to the AUI window id passed as parameter.	Yes	No	No	No
`ui.Interface.frontCall("standard", "hardCopy", [pgsize], [result])`	Prints a screen shot of the current window	Yes	No	No	No
`ui.Interface.frontCall("standard", "launchURL", [ url [, mode ] ], [] )`	Opens an URL with the default URL handler of the front-end.	Yes	Yes	Yes	Yes
`ui.Interface.frontCall("standard", "mdClose", [name], [result])`	Unloads a DLL or shared library front call module.	Yes	No	No	No
`ui.Interface.frontCall("standard", "openDir", [path,caption], [result])`	Displays a file dialog window to get a directory path on the local file system.	Yes	No	No	No
`ui.Interface.frontCall("standard", "openFile", [path,name,wildcards,caption], [result])`	Displays a file dialog window to get a path to open a file on the local file system.	Yes	Yes	No	No
`ui.Interface.frontCall("standard", "playSound", [filename], [])`	Plays the sound file passed as parameter on the front-end platform.	Yes	Yes	Yes	Yes
`ui.Interface.frontCall("standard", "saveFile",`	Displays a file dialog window to get a path to save a file on the local file system.	Yes	No	No	No

Function Name	Description	GDC	GWC-JS	GMA	GMI
`[path,name,filetype,caption], [result])`					
`ui.Interface.frontCall("standard", "setReportFont", [font], [result])`	Override the font used for report generation for the current application.	Yes	No	No	No
`ui.Interface.frontCall("standard", "setReportPrinter", [printer], [result])`	Override the printer configuration used for report generation for the current application.	Yes	No	No	No
`ui.Interface.frontCall("standard", "setWebComponentPath", [path], [])`	Defines the base path where web components are located.	Yes	N/A	Yes	Yes
`ui.Interface.frontCall("standard", "shellExec", [document, action], [result])`	Opens a file on the front-end platform with the program associated to the file extension.	Yes	No	No	No

cbAdd
Adds to the content of the clipboard.

Syntax

```
ui.Interface.frontCall("standard", "cbAdd",
  [text], [result])
```

1. *text* - The text to be added.
2. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage

The "cbAdd" front call adds the text passed as parameter to the content of the clipboard of the front-end platform.

cbClear
Clears the content of the clipboard.

Syntax

```
ui.Interface.frontCall("standard", "cbClear",
  [], [result])
```

1. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage

The "cbClear" front call clears the content of the clipboard. This front call takes no input parameters.

cbGet
Gets the content of the clipboard.

Syntax

```
ui.Interface.frontCall("standard", "cbGet",
   [], [text])
```

1. *text* - Holds the text found in the clipboard.

Usage

The "cbGet" front call returns the current content of the clipboard.

This front call takes no input parameters.

cbPaste
Pastes the content of the clipboard to the current field.

Syntax

```
ui.Interface.frontCall("standard", "cbPaste",
   [], [result])
```

1. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage

The "cbPaste" front call pastes the content of the clipboard to the current field.

This front call takes no input parameters.

cbSet
Set the content of the clipboard.

Syntax

```
ui.Interface.frontCall("standard", "cbSet",
 [text], [result])
```

1. *text* - The text to be set.
2. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage

The "cbSet" front call sets the content of the clipboard with the text passed as parameter.

execute
Executes a command on the front-end platform, with or without waiting.

Syntax

```
ui.Interface.frontCall("standard", "execute",
 [cmd,wait], [result])
```

1. *cmd* - The command to be executed.
2. *wait* - The wait option (TRUE=wait, FALSE=do not wait).
3. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage

The "`execute`" front call runs a command on the front-end platform, with or without waiting option.

If the second parameter is set to 1 (`TRUE`), the runtime system will wait until the front-end gives the control back after the local command was executed.

feInfo
Queries general front-end properties.

Syntax

```
ui.Interface.frontCall("standard", "feInfo",
 [name], [result])
```

1. *name* - The name of the property.
2. *result* - Holds the value of the property.

Usage

The `feInfo` front call returns a front-end property value according to the property name passed in as the parameter.

Some feInfo options take an optional parameter, such as screenresolution:

```
CALL ui.Interface.frontCall("standard", "feInfo", ["screenResolution", 2],
 [resolution])
```

Table 425: Property names and descriptions for the standard.feInfo front call

feInfo property values

Property name	Description	GDC	GWC-JS	GMA	GMI
`dataDirectory`	Returns the directory name that can be used for temporary files on the front-end side. This directory is cleaned at front-end startup and end, and is common to all front-end instances, except GWC. The possible values returned are: • With Genero Web Client, this is not applicable. • With Genero Desktop Client, the local cache directory. For example, "`/home/username/.cache/Four Js/Genero Desktop`". • With Genero Mobile for Android™, this is the GMA application cache directory. Content may be erased, once the app is closed. • With Genero Mobile for iOS, this is the temporary directory in the application sandbox (iOS `NSTemporaryDirectory()` system call). Content may be erased, once the app is closed.	Yes	No	Yes	Yes
`dictionariesDirectory`	Returns the directory name where spell checking dictionary files are located. This parameter is only supported by GDC, for the `spellCheck` style attribute of TextEdit elements.	Yes	N/A	N/A	N/A

Property name	Description	GDC	GWC-JS	GMA	GMI
	A program can query the `dictionariesDirectory` info in order to send dictionary files to the GDC with an `fgl_putfile()` call.				
`deviceModel`	Returns the name of the device, e.g. "iPad4,5".	Yes	No	Yes	Yes
`deviceId`	• With Genero Mobile for iOS, returns the `identifierForVendor`. • With Genero Mobile for Android, returns this IMEI, otherwise the Android id (but may change after device reinstallation)	Yes	No	Yes	Yes
`feName`	The code identifying the type of front-end component. The possible values returned are: • "`Genero Desktop Client`" for Genero Desktop Client. • "`GBC`" for Genero Web Client - JavaScript (GWC-JS). • "`GWC` for Genero Web Client - HTML5 theme. • "`GMA`" for Genero Mobile for Android. • "`GMI`" for Genero Mobile for iOS.	Yes	Yes	Yes	Yes
`fePath`	The installation directory of the front-end executable. • With Genero Desktop Client, it returns the path to the installation directory of the GDC. • When Genero Web Client, it returns the path to the installation directory of the GAS. • With Genero Mobile for Android, it returns the installation directory. For example, "`/data/data/com.fourjs.gma/fgl`". • With Genero Mobile for iOS, it returns the installation directory. For example: "`/private/var/mobile/Applications/B3E6-C48A-ED4EFA`". Below the installation directory are the "`Documents`" (which is by default pwd), "`GMI.app`" (deployed p-code resides in `GMI.app/app/`) and "`tmp`" directories. **Important:** The installation path returned by this front call may change in future versions, do not based application code on this. On mobile devices, consider using the os.Path.pwd on page 2004 utility function to get the application working directory when executing programs.	Yes	No	Yes	Yes
`freeStorageSpace`	Returns the number of bytes available on the device.	Yes	No	Yes	Yes

Property name	Description	GDC	GWC-JS	GMA	GMI
`iccid`	• With Genero Mobile for iOS, returns an error (not allowed). • With Genero Mobile for Android, returns the ICCID if available, otherwise raise an error.	N/A	N/A	Yes	Yes
`imei`	• With Genero Mobile for iOS, returns an error (not allowed). • With Genero Mobile for Android, returns the IMEI if available, otherwise raises an error.	N/A	N/A	Yes	Yes
`ip`	Returns the IP address of the network interface used for the GUI connection. For mobile platforms, this is the preferred IP address of the device: if there is WIFI, either the IPv4 address is given back (for example: `192.168.0.12`) or if there is no IPv4 address, the IPv6 address is given back (for example: `2a02:810a:82c0:478:d462:e334:6a1d:fb78`). If there is no WIFI, either the cellular IPv4 or IPv6 address is given back. If there is no network, `NULL` is returned.	Yes	No	Yes	Yes
`isActiveX`	Returns "`1`" if the front-end runs in Active X mode (GDC specific). For Genero Mobile clients, the return value will always be "`0`"	Yes	No	Yes	Yes
`numScreens`	Number of screens available on the front-end platform. On typical front-end platforms and devices, the number of screens is 1. In some rare cases, a desktop computer can be configured with more than one screen.	Yes	No	No	No
`osType`	The operating system type where the front-end is running. Possible return values include "`WINDOWS`", "`LINUX`", "`OSX`", "`ANDROID`", "`IOS`".	Yes	Yes	Yes	Yes
`osVersion`	The version of the operating system. Example of returned values: "`4.3`", "`5.10.15`".	Yes	No	Yes	Yes
`outputMap`	Returns the GWC application output map of the current application. This option is only supported with a GAS >= 2.22.00. Example of returned value: "`DUA_HTML5`", ...	No	No	No	No
`ppi`	Returns the screen pixel density of the front-end platform (Pixels Per Inch). This front call takes an	Yes	No	Yes	Yes

Property name	Description	GDC	GWC-JS	GMA	GMI
	optional screen number as parameter (1 is the default). • With Genero Mobile for iOS, returns the `PixelsPerInch` of a iOS device. • With Genero Mobile for Android, returns the DPI (ppi == dpi)				
`screenResolution`	Returns the screen resolution of the front-end platform. This front call takes an optional screen number as parameter (1 is the default). Example of returned values: "`1200x1824`", "`1920x1104`". **Note:** For mobile devices, the value can change depending on the device orientation.	Yes	Yes	Yes	Yes
`target`	Returns the build platform target code name, identifying the operating system the front-end binary was compiled. This front call is provided for debugging purpose, do not base code on the returned value, it can change if the target OS version is upgraded for example. Use the `ostype` property instead. Example of returned values: • "`w32v100`" = Windows 32 bits, Visual C++ 10. • "`w64v110`" = Windows 64 bits, Visual C++ 11. • "`d32a040`" = Android 4.0 ARM 32 bits. • "`d32x040`" = Android 4.0 x86 32 bits. • "`i32a070`" = iOS 7.0 ARM 32 bits. • "`i32x070`" = iOS 7.0 x86 32 bits. **Note:** For GWC-JS, will return the same value as osType.	Yes	Yes	Yes	Yes
`windowSize`	Returns the current size of the front-end view-port. • For mobile front-ends, this is the size of the mobile screen. • For Genero Desktop Client, this is the size of the current window. • For Genero Web Client, this is the size of the browser webview. Example of returned values: "`1200x1824`", "`1920x1104`".	Yes	Yes	Yes	Yes

getEnv
Returns an environment variable set in the user session on the front end platform.

Syntax

```
ui.Interface.frontCall("standard", "getEnv",
 [name], [value])
```

1. *name* - The name of the environment variable.
2. *value* - Holds the value of the environment variable.

Usage

The "`getEnv`" front call returns an environment variable set in the user session on the front-end platform.

getWindowId
Returns the local window manager identifier of the window corresponding to the AUI window id passed as parameter.

Syntax

```
ui.Interface.frontCall("standard", "getWindowId",
 [aui-win-id], [loc-win-id])
```

1. *aui-win-id* - The id of the window node in the AUI tree.
2. *loc-win-id* - The id of the window in the window manager where the front-end is running.

Usage

Returns the local identifier that corresponds to the AUI window id passed as parameter, in the window manager where the front-end is displaying the application forms.

The node id must reference a `Window` node, otherwise "0" is returned ; in traditional mode, window widgets are simple frames ; Use "0" as `aui-win-id` parameter to get the top level window id in the local windowing system.

hardCopy
Prints a screen shot of the current window

Syntax

```
ui.Interface.frontCall("standard", "hardCopy",
 [pgsize], [result])
```

1. *pgsize* - Pass "1" to adapt the screen shot to the page size.
2. *result* - Holds the execution result (`TRUE`=success, `FALSE`=error).

Usage

The "`hardCopy`" front call allows you to print a screen shot of the current window.

The *pgsize* parameter is optional; Either leave out, or enter "1" to indicate that the screen shot must be adapted to the page size.

launchURL
Opens an URL with the default URL handler of the front-end.

Syntax

```
ui.Interface.frontCall("standard", "launchURL",
  [ url [, mode ] ], [] )
```

1. *url* - The URL to invoke.
2. *mode* (optional) - front-end specific meaning (see below).

Usage (General)

The "launchURL" front call opens an URL with the default URL handler available on the front-end platform; This is typically the web browser for "HTTP:" URLs, or the mailer for "mailto:" URLs, but the corresponding application may also be dedicated to the type of object specified by the URL (for example, a mapping service or to initiate a phone call).

This front call is a powerful feature: Front-end applications can register themselves as URL handlers, so you can start applications on the front-end through the lauchurl front call.

Supported schemes depend on your system configuration.

> **Important:** Some type of URLs are not supported by all front-end platforms. Make sure that you test all target front-ends when using a lauchurl front call.

The *mode* parameter is optional and is interpreted differently according to the front-end type:

- With Genero Web Client (GWC), use "replace" for the *mode* parameter, if you want the current application in the browser window or tab to be replaced with the new URL, instead of launching a new browser window or tab. If it is not present, or if a value other than "replace" is specified, the Genero Web Client behaves like the Genero Desktop Client, opening the URL in a new browser window.
- With Genero Mobile and Genero Desktop Client (GDC) front-ends, the *mode* parameter is ignored if specified.

Example

To invoke Google Play Store:

```
CALL ui.Interface.frontCall("standard", "launchURL",
 ["market://details?id=com.google.android.apps.currents"], [])
```

```
CALL ui.Interface.frontCall("standard", "launchURL",
 ["market://details?id=com.google.zxing.client.android"], [])
```

To open Google Maps:

```
CALL ui.Interface.frontCall("standard", "launchURL",
 ["geo:48.613363,7.711083?z=17"], [])
```

To open Google Street View:

```
CALL ui.Interface.frontCall("standard", "launchURL",
 ["google.streetview:cbll=48.613363,7.711083&cbp=1,0,,0,1.0&mz=17"],
 [])
```

To initiate a phone call:

```
CALL ui.Interface.frontCall("standard", "launchURL", ["tel:
+336717623"], [])
```

mdClose
Unloads a DLL or shared library front call module.

Syntax

```
ui.Interface.frontCall("standard", "mdClose",
 [name], [result])
```

1. *name* - The name of the module to be closed.
2. *result* - Holds the result (0 = success, -1 = module not found, -2 = cannot unload (busy)).

Usage
Front call modules are loaded on demand. After calling a function of a specific module, you can use the "`mdClose`" front call to unload the shared library and save resources.

openDir
Displays a file dialog window to get a directory path on the local file system.

Syntax

```
ui.Interface.frontCall("standard", "openDir",
 [path,caption], [result])
```

1. *path* - The default path.
2. *caption* - The caption to be displayed.
3. *result* - Holds the name of the selected directory (or `NULL` if canceled).

Usage
When invoking the "`openDir`" front call, the front-end displays the typical file dialog window on the local file system, to let the end user enter a directory path.

If the user cancels the dialog, the front call returns `NULL` in the result variable.

openFile
Displays a file dialog window to get a path to open a file on the local file system.

Syntax

```
ui.Interface.frontCall("standard", "openFile",
 [path,name,wildcards,caption],
 [result])
```

1. *path* - The default path.
2. *name* - The name to be displayed for the file type.
3. *wildcards* - A blank separated list of wildcards (for ex: "*.pdf" or "README* test*.txt")
4. *caption* - The caption to be displayed.
5. *result* - Holds the name of the selected file (or `NULL` if canceled).

Usage

When invoking the "`openFile`" front call, the front-end displays a file dialog window using the local file system, to let the end user enter a file path, to select an existing file.

If the user cancels the dialog, the front call returns `NULL` in the result variable.

> **Note:** With the GWS-JS front-end, the *path* parameter is ignored, and *wildcards* can only be hold one type of file extension.

playSound
Plays the sound file passed as parameter on the front-end platform.

Syntax

```
ui.Interface.frontCall("standard", "playSound",
  [filename], [])
```

1. *filename* - The sound file to play.

Usage

The "`playSound`" front call opens the sound file passed as parameter and plays the sound on the front-end.

If the file is not located on the front-end, it will automatically be transfered to the front-end through the file-transfer facility.

Supported sound file format depends on the front-end infastructure (platform, technology, web browser, ...)

Example

```
CALL ui.Interface.frontCall("standard", "playSound",
    ["/opt/var/sounds/beep.mp3"], [])
```

saveFile
Displays a file dialog window to get a path to save a file on the local file system.

Syntax

```
ui.Interface.frontCall("standard", "saveFile",
  [path,name,filetype,caption],
  [result])
```

1. *path* - The default path.
2. *name* - The name to be displayed for the file type.
3. *filetype* - The file types (as a blank separated list of extensions).
4. *caption* - The caption to be displayed.
5. *result* - Holds the name of the selected file (or `NULL` if canceled).

Usage
When invoking the "`saveFile`" front call, the front-end displays the typical file dialog window on the local file system, to let the end user enter a file path, to save data to a new file.

If the user cancels the dialog, the front call returns `NULL` in the result variable.

setReportFont
Override the font used for report generation for the current application.

Syntax

```
ui.Interface.frontCall("standard", "setReportFont",
  [font], [result])
```

1. *font* - A string describing the font to use for report generation (see Usage for details).
2. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage
The "setReportFont" front call allows you to override the font used for report generation for the current application. You can simply copy/paste the font string from the "Report To Printer" font panel from GDC Monitor. An empty or null string reset to the default behavior.

The *font* parameter is a string that describe the font to use for report generation. For example: "Helvetica, Bold, Italic, 13". Alternatively, you can specify "<ASK_ONCE>" , "<ASK_ALWAYS>" , "<USER_DEFINED>" or "<USE_DEFAULT>" " which will perform the corresponding actions.

setReportPrinter
Override the printer configuration used for report generation for the current application.

Syntax

```
ui.Interface.frontCall("standard", "setReportPrinter",
  [printer], [result])
```

1. *printer* - A string describing the printer to use for report generation (see Usage for details).
2. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage
The "setReportPrinter" front call allows you to override the printer configuration used for report generation for the current application. You can simply copy/paste the printer string from the "Report To Printer" printer panel from GDC Monitor. An empty or null string reset to the default behavior.

The *printer* parameter is a string that describe the printer to use for report generation. For example: "moliere, Portrait, A4, 96 dpi, 1 copy, Ascendent, Color, Auto". Alternatively, you can specify "<ASK_ONCE>" , "<ASK_ALWAYS>" , "<USER_DEFINED>" or "<USE_DEFAULT>" " which will perform the corresponding actions.

setWebComponentPath
Defines the base path where web components are located.

Syntax

```
ui.Interface.frontCall("standard", "setWebComponentPath",
  [path], [])
```

1. *path* - The base url. For example, "http://myserver/components" or "file:///c:/components".

Usage

This front call defines the base path to find gICAPI web components files.

For the Genero Desktop Client, it defines the base path where web components are located, when GDC is directly connected to the runtime system. This is ignored when GDC is connected to the GAS.

For Genero Mobile, it sets the main web component lookup path. An URI is expected. For example, "file:///data/data/com.fourjs.gma/cache/appdata/mywebcomponents"or "http://mygas/mywebcomponents/".

shellExec
Opens a file on the front-end platform with the program associated to the file extension.

Syntax

```
ui.Interface.frontCall("standard", "shellExec",
  [document, action], [result])
```

1. *document* - The document file to be opened.
2. *action* - (optional, Windows™ Only!) The action to perform, related to the way the file type is registered in Windows™ Registry.
3. *result* - Holds the execution result (TRUE=success, FALSE=error).

Usage
The "shellExec" front call opens a file on the front-end platform with the program associated to the file extension.

This front call is mainly designed for the Genero Desktop Client on Windows™ platforms.

> **Important:** Under X11 Systems, this uses xdg-open, which needs to be installed and configured on your system. Kfmclient will be used as a workaround when xdg-open is not available.
>
> **Tip:** In order to view a document (like a PDF for example), if that document can be displayed by web browsers, use the launchURL on page 1898 front call instead, especially if you want to use both the Genero Desktop Client (GDC) and the Genero Web Client (GWC) front-ends.

Webcomponent front calls
This section describes Webcomponent specific front calls.

This table shows the functions provided by the "webcomponent" module on the front-ends supporting web components.

Table 426: Webcomponent module front-end functions

Function Name	Description
`ui.Interface.frontCall("webcomponent", "call", [aui-name, function-name, [ param1, param2, ... ] ], [result] )`	Calls a JavaScript function through the web component.
`ui.Interface.frontCall("webcomponent", "frontCallAPIVersion", [],[result])`	Returns the API version of web component front-end calls.
`ui.Interface.frontCall("webcomponent", "getTitle", [aui-name], [result] )`	Returns the title of the HTML doc rendered by a web component.

call
Calls a JavaScript function through the web component.

Syntax

```
ui.Interface.frontCall("webcomponent", "call",
```

```
  [aui-name, function-name, [ param1, param2, ... ] ],
  [result]
)
```

1. *aui-name* - This is the name of the web component name in the AUI tree.
2. *function-name* - This is the name of the web component JavaScript function to be called.
3. *param1*, *param2*, ... - Optional parameters to be passed to the web component JavaScript function.
4. *result* - Holds the JavaScript function return value.

Usage

Calls a JavaScript function through the web component. The JavaScript function must be implemented in the HTML content pointed by the URL-based web component, or in the user-defined JavaScript of a gICAPI-based web component.

The *aui-name* and *function-name* arguments are mandatory.

The arguments following the *function-name* argument will be passed to the JavaScript function.

That the *result* variable will contain the value returned by the JavaScript function.

Example

```
DEFINE result STRING
CALL ui.Interface.frontCall("webcomponent","call",
        ["formonly.data","echoString","abcdef"],[result])
```

For a complete example, see Example 2: Calling a JavaScript function of a gICAPI web component on page 1432.

frontCallAPIVersion
Returns the API version of web component front-end calls.

Syntax

```
ui.Interface.frontCall("webcomponent", "frontCallAPIVersion",
  [],[result])
```

1. *result* - Holds the API version for web component front calls.

Usage

This front call can be used to check the API version for the web component front calls.

If the API version changes, you must adapt the code to the expected front call API implemented for the web components.

The value returned by this front call is a typicaly version number such as `1.0`, `1.1`, etc.

Example

```
FUNCTION wc_api_version()
    DEFINE vers STRING
    TRY
       CALL
 ui.Interface.frontCall("webcomponent","frontCallAPIVersion",[],
[vers])
       -- we can safely call "webcomponent" "call" in the code
       RETURN vers
    CATCH
       -- we can't call the "webcomponent" functions...
```

```
        RETURN 0
    END TRY
END FUNCTION
```

getTitle
Returns the title of the HTML doc rendered by a web component.

Syntax

```
ui.Interface.frontCall("webcomponent", "getTitle",
  [aui-name], [result] )
```

1. *aui-name* - This is the name of the web component name in the AUI tree.
2. *result* - Holds the title of of the HTML document.

Usage

This front call can be used to get the title of the HTML document that is rendered by the web component identified by the *aui-name*. For more details refer to http://www.w3schools.com/tags/tag_title.asp.

A typical usage of this front call is when implementing a web component based on the O-Auth mechanism to identify the current user: For example, with the Google accounts authentication service, after the login and password were validated by Google, the authentication token will be returned in the title of the HTML document. This token is typically used by the application to identify the user in distant API calls.

Genero Desktop Client front calls
This section describes GDC specific front calls.

The GDC front-end implements the following front call modules:

- Windows DDE Support on page 1904
- Windows COM Support on page 1910
- Windows Mail extension on page 1917

> **Important:** These front call modules are only available on Windows™ platforms.

Windows™ DDE Support
Description of Windows™ DDE support.

> **Important:** The Win DDE front call library is deprecated.

Dynamic Data Exchange (DDE) is a form of inter-process communication implemented by Microsoft™ for Windows™ platforms. DDE uses shared memory to exchange data between applications. Applications can use DDE for one-time data transfers and for ongoing exchanges in applications that send updates to one another as new data becomes available.

Please refer to your Microsoft™ documentation for DDE compatibility between existing versions. As an example, DDE commands were changed between Office 97 and Office 98.

We provide a DDE interface as a Front-End Extension: WinDDE.DLL

- Using the WinDDE API on page 1905
- The DDE API function list on page 1905
- WinDDE example on page 1909

Using the WinDDE API

With WinDDE Support, you can invoke a Windows™ application and send or receive data to or from it. To use this functionality, the program must use the Windows™ Front End.

Before using the DDE functions, the TCP communication channel between the application and the front end must be established with a display (OPEN WINDOW, MENU, DISPLAY TO).

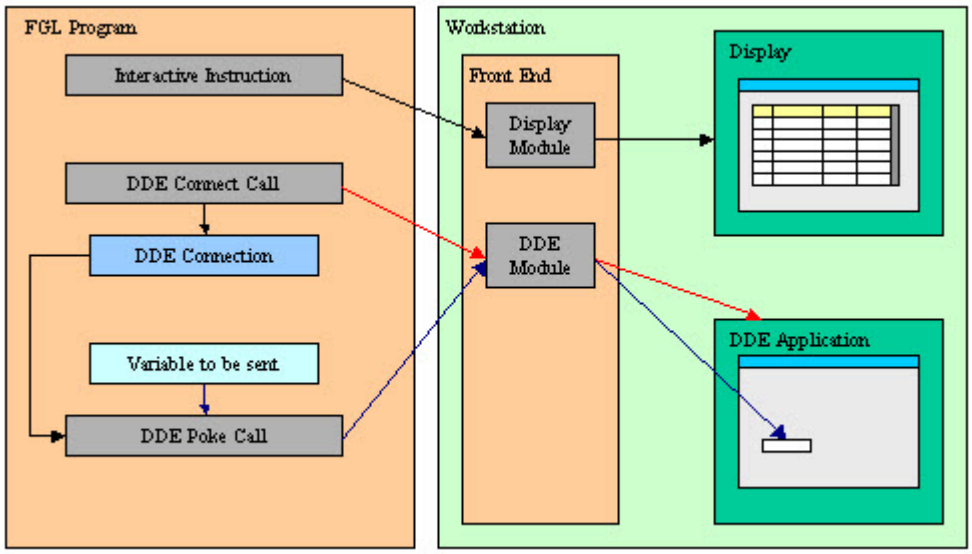

Figure 103: The four-part procedure of the DDE API

The DDE API is used in a four-part procedure, as described in the following steps:

1. The application sends to the Front End the DDE order using the TCP/IP channel.
2. The Front End executes the DDE order and sends the data to the Windows™ application through the DDE API.
3. The Windows™ application executes the command and sends the result, which can be data or an error code, to the Front End.
4. The Windows™ Front End sends back the result to the application using the TCP/IP channel.

A DDE connection is uniquely identified by two values: The name of the DDE Application and the document. Most DDE functions require these two values to identify the DDE source or target.

The DDE API function list

The DDE API is based on the front call technique.

The DDE API is based on the front call technology. All DDE functions are grouped in the **WINDDE** front end function module.

Table 427: Windows DDE front-end functions

Function name	Description
`CALL ui.Interface.frontCall("WINDDE","DDEConnect", [ program, document, encoding ], [result] )`	`DDEConnect` opens a DDE connection.
`CALL ui.Interface.frontCall("WINDDE","DDEExecute",`	`DDEExecute` executes a DDE command.

Function name	Description
`[ program, document, command, encoding ], [result] )`	
`CALL ui.Interface.frontCall("WINDDE","DDEFinish", [ program, document ], [result] )`	`DDEFinish` closes a DDE connection.
`CALL ui.Interface.frontCall("WINDDE","DDEFinishAll", [], [result] )`	`DDEFinishAll` closes all DDE connections.
`CALL ui.Interface.frontCall("WINDDE","DDEError", [], [errmsg] )`	`DDEError` returns error information about the last DDE operation.
`CALL ui.Interface.frontCall("WINDDE","DDEPeek", [ program, container, cells, encoding ], [ result, value ] )`	`DDEPeek` retrieves data from the specified program and document using the DDE channel.
`CALL ui.Interface.frontCall("WINDDE","DDEPoke", [ program, container, cells, values, encoding ], [result] )`	`DDEPoke` sends data to the specified program and document using the DDE channel.

DDEConnect

`DDEConnect` opens a DDE connection.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEConnect",
 [ program, document, encoding ], [result] )
```

- *program* is the name of the DDE application.
- *document* is the document that is to be opened.
- *encoding* is an optional parameter. It allows to force the encoding to use between ASCII and wide char/ unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are:
  - UNICODE
  - ASCII
- *result* is an integer variable receiving the status.
- *result* is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use `DDEError` to get the description of the error.

Warnings

- If the function failed with DMLERR_NO_CONV_ESTABLISHED, then the DDE application was probably not running. Use the execute or shellexec front call to start the DDE application.
- In Microsoft™ Office 2010, the use of DDE is disabled by default. You need to uncheck **Ignore other applications that use Dynamic Data Exchange(DDE)** in advanced options, otherwise DDEConnect will fail.

DDEExecute

`DDEExecute` executes a DDE command.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEExecute",
  [ program, document, command, encoding ], [result] )
```

- *program* is the name of the DDE application.
- *document* is the document that is to be used.
- *command* is the command that needs to be executed.
- *encoding* is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- Refer to the *program* documentation to know the syntax of *command*.
- *result* is an integer variable receiving the status.
- *result* is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use DDEError to get the description of the error.

Warnings

- The DDE connection must be opened see DDEConnect.

DDEFinish

`DDEFinish` closes a DDE connection.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEFinish",
  [ program, document ], [result] )
```

- *program* is the name of the DDE application.
- *document* is the document that is to be closed.
- *result* is an integer variable receiving the status.
- *result* is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use `DDEError` to get the description of the error.

Warnings

- The DDE connection must be opened, see `DDEConnect`.

DDEFinishAll

`DDEFinishAll` closes all DDE connections.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEFinishAll",
  [], [result] )
```

- *result* is TRUE if the function succeeded, FALSE otherwise.

Usage

This function closes all DDE connections, as well as the DDE server program.

DDEError

`DDEError` returns error information about the last DDE operation.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEError",
  [], [errmsg] )
```

- *errmsg* is the error message. It is set to NULL if no error occurred.

DDEPeek

`DDEPeek` retrieves data from the specified program and document using the DDE channel.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEPeek",
  [ program, container, cells, encoding ], [ result, value ] )
```

- *program* is the name of the DDE application.
- *container* is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
- *cells* represents the working items; see the *program* documentation to know the format of *cells*.
- *encoding* is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- *value* represents the data to be retrieved; see the *program* documentation to know the format of*values*.
- *result* is an integer variable receiving the status.
- *result* is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use `DDEError` to get the description of the error.
- *value* is a variable receiving the cells values.

Warnings

- The DDE connection must be opened; see `DDEConnect`.
- `DDEError` can only be called once to check if an error occurred.

DDEPoke

`DDEPoke` sends data to the specified program and document using the DDE channel.

Syntax

```
CALL ui.Interface.frontCall("WINDDE","DDEPoke",
  [ program, container, cells, values, encoding ], [result] )
```

- *program* is the name of the DDE application.
- *container* is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
- *cells* represents the working items; see the *program* documentation to know the format of *cells*.
- *values* represents the data to be sent; see the *program* documentation to know the format of *values*.

- *encoding* is an optional parameter. It allows to force the encoding to use between ASCII and wide char/ unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- *result* is an integer variable receiving the status.
- *result* is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use `DDEError` to get the description of the error.

Warnings

- The DDE connection must be opened; see `DDEConnect`.
- An error may occur if you try to set many (thousands of) cells in a single operation.

WinDDE example
This section provides a WinDDE example.

`dde_example.per`

```
DATABASE formonly
SCREEN
{
Value to be given to top-left corner :

```

Windows™ COM Support
"COM" stands for Component Object Model. It allows anyone to directly access Windows™ Applications Objects. You can create instances of those objects, call methods on them, and get or set their properties.

Important: The WinCOM front call library is deprecated.

- Using the WinCOM API on page 1910
- The WinCOM API function list on page 1910
- WinCOM examples on page 1913

Using the WinCOM API
With WinCOM Support, you can invoke a Windows™ application and send or receive data to or from it.

To use this functionality, the program must use the Windows™ Front End.

The WinCOM API function list
The WinCOM API is based on the front call technique as described in Front End Functions. All WinCOM functions are grouped in the WinCOM front end function module.

Table 428: Windows COM front-end functions

Function name	Description
`CALL ui.Interface.frontCall("WinCOM","CreateInstance", [ program ], [handle] )`	The `CreateInstance` function creates an instance of a registered COM object.
`CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method, arg1, ... ], [result] )` `CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method(arg1, ...) ], [result] )`	The `CallMethod` function calls a method on a specified object.
`CALL ui.Interface.frontCall("WINCOM","GetProperty", [ handle, member ], [result] )`	The `GetProperty` function gets a property of an object.
`CALL ui.Interface.frontCall("WINCOM","SetProperty",`	The `SetProperty` function sets a property of an object.

Function name	Description
[*handle*, *member*, *value*], [*result*])	
CALL ui.Interface.frontCall("WINCOM","GetError", [], [*result*])	The GetError function gets a description of the last error which occurred.
CALL ui.Interface.frontCall("WINCOM","ReleaseInstance", [*handle*], [*result*])	The ReleaseInstance function releases an instance of a COM object.

Supported syntax

COM language syntax is very flexible and allows lots of notation. Genero WinCOM API is slightly more strict:

- := notation **is allowed** in version 2.00.1e (or later) **only**; for instance: `myFunction(SourceType:=3)`
- "no parenthesis" notation **is not allowed**; for instance: `myFunction 3` must be written`myFunction(3)`
- numeric constants **are allowed** in version 2.00.1e (or later) **only**. The constant list depends on the application used via WinCOM, therefore the list is configurable: a file named etc/WinCOM.cst gathers all the constants provided today by Microsoft™ for Office XP. It can be modified to add user-defined constants. Example with Word: `CALL ui.Interface.frontCall("WINCOM","SetProperty", [wdapp,"Selection.Font.Bold","9999998"],[wddoc])` Here, "9999998" stands for the constant **wdToggle** (see etc/WinCOM.cst).
- There is no way to handle an array as a method argument. This is also due to BDL limitation: you can't pass BDL Arrays to frontcalls.

CreateInstance

The `CreateInstance` function creates an instance of a registered COM object.

Syntax

```
CALL ui.Interface.frontCall("WinCOM","CreateInstance",
  [ program ], [handle] )
```

- *program* is the classname of the registered COM object.
- *handle* is an integer variable receiving the status.
- *handle* is -1 if there as an error, otherwise an integer value that can be used for a later call to the API.
- If the function failed, use `GetError` to get the description of the error.

CallMethod

The `CallMethod` function calls a method on a specified object.

Syntax

```
CALL ui.Interface.frontCall("WINCOM","CallMethod",
  [ handle, method, arg1, ... ], [result] )
```

OR

```
CALL ui.Interface.frontCall("WINCOM","CallMethod",
  [ handle, method(arg1, ...) ], [result] )
```

- *handle* is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).
- *method* is the member name to call.
- *arg1 (and ...)* are the arguments to pass to the method call. Depending on the syntax allowed by the version of the program you're interacting with, arguments might be used inside brackets or outside. The best way for Microsoft™ applications (such as Excel or Word) is to initially test your code with a macro of the manipulation you're expecting to do. According to the method which is used, arguments may or may not be optional.
- *result* is either a handle or a value of a predefined type.
- *result* is -1 in case of error (use `GetError` to get the description of the error).

GetProperty

The `GetProperty` function gets a property of an object.

Syntax

```
CALL ui.Interface.frontCall("WINCOM","GetProperty",
  [ handle, member ], [result] )
```

- *handle* is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).
- *member* is the member property name to get.
- *result* is either a handle or a value of a predefined type.
- *result* is -1 in case of error (use `GetError` to get the description of the error).

SetProperty

The `SetProperty` function sets a property of an object.

Syntax

```
CALL ui.Interface.frontCall("WINCOM","SetProperty",
  [handle, member, value], [result] )
```

- *handle* is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).
- *member* is the member property name to set.
- *value* is the value to which the property will be set.
- *result* is -1 in case of error (use `GetError` to get the description of the error), otherwise it is 0.

GetError

The `GetError` function gets a description of the last error which occurred.

Syntax

```
CALL ui.Interface.frontCall("WINCOM","GetError",
  [], [result] )
```

- *result* is the description of the last error.
- the returned value is NULL if there was no error.

ReleaseInstance

The `ReleaseInstance` function releases an Instance of a COM object.

Syntax

```
CALL ui.Interface.frontCall("WINCOM","ReleaseInstance",
  [handle], [result] )
```

- *handle* is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).

- *result* is -1 in case of error (use `GetError` to get the description of the error), otherwise it is 0.

WinCOM examples
Various WinCOM examples.

- Wincom and Excel example on page 1913
- Wincom and Word example on page 1914
- Wincom and Outlook example on page 1915
- Wincom and Internet Explorer example on page 1916

Wincom and Excel example

This section provides a Wincom and Excel example.

This example puts "foo" in the first row of the 1st column of an Excel Sheet.

```
DEFINE xlapp INTEGER
DEFINE xlwb INTEGER
MAIN
  DEFINE result INTEGER
  DEFINE str STRING
--initialization of global variables
  LET xlapp = -1
  LET xlwb = -1
--first, we must create an Instance of an Excel Application
  CALL ui.Interface.frontCall("WinCOM", "CreateInstance",
  ["Excel.Application"], [xlapp])
  CALL CheckError(xlapp, __LINE__)
--then adding a Workbook to the current document
  CALL ui.interface.frontCall("WinCOM", "CallMethod",
  [xlapp, "WorkBooks.Add"], [xlwb])
  CALL CheckError(xlwb, __LINE__)
--then, setting it to be visible
  CALL ui.interface.frontCall("WinCOM", "SetProperty",
  [xlapp, "Visible", true], [result])
  CALL CheckError(result, __LINE__)
--then CALL SetProperty to set the value of the cell
  CALL ui.Interface.frontCall("WinCOM", "SetProperty",
  [xlwb, 'activesheet.Range("A1").Value', "foo"],[result])
  CALL CheckError(result, __LINE__)
--then CALL GetProperty to check the value again
  CALL ui.Interface.frontCall("WinCOM", "GetProperty",
  [xlwb, 'activesheet.Range("A1").Value'], [str])
  CALL CheckError(str, __LINE__)
  DISPLAY "content of the cell is: " || str

 --then Free the memory on the client side
  CALL freeMemory()
END MAIN

FUNCTION freeMemory()
 DEFINE res INTEGER
  IF xlwb != -1 THEN
    CALL ui.Interface.frontCall("WinCOM","ReleaseInstance", [xlwb], [res] )
  END IF
  IF xlapp != -1 THEN
    CALL ui.Interface.frontCall("WinCOM","ReleaseInstance", [xlapp], [res] )
  END IF
END FUNCTION

FUNCTION checkError(res, lin)
  DEFINE res INTEGER
  DEFINE lin INTEGER
  DEFINE mess STRING
```

```
  IF res = -1 THEN
    DISPLAY "COM Error for call at line:", lin
    CALL ui.Interface.frontCall("WinCOM","GetError",[],[mess])
    DISPLAY mess
--let's release the memory on the GDC side
    CALL freeMemory()
    DISPLAY "Exit with COM Error."
    EXIT PROGRAM (-1)
  END IF
END FUNCTION
```

Wincom and Word example

This section provides a Wincom and Word example.

This example puts "This is a title" centered on the page, underlined, and in bold.

```
DEFINE wdapp INTEGER
DEFINE wddoc INTEGER
MAIN
  DEFINE result INTEGER
--initialization of global variables
  LET wdapp = -1
  LET wddoc = -1
--first, we must create an Instance of a Word Application
  CALL ui.Interface.frontCall("WINCOM","CreateInstance",
   ["Word.Application"],[wdapp])
  CALL CheckError(wdapp, __LINE__)
--then adding a document
  CALL ui.Interface.frontCall("WINCOM","CallMethod",
   [wdapp,"Documents.Add"],[wddoc])
  CALL CheckError(wddoc, __LINE__)
--then, setting it to be visible
  CALL ui.Interface.frontCall("WINCOM","SetProperty",
   [wdapp,"Visible",true],[result])
  CALL CheckError(result, __LINE__)
--Centering the cursor for the title
  CALL ui.Interface.frontCall("WINCOM","SetProperty",
   [wdapp,"Selection.ParagraphFormat.Alignment","1"],[wddoc])
  CALL CheckError(wddoc, __LINE__)
--Underlining the title
