    CALL freeMemory()
    DISPLAY "Exit with COM Error."
    EXIT PROGRAM (-1)
  END IF
END FUNCTION
```

Windows™ Mail extension

Description of the Windows™ Mail extension.

> **Important:** The WinMAIL front call library is deprecated. If used, the GDC executable format must match the WinAPI executable format: The 32-bit WinAPI can only be used with a 32-bit GDC.

Send mail using MAPI

MAPI is an acronym for Messaging Application Programming Interface. The **MAPI** extension will create a new mail in the default mailer software, which needs to be "MAPI" compatible, and ask the user to send the mail. The mail sent using MAPI will be stored by the default mailer software in the same way as any other mail created by the user.

Send mail using an SMTP server

Another method of sending mail is to connect directly to an **SMTP** server (Simple Mail Transfer Protocol is the de facto standard for email transmission across the Internet). The extension will connect to a given **SMTP** server and send the mail through this server. The mail is not kept on the client side.

- The WinMail API on page 1918

- WinMail examples on page 1923

The WinMail API

The WinMail API is based on the front call technique as described in Front End Functions. All WinMail functions are grouped in the WinMail front end function module.

Table 429: WinMail front-end functions: General

Function name	Description
`CALL ui.Interface.frontCall("WinMail","Init", [], [id ] )`	The `Init` function initializes the module.
`CALL ui.Interface.frontCall("WinMail","Close", [id], [ result ] )`	The `Close` function clears all information corresponding to a message, and frees the memory occupied by the message.
`CALL ui.Interface.frontCall("WinMail","SetBody", [ id, body ], [ result ] )`	The `SetBody` function sets the body of the mail.
`CALL ui.Interface.frontCall("WinMail","SetSubject", [ id, subject ], [ result ] )`	The `SetSubject` function sets the subject of the mail.
`CALL ui.Interface.frontCall("WinMail","AddTo", [ id, name, address ], [ result ] )`	The `AddTo` function adds a "To" addressee to the mail.
`CALL ui.Interface.frontCall("WinMail","AddCC", [ id, name, address ], [ result ] )`	The `AddCC` function adds a "CC" addressee to the mail.
`CALL ui.Interface.frontCall("WinMail","AddBCC", [ id, name, address ], [ result ] )`	The `AddBCC` function adds a "BCC" addressee to the mail.
`CALL ui.Interface.frontCall("WinMail","AddAttachment", [ id, fileName], [ result ] )`	The `AddAttachment` function adds a file as an attachment to the mail.
`CALL ui.Interface.frontCall("WinMail","SendMailSMTP",`	The `SendMailSMTP` function sends the mail with the SMTP protocol.

Function name	Description
[*id*], [*result*])	
CALL ui.Interface.frontCall("WinMail","SendMailMAPI", [*id*], [*result*])	The `SendMailMAPI` function sends the mail with the MAPI protocol.
CALL ui.Interface.frontCall("WinMail","GetError", [*id*], [*result*])	The `GetError` function gets a description of the last error that occurred.

The following functions are needed when you use SMTP server connections:

Table 430: WinMail front-end functions: SMTP-specific

Function name	Description
CALL ui.Interface.frontCall("WinMail","SetSmtp", [*id*, *smtp:port*], [*result*])	The `SetSmtp` function sets the SMTP server to be used.
CALL ui.Interface.frontCall("WinMail","SetFrom", [*id*, *name*, *address*], [*result*])	The `SetFrom` function sets sender information.

Init

The `Init` function initializes the module.

Syntax

```
CALL ui.Interface.frontCall("WinMail","Init",
  [], [id ] )
```

- *ret* is the identifier of the message initialized.
- For each Init function, a `Close` must be called.

Usage

This function initializes the module. It returns the identifier for the message, which will be used in other functions.

Close

The `Close` function clears all information corresponding to a message, and frees the memory occupied by the message.

Syntax

```
CALL ui.Interface.frontCall("WinMail","Close",
  [id], [ result ] )
```

- *id* is the message identifier.

- *result* is the status of the function.

SetBody

The `SetBody` function sets the body of the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SetBody",
  [ id, body ], [ result ] )
```

- *id* is the message identifier.
- *body* is the string text containing the body of the mail.
- *result* is the status of the function.

SetSubject

The `SetSubject` function sets the subject of the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SetSubject",
  [ id, subject ], [ result ] )
```

- *id* is the message identifier.
- *subject* is the string text containing the subject of the mail.
- *result* is the status of the function.

AddTo

The `AddTo` function adds a "To" addressee to the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","AddTo",
  [ id, name, address ], [ result ] )
```

- *id* is the message identifier.
- *name* is the name to be displayed in the mail.
- *address* is the mail address to be used for this addressee.
- *result* is the status of the function.

Usage

This function adds a "To" Addressee to the mail. The Addressee has a name and a mail address.

AddCC

The `AddCC` function adds a "CC" addressee to the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","AddCC",
  [ id, name, address ], [ result ] )
```

- *id* is the message identifier.
- *name* is the name to be displayed in the mail.
- *address* is the mail address to be used for this addressee.
- *result* is the status of the function.

Usage

This function adds a "CC" Addressee to the mail. The Addressee has a name and a mail address.

AddBCC

The `AddBCC` function adds a "BCC" addressee to the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","AddBCC",
  [ id, name, address ], [ result ] )
```

- *id* is the message identifier.
- *name* is the name to be displayed in the mail.
- *address* is the mail address to be used for this addressee.
- *result* is the status of the function.

Usage

This function adds a "BCC" Addressee to the mail. The Addressee has a name and a mail address.

AddAttachment

The `AddAttachment` function adds a file as an attachment to the mail.

Syntax

```
CALL ui.Interface.frontCall("WinMail","AddAttachment",
  [ id, fileName], [ result ] )
```

- *id* is the message identifier.
- *fileName* is the path of the attachment; the path can be relative to the directory from which GDC is run, or absolute.
- *result* is the status of the function.

Usage

This function adds a file as an attachment to the mail. The file must be located on the front-end.

SendMailSMTP

The `SendMailSMTP` function sends the mail with the SMTP protocol.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SendMailSMTP",
  [ id ], [result] )
```

- *id* is the message identifier.
- *result* is TRUE in case of success; use `GetError` to get the description of the error when needed.

Usage

This function sends the mail by using the SMTP protocol. default mailer software is called to create the mail. The user must press the "send" button to send the mail.

SendMailMAPI

The `SendMailMAPI` function sends the mail with the MAPI protocol.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SendMailMAPI",
  [ id ], [result] )
```

- *id* is the message identifier.
- *result* is TRUE in case of success; use `GetError` to get the description of the error when needed.

Important:

- MAPI needs to log in to the mailer software. The first login could take time, depending on the mailer software. Your Genero application will be blocked until MAPI returns.
- MAPI depends on the mailer software for error management. For instance, Mozilla Thunderbird returns "success" when the mail is created, but Outlook 2002 only returns "success" when the mail is sent.

Usage

This function sends the mail by using the MAPI protocol. With MAPI, the default mailer software is called to create the mail. The user must press the "send" button to send the mail.

GetError

The `GetError` function gets a description of the last error that occurred.

Syntax

```
CALL ui.Interface.frontCall("WinMail","GetError",
  [ id ], [ result ] )
```

- *id* is the message identifier.
- *result* is the description of the last error.
- the returned value is NULL if there was no error.

SetSmtp

The `SetSmtp` function sets the SMTP server to be used.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SetSmtp",
 [ id, smtp:port ], [ result ] )
```

- *id* is the message identifier.
- *smtp* is the string text containing the SMTP server to be used.
- *port* is optional. It allows to specify a port for your SMTP server. When not specified, the default port remains 25.
- *result* is the status of the function.

SetFrom

The `SetFrom` function sets sender information.

Syntax

```
CALL ui.Interface.frontCall("WinMail","SetFrom",
  [ id, name, address ], [ result ] )
```

- *id* is the message identifier.

- *name* is the name to be displayed in the mail.
- *address* is the mail address to be used for this addressee.
- *result* is the status of the function.

WinMail examples
Various WinMail examples.

- Mail using MAPI on page 1923
- Mail using SMTP server on page 1923

Mail using MAPI

This topic provides an example of sending mail using MAPI.

```
MAIN
  DEFINE result, id INTEGER
  DEFINE str STRING

-- first, we initialize the module
  CALL ui.Interface.frontCall("WinMail", "Init", [], [id])

-- Set the body of the mail
  CALL ui.interface.frontCall("WinMail", "SetBody",
   [id, "This is a text mail using WinMail API - MAPI"], [result])

-- Set the subject of the mail
  CALL ui.interface.frontCall("WinMail", "SetSubject",
   [id, "test mail - ignore it"], [result])

-- Add an Addressee as "TO"
  CALL ui.Interface.frontCall("WinMail", "AddTo",
   [id, "myBoss", "boss@mycompany.com"], [result])

-- Add another Addresse as "BCC"
  CALL ui.Interface.frontCall("WinMail", "AddBCC",
   [id, "my friend", "friend@mycompany.com"], [result])

-- Add Two attachments
  CALL ui.Interface.frontCall("WinMail", "AddAttachment",
   [id, "c:\\mydocs\report.doc"], [result])
  CALL ui.Interface.frontCall("WinMail", "AddAttachment",
   [id, "c:\\mydocs\demo.png"], [result])

-- Send the mail via the default mailer
  CALL ui.Interface.frontCall("WinMail", "SendMailMAPI", [id], [result])
  IF result == TRUE THEN
    DISPLAY "Message sent successfully"
  ELSE
    CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
    DISPLAY str
  END IF

  CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN
```

Mail using SMTP server

This topic provides an example of sending mail using an SMTP server.

```
MAIN
  DEFINE result, id INTEGER
  DEFINE str STRING

-- first, we initialize the module
  CALL ui.Interface.frontCall("WinMail", "Init", [], [id])
```

```
-- Set the body of the mail
  CALL ui.interface.frontCall("WinMail", "SetBody", [id,
   "This is a text mail using WinMail API - MAPI"], [result])

-- Set the subject of the mail
  CALL ui.interface.frontCall("WinMail", "SetSubject", [id,
   "test mail - ignore it"], [result])

-- Set the mail sender
  CALL ui.Interface.frontCall("WinMail", "SetFrom", [id, "mySelf",
   "me@mycompany.com"], [result])

-- Set the SMTP server
  CALL ui.Interface.frontCall("WinMail", "SetSmtp", [id,
 "smtp.mycompany.com"],
   [result])

-- Add an Addressee as "TO"
  CALL ui.Interface.frontCall("WinMail", "AddTo", [id, "myBoss",
   "boss@mycompany.com"], [result])

-- Add another Addressee as "BCC"
  CALL ui.Interface.frontCall("WinMail", "AddBCC", [id, "my friend",
   "friend@mycompany.com"], [result])

-- Add Two attachments
  CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id,
   "c:\\mydocs\report.doc"], [result])
  CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id,
   "c:\\mydocs\demo.png"], [result])

-- Send the mail via smtp
  CALL ui.Interface.frontCall("WinMail", "SendMailSMTP", [id], [result])
  IF result == TRUE THEN
    DISPLAY "Message sent successfully"
  ELSE
    CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
    DISPLAY str
  END IF
  CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN
```

Genero Application Server front calls

Front-end functions of the session module allow you to dynamically set and get session variables from within your Genero application.

Table 431: Session module front-end functions

Function name	Description
`ui.Interface.frontCall("session", "getVar", [name], [result])`	Returns the value of a session variable.
`ui.Interface.frontCall("session", "setVar", [name,value], [result])`	Sets a value of a session variable.

setVar
Sets a value of a session variable.

Syntax

```
ui.Interface.frontCall("session", "setVar",
   [name,value], [result])
```

- *name* is the name of the session variable.
- *value* is the value to set to the named session variable.
- *result* returns 1 if successful; 0 otherwise.

Usage

The `setVar` function sets a session variable to the value specified.

Setting a variable to an empty string is equivalent to deleting the variable.

getVar
Returns the value of a session variable.

Syntax

```
ui.Interface.frontCall("session", "getVar",
   [name], [result])
```

- *name* is the name of the session variable.
- *result* is the value of the session variable, or an empty string if the variable does not exist.

Usage

The `getVar` function retrieves the value for a session variable.

Genero Mobile common front calls
This section describes common front calls provided by all mobile front-ends.

This table shows the functions implemented by all mobile front-ends in the "`mobile`" module.

Table 432: Common mobile module front-end functions

Function Name	Description
`ui.Interface.frontCall("mobile", "chooseContact", [], [result])`	Lets the user choose a contact from the mobile device contact list and returns the vCard.
`ui.Interface.frontCall("mobile", "choosePhoto", [], [path])`	Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.
`ui.Interface.frontCall("mobile", "chooseVideo", [], [path])`	Lets the user select a video from the mobile device's video gallery and returns a video identifier.
`ui.Interface.frontCall("mobile", "composeMail", [to, subject, content, cc, bcc, attachments ...],`	Invokes the user's default mail application for a new mail to send.

Function Name	Description
`[result])`	
`ui.Interface.frontCall("mobile", "composeSMS", [ recipients, content ], [ result ] )`	Sends an SMS text to one or more phone numbers.
`ui.Interface.frontCall("mobile", "connectivity", [], [result] )`	Returns the type of network available for the mobile device.
`ui.Interface.frontCall("mobile", "getGeolocation", [], [status, latitude, longitude] )`	Returns the Global Positioning System (GPS) location of a mobile device.
`ui.Interface.frontCall("mobile","getRemoteNotifications", [sender_id], [data] )`	This front call retrieves push notification messages.
`ui.Interface.frontCall("mobile", "importContact", [vcard], [result] )`	Creates a new, or merges to an existing entry, the contact details passed in VCard string.
`ui.Interface.frontCall("mobile","registerForRemoteNotifications", [sender_id], [registration_token] )`	This front call registers a mobile device for push notifications.
`ui.Interface.frontCall("mobile", "runOnServer", [ appurl, timeout ], [] )`	Run an application from the Genero Application Server according to the specified URL.
`ui.Interface.frontCall("mobile", "scanBarCode", [], [code, type] )`	Allow the user to scan a barcode with a mobile device
`ui.Interface.frontCall("mobile", "takePhoto", [], [path] )`	Lets the user take a picture with the mobile device and returns the corresponding picture identifier.
`ui.Interface.frontCall("mobile", "takeVideo", [], [path])`	Lets the user take a video with the mobile device and returns the corresponding video identifier.
`ui.Interface.frontCall("mobile","unregisterFromRemoteNotifications", [ sender_id ], [] )`	This front call unregisters the mobile device from push notifications.

chooseContact
Lets the user choose a contact from the mobile device contact list and returns the vCard.

Syntax

```
ui.Interface.frontCall("mobile", "chooseContact",
   [], [result])
```

- *result* - The vCard string from the device's contacts database.

Usage

The "`chooseContact`" front call opens the mobile device contact chooser, lets the user select a contact and returns the contact as a vCard string.

If the user cancels the contact chooser, `NULL` is returned.

Example

```
DEFINE vcard STRING
CALL ui.Interface.frontCall("mobile", "chooseContact", [],
 [vcard] )
```

choosePhoto
Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.

Syntax

```
ui.Interface.frontCall("mobile", "choosePhoto",
   [], [path])
```

1. *path* - Holds the device opaque path to the chosen photo.

Usage

The "`choosePhoto`" front call starts the system's photo chooser (the device's photo gallery), allows the user to choose a photo, and returns the path/URL on the mobile device of the chosen photo.

If the user cancels the photo chooser, `NULL` is returned.

The value returned in the *path* variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see images handling on mobile devices.

chooseVideo
Lets the user select a video from the mobile device's video gallery and returns a video identifier.

Syntax

```
ui.Interface.frontCall("mobile", "chooseVideo",
  [], [path])
```

1. *path* - Holds the device opaque path to the selected video.

Usage

The "`chooseVideo`" front call starts the system's video chooser (the device's video gallery), allows the user to choose a video, and returns the path/URL on the mobile device of the selected video.

If the user cancels the video chooser, `NULL` is returned.

The value returned in the *path* variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the `fgl_getfile()` API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a `"launchURL"` front call, with the opaque path returned by this front call.

composeMail
Invokes the user's default mail application for a new mail to send.

Syntax

```
ui.Interface.frontCall("mobile", "composeMail",
   [to, subject, content, cc, bcc, attachments ...],
   [result])
```

- *to* - A list of recipients, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- *subject* - The subject of the email.
- *content* - The body of the email.
- *cc* - (optional) A list of recipients for the carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- *bcc* - (optional) A list of recipients for the blind carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- *attachments ...* - (optional) All remaining arguments are treated as paths to attachment files. Each attachment file name is enclosed in its own set of quotes. The comma is used to separate the attachments in the list.
- *result* - Holds a status message.

Usage

The "`composeMail`" front call invokes the user's default mail application and sets up a new mail to send.

The returned result string can take one of the following values:

- "`ok`": The email was send.
- "`cancel`": The email was canceled.
- "`saved`": The email was saved.
- "`failed: reason`": The email could not be sent.

This example opens an email and populates the To, CC, and BCC fields, the Subject line, the message body, and it specifies two attachments..

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeMail",
 ["john.doe@4js.com,jane.doe@4js.com", "Hello world",
  "This is the hello world text", "john.doe@4js.com,jane.doe@4js.com",
 "hidden@4js.com",
```

```
   "/sdcard/Pictures/photo1.jpg", "/sdcard/Pictures/photo2.jpg" ], [result])
```

The next example opens an email and populates the To field, the Subject line, and the message body. No CC or BCC recipients and no attachments are specified.

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile","composeMail",
 ["huhu@haha.com","test mail","sent from my device"],[result])
```

composeSMS
Sends an SMS text to one or more phone numbers.

Syntax

```
ui.Interface.frontCall("mobile", "composeSMS",
  [ recipients, content ],
  [ result ] )
```

- *recipients* - A list of phone numbers, separated by commas. While the list uses commas to separate the phone numbers in the list, the list itself is enclosed in a single set of quotes.
- *content* - The SMS message.
- *result* - Holds a status message.

Usage

The "composeSMS" front call sends an SMS text to one or more phone numbers.

Consider using global phone numbers with a + plus sign, as described in [RFC3966].

The returned result string can take one of the following values:

- "ok": The SMS was send.
- "cancel": The SMS was canceled.
- "failed": The SMS could not be sent.

Error -6333 is raised, if there is no permission to compose an SMS on the mobile phone.

Example

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeSMS",
     ["+332781211,+339956789", "This is the SMS text"],
     [result])
```

connectivity
Returns the type of network available for the mobile device.

Syntax

```
ui.Interface.frontCall("mobile", "connectivity",
   [], [result] )
```

- *result* - Holds the type of network available.

Usage

The "connectivity" front call checks for the best available mobile network connectivity to the internet.

The returned result string can take one of the following values:

- "NONE": No connectivity is available to the internet or the specified host.
- "MobileNetwork": Connectivity is available via the mobile network (Edge, 3G, 4G).
- "WIFI": Connectivity is available via a WIFI connection.

Example

```
DEFINE network STRING
CALL ui.Interface.frontCall("mobile", "connectivity", [],
 [network] )
IF network == "WIFI" THEN
   ...
END IF
```

getGeolocation

Returns the Global Positioning System (GPS) location of a mobile device.

Syntax

```
ui.Interface.frontCall("mobile", "getGeolocation",
   [], [status, latitude, longitude] )
```

1. *status* - Holds the status of the front call execution.
2. *latitude* - Holds the current latitude.
3. *longitude* - Holds the current longitude.

Usage

The "getGeolocation" front call returns the current location of the mobile device, based on the current GPS information.

The possible values returned in the *status* parameter are:

- "ok": The mobile device location could be found.
- In case of failre, the status variable contains the error description, for example, "location services not enabled".

The returned coordinates should be stored in FLOAT variables.

If the device location cannot be found within a given period, the front call returns an error status.

Example

```
DEFINE status STRING, latitude, longitude FLOAT
CALL ui.Interface.frontCall("mobile", "getGeolocation",
     [], [status, latitude, longitude] )
MESSAGE SFMT(
  "Geo location: (status=%1) Latitude=%2 Longitude=%3",
  status, latitude, longitude )
```

getRemoteNotifications

This front call retrieves push notification messages.

Syntax

```
ui.Interface.frontCall("mobile","getRemoteNotifications",
   [sender_id], [data] )
```

1. *sender_id* - For GMA, the sender_id identifies the mobile device. It's obtained when you create a GCM project. This parameter is ignored by GMI.
2. *data* - `STRING` containing a JSON array of notifications.

Usage

After registering for push notifications with the registerForRemoteNotifications on page 1934 front call, the `getRemoteNotifications` front call can be called in the context of an `ON ACTION notificationpushed` action handler.

The GMI or GMA front-end will send the `notificationpushed` special action, when it receives notifications from the push notification server. When this action is fired, use the `getRemoteNotifications` front call to get notification data. On GMA, identify the GCM client by passing the *sender_id* obtained from the GCM project as a parameter. On GMI, the `sender_id` can be `NULL`, as it is ignored.

> **Important:**
>
> When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding `ON ACTION` handler activates. The app should then perform a getRemoteNotifications on page 1930 front call as in the regular case, to get the pending notifications pushed to the device while the app was off.
>
> However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never have any push data available. Depending on the context, implement the following programming patterns to solve this problem:
>
> 1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, the app should directly ask the server push provider to get last push data.
> 2. If the push notification does not contain badge numbers, the app should always perform a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the app should ask the server push provider if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.
> 3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. The app should the perform, the `getRemoteNotifications` front call and get the push data.

The "`getRemoteNotifications`" front call returns a list of notification records as a JSON array string. Use the util.JSONArray or util.JSON class to extract notification data from the returned string. The structure of a push notification is platform specific. See below for details.

> **Important:** When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the `notificationpushed` action, but the `getRemoteNotifications` front call will return no message data (*data* return param is `NULL`). If such case, implement a fallback mechanism (based on RESTFul web services for example), to contact the push notification provider and retrieve the message information.

Push notification records with GMA / Android™

The returned JSON string from a GCM notification server contains an array of notification records.

A notification record contains the following JSON keys:

- `"type"` - can be `"message"` or `"token"`.
- `"data"` - Contains notification data.
  - When `"type":"message"`, the notification record is a GCM application message, and the `data` attribute contains custom notification information.

    An element of "data" can be a `"genero_notification"` record, that will produce an Android graphical notification. This record must define the following attributes:

    - `"title"` - title of the graphical notification
    - `"content"` - text content of the graphical notification
    - `"icon"` - icon of the graphical notification

    The `"genero_notification"` record can be followed by custom notification data.
  - When `"type":"token""`, the notification record is a registration token update, and the `"data"` attribute contains the new registration token, which should be re-sent to the push notification server.
- `"from"` - Contains the GCM project id.

JSON push notification data example for GMA:

```
[
 {
  "type": "message",
  "data": { custom-attributes ... },
  "from": "project-id"
 },
 {
  "type": "token",
  "data": "new-registration-token",
  "from": "project-id"
 },
 ...
]
```

Note that the JSON push notification data can contain a `"data"` attribute with a `"genero_notification"` record, that will produce an Android graphical notification:

```
[
 {
  "type": "message",
  "data": {
            "genero_notification" :
            {
             "title"   : "Game Request!",
             "content" : "Bob wants to play poker...",
             "icon"    : "smiley"
            },
            custom-attributes
            ...
          },
  "from": "project-id"
 },
 ...
]
```

Push notification records with GMI / iOS

The returned JSON string from an Apple Push Notification contains an array of notification records.

A push notification record contains the following JSON attributes:

- `"aps"` (required) - key to be recognized by devices as an Apple Push Notification

- "alert" (required) - key of the push notification content. If not specified as a single value, the alert key can hold:
  - "title" - title of the alert.
  - "body" - the message to be displayed.
- "badge" (optional) - the number to display as the badge of the app icon. If this property is absent, the badge is not changed. You need to manage it through your push notification provider.
- "sound" (optional) - the sound played by the alert (aiff, wav, or caf format). default value : "default". To use a custom file you will need to use the gmi extension project and be familiar with Objective-C. The file must bundled with the app.
- "content-available" (required) - The content-available property with a value of 1 lets the remote notification act as a “silent” notification. Notifications received in background mode should be stored for delivery when the app enters foreground mode.

JSON push notification data example for GMI:

```
[
 {
  "aps" :
  {
    "alert" : "My first push",
    "badge" : 1,
    "sound" : "default",
    "content-available" : 1
  }
 },
 {
  "aps" :
  {
    "alert" :
    {
      "title" : "Push",
      "body" : "My second push"
    }
    "badge" : 2,
    "sound" : "default",
    "content-available" : 1
  },
  "new_ids" : [ "XV234", "ZF452", "RT563" ],
  "updated_ids" : [ "AC634", "HJ153" ]
 }
]
```

In the last record, custom information is provided in the "new_ids" and "updated_ids" attributes, as a JSON array of identifiers.

For more details, see Apple Push Notification Service.

Example

```
IMPORT util -- JSON API
CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID (NULL for
 APNs)>"
...
DEFINE notif_list STRING,
       sender_id STRING

LET sender_id = GCM_SENDER_ID

DIALOG ...
  ...
```

```
  ON ACTION notificationpushed

     CALL ui.Interface.frontCall(
             "mobile", "getRemoteNotifications",
             [ sender_id ], [ notif_list ] )

     -- Analyse content of notiflist
     DISPLAY util.JSON.format(notif_list)
  ...
```

importContact
Creates a new, or merges to an existing entry, the contact details passed in vCard string.

Syntax

```
ui.Interface.frontCall("mobile", "importContact",
   [vcard], [result] )
```

1. *vcard* - Holds a vCard string to be imported into the device's contacts database.
2. *result* - Holds the completed vCard string.

Usage

The "`importContact`" front call sends the vCard definition passed as parameter to the mobile device.

If the contact import is canceled, the front-end returns `NULL`. Otherwise, it returns the vCard data.

On iOS devices, the user has the choice to create a new contact, or complete an existing contact entry. When creating a new entry, the contact input form is opened on the mobile device, to let the user complete the default values passed as parameter. When merging contact information to an existing entry, the user selects an entry from the contact list. If the contact import is validated, the front call returns the completed vCard string.

On Android™ devices, this front call creates a new contact entry directly in the mobile contact list, according to the VCard definition passed as parameter, no intermediate input form is proposed to the end user. If the contact import is validated, the front call returns the original vCard string passed as parameter.

Example

```
DEFINE vcard, result STRING
LET vcard="BEGIN:VCARD\n"
      ||"VERSION:3.0\n"
      ||"N:Willi;;;;\n"
      ||"TEL;type=HOME;type=VOICE;type=pref:03812225610\n"
      ||"END:VCARD\n"
CALL ui.interface.frontcall("mobile","importContact",[vcard],
[result])
```

registerForRemoteNotifications
This front call registers a mobile device for push notifications.

Syntax

```
ui.Interface.frontCall("mobile","registerForRemoteNotifications",
   [sender_id], [registration_token] )
```

1. *sender_id* - For GMA, the sender_id identifies the mobile device. It's obtained when you create a GCM project. This parameter is ignored by GMI.

2. *registration_token* - Registration token to be sent to the push notification provider. For GMA/Android, this is the "registration token" obtained from GCM, for GMI/iOS, this is the "device token" obtained from APNs.

Usage

The "`registerForRemoteNotifications`" front call registers the mobile device for push notifications. Once the registration procedure is done (see below for platform specifics), it is possible to get notification events through the `notificationpushed` predefined action, and retrieve notification data with the getRemoteNotifications on page 1930 front call.

> **Note:** The app does not need to register for notification each time it is restarted: Even if the app is closed, the registration is still active until the `unregisterFromRemoteNotifications` front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android, that the app must register for notification each time it is upgraded.

On Android when using GCM, you get the *sender_id* and an API key when you create a GCM project (see https://developers.google.com/cloud-messaging/android/client#get-config). The *registration_token* is the registration token returned by GCM. Once registered with the GCM service, the app must also send this registration token to the GCM application server. Registration tokens are typically sent to the GCM application server using a RESTFul HTTP POST. For more details, see GCM documentation on the Google developer web site. For more details about GCM registration, see About GCM Connection Server.

> **Note:** Android apps using push notification services need specific permissions to be defined in the manifest, such as `android.permission.GET_ACCOUNTS`, `com.google.android.c2dm.permission.RECEIVE`, and especially *`application-package-name`*`.permission.C2D_MESSAGE`. These Android permissions will be automatically set by the gmabuildtool, according to the package name specified with the `--build-app-package-name` option. For more details, see GCM documentation.

On iOS when using APNs, the *sender_id* is ignored. The *registration_token* is the device token returned by the Apple Push Notification service. Once registered with the Apple Push Notification service, the app must also send this device token to the push notification provider, typically using a RESTFul HTTP POST. For more details about Apple Push Notification Provider, see Provider Communication with Apple Push Notification Service.

Example

The following code example registers with Google Cloud Messaging or Apple Push Notification service. It then sends the registration token to the push notification provider (the get_device_type() function returns the front-end type from the feInfo/feName front call):

```
IMPORT com  -- For RESTful post
IMPORT util -- JSON API

CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID (NULL for
 APNs)>"
...

DEFINE sender_id STRING,
       registration_token STRING
DEFINE req com.HTTPRequest,
       obj util.JSONObject,
       resp com.HTTPResponse

-- First get the registration token
LET sender_id = GCM_SENDER_ID
CALL ui.Interface.frontCall(
```

```
        "mobile", "registerForRemoteNotifications",
        [ sender_id ], [ registration_token ] )

-- Then send registration token to push notification provider
TRY
    LET req = com.HTTPRequest.create("http://SERVER_IP:4930")
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setMethod("POST")
    CALL req.setTimeOut(5)
    LET obj = util.JSONObject.create()
    CALL obj.put("registration_token", registration_token)
    CALL req.doTextRequest(obj.toString())
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
       MESSAGE SFMT("HTTP Error (%1) %2",
                    resp.getStatusCode(),
                    resp.getStatusDescription())
    ELSE
       MESSAGE "Registration token sent."
    END IF
CATCH
    MESSAGE SFMT("Could not post registration token to server:
 %1", STATUS)
END TRY
...
```

runOnServer
Run an application from the Genero Application Server according to the specified URL.

Syntax

```
ui.Interface.frontCall("mobile", "runOnServer",
   [ appurl, timeout ], [] )
```

- *appurl* - The GAS URL to the Genero application (this must be a `ua/r` URL).
- *timeout* - The timeout (in seconds) to wait for the remote application.

Usage

The `runOnServer` front call allows you to start an application in the Genero Application Server (GAS), from an embedded/local application running on the mobile device. The remote application's graphical user interface displays on the mobile device.

The front call returns when the called application ends, and the control goes back to the initial application executing on the mobile device.

The applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

The remote application cannot use `RUN WITHOUT WAITING` to start child programs. Only `RUN` is supported.

The first parameter (*appurl*) identifies the remote application to be started and must contain an "`ua/r`" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: `http://myappserver:6394/ua/r/myapp`.

This URL may contain a query string, with parameters for the application to be executed by the GAS.

The *timeout* parameter is optional. It can be used to give the control back to the local app, if the remote app takes too long to respond. If not specified, or when zero is passed, the timeout is infinite.

In case of failure (such as application not found, or timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details.

> **Note:** The application running on the GAS can only access the *data-directory* directory, in the sandbox of the embedded application that executes the `runOnServer` front call. File handling APIs like `fgl_getfile()` and `fgl_putfile()` can only access this directory on the mobile device. If no absolute path is specified in the file path for the mobile device, the *`data-directory`* is used.

Example

```
TRY
    CALL ui.interface.frontcall("mobile","runOnServer",["http://
santana:6394/ua/r/orders"],[])
CATCH
    ERROR err_get(STATUS)
END TRY
```

scanBarCode
Allow the user to scan a barcode with a mobile device

Syntax

```
ui.Interface.frontCall("mobile", "scanBarCode",
   [], [code, type] )
```

1. *code* - Holds a string representation of the barcode.
2. *type* - Holds the name of the barcode type.

Usage

The "`scanBarCode`" front call starts the barcode scanner to let the user scan a barcode with the device.

After reading the barcode, the front call returns the string representation of the barcode and the barcode type (i.e. symbology).

The *code* return parameter contains the barcode string.

The *type* return parameter indicates the type of barcode that was scanned.

If the barcode scan was canceled, the *code* return parameter is set to `NULL` and *type* is set to "canceled".

- On iOS devices, the barcode reader used by GMI is "ZBar". For more details, see http://zbar.sourceforge.net
- On Android™ devides, the barcode reader used by GMA is "zxing". The zxing barcode reader must be installed as a separate app. For more details, see https://play.google.com/store/apps/details?id=com.google.zxing.client.android.

Table 433: Barcode type codes returned by GMI and GMA

Barcode type name (GMI/iOS)	Barcode type name (GMA/ Android)	Description
N/A	AZTEC	Aztec barcode format
N/A	CODEBAR	CODABAR format
CODE-39	CODE_39	AKA Alpha39, Code 3 of 9 or USD-3 format
CODE-93	CODE_93	Intermec (Canada Post) format

Barcode type name (GMI/iOS)	Barcode type name (GMA/ Android)	Description
CODE-128	CODE_128	High-density barcode (128 chars) format
N/A	DATA_MATRIX	Data Matrix format
EAN-8	EAN_8	European/International Article Number (8 digits) format
EAN-13	EAN_13	European/International Article Number (13 digits) format
I2/5	ITF	Interleaved 2 of 5 format
ISBN-10	N/A	International Standard Book Number (10 digits) format
ISBN-13	N/A	International Standard Book Number (13 digits) format
N/A	MAXICODE	ISO/IEC 16023 format
PDF417	PDF_417	Portable Data File - 417 format
QR-Code	QR_CODE	Quick Response Code format
N/A	RSS_14	GS1 DataBar (Reduce Space Symbology) format
N/A	RSS_EXPANDED	GS1 DataBar Expanded (Reduce Space Symbology expanded) format
UPC-A	UPC_A	Universal Product Code (12 digits) format
UPC-E	UPC_E	Universal Product Code (6 digits) format
N/A	UPC_EAN_EXTENSION	UPC/EAN extension format

takePhoto
Lets the user take a picture with the mobile device and returns the corresponding picture identifier.

Syntax

```
ui.Interface.frontCall("mobile", "takePhoto",
   [], [path] )
```

1. *path* - Holds the device opaque path to the picture that has been taken.

Usage

The "takePhoto" front call invokes the mobile device's camera to let the user take a picture and returns the local path/URL on the mobile device to the picture.

If the photo is canceled by the user, the front call returns NULL.

The value returned in the *path* variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see images handling on mobile devices.

takeVideo
Lets the user take a video with the mobile device and returns the corresponding video identifier.

Syntax

```
ui.Interface.frontCall("mobile", "takeVideo",
  [], [path])
```

1. *path* - Holds the device opaque path to the video.

Usage

The "`takeVideo`" front call invokes the mobile device's camera to let the user take a video and returns the local path/URL to the video on the mobile device.

If the photo is canceled by the user, the front call returns `NULL`.

The value returned in the *path* variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the `fgl_getfile()` API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a `"launchURL"` front call, with the opaque path returned by this front call.

unregisterFromRemoteNotifications
This front call unregisters the mobile device from push notifications.

Syntax

```
ui.Interface.frontCall("mobile","unregisterFromRemoteNotifications",
   [ sender_id ], [] )
```

1. *sender_id* - For GMA, the sender_id identifies the mobile device. It's obtained when you create a GCM project. This parameter is ignored by GMI.

Usage

The "`unregisterFromRemoteNotifications`" front call unregisters the device from push notifications after it has been registered with the registerForRemoteNotifications on page 1934 front call.

On Android with GCM, to unregister the mobile device from GCM push notifications, pass the *sender_id* used to identify the GCM client. You obtain the *sender_id* when you create the GCM project.

On iOS with APNs, provide a `NULL` as `sender_id`, to unregister the iOS mobile device from push notifications.

Example

```
DEFINE sender_id STRING
...
IF get_device_type() == "GMA" THEN
   LET sender_id = "94019931415" -- Got from GCM project
 creation
ELSE
   LET sender_id = NULL -- Ignored by GMI
END IF
```

```
CALL ui.Interface.frontCall(
        "mobile", "unregisterFromRemoteNotifications",
        [ sender_id ], [ ] )
...
```

Genero Mobile Android™ front calls
This section describes front calls specific to the Android platform.

This table shows the functions implemented by the Android front-end in the "`android`" module.

Table 434: Android module front-end functions

Function Name	Description
`ui.Interface.frontCall("android", "askForPermission", [permission], [result])`	Ask the user to enable a dangerous feature on the Android device.
`ui.Interface.frontCall("android", "showAbout", [],[])`	Shows the GMA about box displaying version information.
`ui.Interface.frontCall("android", "showSettings", [], [])`	Shows the GMA settings box controlling debug options.
`ui.Interface.frontCall("android", "startActivity", [action, data, category, type, component, extras], [])`	Starts an external Android application (activity), and returns to the GMA application immediately.
`ui.Interface.frontCall("android", "startActivityForResult", [action, data, category, type, component, extras], [outdata, outextras])`	Starts an external application (Android activity) and waits until the activity is closed.

askForPermission (Android™)
Ask the user to enable a dangerous feature on the Android device.

Syntax

```
ui.Interface.frontCall("android","askForPermission",
  [permission], [result])
```

1. *permission* - Identifies the Android permission to enable.
2. *result* - Holds the execution status of the front call:
   - "`ok`" : the user accepted the permission.
   - "`rejected`" : the user refused the permission.

Usage

The "`askForPermission`" front call opens a message box to let the end user confirm the access to a "dangerous" Android permission, in order to enable a risky feature of the mobile device for the current app.

> **Important:** Starting with Android 6, permissions to access dangerous mobile functions are no longer asked during app installation: The app must ask the user for dangerous permissions when needed, by using the `askForPermission` front call.

The *permissions* parameter defines the Android permission to be asked. It must be a string representing one of the Android permission contants, as defined in Android's Manifest permissions, prefixed by the `"android.permission."` string. For example, the `"android.permission.WRITE_EXTERNAL_STORAGE"` string can be used to identify the permission to access the SDCARD storage unit.

> **Important:** Specific Android permissions required by the app still need to be specified when building the app. However, it is not needed to specifiy Android permissions required for built-in front calls: For example, if the app code makes a `choosePhoto` front call, the GMA will implicitely ask the user and set the Android permission to access the photo gallery. For more details, see Android permissions on page 2577.

The front call will raise a runtime exception if the permission identifier is not valid.

Example

The following code example asks the user to access the SDCARD, and handles the user choice:

```
DEFINE result STRING
CALL ui.Interface.frontCall(
        "android", "askForPermission",
        ["android.permission.WRITE_EXTERNAL_STORAGE"],
        [result] )
CASE result
   WHEN "ok"
      CALL os.Path.mkDir("/sdcard/myfiles")
   WHEN "rejected"
      ERROR "SDCARD access was denied by user"
END CASE
```

showAbout (Android™)
Shows the GMA about box displaying version information.

Syntax

```
ui.Interface.frontCall("android", "showAbout",
  [],[])
```

Usage

This front call simply shows a typical about box, indicating GMA version information.

> **Important:** This front call is only available for an application running on an Android device.

No input parameters are required, and no parameters are returned.

showSettings (Android™)
Shows the GMA settings box controlling debug options.

Syntax

```
ui.Interface.frontCall("android", "showSettings", [], [])
```

Usage

This front call opens the settings box to enable or disable GMA programming options.

> **Important:** This front call is only available for an application running on an Android device.

No input parameters are required, and no parameters are returned.

The following features can be controlled with the GMA settings box:

- HTTP debug server on port 6480 (to inspect the AUI tree and show app logs)
- GUI display (FGLSERVER on page 185) and remote debug with `fgldb` on port 6400
- Android logcat recording
- Managing allowed certificates (SSH connections)
- Cookies cleanup (for SSO authentication tokens)

startActivity (Android™)
Starts an external Android application (activity), and returns to the GMA application immediately.

Syntax

```
ui.Interface.frontCall("android","startActivity",
  [action, data, category, type, component, extras],
  [])
```

1. *action* - Identifies the activity to be started on the Android device.
2. *data* - (optional) The data to operate on in the activity (URL, etc).
3. *category* - (optional) A comma separated list of categories.
4. *type* - (optional) Specifies the type of the data passed to the activity.
5. *component* - (optional) Specifies a component class to use for the intent.
6. *extras* - (optional) This is a JSON string containing parameters to pass to the activity.

Usage

The "`startActivity`" front call starts an external application (Android activity), and returns to the GMA application immediately after invoking the activity.

> **Important:** This front call is only available for an application running on an Android device.

This front call is similar to the `RUN WITHOUT WAITING` statement: It allows the user to switch between the GMA and the launched application.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the Android "Intent" defintion.

The *action* parameter defines the Android activity to perform, such as `"android.intent.action.MAIN"`, `"android.intent.action.VIEW"`, and so on.

The *data* (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.

The *category* (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, `"android.intent.category.LAUNCHER"` means it should appear in the Launcher as a top-level application. See the Android documentation for details about possible categories for a given activity.

The *type* (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.

The *component* (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "*apk-package-name/java-class-name*" or "*java-class-name*" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.

The *extras* (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

Example

The following code example starts the VIEW Android activity to show an image. The Genero program flow will continue after this call, but the started activity will be shown. Note that such action is rather performed with a `launchurl` front call.

```
CALL ui.Interface.frontCall(
        "android", "startActivity",
        [ "android.intent.action.VIEW",
          "file:///storage/path_to_image_file",
          NULL, "image/*" ],
        [ ] )
```

startActivityForResult (Android™)

Starts an external application (Android activity) and waits until the activity is closed.

Syntax

```
ui.Interface.frontCall("android", "startActivityForResult",
  [action, data, category, type, component, extras],
  [outdata, outextras])
```

1. *action* - Identifies the activity to be started on the Android device.
2. *data* - (optional) The data to operate on in the activity (URL, etc).
3. *category* - (optional) A comma separated list of categories.
4. *type* - (optional) Specifies the type of the data passed to the activity.
5. *component* - (optional) Specifies a component class to use for the intent.
6. *extras* - (optional) This is a JSON string containing parameters to pass to the activity.

Return values include:

1. *outdata* - holds the flat value returned by the invoked activity.
2. *outextras* - holds the JSON data of structured value returned by the invoked activity.

The return values depend entirely on the invoked activity.

Usage

The "`startActivityForResult`" front call starts an external application (Android activity), then waits for the user to exit the external application prior to returning the the GMA application.

> **Important:** This front call is only available for an application running on an Android device.

This front call is similar to the `RUN` statement: The user cannot return to the GMA application while the activity is executing.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the Android "Intent" defintion.

The *action* parameter defines the Android activity to perform, such as `"android.intent.action.MAIN"`, `"android.intent.action.VIEW"`, and so on.

The *data* (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.

The *category* (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, `"android.intent.category.LAUNCHER"` means it should appear in the Launcher as a top-level application. See the Android documentation for details about possible categories for a given activity.

The *type* (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.

The *component* (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "*apk-package-name/java-class-name*" or "*java-class-name*" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.

The *extras* (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

The *outdata* returning argument will contain the flag value returned from the activity, typically when the data is simple and not structured.

The *outextras* returning argument can hold JSON data of any structured value returned by the invoked activity, or `NULL` in case of error (for example, when the application corresponding to the activity is not installed)

Example

This example invokes the barcode scanner application, and returns the scanned barcode.

```
IMPORT util
...
DEFINE data, extras STRING,
       json_object util.JSONObject,
       scanned_value STRING
...
CALL ui.Interface.frontCall(
        "android", "startActivityForResult",
        [ "com.google.zxing.client.android.SCAN",
          NULL, "android.intent.category.DEFAULT" ],
        [ data, extras ])
IF extras IS NULL THEN
  -- If the application isn't installed invoke
  -- the Play Store to give the user a chance to install it
  CALL ui.Interface.frontCall("standard", "launchurl",
          ["market://details?
id=com.google.zxing.client.android"], [])
ELSE
  LET json_object = util.JSONObject.parse(extras)
  -- Fetch the scanned value
  LET scanned_value = json_object.get("SCAN_RESULT")
END IF
```

Genero Mobile iOS front calls

This section describes front calls specific to the iOS platform.

This table shows the functions implemented by the iOS front-end in the "`ios`" module.

Table 435: iOS module front-end functions

Function Name	Description
`ui.Interface.frontCall("ios", "getBadgeNumber", [],[value])`	Returns the current badge number associated to the app.
`ui.Interface.frontCall("ios", "newContact", [defaults],[vcard])`	Lets the user input contact information to create a new entry in the contact database of the mobile device.
`ui.Interface.frontCall("ios", "setBadgeNumber", [value], [])`	Sets the current badge number associated to the app.

getBadgeNumber (iOS)

Returns the current badge number associated to the app.

Syntax

```
ui.Interface.frontCall("ios", "getBadgeNumber",
  [],[value])
```

- *value* - Holds the current badge number.

Usage

The iOS "`getBadgeNumber`" front call returns the current badge number associated to the app.

> **Important:** This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for Push notifications on page 2599.

> **Important:** In order to query or set the badge number, the app program must have executed a `registerForRemoteNotifications` front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.

Example

```
DEFINE value INTEGER
CALL ui.interface.frontcall("ios","getBadgeNumber",[],[value])
```

newContact (iOS)

Lets the user input contact information to create a new entry in the contact database of the mobile device.

Syntax

```
ui.Interface.frontCall("ios", "newContact",
  [defaults],[vcard])
```

- *defaults* - A vCard string with default values for the new contact input.

- *vcard* - Holds the vCard string of the new created contact.

Usage

The iOS "`newContact`" front call opens the contact input form on the mobile device, with default values passed in the vCard structure of the first parameter, lets the user enter contact information.

> **Important:** This front call is only available for an application running on an iOS device.

If the contact creation is validated, the front call returns the completed vCard string. If the contact import is canceled, the front-end returns `NULL`.

Example

```
DEFINE defaults, vcard STRING
LET defaults="BEGIN:VCARD\n"
      ||"VERSION:3.0\n"
      ||"N:Willi;;;;\n"
      ||"TEL;type=HOME;type=VOICE;type=pref:03812225610\n"
      ||"END:VCARD\n"
CALL ui.interface.frontcall("ios","newContact",[defaults],
[vcard])
```

setBadgeNumber (iOS)

Sets the current badge number associated to the app.

Syntax

```
ui.Interface.frontCall("ios", "setBadgeNumber",
  [value], [])
```

- *value* - Holds the badge number to be set.

Usage

The iOS "`setBadgeNumber`" front call sets the badge number associated to the app.

> **Important:** This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for Push notifications on page 2599.

> **Important:** In order to query or set the badge number, the app program must have executed a `registerForRemoteNotifications` front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.

Example

```
DEFINE value INTEGER
LET value = 2
CALL ui.interface.frontcall("ios","setBadgeNumber",[value],[])
```

Extension packages

Several utility classes and functions are provided in additional packages to be included with the `IMPORT` instruction.

- The util package on page 1947
- The os package on page 1990
- The com package on page 2009
- The xml package on page 2103
- The security package on page 2278

The util package

These topics cover the classes for the `util` package.

The util.Date class

The `util.Date` class provides `DATE` data-type related utility methods.

This class is provided in the `util` C-Extension library; To use the `util.Date` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

util.Date methods

Methods for the `util.Date` class.

Table 436: Class methods

Name	Description
`util.Date.isLeapYear( year )` `  RETURNING res BOOLEAN`	Checks is the year passed as parameter is a leap year.

`util.Date.parse(`
`  src STRING,`
`  fmt STRING`
`  )`
`  RETURNING res DATE`
	Converts a string to a `DATE` value according to a format specification.

util.Date.parse

Converts a string to a `DATE` value according to a format specification.

Syntax

```
util.Date.parse(
  src STRING,
  fmt STRING
 )
  RETURNING res DATE
```

1. *src* is the source string to be parsed.
2. *fmt* is the format specification (see Formatting DATE values on page 220).

Usage

The `util.Date.parse()` method parses a string according to a format specification, to produce a `DATE` value.

The format specification must be a combination of `dd`, `mm`, `yyyy` place holders as with the `USING` operator.

The method returns `NULL`, if the source string cannot be converted to a `DATE` value according to the format specification.

For more details about the supported formats, see Formatting DATE values on page 220.

Example

```
IMPORT util
MAIN
    DISPLAY util.Date.parse( "2014-03-15", "yyyy-mm-dd" )
END MAIN
```

util.Date.isLeapYear
Checks is the year passed as parameter is a leap year.

Syntax

```
util.Date.isLeapYear( year )
  RETURNING res BOOLEAN
```

1. *year* is an `INTEGER` representing a year.
2. *res* is `TRUE` if year is a leap year, otherwise res is `FALSE`.

Usage

The `util.Date.isLeapYear()` method returns `TRUE` if the year passed in parameter is a leap year.

Example

```
IMPORT util
MAIN
    DISPLAY util.Date.isLeapYear( 2003 )
    DISPLAY util.Date.isLeapYear( 2004 )
END MAIN
```

The util.Datetime class
The `util.Datetime` class provides `DATETIME` data-type related utility methods.

This class is provided in the `util` C-Extension library; To use the `util.Datetime` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

util.Datetime methods

Methods for the `util.Datetime` class.

Table 437: Class methods

Name	Description

`util.Datetime.format(`
`  value DATETIME q1 TO q2,`
`  fmt STRING`
`)`
`  RETURNING res STRING`
	Formats a datetime value according to format specification.

`util.Datetime.fromSecondsSinceEpoch(`
`  seconds FLOAT`
`)`
`  RETURNING local DATETIME q1 TO q2`
	Converts a number of seconds since Epoch to a datetime.

`util.Datetime.getCurrentAsUTC( )` `  RETURNING utc DATETIME YEAR TO FRACTION(5)`	Returns the current date/time in UTC.

`util.Datetime.parse(`
`  src STRING,`
`  fmt STRING`
`)`
`  RETURNING res DATETIME q1 TO q2`
	Converts a string to a `DATETIME` value according to a format specification.

`util.Datetime.toLocalTime(`
`  utc DATETIME q1 TO q2`
`)`
`  RETURNING local DATETIME q1 TO q2`
	Converts a UTC datetime to the local time.

`util.Datetime.toSecondsSinceEpoch(`
`  local DATETIME q1 TO q2`
`)`
`  RETURNING seconds FLOAT`
	Converts a datetime to a number of seconds since Epoch.

`util.Datetime.toUTC(`
`  local DATETIME q1 TO q2`
`)`
`  RETURNING utc DATETIME q1 TO q2`
	Converts a datetime value to the UTC datetime.

util.Datetime.format

Formats a datetime value according to format specification.

Syntax

```
util.Datetime.format(
   value DATETIME q1 TO q2,
   fmt STRING
)
```

```
  RETURNING res STRING
```

1. *value* is the datetime value to be formatted.
2. *fmt* is the format string, as described in Formatting DATETIME values on page 221.

Usage

The `util.Datetime.format()` method formats a `DATETIME` value according to the format specification.

The format string must be a combination of place holders such as `%Y`, `%m`, `%d`, as described in Formatting DATETIME values on page 221.

If the source value is `NULL` the result will be `NULL`.

Example

```
IMPORT util
MAIN
    DISPLAY util.Datetime.format( CURRENT, "%Y-%m-%d %H:%M" )
END MAIN
```

util.Datetime.fromSecondsSinceEpoch
Converts a number of seconds since Epoch to a datetime.

Syntax

```
util.Datetime.fromSecondsSinceEpoch(
  seconds FLOAT
 )
  RETURNING local DATETIME q1 TO q2
```

1. *seconds* is the number of seconds since Epoch. This can be a whole integer or a decimal, if the target datetime
2. *local* is the local datetime value.

Usage

The `util.Datetime.fromSecondsSinceEpoch()` method converts the number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT) passed as parameter, to a `DATETIME` value, in the local time.

Important: If the number of seconds passed as parameter is a floating point number including a fraction of seconds, the result will be a `DATETIME YEAR TO FRACTION(N)`, otherwise it is `DATETIME YEAR TO SECOND`.

Example

```
IMPORT util
MAIN
    DEFINE dt DATETIME YEAR TO SECOND
    LET dt = util.Datetime.fromSecondsSinceEpoch( 9876234 )
    DISPLAY dt
END MAIN
```

util.Datetime.getCurrentAsUTC
Returns the current date/time in UTC.

Syntax

```
util.Datetime.getCurrentAsUTC( )
  RETURNING utc DATETIME YEAR TO FRACTION(5)
```

1. *utc* is the datetime value in UTC, with the precision `DATETIME YEAR TO FRACTION(5)`.

Usage

The `util.Datetime.getCurrentAsUTC()` method returns the current system date/time in UTC (Universal Time).

This method is provided to solve the daylight saving time transition issue of the `util.Datetime.toUTC()` method.

> **Note:** The precision of the value returned by this method is a `DATETIME YEAR TO FRACTION(5)`. Note that this precision is different from the default `CURRENT` precision when no qualifiers are specified.

Example

```
IMPORT util
MAIN
    DEFINE utc DATETIME YEAR TO FRACTION(5)
    LET utc = util.Datetime.getCurrentAsUTC( )
    DISPLAY "Current UTC: ", utc
END MAIN
```

util.Datetime.parse
Converts a string to a `DATETIME` value according to a format specification.

Syntax

```
util.Datetime.parse(
  src STRING,
  fmt STRING
)
  RETURNING res DATETIME q1 TO q2
```

1. *src* is the source string to be parsed.
2. *fmt* is the format specification (see Formatting DATETIME values on page 221).

Usage

The `util.Datetime.parse()` method parses a string according to a format specification, to produce a `DATETIME` value.

The format specification must be a combination of place holders such as `%Y`, `%m`, `%d`, etc.

The precision of the resulting `DATETIME` value depends on the format specification. For example, when using `"%y-%m-%d %H:%M"`, the resulting value will be a `DATETIME YEAR TO MINUTE`.

The method returns `NULL`, if the source string cannot be converted to a `DATETIME` value according to the format specification.

For more details about the supported formats, see Formatting DATETIME values on page 221.

Example

```
IMPORT util
MAIN
    DEFINE dt DATETIME YEAR TO MINUTE
    LET dt = util.Datetime.parse( "2014-12-24 23:45", "%Y-%m-%d
 %H:%M" )
    DISPLAY dt
END MAIN
```

util.Datetime.toLocalTime
Converts a UTC datetime to the local time.

Syntax

```
util.Datetime.toLocalTime(
  utc DATETIME q1 TO q2
 )
  RETURNING local DATETIME q1 TO q2
```

1. *utc* is the datetime value in UTC.
2. *local* is the local tinezone datetime value.

Usage

The `util.Datetime.toLocalTime()` method converts a `DATETIME` value from "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT), to the local timezone datetime.

Example

```
IMPORT util
MAIN
    DEFINE loc DATETIME YEAR TO SECOND
    LET loc = util.Datetime.toLocalTime( DATETIME(2015-08-22
 15:34:56) YEAR TO SECOND )
    DISPLAY "LOC: ", loc
END MAIN
```

util.Datetime.toSecondsSinceEpoch
Converts a datetime to a number of seconds since Epoch.

Syntax

```
util.Datetime.toSecondsSinceEpoch(
  local DATETIME q1 TO q2
 )
  RETURNING seconds FLOAT
```

1. *local* is the local datetime value.
2. *seconds* is the number of seconds since Epoch. Note that this is a `FLOAT` value as the source can be a `DATETIME YEAR TO FRACTION(N)`.

Usage

The `util.Datetime.toSecondsSinceEpoch()` method converts the `DATETIME` value passed as parameter to a number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT)

Important: The result is a whole number when the source is a `DATETIME YEAR TO SECOND`, but will be a floating point number when the source is a `DATETIME YEAR TO FRACTION(N)`, to include the fractional part.

Example

```
IMPORT util
MAIN
    DEFINE sec INTEGER, loc DATETIME YEAR TO SECOND
    LET loc = CURRENT YEAR TO SECOND
    LET sec = util.Datetime.toSecondsSinceEpoch( loc )
    DISPLAY sec
END MAIN
```

util.Datetime.toUTC
Converts a datetime value to the UTC datetime.

Syntax

```
util.Datetime.toUTC(
   local DATETIME q1 TO q2
)
  RETURNING utc DATETIME q1 TO q2
```

1. *local* is the local timezone datetime value.
2. *utc* is the datetime value in UTC.

Usage

The `util.Datetime.toUTC()` method converts the local timezone `DATETIME` value passed as parameter to the "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT).

The `toUTC()` method on local timezone information settings.

Fall/Autumn daylight saving time transition period

Important: The `toUTC()` function cannot determine if the local datetime value represents a time before or after the daylight saving time change, when the value is in the hour of the daylight saving time transition period in the fall (this is for example, the hour 02:00 PM to 03:00 PM on the last Sunday of October in Europe and first Sunday of November in the USA). Depending on the operating system, the `toUTC()` method can interpret the local time as a Summer time or as a Winter time. In order to get the current system time in UTC, use the `util.Datetime.getCurrentAsUTC()` method.

The `DATETIME` value passed as parameter to the `toUTC()` method is the datetime in the local timezone. However, this value does not contain the GMT offset indicator or daylight saving time information.

When passing local datetime values in the hour of the daylight saving time transition period in the fall (when clocks roll back one hour), the `toUTC()` function cannot determine if the local datetime value represents a point in time before or after the daylight saving time transition occured. Depending on the operating system, the `toUTC()` method can interpret the local time as a Summer time or as a Winter time. As a result, the conversion to the UTC time can be mis-interpreted.

For example, in Europe, the fall daylight saving time changes on the 25 of October, at 3:00 PM. The ambigous period is between 2:00 PM and 3:00 PM (local time). If you pass for example, the datetime value 2015-10-25 02:34:11 to the `toUTC()` method, there is no way for the method to know if this local time is the time before (CEST / UTC+2h) or after (CET / UTC+1h) the daylight saving time change.

This behavior can be illustrated with the following code example:

```
IMPORT util

MAIN
    DISPLAY "Original UTC         Local time (Paris)   toUTC(local-time)
 ( toUTC() - Orig UCT )"
    CALL test( "2015-10-24 23:59:59" )
    CALL test( "2015-10-25 00:59:59" )
    CALL test( "2015-10-25 01:59:59" )
    CALL test( "2015-10-25 02:59:59" )
END MAIN

FUNCTION test(utc)
    DEFINE utc, loc, utc2 DATETIME YEAR TO SECOND
    LET loc = util.Datetime.toLocalTime(utc)
    LET utc2 = util.Datetime.toUTC(loc)
    DISPLAY SFMT("%1  %2  %3  %4", utc,loc,utc2,utc2-utc)
END FUNCTION
```

The above code will produce the following output on Linux, with with `TZ='Europe/Paris'`:

```
Original UTC         Local time (Paris)   toUTC(local-time)     ( toUTC() -
 Orig UCT )
2015-10-24 23:59:59  2015-10-25 01:59:59  2015-10-24 23:59:59          0
 00:00:00
2015-10-25 00:59:59  2015-10-25 02:59:59  2015-10-25 00:59:59          0
 00:00:00
2015-10-25 01:59:59  2015-10-25 02:59:59  2015-10-25 00:59:59         -0
 01:00:00
2015-10-25 02:59:59  2015-10-25 03:59:59  2015-10-25 02:59:59          0
 00:00:00
```

As you can see, the local time 2015-10-25 02:59:59 is always converted to UTC 2015-10-25 00:59:59.

Example

```
IMPORT util
MAIN
    DEFINE utc DATETIME YEAR TO SECOND
    LET utc = util.Datetime.toUTC( DATETIME(2015-08-22 15:34:56)
 YEAR TO SECOND )
    DISPLAY "UTC: ", utc
END MAIN
```

The util.Interval class

The `util.Interval` class provides `INTERVAL` data-type related utility methods.

This class is provided in the `util` C-Extension library; To use the `util.Interval` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

util.Interval methods

Methods for the `util.Interval` class.

Table 438: Class methods

Name	Description

`util.Interval.format(`
`  value INTERVAL q1 TO q2,`
`  fmt STRING`
`)`
`  RETURNING res STRING`
	Formats an interval value according to format specification.

`util.Interval.parse(`
`  src STRING,`
`  fmt STRING`
`)`
`  RETURNING res DATETIME q1 TO q2`
	Converts a string to a `DATETIME` value according to a format specification.

util.Interval.format

Formats an interval value according to format specification.

Syntax

```
util.Interval.format(
   value INTERVAL q1 TO q2,
   fmt STRING
)
  RETURNING res STRING
```

1. *value* is the interval value to be formatted.
2. *fmt* is the format string, as described in Formatting INTERVAL values on page 223.

Usage

The `util.Interval.format()` method formats an `INTERVAL` value according to the format specification.

The format string must be a combination of place holders such as `%Y`, `%m`, `%d`, as described in Formatting INTERVAL values on page 223.

If the source value is `NULL` the result will be `NULL`.

Example

```
IMPORT util
MAIN
    DEFINE iv INTERVAL DAY(6) TO MINUTE
    LET iv = "-157 11:23"
    DISPLAY util.Interval.format(iv, "%d %H:%M")
END MAIN
```

util.Interval.parse
Converts a string to a DATETIME value according to a format specification.

Syntax

```
util.Interval.parse(
  src STRING,
  fmt STRING
)
  RETURNING res DATETIME q1 TO q2
```

1. *src* is the source string to be parsed.
2. *fmt* is the format specification (see Formatting INTERVAL values on page 223).

Usage

The `util.Interval.parse()` method parses a string according to a format specification, to produce an `INTERVAL` value.

The format specification must be a combination of place holders such as `%Y`, `%m`, `%d`, etc.

The precision of the resulting `INTERVAL` value depends on the format specification. For example, when using `"%Y-%m"`, the resulting value will be an `INTERVAL YEAR TO MONTH`.

The method returns `NULL`, if the source string cannot be converted to an `INTERVAL` value according to the format specification.

For more details about the supported formats, see Formatting INTERVAL values on page 223.

Example

```
IMPORT util
MAIN
    DEFINE iv INTERVAL DAY(6) TO FRACTION(5)
    LET iv = util.Interval.parse( "-37467 + 23:45:34.12345", "%d
 + %H:%M:%S%F5" )
END MAIN
```

The util.Strings class

The `util.Strings` class provides `STRING` data-type related utility methods.

This class is provided in the `util` C-Extension library; To use the `util.Strings` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

util.Strings methods

Methods for the `util.Strings` class.

Table 439: Class methods

Name	Description
`util.Strings.base64Decode( source STRING, filename STRING`	Decodes a Base64 encoded string and writes the bytes to a file.

Name	Description
)	

`util.Strings.base64Encode(`
`  filename STRING`
`  )`
`  RETURNING result STRING`
	Converts the content of a file to a Base64 encoded string.

`util.Strings.base64DecodeToString(`
`  source STRING`
`  )`
`  RETURNING result STRING`
	Decodes a base64 encoded string and returns the corresponding string.

`util.Strings.base64EncodeFromString(`
`  source STRING`
`  )`
`  RETURNING result STRING`
	Converts the string passed as parameter to a Base64 encoded string.

`util.Strings.urlDecode(`
`  source STRING`
`  )`
`  RETURNING result STRING`
	Converts the URL-encoded string to a string in the current application locale.

`util.Strings.urlEncode(`
`  source STRING`
`  )`
`  RETURNING result STRING`
	Converts a string from the current codeset to a URL-encoded string.

util.Strings.base64Decode
Decodes a Base64 encoded string and writes the bytes to a file.

Syntax

```
util.Strings.base64Decode(
  source STRING,
  filename STRING
 )
```

1. *source* is the Base64 encoded string.
2. *filename* is the name of the file to write to.

Usage

The `util.Strings.base64Decode()` method converts the Base64 encoded string passed as first parameter, and writes the bytes to file specified as second parameter.

Example

```
IMPORT util
MAIN
    DEFINE base64 STRING
    LET base64 = util.Strings.base64Encode( "picture1.png" )
    DISPLAY base64
```

```
    CALL util.Strings.base64Decode( base64, "picture2.png" )
END MAIN
```

util.Strings.base64Encode
Converts the content of a file to a Base64 encoded string.

Syntax

```
util.Strings.base64Encode(
  filename STRING
 )
  RETURNING result STRING
```

1. *filename* is the name of the file to read from.
2. *result* is the resulting Base64 encoded string.

Usage

The `util.Strings.base64Encode()` method reads the content of the file passed as parameter, and converts the bytes to a Base64 encoded string.

Example

```
IMPORT util
MAIN
    DISPLAY util.Strings.base64Encode( "picture.png" )
END MAIN
```

util.Strings.base64DecodeToString
Decodes a base64 encoded string and returns the corresponding string.

Syntax

```
util.Strings.base64DecodeToString(
  source STRING
 )
  RETURNING result STRING
```

1. *source* is the Base64 encoded string.
2. *result* is the decoded string.

Usage

The `util.Strings.base64DecodeToString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to a string representation in the current locale, and returns that string.

If the Base64 source string contains a sequence of bytes that does not represent a valid character in the current application locale, the function returns `NULL`.

Note: In contrast to util.Strings.urlDecode on page 1959, the original string is not converted from UTF-8 to the application character encoding: The Base64 source string must represent valid characters in the current application locale.

Example

```
IMPORT util
MAIN
```

```
    DEFINE base64 STRING
    LET base64 = util.Strings.base64EncodeFromString( "Forêt" )
    DISPLAY base64
    DISPLAY util.Strings.base64DecodeToString( base64 )
END MAIN
```

util.Strings.base64EncodeFromString
Converts the string passed as parameter to a Base64 encoded string.

Syntax

```
util.Strings.base64EncodeFromString(
  source STRING
 )
  RETURNING result STRING
```

1. *source* is the source string to convert in Base64.
2. *result* is the resulting Base64 encoded string.

Usage

The `util.Strings.base64EncodeFromString()` method first converts the string passed as parameter to an array of bytes, then it converts the array of bytes the a Base64 representation, and returns the resulting Base64 encoded string.

> **Note:** In contrast to util.Strings.urlEncode on page 1960, the original string is not converted from the application locale to UTF-8, before performing the encoding to Base64: The resulting Base64 encoded string will contain byte sequences representing characters in the current application locale.

Example

```
IMPORT util
MAIN
    DISPLAY util.Strings.base64EncodeFromString( "Forêt" )
END MAIN
```

util.Strings.urlDecode
Converts the URL-encoded string to a string in the current application locale.

Syntax

```
util.Strings.urlDecode(
  source STRING
 )
  RETURNING result STRING
```

1. *source* is the URL-encoded source string (UTF-8 bytes).
2. *result* is the resulting Base64 encoded string.

Usage

The `util.Strings.urlDecode()` method converts the URL-encoded string passed as parameter to a character string.

The source string must contain ASCII characters and/or `%xx` hexadecimal representation of UTF-8 encoding bytes.

The decoder is error tolerant:

- Alphabetical characters of a %xx element can be uppercase or lowercase (%b2 = %B2).
- If the source string contains a set of %xx elements that represent a UTF-8 encoded character which is not existing in the current application locale, it will be converted to a ? question mark.
- If the percent character is not followed by two hexadecimal digits, then a "%" is copied to the result string and the decoder continues at the next character.

Example

```
IMPORT util
MAIN
    DISPLAY util.Strings.urlDecode("abc%C3%84%E2%82%AC")
END MAIN

Output:
abcÄ€
```

util.Strings.urlEncode
Converts a string from the current codeset to a URL-encoded string.

Syntax

```
util.Strings.urlEncode(
  source STRING
 )
  RETURNING result STRING
```

1. *source* is the source string to url-encode.
2. *result* is the resulting url encoded string.

Usage

The `util.Strings.urlEncode()` method converts the character string passed as parameter to a URL-encoded string.

All characters not matching `[-_.~a-zA-Z0-9]` are "percent encoded": Percent-encoding involves converting those characters to UTF-8 and representing its corresponding byte values by a percent sign ("%") and a pair of hexadecimal digits.

Example

```
IMPORT util
MAIN
    DISPLAY util.Strings.urlEncode("abcÄ€")
END MAIN

Output:
abc%C3%84%E2%82%AC
```

The util.Math class

The `util.Math` class provides basic mathematical functions based on floating point numbers (`FLOAT`).

This class does not have to be instantiated; it provides class methods for the current program.

This class is provided in the `util` C-Extension library; To use the `util.Math` class, you must import the `util` package in your program:

```
IMPORT util
```

util.Math methods

Methods for the `util.Math` class.

Table 440: Class methods

Name	Description
`util.Math.acos( val FLOAT ) RETURNING result FLOAT`	Computes the arc cosine of the passed value, measured in radians.
`util.Math.asin( val FLOAT ) RETURNING result FLOAT`	Computes the arc sine of the passed value, measured in radians.
`util.Math.atan( val FLOAT ) RETURNING result FLOAT`	Computes the arc tangent of the passed value, measured in radians.
`util.Math.cos( val FLOAT ) RETURNING result FLOAT`	Computes the cosine of the passed value, measured in radians.
`util.Math.exp( val FLOAT ) RETURNING result FLOAT`	Computes the base-e exponential of the value passed as parameter.
`util.Math.log( val FLOAT ) RETURNING result FLOAT`	Computes the natural logarithm of the passed value.
`util.Math.pi() RETURNING result FLOAT`	Returns the FLOAT value of PI.
`util.Math.pow( x FLOAT, y FLOAT ) RETURNING result FLOAT`	Computes the value of *x* raised to the power *y*.
`util.Math.rand( max INTEGER ) RETURNING result INTEGER`	Returns a positive pseudo-random number.
`util.Math.sin( val FLOAT ) RETURNING result FLOAT`	Computes the sine of the passed value, measured in radians.
`util.Math.sqrt( val FLOAT )`	Returns the square root of the argument provided.

Name	Description
`RETURNING result FLOAT`	
`util.Math.srand()`	Initializes the pseudo-random numbers generator.
`util.Math.tan( val FLOAT ) RETURNING result FLOAT`	Computes the tangent of the passed value, measured in radians.
`util.Math.toDegrees( val FLOAT ) RETURNING result FLOAT`	Converts an angle measured in radians to an approximately equivalent angle measured in degrees.
`util.Math.toRadians( val FLOAT ) RETURNING result FLOAT`	Converts an angle measured in degrees to an approximately equivalent angle measured in radians.

util.Math.acos
Computes the arc cosine of the passed value, measured in radians.

Syntax

```
util.Math.acos(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.asin
Computes the arc sine of the passed value, measured in radians.

Syntax

```
util.Math.asin(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.atan
Computes the arc tangent of the passed value, measured in radians.

Syntax

```
util.Math.atan(
```

```
    val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.cos
Computes the cosine of the passed value, measured in radians.

Syntax

```
util.Math.cos(
    val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage:

Returns `NULL` if the argument provided is invalid.

util.Math.exp
Computes the base-e exponential of the value passed as parameter.

Syntax

```
util.Math.exp(
    val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided on error.

util.Math.pi
Returns the FLOAT value of PI.

Syntax

```
util.Math.pi()
  RETURNING result FLOAT
```

util.Math.pow
Computes the value of *x* raised to the power *y*.

Syntax

```
util.Math.pow(
    x FLOAT,
    y FLOAT )
  RETURNING result FLOAT
```

1. *x* is the value to be raised.
2. *y* is the power operand.

Usage

The function returns `NULL` if one of the argument provided is invalid.

If *x* is negative, the caller should ensure that *y* is an integer value.

util.Math.rand
Returns a positive pseudo-random number.

Syntax

```
util.Math.rand(
   max INTEGER )
  RETURNING result INTEGER
```

1. *max* is the maximum random number that can be generated.

Usage

The `rand()` function returns a pseudo-random integer number between zero and *max*.

> **Important:**
>
> The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary according to the operating system.

The maximum random number returned by the `rand()` function is 2,147,483,646.

The `rand()` function returns zero if the argument is lower or equal to 0.

Example

```
IMPORT util
MAIN
    DEFINE i SMALLINT
    DISPLAY "Before srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
    CALL util.Math.srand()
    DISPLAY "After srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
END MAIN
```

(run this example several times)

util.Math.sin
Computes the sine of the passed value, measured in radians.

Syntax

```
util.Math.sin(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.sqrt
Returns the square root of the argument provided.

Syntax

```
util.Math.sqrt(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

The function returns `NULL` if the argument provided is invalid.

util.Math.srand
Initializes the pseudo-random numbers generator.

Syntax

```
util.Math.srand()
```

Usage

The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary according to the operating system.

util.Math.tan
Computes the tangent of the passed value, measured in radians.

Syntax

```
util.Math.tan(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.log
Computes the natural logarithm of the passed value.

Syntax

```
util.Math.log(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value.

Usage

Returns `NULL` if the argument provided is invalid.

util.Math.toDegrees
Converts an angle measured in radians to an approximately equivalent angle measured in degrees.

Syntax

```
util.Math.toDegrees(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value to be converted to degrees.

util.Math.toRadians
Converts an angle measured in degrees to an approximately equivalent angle measured in radians.

Syntax

```
util.Math.toRadians(
   val FLOAT )
  RETURNING result FLOAT
```

1. *val* is a floating point value to be converted to radians.

The util.JSON class
The `util.JSON` class provides a basic interface to convert program variable values to/from JSON data.

The `util.JSON` class is provided in the `util` C-Extension library; To use the `util.JSON` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

The purpose of the `util.JSON` class is to convert a JSON string from/to a BDL variable, to interface with other software based on the JSON format.

The BDL variable can be a simple variable (defined with a primitive type), a structured variable (`RECORD`), or dynamic array.

It is not possible to modify JSON elements with this class. In order to manipulate JSON objects, use the `util.JSONObject` and `util.JSONArray` classes.

util.JSON methods
Methods for the `util.JSON` class.

Table 441: Class methods

Name	Description
`util.JSON.format( source STRING ) RETURNING result STRING`	Formats JSON string with indentation.
`util.JSON.parse( source STRING,`	Parses a JSON string and fills program variables with the values.

Name	Description
destination { RECORD | DYNAMIC ARRAY })	
util.JSON.proposeType(*source* STRING) RETURNING *result* STRING	Describes the record structure that can hold a given JSON data string.
util.JSON.stringify(*source* { RECORD | DYNAMIC ARRAY }) RETURNING *result* STRING	Transforms a record variable to a flat JSON formatted string.

util.JSON.format
Formats JSON string with indentation.

Syntax

```
util.JSON.format(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string value that contains JSON formatted data.
2. *result* is a string that is well formatted and indented.

Usage

The `util.JSON.format()` class method takes a JSON formatted string as parameter and indents the JSON string.

The main purpose of this method is to beautify a JSON data string that is on a single line, by adding line breaks and indentation.

util.JSON.parse
Parses a JSON string and fills program variables with the values.

Syntax

```
util.JSON.parse(
   source STRING,
   destination { RECORD | DYNAMIC ARRAY } )
```

1. *source* is a string value that contains JSON formatted data.
2. *destination* is the variable to be initialized with values of the JSON string.

> **Important:** The *dest* record is passed by reference to the method.

Usage

The `util.JSON.parse()` class method scans the JSON source string passed as parameter and fills the destination variable members by name.

The destination variable should have the same structure as the JSON source data, it can be a `RECORD` or a `DYNAMIC ARRAY`.

See JSON to Genero BDL conversion rules on page 1987 for details on how the destination variable is populated when the structures are not identical.

Example

```
IMPORT util
MAIN
    DEFINE cust_rec RECORD
               cust_num INTEGER,
               cust_name VARCHAR(30),
               order_ids DYNAMIC ARRAY OF INTEGER
           END RECORD
    DEFINE js STRING
    LET js='{ "cust_num":2735, "cust_name":"McCarlson",
              "order_ids":[234,3456,24656,34561] }'
    CALL util.JSON.parse( js, cust_rec )
    DISPLAY cust_rec.cust_name
    DISPLAY cust_rec.order_ids[4]
END MAIN
```

util.JSON.proposeType
Describes the record structure that can hold a given JSON data string.

Syntax

```
util.JSON.proposeType(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string value that contains JSON formatted data.
2. *result* is a string that represents the definition of a `RECORD`.

Usage

The `util.JSON.proposeType()` class method takes a JSON formatted string as parameter and generates the `RECORD` definition that corresponds to the source JSON string.

This method is useful to define a record variable that must hold the given JSON string.

Example

```
IMPORT util
MAIN
    DEFINE js STRING
    LET js='{ "cust_num":2735, "cust_name":"McCarlson",
              "orderids":[234,3456,24656,34561] }'
    DISPLAY util.JSON.proposeType( js )
END MAIN
```

Displays:

```
 RECORD
    cust_num FLOAT,
    cust_name STRING,
    orderids DYNAMIC ARRAY OF FLOAT
END RECORD
```

util.JSON.stringify
Transforms a record variable to a flat JSON formatted string.

Syntax

```
util.JSON.stringify(
   source { RECORD | DYNAMIC ARRAY } )
  RETURNING result STRING
```

1. *source* is the program variable to be converted to a JSON string.
2. *result* is a JSON formatted string created from the source record.

Usage

The `util.JSON.stringify()` class method takes a `RECORD` or `DYNAMIC ARRAY` variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1988.

The method raises error -8110 if the JSON string cannot be generated.

Example

```
IMPORT util
MAIN
    DEFINE cust_rec RECORD
                cust_num INTEGER,
                cust_name VARCHAR(30),
                order_ids DYNAMIC ARRAY OF INTEGER
            END RECORD
    DEFINE js STRING
    LET cust_rec.cust_num = 345
    LET cust_rec.cust_name = "McMaclum"
    LET cust_rec.order_ids[1] = 4732
    LET cust_rec.order_ids[2] = 9834
    LET cust_rec.order_ids[3] = 2194
    LET js = util.JSON.stringify( cust_rec )
    DISPLAY util.JSON.format( js )
END MAIN
```

Displays following output:

```
{
    "cust_num": 345,
    "cust_name": "McMaclum",
    "order_ids": [4732,9834,2194
    ]
}
```

Examples

Example 1: Reading a JSON file

This program reads JSON data from `customers.json`, parses the line to fill the program variables, coverts the program variable back to JSON and writes a formatted JSON string to the standard output.

We assume that the source file contains the list of customers in a single line that can be read with `base.Channel.readLine()`:

```
IMPORT util
MAIN
  DEFINE custlist DYNAMIC ARRAY OF RECORD
            num INTEGER,
            name VARCHAR(40)
          END RECORD
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL ch.openFile("customers.json","r")
  CALL util.JSON.parse( ch.readLine(), custlist )
  DISPLAY custlist.getLength()
  DISPLAY util.JSON.format( util.JSON.stringify(custlist) )
  CALL ch.close()
END MAIN

-- customers.json file:
[ {"num":823, "name":"Mark Renbing" }, {"num":234, "name":"Clark
 Gambler" } ]
```

Note that the JSON file does not contain the name of the dynamic array (custlist), but starts directly with the JSON array in `[ ]` square braces.

The util.JSONObject class

The `util.JSONObject` class provides methods to handle an structured data object following the JSON string syntax.

The `util.JSONObject` class is provided in the `util` C-Extension library; To use the `util.JSONObject` class, you must import the `util` package in your program:

```
IMPORT util
```

A `JSONObject` is an unordered collection of name/value pairs. The format of a JSON object string is a coma-separated "name":value pairs, wrapped in curly braces. The value can be simple numeric or string value, but it can also be an array of values enclosed in square braces, or a sub-element enclosed in curly braces:

```
{
  "cust_num":2735,
  "cust_name":"McCarlson",
  "order_ids":[234,3456,24656,34561],
  "address": {
          "street":"34, Sunset Bld",
          "city":"Los Angeles",
          "state":"CA"
        }
}
```

A `JSONObject` object must be created before usage with one of the class methods like `util.JSONObject.create()`.

The `JSONObject` class provides methods for accessing, adding/replacing or deleting the values by name with the `get()`, `put()` and `remove()` methods.

The `get()` method can return a simple value, a `util.JSONObject` or a `util.JSONArray` object reference.

The `put()` method can take a simple value, a `RECORD`, or an `ARRAY` as parameter.

If the structure of the JSON object is not known at compile time, you can introspect the elements of the object with the `getLength()`, `getType()` and `name()` methods.

util.JSONObject methods
Methods for the `util.JSONObject` class.

Table 442: Class methods

Name	Description
`util.JSONObject.create()` `  RETURNING object util.JSONObject`	Creates a new JSON object.

`util.JSONObject.fromFGL(`
`  source RECORD )`
`  RETURNING object util.JSONObject`
	Creates a new JSON object from a `RECORD`.

`util.JSONObject.parse(`
`  source STRING )`
`  RETURNING result util.JSONObject`
	Parses a JSON string and creates a JSON object from it.

Table 443: Object methods

Name	Description

`util.JSONObject.get(`
`  name STRING )`
`  RETURNING result result-type`
	Returns the value corresponding to the specified entry name.

`util.JSONObject.getLength()` `  RETURNING len INTEGER`	Returns the number of name-value pairs in the JSON object.

`util.JSONObject.getType(`
`  name STRING )`
`  RETURNING type STRING`
	Returns the type of a JSON object element.

`util.JSONObject.has(`
`  name STRING )`
`  RETURNING result BOOLEAN`
	Checks if the JSON object contains a specific entry name.

`util.JSONObject.name(`
`  index INTEGER )`
`  RETURNING result STRING`
	Returns the name of a JSON object entry by position.

`util.JSONObject.put(`
`  name STRING,`
`  value value-type )`
	Sets a name-value pair in the JSON object.

`util.JSONObject.remove(`	Removes the specified element in the JSON object.

Name	Description
name STRING)	
util.JSONObject.toFGL(*dest* RECORD)	Fills a record variable with the entries contained in the JSON object.
util.JSONObject.toString() RETURNING *result* STRING	Builds a JSON string from the values contained in the JSON object.

util.JSONObject.create
Creates a new JSON object.

Syntax

```
util.JSONObject.create()
  RETURNING object util.JSONObject
```

Usage

The `util.JSONObject.create()` method create a new JSON object.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    ...
END MAIN
```

util.JSONObject.fromFGL
Creates a new JSON object from a `RECORD`.

Syntax

```
util.JSONObject.fromFGL(
   source RECORD )
  RETURNING object util.JSONObject
```

1. *source* is the `RECORD` variable used to create the JSON object.

Usage

The `util.JSONObject.fromFGL()` method creates a new JSON object from the `RECORD` variable passed as parameter.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

The members of the `RECORD` are converted to name/value pairs in the JSON object.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1988.

Example

```
IMPORT util
MAIN
    DEFINE cust_rec RECORD
                cust_num INTEGER,
                cust_name VARCHAR(30),
                order_ids DYNAMIC ARRAY OF INTEGER
            END RECORD
    DEFINE obj util.JSONObject
    LET cust_rec.cust_num = 345
    LET cust_rec.cust_name = "McMaclum"
    LET cust_rec.order_ids[1] = 4732
    LET cust_rec.order_ids[2] = 9834
    LET cust_rec.order_ids[3] = 2194
    LET obj = util.JSONObject.fromFGL(cust_rec)
    DISPLAY obj.toString()
END MAIN
```

util.JSONObject.parse
Parses a JSON string and creates a JSON object from it.

Syntax

```
util.JSONObject.parse(
   source STRING )
  RETURNING result util.JSONObject
```

1. *source* is a string value that contains JSON formatted data.

Usage

The `util.JSONObject.parse()` method scans the JSON source string passed as parameter and creates a JSON object from it.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

The source string must follow the JSON format specification. It can contain multi-level structured data, but it must start with a curly brace.

The method raises error -8109 if the JSON source string is not properly formatted.

Example

```
IMPORT util
MAIN
    DEFINE js STRING
    DEFINE obj util.JSONObject
    LET js='{ "cust_num":2735, "cust_name":"McCarlson",
              "orderids":[234,3456,24656,34561] }'
    LET obj = util.JSONObject.parse( js )
    DISPLAY obj.get("cust_name")
END MAIN
```

util.JSONObject.get
Returns the value corresponding to the specified entry name.

Syntax

```
util.JSONObject.get(
   name STRING )
  RETURNING result result-type
```

1. *name* is the string identifying the JSON object property.
2. *result-type* can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

Usage

The `get()` method returns the value or JSON object corresponding to the element name passed as parameter.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

Example

```
IMPORT util
MAIN
    DEFINE obj, sub util.JSONObject
    DEFINE jarr util.JSONArray
    DEFINE rec RECORD
                id INTEGER,
                name STRING
            END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    DEFINE x INT
    LET obj = util.JSONObject.create()
    -- Simple value
    CALL obj.put("simple", 234)
    LET x = obj.get("simple")
    -- Sub-element
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET sub = obj.get("record")
    -- Array
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    LET jarr = obj.get("array")
END MAIN
```

util.JSONObject.getLength
Returns the number of name-value pairs in the JSON object.

Syntax

```
util.JSONObject.getLength()
```

```
   RETURNING len INTEGER
```

Usage

The `getLength()` method returns the number of name-value pairs in the JSON object.

This method can be used in conjunction with the `name()` and `getType()` methods to read the entries of a JSON object.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE i INTEGER
    LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
    FOR i=1 TO obj.getLength()
        DISPLAY i, ": ", obj.name(i), "=", obj.get(obj.name(i))
    END FOR
END MAIN
```

util.JSONObject.getType
Returns the type of a JSON object element.

Syntax

```
util.JSONObject.getType(
   name STRING )
  RETURNING type STRING
```

1. *name* is the name of the element.

Usage

The `getType()` method returns the JSON data type name corresponding to the entry identified by the name passed as parameter.

This method can be used in conjunction with the `name()` and `getLength()` methods to read the entries of a JSON object.

Possible values returned by this method are:

- `NUMBER`: A numeric value.
- `STRING`: A string value delimited by double quotes.
- `BOOLEAN`: A boolean value (true/false)
- `NULL`: A un-existing element.
- `OBJECT`: A structured object.
- `ARRAY`: An ordered list of elements.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("id", 8723)
    DISPLAY obj.getType("id") -- NUMBER
    CALL obj.put("name", "Brando")
    DISPLAY obj.getType("name") -- STRING
```

```
    DISPLAY obj.getType("undef") -- NULL
END MAIN
```

util.JSONObject.has
Checks if the JSON object contains a specific entry name.

Syntax

```
util.JSONObject.has(
   name STRING )
  RETURNING result BOOLEAN
```

1. *name* is a string identifying a JSON object property.

Usage

The `has()` method determines if the JSON object holds a property identified by the name passed as parameter.

The method returns `TRUE` if the name/value pair exists in the JSON object.

A name/value pair can be set with the `put()` method.

util.JSONObject.name
Returns the name of a JSON object entry by position.

Syntax

```
util.JSONObject.name(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the index of the name-value pair in the JSON object.

Usage

The `name()` method returns the entry name in the JSON object at the given position.

The index corresponding to the first name-value pair is 1.

If no entry exists at the given index, the method returns `NULL`.

This method can be used in conjunction with the `getLength()` and `getType()` methods to read the entries of a JSON object.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE i INTEGER
    LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
    FOR i=1 TO obj.getLength()
        DISPLAY i, ": ", obj.name(i)
    END FOR
END MAIN
```

util.JSONObject.put
Sets a name-value pair in the JSON object.

Syntax

```
util.JSONObject.put(
   name STRING,
   value value-type )
```

1. *name* is a string defining the entry name.
2. *value* is the value to be associated to the name.
3. *value-type* can be a simple string or numeric type, a `RECORD` or an `DYNAMIC ARRAY`.

Usage

The `put()` method adds a name-value pair to the JSON object.

The first parameter is the name of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as `RECORD` or `DYNAMIC ARRAY`.

If the element exists, the existing value is replaced.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE rec RECORD
                id INTEGER,
                name STRING
            END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET obj = util.JSONObject.create()
    CALL obj.put("simple", 234)
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    DISPLAY obj.toString()
END MAIN
```

util.JSONObject.remove
Removes the specified element in the JSON object.

Syntax

```
util.JSONObject.remove(
   name STRING )
```

1. *name* is the string identifying the JSON object property.

Usage

The `remove()` method deletes a name-value pair identified by the name passed as parameter.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("address", "5 Brando Street")
    CALL obj.remove("address")
    DISPLAY obj.get("address")
END MAIN
```

util.JSONObject.toFGL
Fills a record variable with the entries contained in the JSON object.

Syntax

```
util.JSONObject.toFGL(
  dest RECORD )
```

1. *dest* is the variable to be set with values of the JSON string.

Important: The *dest* is a `RECORD` variable is passed by reference to the method.

Usage

The `toFGL()` method fills the `RECORD` variable passed as parameter with the corresponding values defined in the JSON object.

The destination record must have the same structure as the JSON source data. For more details see JSON to Genero BDL conversion rules on page 1987.

Example

```
IMPORT util
MAIN
    DEFINE cust_rec RECORD
                cust_num INTEGER,
                cust_name VARCHAR(30),
                order_ids DYNAMIC ARRAY OF INTEGER
            END RECORD
    DEFINE js STRING
    DEFINE obj util.JSONObject
    LET js='{ "cust_num":2735, "cust_name":"McCarlson",
              "order_ids":[234,3456,24656,34561] }'
    LET obj = util.JSONObject.parse( js )
    CALL obj.toFGL( cust_rec )
    DISPLAY cust_rec.cust_name
    DISPLAY cust_rec.order_ids[4]
END MAIN
```

util.JSONObject.toString
Builds a JSON string from the values contained in the JSON object.

Syntax

```
util.JSONObject.toString()
  RETURNING result STRING
```

Usage

The `toString()` method produces a JSON formatted string from the name-value pairs contained in the JSON object.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("num", "75263")
    CALL obj.put("name", "Ferguson")
    CALL obj.put("address", "12 Marylon Street")
    DISPLAY obj.toString()
END MAIN
```

The util.JSONArray class

The `util.JSONArray` class provides methods to handle an array of values, following the JSON string syntax.

The `util.JSONArray` class is provided in the `util` C-Extension library; To use the `util.JSONArray` class, you must import the `util` package in your program:

```
IMPORT util
```

A `JSONArray` is an sequence of unnamed values. The format of a JSON array string is a list of values wrapped in square braces with commas between the values:

```
[123,546,"abc","def","xyz"]
```

A `JSONArray` object must be created before usage with one of the class methods like `util.JSONArray.create()`.

The `JSONArray` class provides methods for accessing, adding/replacing or deleting the array values by index with the `get()`, `put()` and `remove()` methods.

If the structure of the JSON array is not known at compile time, you can introspect the elements of the array with the `getLength()` and `getType()` methods.

util.JSONArray methods

Methods for the `util.JSONArray` class.

Table 444: Class methods

Name	Description
`util.JSONArray.create()` `  RETURNING` *`array`* `util.JSONArray`	Creates a new JSON array object.

`util.JSONArray.fromFGL(`
`  `*`source`* `DYNAMIC ARRAY )`
`  RETURNING` *`array`* `util.JSONArray`
	Creates a new JSON array object from a `DYNAMIC ARRAY`.

`util.JSONArray.parse(` `  `*`source`* `STRING )`	Parses a JSON string and creates a JSON array object from it.

Name	Description
`RETURNING result util.JSONArray`	

Table 445: Object methods

Name	Description
`util.JSONArray.get( index INTEGER ) RETURNING result result-type`	Returns the value of a JSON array element.
`util.JSONArray.getLength() RETURNING length INTEGER`	Returns the number of elements in the JSON array object.
`util.JSONArray.getType( index INTEGER ) RETURNING type STRING`	Returns the type of a JSON array element.
`util.JSONArray.put( index INTEGER, value value-type )`	Sets an element by position in the JSON array object.
`util.JSONArray.remove( index INTEGER )`	Removes the specified entry in the JSON array object.
`util.JSONArray.toFGL( dest DYNAMIC ARRAY )`	Fills a dynamic array variable with the elements contained in the JSON array object.
`util.JSONArray.toString() RETURNING result STRING`	Builds a JSON string from the elements contained in the JSON array object.

util.JSONArray.create
Creates a new JSON array object.

Syntax

```
util.JSONArray.create()
  RETURNING array util.JSONArray
```

Usage

The `util.JSONArray.create()` method create a new JSON array object.

The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

Example

```
IMPORT util
MAIN
```

```
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.create()
    ...
END MAIN
```

util.JSONArray.fromFGL
Creates a new JSON array object from a `DYNAMIC ARRAY`.

Syntax

```
util.JSONArray.fromFGL(
   source DYNAMIC ARRAY )
  RETURNING array util.JSONArray
```

1. *source* is the `DYNAMIC ARRAY` variable used to create the JSON array object.

Usage

The `util.JSONArray.fromFGL()` method creates a new JSON array from the `DYNAMIC ARRAY` variable passed as parameter.

The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

The members of the `DYNAMIC ARRAY` are converted to a list of name/value pairs in the JSON array object.

The dynamic array can be structured with a `RECORD` definition: the elements of the array will be converted individually.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1988.

Example

```
IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET da[1] = 123
    LET da[2] = 972
    LET arr = util.JSONArray.fromFGL(da)
    DISPLAY arr.toString()
END MAIN
```

util.JSONArray.parse
Parses a JSON string and creates a JSON array object from it.

Syntax

```
util.JSONArray.parse(
   source STRING )
  RETURNING result util.JSONArray
```

1. *source* is a string value that contains JSON formatted data as a list of elements delimited by square braces.

Usage

The `util.JSONArray.parse()` method scans the JSON source string passed as parameter and creates a new JSON array object from it.

The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

The source string must follow the JSON format specification. Elements of the list can contain multi-level structured data, but the string must follow the JSON array string syntax '`[ element, ... ]`' with square braces.

The method raises error -8109 if the JSON source string is not properly formatted.

Example

```
IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse("[1,2,3,4,5]")
    DISPLAY arr.toString()
END MAIN
```

util.JSONArray.get
Returns the value of a JSON array element.

Syntax

```
util.JSONArray.get(
   index INTEGER )
  RETURNING result result-type
```

1. *index* is the index of the element in the JSON array object.
2. *result-type* can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

Usage

The `get()` method returns the value or JSON object corresponding to the element at the given position.

The index corresponding to the first element is 1.

If no element exists at the given index, the method returns `NULL`.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

Example

```
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('[123,"abc",null]')
    DISPLAY arr.get(2) -- abc
END MAIN
```

util.JSONArray.getLength
Returns the number of elements in the JSON array object.

Syntax

```
util.JSONArray.getLength()
  RETURNING length INTEGER
```

Usage

The `getLength()` method returns the number of elements in the JSON array object.

This method can be used in conjunction with the `get()` and `getType()` method to read elements of a JSON array object.

Example

```
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    DEFINE i INTEGER
    LET arr = util.JSONArray.parse('[123,8723,9232]')
    FOR i=1 TO arr.getLength()
        DISPLAY i, ": ", arr.get(i)
    END FOR
END MAIN
```

util.JSONArray.getType
Returns the type of a JSON array element.

Syntax

```
util.JSONArray.getType(
   index INTEGER )
  RETURNING type STRING
```

1. *index* is the ordinal position of the element.

Usage

The `getType()` method returns the data type name corresponding to the JSON array element at the given position.

The index corresponding to the first element is 1.

This method can be used in conjunction with the `getLength()` method to read the entries of a JSON array object.

Possible values returned by this method are:

- `NUMBER`: A numeric value.
- `STRING`: A string value delimited by double quotes.
- `BOOLEAN`: A boolean value (true/false)
- `NULL`: A un-existing element.
- `OBJECT`: A structured object.
- `ARRAY`: An ordered list of elements.

Example

```
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('[123,"abc",null]')
    DISPLAY arr.getType(1) -- NUMBER
    DISPLAY arr.getType(2) -- STRING
    DISPLAY arr.getType(3) -- NULL
END MAIN
```

util.JSONArray.put
Sets an element by position in the JSON array object.

Syntax

```
util.JSONArray.put(
   index INTEGER,
   value value-type )
```

1. *index* is the index of the element in the JSON array object.
2. *value* is the value to be associated to the index.
3. *value-type* can be a simple string or numeric type, a `RECORD` or an `DYNAMIC ARRAY`.

Usage

The `put()` method sets an element value by position in the JSON array object.

The first parameter is the index of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as `RECORD` or `DYNAMIC ARRAY`.

The index corresponding to the first element is 1.

If the element exists, the existing value is replaced.

Example

```
IMPORT util
MAIN
    DEFINE ja util.JSONArray
    DEFINE rec RECORD
                id INTEGER,
                name STRING
            END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET ja = util.JSONArray.create()
    CALL ja.put(1, 234)
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL ja.put(2, rec)
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL ja.put(3, arr)
    DISPLAY ja.toString()
END MAIN
```

util.JSONArray.remove
Removes the specified entry in the JSON array object.

Syntax

```
util.JSONArray.remove(
   index INTEGER )
```

1. *index* is the index of the element in the JSON array object.

Usage

The `remove()` method deletes an element in the JSON array object at the given position.

The index corresponding to the first element is 1.

If no element exists at the specified index, the method returns silently.

Example

```
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('["aa","bb","cc"]')
    CALL arr.remove(2)
    DISPLAY arr.get(2) -- cc
END MAIN
```

util.JSONArray.toFGL
Fills a dynamic array variable with the elements contained in the JSON array object.

Syntax

```
util.JSONArray.toFGL(
   dest DYNAMIC ARRAY )
```

1. *dest* is the array variable to be set with values of the JSON string.

Important: The *dest* is a dynamic array passed by reference to the method.

Usage

The `toFGL()` method fills the `DYNAMIC ARRAY` passed as parameter with the corresponding values defined in the JSON array object.

The destination array must have the same structure as the JSON source data. For more details see JSON to Genero BDL conversion rules on page 1987.

Example

```
IMPORT util
MAIN
    DEFINE ja util.JSONArray
    DEFINE arr DYNAMIC ARRAY OF STRING
    LET ja = util.JSONArray.parse('["aa","bb","cc"]')
    CALL ja.toFGL(arr)
    DISPLAY arr[2] -- bb
END MAIN
```

util.JSONArray.toString
Builds a JSON string from the elements contained in the JSON array object.

Syntax

```
util.JSONArray.toString()
  RETURNING result STRING
```

Usage

The `toString()` method produces a JSON formatted string from the elements contained in the JSON array object.

Example

```
IMPORT util
MAIN
    DEFINE ja util.JSONArray
    LET ja = util.JSONArray.create()
    CALL ja.put(1,"aa")
    CALL ja.put(2,"bb")
    CALL ja.put(3,"cc")
    DISPLAY ja.toString() -- ["aa","bb","cc"]
END MAIN
```

JSON classes

Gives a basic introduction to JSON.

What is JSON?

JSON (JavaScript™ Object Notation) is a well known lightweight data-interchange format for JavaScript™.

A JSON string (or object) is a comma-separated list of name/value pairs, with a `:` colon separating the key and the value. The list of name/value pairs is enclosed in `{}` curly braces. The names are delimited by double-quotes. The value can be a single numeric value, a double-quotes string, an array, or a sub-element. Arrays are defined by a comma-separated list of values enclosed in `[]` square brackets. Sub-elements are defined inside {} curly braces and defineds name/value pairs.

For example:

```
{
   "cust_num":865234,
   "cust_name":"McCarlson",
   "order_ids":[234,3456,24656,34561],
   "address": {
          "street":"34, Sunset Bld",
          "city":"Los Angeles",
          "state":"CA"
       }
}
```

For more details, see http://www.json.org.

JSON utility classes

The `util` library provides a set of JSON classes to convert JSON documents to/from `RECORD` and `ARRAY` variables, and to manipulate JSON objects, if you need to handle JSON objects that do not map to a `RECORD` or `ARRAY`:

- The util.JSON class on page 1966
- The util.JSONObject class on page 1970
- The util.JSONArray class on page 1979

JSON to Genero BDL conversion rules

The JSON utility classes implement methods that can fill a Genero BDL `RECORD` or `DYNAMIC ARRAY`. This topic describes how JSON data is converted to Genero BDL data.

The destination record or array must have the same structure as the JSON source data.

Each JSON element is assigned to a record member by name, not by position. Elements in the JSON string can be at a different ordinal position as the corresponding members in the destination record.

Element name matching is case-insensitive. For example, if the Genero BDL record member is defined as `CustNo`, and the JSON data string contains the `"custno":999` name/value pair, the value will be assigned. However, since Genero BDL record member names are used as-is to write JSON data, is it strongly recommended to define the Genero BDL records with the exact names used in JSON data string.

Elements in the JSON string that do not match an Genero BDL record member are ignored; no error is thrown if there is no corresponding Genero BDL member.

Genero BDL record members that have no matching JSON element are initialized to `NULL`.

> **Important:** JSON specifications allow you to define element names with characters that cannot be used in Genero BDL identifiers. For example, a JSON element name can be `"customer.name"` or `"customer:name"`, however it is not possible to define a program variable with these same names. To work around this issue, define the record elements with underscores in place of unsupported characters, and before assigning the JSON string to the Genero BDL record, replace all element names by the corresponding record member names (using `base.StringBuffer.replace` to do the replacements).

The JSON value must match the data format of the destination member. If the value does not correspond to the type (for example, if the JSON value is a character string while the target record member is defined with a numeric type), the target member will be set to `NULL`.

JSON arrays delimited by square brackets are used to fill a program array of the destination record. The destination array should be a dynamic array. If the array is defined as static, the additional elements of the source JSON array will be discarded, while missing elements will be initialized to `NULL`.

The JSON source string must follow the JSON format specification. It can contain multilevel structured data. If the source string is not well formatted, the runtime system will throw error -8109.

Table 446: JSON to Genero BDL type conversion rules

Target Genero BDL type	Description
`BOOLEAN`	The JSON value should be `null`, `true` or `false`. If the JSON value is a number or a string, the language conversion rules from number/string to `BOOLEAN` apply.
`TINYINT`, `SMALLINT`, `INTEGER`, `BIGINT`, `SMALLFLOAT`, `FLOAT`, `DECIMAL`, `MONEY`	A JSON number can be assigned to any language numeric type. The limits of the target type cause potential overflows errors. On error the target variable will be initialized to `NULL`, the parser continues without an error.
`DATE`	The JSON value must be a string formatted as `"YYYY-MM-DD"`.
`DATETIME`	If the value is a JSON string, it must be formatted as `"YYYY-MM-DD hh:mm:ss.fffff"`,

Target Genero BDL type	Description
	or represent as an ISO 8601 formatted date-time, in UTC (with Z indicator) or with a timezone offset (+/-hh[:mm]). For example: `"2013-02-21T15:18:44.456Z"`, `"2013-02-21T20:18:44.456+02:00"`. If the value is a JSON number, it is interpreted as UNIX™ time (seconds since the Epoch 00:00:00 UTC, January 1, 1970). Note that the `YYYY-MM-DD hh:mm:ss.ffff` format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider to convert date-time values to Coordinated Universal Time (UTC), by using the `util.Datetime` methods.
`INTERVAL`	The JSON valid must be a string formatted as "`YYYY-MM`" or "`DD hh:mm:ss.fffff`", according to interval class of the target variable.
`BYTE`	The JSON string value must be encoded in Base64. The Base64 encoding is described in [RFC4648].
`TEXT`, `CHAR`, `VARCHAR`, `STRING`	If the value is a number, the result string uses the locale specific decimal point. Any character in the Basic Multilingual Plane (U+0000 through U+FFFF) may be escaped: `\u` followed by exactly 4 hexadecimal digits (`[0-9a-fA-F]`). The hexadecimal digits encode the code point. Escaping of characters outside the Basic Multilingual Plane my be escaped by there UTF-16 surrogate pairs. Example: This is the representation of the G clef character (`U+1D11E`) "`\uD834\uDD1E`".

Genero BDL to JSON conversion rules

The JSON utility classes implement methods that can convert an Genero BDL `RECORD` or `DYNAMIC ARRAY` to a JSON data string. This topic describes how Genero BDL data is converted to JSON data.

To name the JSON elements, the names of the record members are used as defined in the program source. Since JSON is case-sensitive, make sure the names of the Genero BDL record members match exactly the names expected in the resulting JSON data string: `CustNo` will be different from `custNo`.

> **Important:** JSON specifications allow you to define element names with characters that cannot be used in Genero BDL identifiers. For example, a JSON element name can be `"customer.name"` or `"customer:name"`, however it is not possible to define a program variable with these same names. To work around this issue, define the record elements with underscores in place of unsupported characters, and before assigning the JSON string to the Genero BDL record, replace all element names by the corresponding record member names (using `base.StringBuffer.replace` to do the replacements).

If a record member is `NULL`, then the resulting JSON string or object omits that member.

Program array members in the record are converted to JSON arrays delimited by square brackets (`[]`).

Table 447: Genero BDL to JSON type conversion rules

Target Genero BDL type	Description
`BOOLEAN`	Will be serialized with the JSON values `true` or `false`.
`TINYINT`, `SMALLINT`, `INTEGER`, `BIGINT`, `SMALLFLOAT`, `FLOAT`, `DECIMAL`, `MONEY`	Any numeric type will be serialized to this form: an optional minus sign (`-`), a sequence of digits (`0-9`), containing a optional decimal separator (`.`), followed by an optional exponent. The exponent has the form (e) followed by an optional minus sign and an sequence of digits. The representation of numeric values does not depend from the current locale. The decimal separator is always a dot (`.`). `MONEY` values will be represented like `DECIMAL` values: the currency symbol will be omitted.
`DATE`	The date value will be formatted as `"YYYY-MM-DD"` (with double quotes)
`DATETIME`	The date-time value will be formatted as `"YYYY-MM-DD hh:mm:ss.fffff"` (with double quotes), according to the date-time type definition. For example, a `DATETIME HOUR TO MINUTE` will produce `"hh:mm"` formatted values. Note that the `YYYY-MM-DD hh:mm:ss.ffff` format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider to convert date-time values to Coordinated Universal Time (UTC), by using the `util.Datetime` methods.
`INTERVAL`	The interval value will be formatted as `"YYYY-MM"` or `"DD hh:mm:ss.fffff"` (with double quotes), according to the interval type definition.
`BYTE`	Will be serialized to a Base64 encoded double quoted string. The Base64 encoding is described in [RFC4648].

`TEXT`, `CHAR`, `VARCHAR`, `STRING`	Character string data will be serialized as a double quoted string with backslash escaping.
	List of characters requiring escaping:
	`\\ backslash U+005C`
	`\" quotation mark U+0022`
	`\b backspace U+0008`
	`\f form feed U+000C`
	`\n line feed U+000A`
	`\r carriage return U+000D`
	`\t tab U+0009`

Other	Any other type will be serialized as a double quoted (") string.

The os package

These topics cover the classes for the `os` package.

The os.Path class

The `os.Path` class provides functions to manipulate files and directories on the machine where the program executes.

This class is provided in the `util` C-Extension library; To use the `os.Path` extension, you must import the `os` package in your program:

```
IMPORT os
```

In order to manipulate files, this API give you access to low-level system functions. Pay attention to operating system specific conventions like path separators. Some functions are OS specific, like `rwx()` which works only on UNIX™ systems.

os.Path methods

Table 448: Class methods

Name	Description
`os.Path.atime( fname STRING) RETURNING result STRING`	Returns the time of the last file access.
`os.Path.baseName( filename STRING) RETURNING result STRING`	Returns the last element of a path.
`os.Path.chDir( newdir STRING) RETURNING result INTEGER`	Changes the current working directory.
`os.Path.chOwn( fname STRING, uid INTEGER, gui INTEGER ) RETURNING result INTEGER`	Changes the UNIX™ owner and group of a file.
`os.Path.chRwx( fname STRING, mode INTEGER ) RETURNING result INTEGER`	Changes the UNIX™ permissions of a file.
`os.Path.chVolume( new STRING) RETURNING result INTEGER`	Changes the current working volume.
`os.Path.copy( source STRING, dest STRING )`	Creates a new file by copying an existing file.

Name	Description
`RETURNING result INTEGER`	
`os.Path.delete( dname STRING) RETURNING result INTEGER`	Deletes a file or a directory.
`os.Path.dirClose( dirhandle INTEGER)`	Closes the directory referenced by the directory opened by `os.Path.diropen()`.
`os.Path.dirFMask( mask INTEGER)`	Defines a filter mask for `os.Path.dirOpen()`.
`os.Path.dirName( filename STRING) RETURNING result STRING`	Returns all components of a path excluding the last one.
`os.Path.dirNext( dirhandle INTEGER) RETURNING direntry STRING`	Reads the next entry in the directory opened with `os.Path.dirOpen()`.
`os.Path.dirOpen( dname STRING) RETURNING dirhandle INTEGER`	Opens a directory and returns an integer handle to this directory.
`os.Path.dirSort( criteria STRING, order INTEGER )`	Defines the sort criteria and sort order for `os.Path.dirOpen()`.
`os.Path.executable( fname STRING) RETURNING result INTEGER`	Checks if a file is executable.
`os.Path.exists( fname STRING) RETURNING result INTEGER`	Checks if a file exists.
`os.Path.extension( fname STRING) RETURNING result STRING`	Returns the file extension.
`os.Path.fullPath( path STRING) RETURNING result STRING`	Returns the canonical equivalent of a path.
`os.Path.gid(`	Returns the UNIX™ group id of a file.

Name	Description
fname STRING) RETURNING *id* INTEGER	
os.Path.homeDir() RETURNING *homedir* STRING	Returns the path to the HOME directory of the current user.
os.Path.isDirectory(*fname* STRING) RETURNING *result* BOOLEAN	Checks if a file is a directory.
os.Path.isFile(*fname* STRING) RETURNING *result* BOOLEAN	Checks if a file is a regular file.
os.Path.isHidden(*fname* STRING) RETURNING *result* BOOLEAN	Checks if a file is hidden.
os.Path.isLink(*fname* STRING) RETURNING *result* BOOLEAN	Checks if a file is UNIX™ symbolic link.
os.Path.isRoot(*path* STRING) RETURNING *result* BOOLEAN	Checks if a file path is a root path.
os.Path.join(*begin* STRING, *end* STRING) RETURNING *result* STRING	Joins two path segments adding the platform-dependent separator.
os.Path.makeTempName() RETURNING *result* STRING	Generates a temporary file name.
os.Path.mkDir(*dname* STRING) RETURNING *result* INTEGER	Creates a new directory.
os.Path.mtime(*fname* STRING) RETURNING *result* STRING	Returns the time of the last file modification.
os.Path.pathSeparator()	Returns the character used in environment variables to separate path elements.

Name	Description
`RETURNING result STRING`	
`os.Path.pathType( path STRING) RETURNING result STRING`	Checks if a path is a relative path or an absolute path.
`os.Path.pwd() RETURNING result STRING`	Returns the current working directory.
`os.Path.readable( fname STRING) RETURNING result INTEGER`	Checks if a file is readable.
`os.Path.rename( oldname STRING, newname STRING ) RETURNING result INTEGER`	Renames a file or a directory.
`os.Path.rootDir() RETURNING rootdir STRING`	Returns the root directory of the current working path.
`os.Path.rootName( filename STRING) RETURNING result STRING`	Returns the file path without the file extension of the last element of the file path.
`os.Path.rwx( fname STRING) RETURNING mode INTEGER`	Returns the UNIX™ file permissions of a file.
`os.Path.separator() RETURNING result STRING`	Returns the character used to separate path segments.
`os.Path.size( fname STRING) RETURNING result INTEGER`	Returns the size of a file.
`os.Path.type( fname STRING) RETURNING result STRING`	Returns the file type as a string.
`os.Path.uid( fname STRING) RETURNING id INTEGER`	Returns the UNIX™ user id of a file.
`os.Path.volumes()`	Returns the available volumes.

Name	Description
`RETURNING volumes STRING`	
`os.Path.writable( fname STRING) RETURNING result INTEGER`	Checks if a file is writable.

os.Path.atime
Returns the time of the last file access.

Syntax

```
os.Path.atime(
   fname STRING)
  RETURNING result STRING
```

1. *fname* is the name of the file.

Usage

The function returns a string containing the last access time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns NULL.

os.Path.baseName
Returns the last element of a path.

Syntax

```
os.Path.baseName(
   filename STRING)
  RETURNING result STRING
```

1. *filename* is the name of the file.

Usage

This method extracts the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "file.ext".

See Example 1: Extracting the parts of a file name on page 2007 for more examples.

os.Path.copy
Creates a new file by copying an existing file.

Syntax

```
os.Path.copy(
   source STRING,
   dest STRING )
  RETURNING result INTEGER
```

1. *source* is the name of the file to copy.
2. *dest* is the destination name of the copied file.

Usage

The function returns TRUE if the file has been successfully copied, FALSE otherwise.

os.Path.chDir
Changes the current working directory.

Syntax

```
os.Path.chDir(
   newdir STRING)
  RETURNING result INTEGER
```

1. *newdir* is the directory to select.

Usage

Use this function to change the current working directory.

The function returns TRUE if the current directory could be successfully selected, FALSE otherwise.

os.Path.chRwx
Changes the UNIX™ permissions of a file.

Syntax

```
os.Path.chRwx(
   fname STRING,
   mode INTEGER )
  RETURNING result INTEGER
```

1. *fname* is the name of the file.
2. *mode* is the UNIX™ permission combination in decimal (not octal!).

Usage

This method can only be used on UNIX™!

Function returns TRUE on success, FALSE otherwise.

The *mode* must be a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. Make sure to pass the *mode* as the decimal version of permissions, not as octal (the chrwx UNIX™ command takes an octal value as parameter). For example, to set `-rw-r--r--` permissions, you must pass (((4+2) *64) + (4 * 8) + 4) = 420 to this method.

os.Path.chOwn
Changes the UNIX™ owner and group of a file.

Syntax

```
os.Path.chOwn(
   fname STRING,
   uid INTEGER,
   gui INTEGER )
  RETURNING result INTEGER
```

1. *fname* is the name of the file.
2. *uid* is the user id.
3. *gui* is the group id.

Usage

This method can only be used on UNIX™!

Function returns TRUE on success, FALSE otherwise.

os.Path.chVolume
Changes the current working volume.

Syntax

```
os.Path.chVolume(
   new STRING)
  RETURNING result INTEGER
```

1. *new* is the volume to select as the new current working volume.

Usage

To change the current volume to C:

```
LET result = os.Path.chVolume("C:\\")
```

The function returns TRUE if the current working volume could be successfully changed, FALSE otherwise.

os.Path.delete
Deletes a file or a directory.

Syntax

```
os.Path.delete(
   dname STRING)
  RETURNING result INTEGER
```

1. *dname* is the name of the file or directory to delete.

Usage

A directory can only be deleted if it is empty.

The function TRUE if the file has been successfully deleted, FALSE otherwise.

os.Path.dirClose
Closes the directory referenced by the directory opened by `os.Path.diropen()`.

Syntax

```
os.Path.dirClose(
   dirhandle INTEGER)
```

1. *dirhandle* is the directory handle of the directory to close.

Usage

This function closes the directory search handle opened with `os.Path.dirOpen()`.

os.Path.dirFMask
Defines a filter mask for `os.Path.dirOpen()`.

Syntax

```
os.Path.dirFMask(
   mask INTEGER)
```

1. *mask* defines the filter mask.

Usage

When you call this function, you define the filter mask for any subsequent `os.Path.dirOpen()` call.

By default, all kinds of directory entries are selected by the `dirOpen()` function. You can restrict the number of entries by using a filter mask.

The parameter of the `os.Path.dirFMask()` function must be a combination of the following bits:

- `0x01` = Exclude hidden files (.*)
- `0x02` = Exclude directories
- `0x04` = Exclude symbolic links
- `0x08` = Exclude regular files

For example, to retrieve only regular files, you must call:

```
CALL os.Path.dirFMask( 1 + 2 + 4 )
```

os.Path.dirName
Returns all components of a path excluding the last one.

Syntax

```
os.Path.dirName(
   filename STRING)
  RETURNING result STRING
```

1. *filename* is the name of the file.
2. *result* contains all the elements of the path excluding the last one.

Usage

This method removes the last component of a path provided as argument.

For example, if you pass `"/root/dir1/file.ext"` as the parameter, it will return `"/root/dir1"`.

See Example 1: Extracting the parts of a file name on page 2007 for more examples.

os.Path.dirNext
Reads the next entry in the directory opened with `os.Path.dirOpen()`.

Syntax

```
os.Path.dirNext(
   dirhandle INTEGER)
  RETURNING direntry STRING
```

1. *dirhandle* is the directory handle of the directory to read.
2. *direntry* is the name of the entry read or `NULL` if all entries have been read.

Usage

This function returns the next entry of the directory opened with `os.Path.dirOpen()`.

os.Path.dirOpen
Opens a directory and returns an integer handle to this directory.

Syntax

```
os.Path.dirOpen(
   dname STRING)
  RETURNING dirhandle INTEGER
```

1. *dname* is the name of the directory.
2. *dirhandle* is the directory handle.

Usage

This function creates a handle to scan the elements of a directory.

The function returns a value of 0 if it fails to open the directory.

Before calling the `dirOpen()` method, you can define a filter with `os.Path.dirFMask()`, and a sort order with `os.Path.dirSort()`.

os.Path.dirSort
Defines the sort criteria and sort order for `os.Path.dirOpen()`.

Syntax

```
os.Path.dirSort(
   criteria STRING,
   order INTEGER )
```

1. *criteria* is the sort criteria.
2. *order* defines ascending (1) or descending (-1) order.

Usage

When you call this function, you define the sort criteria and sort order for any subsequent `os.Path.dirOpen()` call.

The *criteria* parameter must be one of the following strings:

- `"undefined"` = No sort. This is the default. Entries are read as returned by the OS functions.
- `"name"` = Sort by file name.
- `"size"` = Sort by file size.
- `"type"` = Sort by file type (directory, link, regular file).
- `"atime"` = Sort by access time.
- `"mtime"` = Sort by modification time.
- `"extension"` = Sort by file extension.

When sorting by name, directory entries will be ordered according to the current locale.

When sorting by any criteria other than the file name, entries having the same value for the given criteria are ordered by name following the value of the *order* parameter.

os.Path.executable
Checks if a file is executable.

Syntax

```
os.Path.executable(
   fname STRING)
  RETURNING result INTEGER
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is executable, FALSE otherwise.

os.Path.exists
Checks if a file exists.

Syntax

```
os.Path.exists(
   fname STRING)
  RETURNING result INTEGER
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file exists, FALSE otherwise.

os.Path.extension
Returns the file extension.

Syntax

```
os.Path.extension(
   fname STRING)
  RETURNING result  STRING
```

1. *fname* is the file name.

Usage

The function returns the string following the last dot found in *fname*.

If *fname* does not have an extension, the function returns NULL.

os.Path.fullPath
Returns the canonical equivalent of a path.

Syntax

```
os.Path.fullPath(
   path STRING)
  RETURNING result STRING
```

1. *path* is the path to complete.

Usage

The `os.path.fullPath()` class method takes a path as parameter and resolves extra path separator characters (`/` on UNIX™, `\` on Windows™), as well as references to current (`.`) and parent directory (`..`). The result is called a canonical path.

On UNIX™, symbolic links are not followed. Use the `os.Path.isLink()` method to identify symbolic links.

Example

```
DISPLAY os.Path.fullPath("/home/usr//scott/tmp/../images")
```

Resolves to:

```
/home/usr/scott/images
```

os.Path.gid
Returns the UNIX™ group id of a file.

Syntax

```
os.Path.gid(
   fname STRING)
  RETURNING id INTEGER
```

1. *fname* is the name of the file.
2. *id* is the group id.

Usage

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

os.Path.homeDir
Returns the path to the HOME directory of the current user.

Syntax

```
os.Path.homeDir()
  RETURNING homedir STRING
```

1. *homedir* Path to the HOME directory of the user.

os.Path.isDirectory
Checks if a file is a directory.

Syntax

```
os.Path.isDirectory(
   fname STRING)
  RETURNING result BOOLEAN
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is a directory, FALSE otherwise.

os.Path.isFile
Checks if a file is a regular file.

Syntax

```
os.Path.isFile(
   fname STRING)
  RETURNING result BOOLEAN
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is a regular file, FALSE otherwise.

os.Path.isHidden
Checks if a file is hidden.

Syntax

```
os.Path.isHidden(
   fname STRING)
  RETURNING result BOOLEAN
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is hidden, FALSE otherwise.

For example, on UNIX™, files starting with a dot in the file name are considered as hidden when using the ls command.

os.Path.isLink
Checks if a file is UNIX™ symbolic link.

Syntax

```
os.Path.isLink(
   fname STRING)
  RETURNING result BOOLEAN
```

1. *fname* is the file name.

Usage

The function returns TRUE if the files is a symbolic link, FALSE otherwise.

This method can only be used on UNIX™!

os.Path.isRoot
Checks if a file path is a root path.

Syntax

```
os.Path.isRoot(
   path STRING)
  RETURNING result BOOLEAN
```

x

1. *path* is the path to check.

Usage

The function returns TRUE if the path is a root path, FALSE otherwise.

On UNIX™ the root path is '/'.

On Windows™ the root path matches "[a-zA-Z]:\".

os.Path.join
Joins two path segments adding the platform-dependent separator.

Syntax

```
os.Path.join(
   begin STRING,
   end STRING )
  RETURNING result STRING
```

1. *begin* is the beginning path segment.
2. *end* is the ending path segment.

Usage

Use this method to construct a path with no system-specific code to use the correct path separator:

```
LET path = os.Path.join(os.Path.homedir(), name)
```

This method returns the ending path segment if it is an absolute path.

If one of the arguments is NULL, the function returns NULL.

os.Path.makeTempName
Generates a temporary file name.

Syntax

```
os.Path.makeTempName()
  RETURNING result STRING
```

Usage

This method creates a new temporary file path, with the unique file name, in the temporary directory of the process.

The temporary directory is found according to the type of platform, see DBTEMP environment variable for more details.

> **Note:** If a file is created with the given path, it must be deleted explicitely.

os.Path.mtime
Returns the time of the last file modification.

Syntax

```
os.Path.mtime(
   fname STRING)
  RETURNING result STRING
```

1. *fname* is the name of the file.
2. *result* is the last modification time.

Usage

The function returns a string containing the last modification time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns NULL.

os.Path.mkDir
Creates a new directory.

Syntax

```
os.Path.mkDir(
   dname STRING)
  RETURNING result INTEGER
```

1. *dname* is the name of the directory to create.

Usage

The function returns TRUE if the directory has been successfully created, FALSE otherwise.

os.Path.pathSeparator
Returns the character used in environment variables to separate path elements.

Syntax

```
os.Path.pathSeparator()
  RETURNING result STRING
```

Usage

You typically use this method to build a path from two components.

On UNIX™, the path separator is ':'.

On Windows™, the path separator is ';'.

os.Path.pathType
Checks if a path is a relative path or an absolute path.

Syntax

```
os.Path.pathType(
   path STRING)
  RETURNING result STRING
```

1. *path* is the path to check.

Usage

The function returns "absolute" if the path is an absolute path, or "relative" if the path is a relative path.

If the path is NULL, the function returns NULL.

os.Path.pwd
Returns the current working directory.

Syntax

```
os.Path.pwd()
  RETURNING result STRING
```

Usage

This function returns the path of the current working directory.

On a mobile device, this front call returns the current application working directory:

- On Android™, it returns the directory where the program executes.
- On iOS, it returns the "Documents" directory under the application directory.

os.Path.readable
Checks if a file is readable.

Syntax

```
os.Path.readable(
   fname STRING)
  RETURNING result INTEGER
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is readable, FALSE otherwise.

os.Path.rename
Renames a file or a directory.

Syntax

```
os.Path.rename(
   oldname STRING,
   newname STRING )
  RETURNING result INTEGER
```

1. *oldname* is the current name of the file or directory to be renamed.
2. *newname* is the new name to assign to the file or directory.

Usage

The function returns TRUE if the file or directory has been successfully renamed, FALSE otherwise.

On UNIX™ platforms, you can rename/move files and directories.

On Microsoft™ Windows™ platforms only files can be renamed/moved. However, on Windows™ you can move files across disks and directories.

os.Path.separator
Returns the character used to separate path segments.

Syntax

```
os.Path.separator()
```

```
   RETURNING result STRING
```

Usage

Use this method to build a path from two components.

On UNIX™, the directory separator is '/'.

On Windows™, the directory separator is '\'.

os.Path.size
Returns the size of a file.

Syntax

```
os.Path.size(
   fname STRING)
  RETURNING result INTEGER
```

1. *fname* is the file name.

Usage

The function returns the size in bytes for the specified file.

os.Path.rootDir
Returns the root directory of the current working path.

Syntax

```
os.Path.rootDir()
  RETURNING rootdir STRING
```

1. *rootdir* is the root directory of the current working path.

Usage

On UNIX™, it always returns "/".

On Windows™ it returns the current working drive as "[a-zA-Z]:\"

os.Path.rootName
Returns the file path without the file extension of the last element of the file path.

Syntax

```
os.Path.rootName(
   filename STRING)
  RETURNING result STRING
```

1. *filename* is the file path.

Usage

This method removes the file extension from the path provided as parameter.

For example, if you pass "/root/dir1/file.ext" as the parameter it will return "/root/dir1/file".

See Example 1: Extracting the parts of a file name on page 2007 for more examples.

os.Path.rwx
Returns the UNIX™ file permissions of a file.

Syntax

```
os.Path.rwx(
   fname STRING)
  RETURNING mode INTEGER
```

1. *fname* is the name of the file.
2. *mode* is the combination of permissions for user, group and other.

Usage

This method can only be used on UNIX™!

Function returns -1 if it fails to get the permissions.

The *mode* is returned as a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. For example, if a file has the `-rwxr-xr-x` permissions, the method returns ((4+2+1) * 64 + (4+1) * 8) + (4+1)) = 493.

os.Path.type
Returns the file type as a string.

Syntax

```
os.Path.type(
   fname STRING)
  RETURNING result STRING
```

1. *fname* is the file name.

Usage

On UNIX™, this method follows symbolic links. Use the `os.Path.islink()` method to identify symbolic links.

The possible values returned by this method are:

1. `file`: the file is a regular file
2. `directory`: the file is a directory
3. `socket`: the file is a socket
4. `fifo`: the file is a fifo
5. `block`: the file is a block device
6. `char`: the file is a character device

os.Path.uid
Returns the UNIX™ user id of a file.

Syntax

```
os.Path.uid(
   fname STRING)
  RETURNING id INTEGER
```

1. *fname* is the name of the file.
2. *id* is the user id.

Usage

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

os.Path.volumes
Returns the available volumes.

Syntax

```
os.Path.volumes()
  RETURNING volumes STRING
```

1. *volumes* contains the list of all available volumes separated by "|".

Usage

To display the list of available volumes, a volume is identified by its letter, followed by a colon and a backslash (:\).

```
DISPLAY os.Path.volumes()
```

Output example:

```
C:\|E:\|F:\
```

os.Path.writable
Checks if a file is writable.

Syntax

```
os.Path.writable(
   fname STRING)
  RETURNING result INTEGER
```

1. *fname* is the file name.

Usage

The function returns TRUE if the file is writable, FALSE otherwise.

Examples
Example 1: Extracting the parts of a file name

This program uses the file functions to extract the directory name, the base name, the root name, and the file extension:

```
IMPORT os
MAIN
  DISPLAY "Dir name   = ", os.Path.dirName(arg_val(1))
  DISPLAY "Base name  = ", os.Path.baseName(arg_val(1))
  DISPLAY "Root name  = ", os.Path.rootName(arg_val(1))
  DISPLAY "Extension  = ", os.Path.extension(arg_val(1))
END MAIN
```

Example results:

Table 449: Example results

Path	os.Path.dirname	os.Path.basename	os.Path.rootname	os.Path.extension
.	.	.		NULL
..	.	..	.	NULL
/	/	/	/	NULL
/usr/lib	/usr	lib	/usr/lib	NULL
/usr/	/	usr	/usr/	NULL
usr	.	usr	usr	NULL
file.xx	.	file.xx	file	xx
/tmp.yy/ file.xx	/tmp.yy	file.xx	/tmp.yy/file	xx
/tmp.yy/ file.xx.yy	/tmp.yy	file.xx.yy	/tmp.yy/ file.xx	yy
/tmp.yy/	/	tmp.yy	/tmp.yy/	NULL
/tmp.yy/.	/tmp.yy	.	/tmp.yy/	NULL

These examples use UNIX™ file names. On Windows™ the result would be different, as the file name separator is a backslash (\).

Example 2: Browsing directories

This program takes a directory path as an argument and scans the content recursively:

```
IMPORT os

MAIN
  CALL showDir(arg_val(1))
END MAIN

FUNCTION showDir(path)
  DEFINE path STRING
  DEFINE child STRING
  DEFINE h INTEGER

  IF NOT os.Path.exists(path) THEN
     RETURN
```

```
  END IF

  IF NOT os.Path.isDirectory(path) THEN
     DISPLAY " ", os.Path.baseName(path)
     RETURN
  END IF

  DISPLAY "[", path, "]"
  CALL os.Path.dirSort("name", 1)
  LET h = os.Path.dirOpen(path)
  WHILE h > 0
     LET child = os.Path.dirNext(h)
     IF child IS NULL THEN EXIT WHILE END IF
     IF child == "." OR child == ".." THEN CONTINUE WHILE END IF
     CALL showDir( os.Path.join( path, child ) )
  END WHILE

  CALL os.Path.dirClose(h)

END FUNCTION
```

The com package

The Genero Web Services `com` package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

Use the `IMPORT` statement at the top of the module using this library:

```
IMPORT com
```

Web services classes

The Web services classes manage Web Services servers.

- The WebService class on page 2009
- The WebOperation class on page 2018
- The WebServiceEngine class on page 2025
- The HTTPServiceRequest class on page 2036

The WebService class

The `com.WebService` class provides an interface to create and manage Genero Web Services.

The `com.WebServices` class is used to implement a Web Service on the server.

> **Important:** This Web Services class is not supported on GMI mobile devices.

com.WebServices methods

Methods for the `com.WebService` class.

Table 450: Class methods

Name	Description

`com.WebService.CreateStatefulWebService(`
`  name STRING,`
`  namespace STRING,`
`  state state-type )`
`  RETURNING result com.WebService`
	Creates a new object to implement a stateful Web Service.

`com.WebService.CreateWebService(` `  name STRING,`	Creates a new object to implement a Web Service.

Name	Description
namespace STRING) RETURNING *result* com.WebService	

Table 451: Object methods

Name	Description
createFault(*fault fault-type*, *encoded* BOOLEAN)	Creates a new object to implement a Web Service.
createHeader(*header header-type*, *encoded* BOOLEAN)	Defines the header for the Web Service object.
generateWSDL(*location* STRING) RETURNING *result* xml.DomDocument	Creates a `xml.DomDocument` object with the WSDL corresponding to the Web Service object.
publishOperation(*operation* com.WebOperation, *role* STRING)	Publishes a Web Operation.
registerInputHTTPVariable(*http-in http-in-type*)	Registers the record variable for HTTP input.
registerInputRequestHandler(*funcname* STRING)	Registers the function to be executed on incoming SOAP requests.
registerOutputHTTPVariable(*http-out http-out-type*)	Registers the record variable for HTTP output.
registerOutputRequestHandler(*funcname* STRING)	Registers the function to be executed just before the SOAP response is forwarded to the client.
registerWSDLHandler(*funcname* STRING)	Registers the function to be executed when a WSDL is generated.
saveWSDL(*location* STRING) RETURNING *result* INTEGER	Writes to a file the WSDL corresponding to the Web Service object.
setComment(	Defines the comment for the Web Service object.

Name	Description
comment STRING)	
setFeature(*name* STRING, *value* STRING)	Defines a feature for the current Web Service object.

com.WebService.createFault

Creates a new object to implement a Web Service.

Syntax

```
createFault(
   fault fault-type,
   encoded BOOLEAN )
```

1. *fault* defines the header for the Web Service object.
2. *fault-type* is a simple data type, a RECORD or an ARRAY.
3. *encoded* specifies the encoding mechanism.

Usage

The `createFault()` method creates a global fault for this Web Service object.

The *fault* parameter can be of any type and defines the SOAP fault in a SOAP response. In case of SOAP fault, the client for this Web Service will receive a variable with the same structure.

When *encoded* is TRUE, the SOAP Section 5 encoding mechanism is used, when FALSE, the XML Schema mechanism is used.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.createHeader

Defines the header for the Web Service object.

Syntax

```
createHeader(
   header header-type,
   encoded BOOLEAN )
```

1. *header* defines the header for the Web Service object.
2. *header-type* is a simple data type or a RECORD structure, or an ARRAY.
3. *encoded* specifies the encoding mechanism.

Usage

The `createHeader()` method creates a global header for the current Web Service object.

The Web Service header is defined by the first parameter. This will define SOAP headers exchanged by the client and server.

When *encoded* is TRUE, the SOAP Section 5 encoding mechanism will be used. If FALSE, the XML Schema mechanism will be used.

Important: Since Web Services headers are generally in Document Style, we recommend to set the *encoded* parameter to FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.CreateWebService

Creates a new object to implement a Web Service.

Syntax

```
com.WebService.CreateWebService(
   name STRING,
   namespace STRING )
  RETURNING result com.WebService
```

1. *name* is the Web Service identifier.
2. *namespace* is the name space for the Web Service name.

Usage

The com.WebService.CreateWebService() class method creates a new com.WebService object implementing a Web Service.

The *name* and *namespace* must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, *namespace+name* must be unique on the internet.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.CreateStatefulWebService

Creates a new object to implement a stateful Web Service.

Syntax

```
com.WebService.CreateStatefulWebService(
   name STRING,
   namespace STRING,
   state state-type )
  RETURNING result com.WebService
```

1. *name* is the Web Service identifier.
2. *namespace* is the name space for the Web Service name.
3. *state* is used to identify the state between the client and server.
4. *state-type* is a regular data type or RECORD structure.

Usage

The com.WebService.CreateStatefulWebService() class method creates a new com.WebService object implementing a Web Service that is stateful.

The *name* and *namespace* must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, *namespace+name* must be unique on the internet.

The *state* variable used to identify the state between the client and the server:

- For a WS-Addressing stateful service, the *state* variable must be a `RECORD` with the following structure, with the `W3CEndpointReference` variable attribute:

```
RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, -- The location of the Web Service (for ex: URL)
  ref RECORD
    ... (other members defining the state)
  END RECORD
END RECORD
```

- For a stateful service based on HTTP cookies, the *state* variable must be a simple variable defined with a basic data type.

It is up to the programmer to manage the *state* variable and to restore the service state from a database.

When creating a stateful Web Service, all published Web Operations require a session in the client request excepted those defined as '`initiateSession`'.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.generateWSDL

Creates a `xml.DomDocument` object with the WSDL corresponding to the Web Service object.

Syntax

```
generateWSDL(
   location STRING )
  RETURNING result xml.DomDocument
```

1. *location* is the URL where the Web Service will be deployed.

Usage

The `generateWSDL()` method creates a new `xml.DomDocument` object containing the WSDL data of the Web Service object.

The URL where the Web Service will be deployed must be specified.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.publishOperation

Publishes a Web Operation.

Syntax

```
publishOperation(
   operation com.WebOperation,
   role STRING )
```

1. *operation* is the Web Operation object.
2. *role* identifies uniquely the Web Operation.

Usage

The `publishOperation()` method publishes the Web Operation specified by the `com.WebOperation` object passed as parameter.

The *role* identifies the operation, if several operations have the same name, by setting the SOAPAction HTTP header. Usually this parameter is set to NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.registerInputHTTPVariable

Registers the record variable for HTTP input.

Syntax

```
registerInputHTTPVariable(
   http-in http-in-type )
```

1. *http-in* is the HTTP input record variable.
2. *http-in-type* must be a RECORD with following structure:

```
RECORD
  verb  STRING,
  url   STRING,
  headers DYNAMIC ARRAY OF RECORD
    name  STRING,
    value  STRING
  END RECORD
END RECORD
```

Usage

The registerInputHTTPVariable() method registers a program variable with a specific structure, that will be filled with the HTTP request headers when a Web Operation arrives.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.registerInputRequestHandler

Registers the function to be executed on incoming SOAP requests.

Syntax

```
registerInputRequestHandler(
   funcname STRING )
```

1. *funcname* is the name of a program function.

Usage

The registerInputRequestHandler() method registers a function to be called when an incoming SOAP request is received and before the SOAP engine has processed it.

The callback function must be defined with a unique parameter of type xml.DomDocument, and must return the reference to this object, or NULL:

```
FUNCTION myRequestInputHandler( in )
    DEFINE in xml.DomDocument
    ...
    RETURN in
END FUNCTION
```

The input callback function typically modifies the content of the SOAP input request DOM document object passed as parameter.

When returning `NULL` from the input callback function, the output callback function will be called with the default SOAP fault node, which can then be modified.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.registerOutputHTTPVariable

Registers the record variable for HTTP output.

Syntax

```
registerOutputHTTPVariable(
   http-out http-out-type )
```

1. *http-out* is the HTTP output record variable.
2. *http-out-type* is a `RECORD` with the following structure:

```
RECORD
  code INTEGER,
  desc STRING,
  headers DYNAMIC ARRAY OF RECORD
    name  STRING,
    value  STRING
  END RECORD
END RECORD
```

Usage

The `registerOutputHTTPVariable()` method registers a program variable with a specific structure, that will be used to fill the HTTP response headers when a Web Operation is completed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.registerOutputRequestHandler

Registers the function to be executed just before the SOAP response is forwarded to the client.

Syntax

```
registerOutputRequestHandler(
   funcname STRING )
```

1. *funcname* is the name of a program function.

Usage

The `registerOutputRequestHandler()` method registers a function to be called just after the SOAP engine has processed the request and before the SOAP response is forwarded to the client.

The output callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```
FUNCTION myRequestOutputHandler( out )
    DEFINE out xml.DomDocument
    ...
```

```
    RETURN out
END FUNCTION
```

The output callback function typically modifies the content of the SOAP output request DOM document object passed as parameter.

If `NULL` was returned from the input callback function, the output callback function will be called with the default SOAP fault node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.registerWSDLHandler

Registers the function to be executed when a WSDL is generated.

Syntax

```
registerWSDLHandler(
   funcname STRING )
```

1. *funcname* is the name of a program function.

Usage

The `registerWSDLHandler()` method registers a function to be called when the WSDL of the current Web Service object is generated.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```
FUNCTION myWSDLHandler( wsdl )
    DEFINE wsdl xml.DomDocument
    ...
    RETURN wsdl
END FUNCTION
```

The callback function typically modifies the content of the WSDL DOM document object passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.saveWSDL

Writes to a file the WSDL corresponding to the Web Service object.

Syntax

```
saveWSDL(
   location STRING )
  RETURNING result INTEGER
```

1. *location* is the URL where the Web Service will be deployed.

Usage

The `saveWSDL()` method writes the WSDL data corresponding to the Web Service object.

The URL where the Web Service will be deployed must be specified.

The name of the file will be the name of the Web Service defined by the *name* parameter passed to the `createWebService()` or `createStatefulWebService()` methods.

The method returns 0 if the file was saved, -1 in case of error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.setComment

Defines the comment for the Web Service object.

Syntax

```
setComment(
   comment STRING )
```

1. *comment* is the description of the Web Service.

Usage

The `setComment()` method defines the comment associated to a `com.WebService` object.

The comment will be used when generating the WSDL file, as defined by the standard.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebService.setFeature

Defines a feature for the current Web Service object.

Syntax

```
setFeature(
   name STRING,
   value STRING )
```

1. *name* is the name of the Web Service feature.
2. *value* is the value of the feature.

Usage

The `setFeature()` method defines a feature for the current Web Service object by specifying a feature name and a value.

The features names are predefined. The second parameter must a a valid value for the specified feature.

Table 452: Support Web Service features for the setFeature() method

Name	Description
`Soap1.1`	Defines whether the Web Service supports the SOAP 1.1 protocol. Default value is FALSE.
`Soap1.2`	Defines whether the Web Service supports the SOAP 1.2 protocol. Default value is FALSE.
`WS-Addressing1.0`	Defines whether the Web Service supports WS-Addressing 1.0. Valid values include:

Name	Description
	• TRUE - The service supports WS-Addressing 1.0 and accepts requests without WS-Addressing. • REQUIRED - The service supports WS-Addressing 1.0 and accepts only requests with WS-Addressing. • FALSE - WS-Addressing 1.0 is disabled (Default).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The WebOperation class
The com.WebOperation class provides an interface to create and manage the operations of a Genero Web Service.

> **Important:** This Web Services class is not supported on GMI mobile devices.

The Web Operation can be created as RPC Style or Document Style. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (standards set by the Web Services Interoperability organization).

RPC Style Service (RPC/Literal) is generally used to execute a function, such as a service that returns a stock option. Document Style Service (Doc/Literal) is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS. Net default. The input or output RECORD cannot have XMLNamespace attributes set on their members.

Calling the appropriate function to create the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

Do not use the setInputEncoded() and setOutputEncoded() methods, as they will specify the RPC/Encoded Style, which is not recommended (see Choosing a Web Service Style).

Since release 2.0 GWS allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

com.WebOperation methods
Methods for the com.WebOperation class.

Table 453: Class methods

Name	Description
com.WebOperation.CreateDOCStyle(*function* STRING, *operation* STRING, *input* RECORD, *output* RECORD) RETURNING *result* com.WebOperation	Creates a new Web Operation object with Document style.
com.WebOperation.CreateOneWayDOCStyle(*function* STRING, *operation* STRING, *input* RECORD)	Creates a new Web Operation object with One-Way Document style.

Name	Description
RETURNING *result* com.WebOperation	
com.WebOperation.CreateOneWayRPCStyle(*function* STRING, *operation* STRING, *input* RECORD) RETURNING *result* com.WebOperation	Creates a new Web Operation object with One-Way RPC style.
com.WebOperation.CreateRPCStyle(*function* STRING, *operation* STRING, *input* RECORD, *output* RECORD) RETURNING *result* com.WebOperation	Creates a new Web Operation object with RPC style.

Table 454: Object methods

Name	Description
addFault(*fault fault-type*, *wsaaction* STRING)	Adds a fault to the current Web Operation definition.
addInputHeader(*header header-type*)	Adds an input header for the current Web Operation definition.
addOutputHeader(*header header-type*)	Adds an output header for the current Web Operation definition.
initiateSession(*initiator* BOOLEAN)	Defines the Web Operation as session initiator.
setComment(*comment* STRING)	Sets the comment for the Web Operation object.
setInputAction(*ident* STRING)	Sets the WS-Addressing action identifier of the input operation.
setInputEncoded(*encoded* BOOLEAN)	Defines the encoding mechanism for Web Operation input parameters.
setOutputAction(*ident* STRING)	Sets the WS-Addressing action identifier of the output operation.
setOutputEncoded(	Defines the encoding mechanism for Web Operation output parameters.

Name	Description
encoded BOOLEAN)	

com.WebOperation.addFault

Adds a fault to the current Web Operation definition.

Syntax

```
addFault(
   fault fault-type,
   wsaction STRING )
```

1. *fault* is a program variable defining the fault.
2. *fault-type* is a simple data type, a RECORD or an ARRAY.
3. *wsaction* defines the type of action.

Usage

Adds a fault the Web Operation can throw during operation processing, where *fault* is any variable previously created as fault of the `com.WebService` object, and *wsaction* the WS-Addressing action identifier if WS-Addressing is supported. If WS-Addressing is not supported, pass NULL as second parameter.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.addInputHeader

Adds an input header for the current Web Operation definition.

Syntax

```
addInputHeader(
   header header-type )
```

1. *header* is a program variable defining the header.
2. *header-type* is a simple data type, a RECORD or an ARRAY.

Usage

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.addOutputHeader

Adds an output header for the current Web Operation definition.

Syntax

```
addOutputHeader(
   header header-type )
```

1. *header* is a program variable defining the header.
2. *header-type* is a simple data type, a RECORD or an ARRAY.

Usage

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.CreateDOCStyle

Creates a new Web Operation object with Document style.

Syntax

```
com.WebOperation.CreateDOCStyle(
   function STRING,
   operation STRING,
   input RECORD,
   output RECORD)
  RETURNING result com.WebOperation
```

1. *function* is the name of the program function to be called to process the XML operation.
2. *operation* is the name of the XML operation.
3. *input* is the variable defining the input parameters of the operation (or `NULL` if there is none).
4. *output* is the variable defining the output parameters of the operation (or `NULL` if there is none).

Usage

This method creates a Request-Response Document style `com.WebOperation` object, where *function* is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.CreateRPCStyle

Creates a new Web Operation object with RPC style.

Syntax

```
com.WebOperation.CreateRPCStyle(
   function STRING,
   operation STRING,
   input RECORD,
   output RECORD)
  RETURNING result com.WebOperation
```

1. *function* is the name of the program function to be called to process the XML operation.
2. *operation* is the name of the XML operation.
3. *input* is the input record defining the input parameters of the operation (or `NULL` if there is none).
4. *output* is the output record defining the output parameters of the operation (or `NULL` if there is none).

Usage

This method creates a Request-Response RPC style `com.WebOperation` object, where *function* is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.CreateOneWayDOCStyle

Creates a new Web Operation object with One-Way Document style.

Syntax

```
com.WebOperation.CreateOneWayDOCStyle(
   function STRING,
   operation STRING,
   input RECORD)
  RETURNING result com.WebOperation
```

1. *function* is the name of the program function to be called to process the XML operation.
2. *operation* is the name of the XML operation.
3. *input* is the variable defining the input parameters of the operation (or NULL if there is none).

Usage

This method creates a One-Way DOC style com.WebOperation object, where *function* is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.CreateOneWayRPCStyle

Creates a new Web Operation object with One-Way RPC style.

Syntax

```
com.WebOperation.CreateOneWayRPCStyle(
   function STRING,
   operation STRING,
   input RECORD)
  RETURNING result com.WebOperation
```

1. *function* is the name of the program function to be called to process the XML operation.
2. *operation* is the name of the XML operation.
3. *input* is the input record defining the input parameters of the operation (or NULL if there is none).

Usage

This method creates a One-Way RPC Style com.WebOperation object, where *function* is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.initiateSession

Defines the Web Operation as session initiator.

Syntax

```
initiateSession(
   initiator BOOLEAN )
```

1. *initiator* must be TRUE to define a session initiator.

Usage

Pass TRUE as parameter to `initiateSession()` in order to define the current Web Operation as a session initiator.

A new session must be instantiated in this operation, and must be returned to the client via the *state* variable defined at service creation.

This method works only for stateful web services.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.setComment

Sets the comment for the Web Operation object.

Syntax

```
setComment(
   comment STRING )
```

1. *comment* is the comment to be set.

Usage

The `setComment()` method defines a comment to the current Web Operation object.

The comment will appear in the WSDL of the service.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.setInputAction

Sets the WS-Addressing action identifier of the input operation.

Syntax

```
setInputAction(
   ident STRING )
```

1. *ident* is the WSA action identifier.

Usage

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the input operation.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.setInputEncoded

Defines the encoding mechanism for Web Operation input parameters.

Syntax

```
setInputEncoded(
   encoded BOOLEAN )
```

1. *encoded* is a boolean defining the encoding mechanism to be used.

Usage

When the parameter is TRUE, the SOAP Section 5 encoding mechanism is used, FALSE indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.setOutputAction

Sets the WS-Addressing action identifier of the output operation.

Syntax

```
setOutputAction(
   ident STRING )
```

1. *ident* is the WSA action identifier.

Usage

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the ouput operation.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebOperation.setOutputEncoded

Defines the encoding mechanism for Web Operation output parameters.

Syntax

```
setOutputEncoded(
   encoded BOOLEAN )
```

1. *encoded* is a boolean defining the encoding mechanism to be used.

Usage

When the parameter is TRUE, the SOAP Section 5 encoding mechanism is used, FALSE indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The WebServiceEngine class

The `com.WebServiceEngine` class provides an interface to manage the Web Services engine.

> **Important:** This Web Services class is not supported on GMI mobile devices.

com.WebServiceEngine methods

Methods for the `com.WebServiceEngine` class.

Table 455: Class methods

Name	Description
`com.WebServiceEngine.Flush()` `  RETURNING status INTEGER`	Forces the Web Service engine to immediately flush the response of the web service operation.

`com.WebServiceEngine.GetHTTPServiceRequest(`
`  timeout INTEGER)`
`  RETURNING result com.HTTPServiceRequest`
	Get a handle for an incoming HTTP service request.

`com.WebServiceEngine.GetOption(`
`  option STRING )`
`  RETURNING result STRING`
	Returns the value of a Web Service engine option.

`com.WebServiceEngine.HandleRequest(`
`  timeout INTEGER,`
`  status INTEGER )`
`  RETURNING result com.HTTPServiceRequest`
	Get a handle for an incoming HTTP service request.

`com.WebServiceEngine.ProcessServices(`
`  timeout INTEGER )`
`  RETURNING status INTEGER`
	Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

`com.WebServiceEngine.RegisterService(` `  service com.WebService )`	Registers a service in the engine.

`com.WebServiceEngine.SetFaultCode(`
`  code STRING,`
`  code_ns STRING )`
	Get a handle for an incoming HTTP service request.

`com.WebServiceEngine.SetFaultDetail(` `  fault STRING )`	Defines the published SOAP Fault.
`com.WebServiceEngine.SetFaultString(` `  desc STRING )`	Defines the description of a SOAP Fault.
`com.WebServiceEngine.SetOption(` `  option STRING,`	Sets an option for the Web Service engine.

Name	Description
value STRING)	
com.WebServiceEngine.Start()	Starts the Web Service engine.

com.WebServiceEngine.Flush

Forces the Web Service engine to immediately flush the response of the web service operation.

Syntax

```
com.WebServiceEngine.Flush()
  RETURNING status INTEGER
```

Usage

The `com.WebServiceEngine.flush()` class method allows to return the response inside a high-level web service operation, before the end of the web service function.

When this method is used, any other web operation output parameter changes are ignored.

The *status* returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2034

Note: The return status of the `com.WebServiceEngine.flush()` method has the same meaning as a status returned by `com.WebServiceEngine.ProcessServices()`, with the additional status code -32, meaning that the flush method has been called outside a web operation execution context.

Note: `com.WebServiceEngine.ProcessServices()` and `com.WebServiceEngine.HandleRequest()` can return the status code of -31, meaning that the flush function has been called in the last executed web operation.

Example:

In this code example, the `flush()` method is used to force the response of the web service operation.

```
DEFINE echoBoolean_in, echoBoolean_out RECORD
    a_boolean  BOOLEAN ATTRIBUTES(XMLName="Boolean")
  END RECORD

MAIN
  DEFINE ret INTEGER
  ...
  WHILE true
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
      WHEN 0
        DISPLAY "Request automatically processed."
      WHEN -31
        DISPLAY "Operation has been flushed."
      ...
  END WHILE
  ...
END MAIN

FUNCTION echoBoolean()
```

```
  DEFINE ret INTEGER
  -- Assign output parameter with input parameter
  LET echoBoolean_out.a_boolean = echoBoolean_in.a_boolean
  -- Immediate flush of web operation
  LET ret = com.WebServiceEngine.flush()
  IF ret != 0 THEN
     DISPLAY "ERROR Code : ",ret
     EXIT PROGRAM (1)
  END IF
  -- Changing the output parameters after flush() would have no
 effect.
END FUNCTION
```

com.WebServiceEngine.GetHTTPServiceRequest

Get a handle for an incoming HTTP service request.

Syntax

```
com.WebServiceEngine.GetHTTPServiceRequest(
   timeout INTEGER)
  RETURNING result com.HTTPServiceRequest
```

1. *timeout* is the timeout in seconds.

Usage

The `com.WebServiceEngine.GetHTTPServiceRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The *timeout* parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait. When the timeout occurs, the method returns `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

Example

```
TRY
  WHILE true
    LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
    IF req IS NULL THEN
      DISPLAY "HTTP request timeout...: ", CURRENT YEAR TO
 FRACTION
    ELSE
      CALL req.sendTextResponse(200,NULL,"It works")
    END IF
  END WHILE
CATCH
  IF status == -15575 THEN
    DISPLAY "Disconnected : ",SQLCA.SQLERRM
```

```
  ELSE
    DISPLAY "ERROR : ",status,SQLCA.SQLERRM
  END IF
END TRY
```

com.WebServiceEngine.GetOption

Returns the value of a Web Service engine option.

Syntax

```
com.WebServiceEngine.GetOption(
   option STRING )
  RETURNING result STRING
```

1. *option* is the name of the option to queried.

Usage

The `com.WebServiceEngine.GetOption()` class method returns the current value of the given the Web Services engine option.

See WebServiceEngine options on page 2032 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.HandleRequest

Get a handle for an incoming HTTP service request.

Syntax

```
com.WebServiceEngine.HandleRequest(
   timeout INTEGER,
   status INTEGER )
  RETURNING result com.HTTPServiceRequest
```

1. *timeout* is the timeout in seconds.
2. *status* is an `INTEGER` variable receiving the method execution status.

Usage

The `com.WebServiceEngine.HandleRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The *timeout* parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait.

- If there is no request in the given period of time, or if there is an error, the status code is updated by reference, and a `NULL` object is returned.
- If the request is intended to a registered web service, it is processed automatically. The status code is updated by reference and a `NULL` object is returned.
- If the request isn't dedicated to a registered web service, a status code of value 1 is returned by reference, and a valid instance of an `com.HTTPServiceRequest` object, immediately usable to handle the incoming request, is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The *status* returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2034

> **Note:** If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.HandleRequest() will return the code -31, to indicated that a flush was done.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

com.WebServiceEngine.ProcessServices

Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

Syntax

```
com.WebServiceEngine.ProcessServices(
   timeout INTEGER )
  RETURNING status INTEGER
```

1. *timeout* is the timeout in seconds.

Usage

The com.WebServiceEngine.ProcessServices() class method specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

The *timeout* parameter defines the wait period for an HTTP input request, to process an operation of one of the registered Web Services. The value -1 specifies an infinite waiting time.

The *status* returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2034

The execution status is typically handled in a CASE / END CASE block, to treat all possible execution cases. For a complete example of execution status handling, see Process the requests on page 2477.

> **Note:** If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.ProcessServices() will return the code -31, to indicated that a flush was done.

com.WebServiceEngine.SetFaultCode

Get a handle for an incoming HTTP service request.

Syntax

```
com.WebServiceEngine.SetFaultCode(
   code STRING,
   code_ns STRING )
```

1. *code* is the timeout in seconds.

2. *code_ns* is the timeout in seconds.

Usage

The `com.WebServiceEngine.SetFaultCode()` class method defines a user SOAP Fault code to be returned to the client, where *code* is the mandatory SOAP Fault code and *code_ns* is the mandatory code namespace.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.SetFaultDetail

Defines the published SOAP Fault.

Syntax

```
com.WebServiceEngine.SetFaultDetail(
   fault STRING )
```

1. *fault* is the published fault.

Usage

The `com.WebServiceEngine.SetFaultDetail()` class method defines the published SOAP Fault to be returned to the client when operation has finished, where *fault* is one of the published variables defined as Fault for that operation.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.SetFaultString

Defines the description of a SOAP Fault.

Syntax

```
com.WebServiceEngine.SetFaultString(
   desc STRING )
```

1. *desc* is the description of the fault.

Usage

The `com.WebServiceEngine.SetFaultString()` class method defines a user SOAP Fault description to be returned to the client, where *desc* contains the description of the fault.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.SetOption

Sets an option for the Web Service engine.

Syntax

```
com.WebServiceEngine.SetOption(
   option STRING,
   value STRING )
```

1. *option* is the name of the option to set.
2. *value* is the value of the option to set.

Usage

The `com.WebServiceEngine.SetOption()` class method configures the Web Services engine with options.

See WebServiceEngine options on page 2032 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.RegisterService

Registers a service in the engine.

Syntax

```
com.WebServiceEngine.RegisterService(
   service com.WebService )
```

1. *service* is the service object to register.

Usage

The `com.WebServiceEngine.RegisterService()` class method registers the `com.WebService` object passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.WebServiceEngine.Start

Starts the Web Service engine.

Syntax

```
com.WebServiceEngine.Start()
```

Usage

The `com.WebServiceEngine.Start()` class method starts the engine for all registered Web Services.

If you run the Web Services server program in standalone mode, you must set FGLAPPSERVER. If you run the Web Services server program through the Genero Application Server, the FGLAPPSERVER variable is automatically set by the Genero Application Server. Do NOT manually set FGLAPPSERVER in this case.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

WSDL generation options notes
These notes should be reviewed prior to WSDL generation.

1. For the `DECIMAL(5,2)` data type, when `wsdl_decimalsize` is `TRUE`, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

```
<types>
   <schema xmlns="http://www.w3.org/2001/XMLSchema"
           targetNamespace="http://www.mycompany.com/types/">
      <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
         <restriction base="decimal">
            <totalDigits value="5" />
             <fractionDigits value="2" />
          </restriction>
      </simpleType>
   </schema>
 </types>
<message name="echoDecimal5_2">
  <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
 </message>
```

   When `wsdl_decimalsize` is `FALSE`, the total size and the size of the fractional part are not mentioned:

```
<message name="echoDecimal5_2">
  <part name="dec5_2" type="xsd:decimal" />
 </message>
```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this case, a default value for the size is generated. For example, the exported server type `DECIMAL(5,2)` becomes a `DECIMAL(32)` on the client side.
3. It is better to keep the options `wsdl_arraysize`, `wsdl_stringsize` and `wsdl_decimalsize` set to `TRUE` so that the client program can do exact type mapping. The default for all three options is `TRUE`.
4. When setting a facet constraint attribute on a simple data type, the generation of the WSDL will take this attribute into account even if an option has been set to perform the opposite.
5. When setting one facet constraint attribute, all of the default constraint attributes won't be generated anymore unless you specify them as facet constraint attributes.

WebServiceEngine options

Table 456: Options for the com.WebServiceEngine

Flag	Client or Server	Description
readwritetimeout	Client	Defines the default maximum time in seconds a client, a HTTP request/response and a TCP request/response have to wait before raising an error that the server doesn't return or accept data. A value of -1 means infinite wait. The default is -1.
connectiontimeout	Client	Defines the default maximum time in seconds a client, a HTTPRequest and a TCPRequest have to wait for the establishment of a connection with a server. A value of -1 means infinite wait.

Flag	Client or Server	Description
		The default is 30 seconds for non-Windows, 5 seconds for Windows™.
maximumresponselength	Both	Defines the maximum authorized size in **KBytes** for a client, server, HTTP or TCP response, before a break (when it stops and returns from the function because the amount of data surpassed the maximumresponselength.) A value of -1 means no limit. The default is -1.
wsdl_decimalsize	Server	Defines whether the precision and scale of a DECIMAL variable will be taken into account during the WSDL generation. See WSDL generation options notes on page 2032. A value of zero means FALSE. The default is TRUE.
wsdl_arraysize	Server	Defines whether the size of a BDL array will be taken into account during the WSDL generation. See WSDL generation options notes on page 2032. A value of zero means FALSE. The default is TRUE.
wsdl_stringsize	Server	Defines whether the size of a CHAR or VARCHAR variable will be taken into account during the WSDL generation. See WSDL generation options notes on page 2032. A value of zero means FALSE. The default is TRUE.
http_invoketimeout (deprecated)	Client	Defines the default maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding. A value of -1 means that it has to wait until the server responds. The default is -1. **Important:** Deprecated - use readwritetimeout
server_readwritetimeout	Server	Defines how long a socket read or write operation can wait before before raising an error. The default value is 5 seconds. **Note:** Before this option was introduced, the default valus was -1 (infinite) and was configurable with the accept timeout parameter via `ProcessServices()` method.

Flag	Client or Server	Description
SoapModuleURI	Both	Defines the SOAP role of a Genero application with an URI to identify it along a SOAP message path. The default value is NULL.
tcp_connectiontimeout (deprecated)	Client	Defines the default maximum time in seconds a client has to wait for the establishment of a TCP connection with a server. A value of -1 means infinite wait. The default is 30 seconds for non-Windows, 5 seconds for Windows™. **Important:** Deprecated - use connectiontimeout

Error codes of com.WebServicesEngine
Error codes returned by `com.WebServiceEngine` methods.

Table 457: com.WebServiceEngine error codes

Number	Description
-1	`Timeout` com.WebServiceEngine.ProcessServices(x) timeout is reached. No requests to process during x seconds.
-2	`AsCloseCommand` GAS tells the DVM to shutdown. You must exit your application.
-3	`ConnectionBroken` Client has closed the connection in standalone GWS (without GAS).
-4	`ConnectionInterrupted` Ctrl-C received. Interruption received by DVM. You must exit your application.
-5	`BadHTTPHeader` Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-6	`MalformedSOAPEnvelope` Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-7	`MalformedXMLDocument` Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-8	`InternalHTTPError` Communication issue with application server or client.
-9	`Unsupported operation` The URL of the operation requested is unknown. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.DONE

Number	Description
-10	`UnknownError` This is an internal error, contact the support team. You must exit your application.
-11	`WSDL generation failed` You need to debug your application.
-12	`WSDL Service not found` Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-13	`Reserved` No need to exit the application. A new request might not have the issue.
-14	`Incoming request overflow` You exceed the data maximum length allowed by com.WebServiceEngine.SetOption(maximumresponselength).
-15	`Server was not started` Call to com.WebServiceEngine.Start() failed. You must exit your application.
-16	`Request still in progress` With RESTful service, you are currently processing a request and has not yet send the response and try to process another request. You need to debug your application. It depends, you might not need to stop your application.
-17	`Stax response error` You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-18	`Input request handler error` You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-19	`Output request handler error` You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-20	`WSDL handler error` You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-21	`SOAP Version mismatch` Your client SOAP version does not match your server SOAP version, amend either your client or your server code.
-22	`SOAP header not understood` Modify your server code to handled the mustUnderstand attribute. Use the incoming request handler.
-23	`Deserialization error`

Number	Description
	Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.
-24	`Reserved error code -24` This error code is reserved for future use.
-25	`Web Services Addressing action is mandatory` Check that the WSA action is specified in the SOAP message.
-26	`Web Services Addressing message header is invalid` Check that the WSA header is correct in the SOAP message.
-27	`Web Services Addressing message header is mandatory` Check that the WSA header is specified in the SOAP message.
-28	`Web Services Addressing message protocol does not match` Check that the WSA message uses the protocol version of the client matches the version expected by the server.
-29	`Cookie error` Check that the HTTP request contains a valid cookie.
-30	`No active web operation` The method was called outside the context of a web operation processing.
-31	`Web Operation was flushed` This code is returned by the `ProcessServices()` or the `HandlerRequest()` method, to indicated that the `Flush()` method was called during the last web operation execution.
-32	`Serialization error` Check the message with FGLWSDEBUG or display SQLCA.SQLERRM.

The HTTPServiceRequest class

The `com.HTTPServiceRequest` class provides an interface to process incoming XML and TEXT requests over HTTP on the server side, with an access to the HTTP layer and additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.

com.HTTPServiceRequest methods

Methods of the `com.HTTPServiceRequest` class.

Table 458: Object methods: Reading client requests

Name	Description
`beginXmlRequest()` `  RETURNING` *reader* `xml.StaxReader`	Starts an HTTP streaming request.
`endXmlRequest(`	Terminates an HTTP streaming request.

Name	Description
reader xml.StaxReader)	
getMethod() RETURNING *result* STRING	Returns the HTTP method of the service request.
getRequestHeader(name STRING) RETURNING *result* STRING	Returns the value of an HTTP header.
getRequestVersion() RETURNING *result* STRING	Returns the HTTP version of the service request.
getURL() RETURNING *result* STRING	Returns the URL of the HTTP service request.
getRequestHeaderCount() RETURNING *result* INTEGER	Returns number of request headers.
getRequestHeaderName(*index* INTEGER) RETURNING *result* STRING	Returns a request header name by position.
getRequestHeaderValue(*index* INTEGER) RETURNING *result* STRING	Returns a request header value by position.
hasRequestKeepConnection() RETURNING *result* BOOLEAN	Returns TRUE if the connection remains after sending a response.
readDataRequest(*body* BYTE)	Returns the body of a request into a BYTE.
readFileRequest( ) RETURNING *filename* STRING	Returns the body of a request into a file.
readFormEncodedRequest(*utf8* BOOLEAN) RETURNING *result* STRING	Returns the string of a GET request with UTF-8 conversion option.
readTextRequest() RETURNING *result* STRING	Returns the request body as a plain string.
readXmlRequest() RETURNING *result* xml.DomDocument	Returns the request body as an XML document.

Table 459: Object methods: Responding to the client

Name	Description
`beginXmlResponse( code INTEGER, desc STRING ) RETURNING writer xml.StaxWriter`	Starts an HTTP streaming response.
`endXmlResponse( writer xml.StaxWriter )`	Terminates an HTTP streaming response.
`sendDataResponse( code INTEGER, desc STRING, data BYTE )`	Sends and HTTP response with data of a BYTE variable.
`sendFileResponse( code INTEGER, desc STRING, filepath STRING )`	Sends and HTTP response with the data contained in a file.
`sendResponse( code INTEGER, desc STRING )`	Sends and HTTP response without body.
`sendTextResponse( code INTEGER, desc STRING, data STRING )`	Sends and HTTP response with data from a plain string.
`sendXmlResponse( code INTEGER, desc STRING, data xml.DomDocument )`	Sends and HTTP response with data from a XML document object.
`setResponseCharset( charset STRING )`	Defines the HTTP response character set.
`setResponseHeader( name STRING, value STRING )`	Defines a header for the HTTP response.
`setResponseVersion( version STRING )`	Defines the HTTP response version.

Table 460: Object methods: Incoming multipart request

Name	Description
`getRequestMultipartType()` `  RETURNING type STRING`	Returns the multipart type of an incoming request.

`getRequestPart(`
`  idx INTEGER)`
`  RETURNING part-object com.HTTPPart`
	Returns the HTTPPart object at the specified index position.

`getRequestPartCount()` `  RETURNING num INTEGER`	Returns the number of additional multipart elements.

`getRequestPartFromContentID(`
`  id STRING)`
`  RETURNING part-object com.HTTPPart`
	Returns the HTTPPart object of the given Content-ID value.

Table 461: Object methods: Outgoing multipart request

Name	Description

`setResponseMultipartType(`
`  type STRING,`
`  start STRING,`
`  boundary STRING )`
	Sets HTTP response in multipart mode of given type.

`addResponsePart(` `  part-object com.HTTPPart)`	Adds a new part to the HTTP root part response.

com.HTTPServiceRequest.addResponsePart

Adds a new part to the HTTP root part response.

Syntax

```
addResponsePart(
   part-object com.HTTPPart)
```

Usage

Adds a new part to the HTTP root part response. It will be sent after root part has be processed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.beginXmlRequest

Starts an HTTP streaming request.

Syntax

```
beginXmlRequest()
```

```
   RETURNING reader xml.StaxReader
```

1. *reader* is a new `xml.StaxReader` object that will be used for streaming.

Usage

The `beginXmlRequest()` method starts the streaming HTTP request and returns a `xml.StaxReader` object ready to read the XML from the client.

Supported methods are PUT and POST.

The request Content-Type header must be of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.beginXmlResponse

Starts an HTTP streaming response.

Syntax

```
beginXmlResponse(
   code INTEGER,
   desc STRING )
  RETURNING writer xml.StaxWriter
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.
3. *writer* is a new `xml.StaxWriter` the will be used to write the HTTP body.

Usage

The `beginXmlResponse()` method starts a HTTP streaming response by sending the a status (*code*) and description (*desc*), followed by the headers previously set, and returns a `xml.StaxWriter` object ready to send XML as the HTTP body.

If the request failed to be read, its content will be discarded; for example, when a request is not well formatted.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.endXmlRequest

Terminates an HTTP streaming request.

Syntax

```
endXmlRequest(
   reader xml.StaxReader )
```

1. *reader* is the `xml.StaxReader` object used for streaming.

Usage

The `endXmlRequest()` method ends the streaming HTTP request by closing the `xml.StaxReader` object passed as parameter.

The *reader* object must be created with the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.endXmlResponse

Terminates an HTTP streaming response.

Syntax

```
endXmlResponse(
   writer xml.StaxWriter )
```

1. *writer* is the `xml.StaxWriter` used to write the HTTP body.

Usage

The `endXmlResponse()` method terminates the HTTP streaming response by closing the `xml.StaxWriter` object created by `beginXmlResponse`.

The body of the request is discarded.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.getURL

Returns the URL of the HTTP service request.

Syntax

```
getURL()
  RETURNING result STRING
```

Usage

The `getURL()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

URLs are sent in UTF-8 on the network. If the query part of the URL cannot be converted from UTF-8 to the fglrun locale charset, STATUS will be set to -15552. Is this case, the document part of the URL is available, but the query string must be retrieved through HTTPServiceRequest.readFormEncodedRequest(). As a general advice, run you WS server program in UTF-8.

com.HTTPServiceRequest.getMethod

Returns the HTTP method of the service request.

Syntax

```
getMethod()
  RETURNING result STRING
```

Usage

The `getMethod()` method returns the HTTP method of the request (GET, POST, PUT, HEAD, DELETE).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestVersion

Returns the HTTP version of the service request.

Syntax

```
getRequestVersion()
  RETURNING result STRING
```

Usage

The `getRequestVersion()` method returns the HTTP version of the request (1.0 or 1.1).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestHeader

Returns the value of an HTTP header.

Syntax

```
getRequestHeader( name STRING )
  RETURNING result STRING
```

1. *name* is the name of an HTTP header.

Usage

The `getRequestHeader()` method returns the value of the HTTP header specified by the *name* parameter, or `NULL` if there is not found.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestHeaderCount

Returns number of request headers.

Syntax

```
getRequestHeaderCount()
  RETURNING result INTEGER
```

Usage

The `getRequestHeaderCount()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestHeaderName

Returns a request header name by position.

Syntax

```
getRequestHeaderName(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the ordinal position of the header.

Usage

The `getRequestHeaderName()` method returns the name of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestHeaderValue

Returns a request header value by position.

Syntax

```
getRequestHeaderValue(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the ordinal position of the header.

Usage

The `getRequestHeaderValue()` method returns the value of the header at the given position.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestMultipartType
Returns the multipart type of an incoming request.

Syntax

```
getRequestMultipartType()
  RETURNING type STRING
```

Usage

Returns the multipart type of an incoming request, returns NULL if not a multipart request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestPart
Returns the HTTPPart object at the specified index position.

Syntax

```
getRequestPart(
   idx INTEGER)
  RETURNING part-object com.HTTPPart
```

1. *idx* is the index position.

Usage

Returns the HTTPPart object at the specified index position.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Can raise error -15554 (Index is out of bounds).

com.HTTPServiceRequest.getRequestPartCount
Returns the number of additional multipart elements.

Syntax

```
getRequestPartCount()
  RETURNING num INTEGER
```

Usage

The root multipart is handled via standard `readTextRequest()`, `readXmlRequest()`, `readDataRequest()` and `beginXmlRequest()`.

The number of parts is only available when the entire request has been read.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.getRequestPartFromContentID

Returns the HTTPPart object of the given Content-ID value.

Syntax

```
getRequestPartFromContentID(
   id STRING)
  RETURNING part-object com.HTTPPart
```

1. *id* is a Content-ID value.

Usage

Returns the HTTPPart object of the given Content-ID value, returns NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.hasRequestKeepConnection

Returns TRUE if the connection remains after sending a response.

Syntax

```
hasRequestKeepConnection()
  RETURNING result BOOLEAN
```

Usage

The hasRequestKeepConnection() method returns whether the request expect the connection to stay open after the sending of the response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.readDataRequest

Returns the body of a request into a BYTE.

Syntax

```
readDataRequest(
  body BYTE)
```

1. *body* is the BYTE variable that will be filled with the request body.

Usage

The readDataRequest() method returns the body of the request in a BYTE.

Supported methods are PUT and POST.

The BYTE variable must be located in memory, and will be filled with the request body. The existing content of the BYTE will be discarded.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.readFileRequest

Returns the body of a request into a file.

Syntax

```
readFileRequest( )
    RETURNING filename STRING
```

1. *filename* the absolute path to the file containing the HTTP response.

Usage

The `readFileRequest()` method returns the body of the request into a file on the disk.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form : `/tmp/ABC/filename_`*`index`*`.ext`, where *index* represents the number of files with the same name on disk.

Supported methods are PUT and POST.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.readFormEncodedRequest

Returns the string of a GET request with UTF-8 conversion option.

Syntax

```
readFormEncodedRequest(
   utf8 BOOLEAN )
  RETURNING result STRING
```

1. *utf8* defines if the string must be decoded to the current charset.

Usage

The `readFormEncodedRequest()` method returns the query of a POST "application/x-www-form-urlencoded" request or the query string of a GET request, decoded according to HTML4 or XFORM if *utf8* is `TRUE`.

> **Note:** If the result string contains & or = XForms special characters, these are doubled as follows: `na&&me=va==lue`.

If the *utf8* parameter is `TRUE`, the decoded query string is translated from UTF-8 to the current character set. This may lead to a conversion error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.readTextRequest

Returns the request body as a plain string.

Syntax

```
readTextRequest()
  RETURNING result STRING
```

Usage

The `readTextRequest()` method returns the body of the request as a string.

Supported methods are PUT and POST.

The request Content-Type header can be of any form `*/*`. For example: `application/json`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.readXmlRequest

Returns the request body as an XML document.

Syntax

```
readXmlRequest()
  RETURNING result xml.DomDocument
```

Usage

The `readXmlRequest()` method returns the request as an entire XML document, contained in a `xml.DomDocument` object.

Supported methods are PUT and POST.

The request Content-Type header must be of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.sendDataResponse

Sends and HTTP response with data of a `BYTE` variable.

Syntax

```
sendDataResponse(
   code INTEGER,
   desc STRING,
   data BYTE )
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.

3. *data* is the BYTE variable containing the data to be sent.

Usage

The `sendDataResponse()` method performs the HTTP response by sending the status (*code*) and description (*desc*), followed by the headers previously set and binary data contained in the BYTE program variable as body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interprete the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The *data* parameter is defined as a BYTE and must be located in memory and not NULL, otherwise the operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is NULL, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.sendFileResponse

Sends and HTTP response with the data contained in a file.

Syntax

```
sendFileResponse(
   code INTEGER,
   desc STRING,
   filepath STRING )
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.
3. *filepath* is the path the file containing the data to be send.

Usage

The `sendFileResponse()` method performs the HTTP response by sending the status (*code*) and description (*desc*), followed by the headers previously set and the data contained in the specified file as body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interprete the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

If not defined by programmer, the HTTP headers are automatically set as follows:

- `Content-Type` is defined according to the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.

Note: File extensions to `Content-Type` mapping can be customized in the file `FGLDIR/lib/wse/mime.cfg`.

- `Content-Disposition` is set with the base name of the given *filename* as follows: `attachment; filename="basename"`.

For example, when calling the method as follows:

```
CALL server.sendFileResponse( 200, NULL, "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the response will look like:

```
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.sendResponse

Sends and HTTP response without body.

Syntax

```
sendResponse(
   code INTEGER,
   desc STRING )
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.

Usage

The `sendResponse()` method performs the HTTP response by sending the a status (*code*) and description (*desc*), followed by the headers previously set, without a body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interprete the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.sendTextResponse

Sends and HTTP response with data from a plain string.

Syntax

```
sendTextResponse(
   code INTEGER,
   desc STRING,
   data STRING )
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.
3. *data* is the string containing the data to be sent.

Usage

The `sendTextResponse()` method performs the HTTP response by sending the a status (*code*) and description (*desc*), followed by the headers previously set, and text data contained in the string as body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interprete the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic conversion from locale to user-defined charset is performed when possible, otherwise throws an exception.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.sendXmlResponse

Sends and HTTP response with data from a XML document object.

Syntax

```
sendXmlResponse(
   code INTEGER,
   desc STRING,
   data xml.DomDocument )
```

1. *code* is the status code of the response.
2. *desc* is the description of the response.
3. *data* is the XML document containing the data to be sent.

Usage

The `sendXmlResponse()` method performs the HTTP response by sending the a status (*code*) and description (*desc*), followed by the headers previously set, and the XML data contained in the passed `xml.DomDocument` object as body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interprete the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPServiceRequest.setResponseCharset

Defines the HTTP response character set.

Syntax

```
setResponseCharset(
   charset STRING )
```

1. *charset* is the HTTP response character set.

Usage

The `setResponseCharset()` method defines the character set to use when sending an HTTP response.

The server must send a response in a character set that the client understands.

If the response character set is not defined by `setResponseCharset()`, the same character set as the client request is used, or the implicit ISO-8859-1 charset is used if the character is not defined by the client request.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.setResponseHeader

Defines a header for the HTTP response.

Syntax

```
setResponseHeader(
   name STRING,
```

```
   value STRING )
```

1. *name* is the name of a header to define.
2. *value* is the value of a header to define.

Usage

The `setResponseVersion()` method sets (or replaces) the name and value of a HTTP response header.

The Content-Length header cannot be set, because it is computed internally according to the body size.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.setResponseMultipartType

Sets HTTP response in multipart mode of given type.

Syntax

```
setResponseMultipartType(
   type STRING,
   start STRING,
   boundary STRING )
```

1. *type* is one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
   - alternative: Parts are different type of a same document
   - *or any other type*
   - NULL: switch multipart mode off
2. *start* is the Content-ID value of root multipart document. Must be ASCII. (optional)
3. *boundary* is the string used as multipart boundary. Must be ASCII. (optional)

Usage

Sets HTTP response in multipart mode of given type. Calling one of the standard request method will send the HTTP response as given multipart type, even if no other part has been set.

The root HTTP part must be handled via the standard HTTPServiceRequest methods such as `sendTextRequest()`, `sendXmlRequest()`, `sendDataRequest()` and `BeginXmlResponse()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPServiceRequest.setResponseVersion

Defines the HTTP response version.

Syntax

```
setResponseVersion(
   version STRING )
```

1. *version* is the HTTP response version.

Usage

The `setResponseVersion()` method defines the HTML response version (1.0 or 1.1).

If not set, the same version as the request is used.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

HTTP classes

The HTTP classes manage HTTP client network operations on the client side.

- The HTTPRequest class on page 2053
- The HTTPResponse class on page 2070
- The HTTPPart class on page 2077

The HTTPRequest class

The `com.HTTPRequest` class provides an interface to perform asynchronous XML and TEXT requests over HTTP for a specified URL, with additional XML streaming possibilities, on the client side.

The `STATUS` variable is set to zero after a successful method call.

com.HTTPRequest methods
Methods for the `com.HTTPRequest` class.

Table 462: Class methods

Name	Description

`com.HTTPRequest.Create(`
`  url STRING )`
`  RETURNING result com.HTTPRequest`
	Creates an new HTTPRequest object from a URL.

Table 463: Object methods: Configuration methods

Name	Description
`clearAuthentication()`	Removes user-defined authentication.
`clearHeaders()`	Removes all user-defined HTTP request headers.
`removeHeader(` `  name STRING )`	Removes an HTTP header for the request according to a name.

`setAuthentication(`
`  login STRING,`
`  pass STRING,`
`  scheme STRING,`
	Defines the user login and password to authenticate to the server.

Name	Description
realm STRING)	
setAutoReply(*reply* BOOLEAN)	Defines the auto reply option for response methods.
setCharset(*charset* STRING)	Defines the charset used when sending text or XML.
setConnectionTimeOut(*timeout* INTEGER)	Defines the timeout for the establishment of the connection.
setHeader(*name* STRING, *value* STRING)	Sets an HTTP header for the request.
setMethod(*method* STRING)	Sets the HTTP method of the request.
setKeepConnection(*keep* BOOLEAN)	Defines if connection is kept open if a new request occurs.
setMaximumResponseLength(*length* INTEGER)	Defines the maximum size in Kbyte of a response.
setTimeOut(*timeout* INTEGER)	Defines the timeout for a reading or writing operation.
setVersion(*version* STRING)	Sets the HTTP version of the request.

Table 464: Object methods: Sending methods

Name	Description
beginXmlRequest() RETURNING *writer* xml.StaxWriter	Starts a streaming HTTP request.
endXmlRequest(*writer* xml.StaxWriter)	Terminates a streaming HTTP request.
doDataRequest(	Performs the request by sending binary data.

Name	Description
data BYTE)	
doFileRequest(*filepath* STRING)	Performs the request by sending data contained in a file.
doFormEncodedRequest(*query* STRING, *utf8* BOOLEAN)	Performs an "application/x-www-form-urlencoded forms" encoded query.
doRequest()	Performs the HTTP request.
doTextRequest(*data* STRING)	Performs the request by sending an entire string at once.
doXmlRequest(*data* xml.DomDocument)	Performs the request by sending an entire XML document at once.

Table 465: Object methods : Response methods

Name	Description
getAsyncResponse() RETURNING *result* com.HTTPResponse	When available, returns the response produced by one of request methods.
getResponse() RETURNING *result* com.HTTPResponse	Waits and returns the response produced by one of request methods.

Table 466: Object methods of com.HTTPRequest : Multipart methods

Name	Description
addPart(*p* com.HTTPPart)	Adds a new part to the HTTP root part request.
setMultipartType(*type* STRING, *start* STRING, *boundary* STRING)	Switch HTTPRequest in multipart mode of given type.

com.HTTPRequest.addPart

Adds a new part to the HTTP root part request.

Syntax

```
addPart( p com.HTTPPart )
```

1. *p* is the HTTPPart object.

Usage

Adds a new part to the HTTP root part request. This part is sent after root part has been processed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.beginXmlRequest

Starts a streaming HTTP request.

Syntax

```
beginXmlRequest()
  RETURNING writer xml.StaxWriter
```

1. *writer* is the xml.StaxWriter to be used to write the HTTP request.

Usage

The beginXmlRequest() starts a streaming HTTP request and returns an xml.StaxWriter object ready to send XML to the server.

Supported methods are PUT and POST.

The default Content-Type header is text/xml, but it can be changed if of the form */xml or */*+xml. For example: application/xhtml+xml.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.clearAuthentication

Removes user-defined authentication.

Syntax

```
clearAuthentication()
```

Usage

Removes user-defined authentication.

If an authenticate entry exists in the FGLPROFILE file, it will be used for authentication, even if the user-defined authentication was removed.

> **Important:** The iOS HTTP stack doesn't provide a simple way to handle authentication. The GMI front-end uses the global iOS credential management system, that keeps credential value of previous request according to host and realm, until the keep-alive session is closed. Therefore, doing a clearAuthentication() on iOS devices is not working immediately.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.clearHeaders

Removes all user-defined HTTP request headers.

Syntax

```
clearHeaders()
```

Usage

Removes all user-defined HTTP request headers defined with the `setHeader()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.Create

Creates an new HTTPRequest object from a URL.

Syntax

```
com.HTTPRequest.Create(
   url STRING )
  RETURNING result com.HTTPRequest
```

1. *url* is the URL for the HTTP request.

Usage

Creates an `com.HTTPRequest` object by providing a mandatory URL with HTTP or HTTPS as protocol.

The *url* parameter can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.doDataRequest

Performs the request by sending binary data.

Syntax

```
doDataRequest(
   data BYTE )
```

1. *data* is the binary data.

Usage

Performs the request by sending binary data contained in the `BYTE` variable.

Supported methods are PUT and POST.

The `BYTE` must be located in memory and not `NULL` otherwise operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.doFileRequest

Performs the request by sending data contained in a file.

Syntax

```
doFileRequest(
   filepath STRING )
```

1. *filepath* is the path to the file containing the data to be send.

Usage

Performs the request by sending data contained in the file passed as parameter. The data is sent as is without any further conversion.

Supported methods are PUT and POST.

If not defined by programmer, the HTTP headers are automatically set as follows:

- `Content-Type` is defined according to the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.

  Note: File extensions to `Content-Type` mapping can be customized in the file `FGLDIR/lib/wse/mime.cfg`.
- `Content-Disposition` is set with the base name of the given *filename* as follows: `attachment; filename="`*`basename`*`"`.

For example, when calling the method as follows:

```
CALL request.doFileRequest( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the POST or PUT will look like:

```
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.doFormEncodedRequest

Performs an "application/x-www-form-urlencoded forms" encoded query.

Syntax

```
doFormEncodedRequest(
   query STRING,
   utf8 BOOLEAN )
```

1. *query* is a list of name/value pairs separated by an &.
2. *utf8* defines if the query string is UTF-8 encoded.

Usage

The `doFormEncodedRequest()` metho performs request with an "application/x-www-form-urlencoded forms" encoded query.

Supported methods are GET and POST.

The *query* string is a list of name/value pairs separated by an ampersand (&). For example:

```
name1=value1&name2=value2&name3=value3
```

> **Note:** If you need to URL-encode the separator characters & and =, double them as following : `na&&me=va==lue`.

If the *utf8* parameter is TRUE, the query string is encoded in UTF-8 as specified in XForms1.0, otherwise in ASCII as specified in HTML4.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.doRequest

Performs the HTTP request.

Syntax

```
doRequest()
```

Usage

The `doRequest()` method performs the HTTP request.

Supported methods are GET, HEAD and DELETE.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going

on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.doTextRequest

Performs the request by sending an entire string at once.

Syntax

```
doTextRequest(
   data STRING )
```

1. *data* is a string containing the request.

Usage

Performs the request by sending an entire string at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic character set conversion from the application locale to the user-defined charset is performed. In case of conversion error, the method throws an exception.

> **Note:** To avoid character conversion problems when sending text over HTTP, consider setting the same user-define character set as the program defined by the application locale (assuming that the server understands the client application character set).

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.doXmlRequest

Performs the request by sending an entire XML document at once.

Syntax

```
doXmlRequest(
   data xml.DomDocument )
```

1. *data* is the XML document containing the data to be sent..

Usage

The `doXmlRequest()` method performs the request by sending the entire passed `xml.DomDocument` at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

The character set used to send the XML data is defined by the encoding attribute in the XML document prolog. It is recommended that you define the HTTP request character set to `NULL` with the `setCharSet()` method, or that you use the same character set that was set in the XML Document.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.endXmlRequest

Terminates a streaming HTTP request.

Syntax

```
endXmlRequest(
   writer xml.StaxWriter )
```

1. *writer* is the `xml.StaxWriter` used to write the HTTP request.

Usage

The `endXmlRequest()` method terminates a streaming HTTP request by closing the `xml.StaxWriter` object that was created with the `beginXmlRequest()` method.

This HTTP request method is non-blocking: It returns immediatly after the call. Use the com.HTTPRequest.getResponse on page 2062 method, to perform a synchroneous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the com.HTTPRequest.getAsyncResponse on page 2061 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.getAsyncResponse

When available, returns the response produced by one of request methods.

Syntax

```
getAsyncResponse()
  RETURNING result com.HTTPResponse
```

Usage

If a response is available, the `getAsyncResponse()` method returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, doTextRequest(), `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

Unlike `getResponse()`, the `getAsyncResponse()` method is non-blocking: it returns immediatly and does not stop the program flow when waiting for a response.

The method returns `NULL` if the HTTP response was not yet received from the server.

This method is typically called just after a `do*Request()` call, and if the returned value is `NULL`, it is called again after a short period of time, to check for a response. Within a dialog, use an `ON IDLE` block to issue a `getAsyncRequest()` every seconds for example.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.getResponse

Waits and returns the response produced by one of request methods.

Syntax

```
getResponse()
  RETURNING result com.HTTPResponse
```

Usage

The `getResponse()` method wait for a resonse from the server and returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, `doTextRequest()`, `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

> **Note:** On iOS, a long running HTTP request will display a message box, to let the user cancel the request. If the user cancels the HTTP request, the error -15578 will be raised. This error can be trapped with `TRY/CATCH`.

Unlike `getAsyncResponse()`, the `getResponse()` method is blocking: it stops the program flow until the HTTP response is received from the server.

Define a response timeout with the com.HTTPRequest.setTimeOut on page 2067 method.

> **Note:** On iOS devices, when using this method, it is not possible to distinguish different timeouts for the connection and for read/write operation, defined respectively by the `setConnectionTimeOut()` and `setTimeOut()` methods. If both timeouts are defined, the shortest timeout will be used for the connection and read/write operations.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPRequest.removeHeader

Removes an HTTP header for the request according to a name.

Syntax

```
removeHeader(
   name STRING )
```

1. *name* is the HTTP header name to remove.

Usage

The `removeHeader()` method deletes an HTTP header identified by *name*.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setAuthentication

Defines the user login and password to authenticate to the server.

Syntax

```
setAuthentication(
   login STRING,
   pass STRING,
   scheme STRING,
   realm STRING )
```

1. *login* is the login name.
2. *pass* is the password.
3. *scheme* defines the method to be used during authentication.
4. *realm* defines the realm.

Usage

The `setAuthentication()` method defines the mandatory user login and password to authenticate to the server.

The *scheme* parameter defines the method to be used during authentication. The supported values for the *scheme* parameter are `Anonymous`, `Basic` and `Digest`. The default is `Anonymous`.

An optional *realm* can be specified.

With `Anonymous` or `Digest` authentication, you must re-send the request if you get a 401 or 407 HTTP return code (authorization required)

If a user-defined authentication is set and there is an authenticate entry for this URL in the FGLPROFILE file, the user-defined authentication has priority.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setAutoReply

Defines the auto reply option for response methods.

Syntax

```
setAutoReply(
   reply BOOLEAN )
```

1. *reply* defines auto-reply when `TRUE`.

Usage

The `setAutoReply()` method defines whether `getResponse()` or `getAsyncResponse()` will automatically perform another HTTP GET request if response contains HTTP Authentication, Proxy Authentication or HTTP redirect data.

Available for GET method and the HTTP HEAD method.

The default is `TRUE`.

> **Important:** On iOS devices, `setAutoReply()` is ignored for redirection in synchronous requests: The iOS HTTP stack does not allow to set an auto reply option when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setCharset

Defines the charset used when sending text or XML.

Syntax

```
setCharset(
   charset STRING )
```

1. *charset* is the character set to use.

Usage

Defines the character set used when sending an HTTP request.

By default, no character set information will be transmitted in the HTTP header. This is also the case when specifying `NULL` as parameter for this method.

If no character set is specified in HTTP headers, ISO8859-1 will implicitely be used as defined by the HTTP standards.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setConnectionTimeOut

Defines the timeout for the establishment of the connection.

Syntax

```
setConnectionTimeOut(
   timeout INTEGER )
```

1. *timeout* is the number of seconds.

Usage

The `setConnectionTimeOut()` method sets the time value in seconds to wait for the establishment of the connection, before a break.

The value of -1 means infinite wait.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setHeader

Sets an HTTP header for the request.

Syntax

```
setHeader(
   name STRING,
   value STRING )
```

1. *name* is the HTTP header name.
2. *value* is the HTTP header value.

Usage

The `setHeader()` method defines an HTTP header with a *name* and *value* for the request.

If a header exists with the same name, it is replaced with the new value.

Setting a header after the body has been sent, or if a streaming operation has been started, will only be taken into account when a new request is reissued.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setKeepConnection

Defines if connection is kept open if a new request occurs.

Syntax

```
setKeepConnection(
   keep BOOLEAN )
```

1. *keep* defines if the connection is kept.

Usage

The `setKeepConnection()` method defines whether the connection should stay open if a new HTTP request occurs.

The default is `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setMaximumResponseLength

Defines the maximum size in Kbyte of a response.

Syntax

```
setMaximumResponseLength(
   length INTEGER )
```

1. *length* is the maximum size in Kbytes.

Usage

The `setMaximumResponseLength()` method sets the maximum authorized size in Kbytes of the whole response (including headers, body and all control characters), before a break.

The value of -1 means no limit.

> **Note:** Setting the maximum response length is ignored for synchronous requests in a Genero Mobile for iOS (GMI) app: The iOS HTTP stack does not allow you to set a maximum response length when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setMethod

Sets the HTTP method of the request.

Syntax

```
setMethod(
   method STRING )
```

1. *method* is the HTTP method of the request.

Usage

The `setMethod()` method defines the HTTP method of the request.

Supported methods are GET, PUT, POST, HEAD and DELETE.

The default is GET.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setMultipartType

Switch HTTPRequest in multipart mode of given type.

Syntax

```
setMultipartType(
   type STRING,
   start STRING,
   boundary STRING )
```

1. *type* is one of the following:

   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)

- alternative: Parts are different type of a same document
- *or any other type*
- NULL: switch multipart mode off

2. *start* is the Content-ID value of root multipart document. (optional)

3. *boundary* is the string used as multipart boundary. (optional)

Usage

Switch HTTPRequest in multipart mode of given type. Calling one of the standard request method will send the HTTP request as given multipart type, even if no other part has been set.

> **Important:** Multipart HTTP requests is not supported on GMI mobile devices.

The root HTTP part is the part handled via the standard HTTPRequest methods such as `doTextRequest()`, `doXmlRequest()`, `doDataRequest()` and `beginXmlRequest()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setTimeOut

Defines the timeout for a reading or writing operation.

Syntax

```
setTimeOut(
   timeout INTEGER )
```

1. *timeout* specifies the number of seconds.

Usage

The `setTimeOut()` method defines a delay in seconds, to wait for a HTTP request read or write operation. If the operation is not terminated after the timeout, it returns immediately with an error.

Use the value of -1 to define an infinite timeout.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPRequest.setVersion

Sets the HTTP version of the request.

Syntax

```
setVersion(
   version STRING )
```

1. *version* is the HTTP version of the request.

Usage

The `setVersion()` method defines the HTTP version of the request.

Accepted versions are 1.0 and 1.1 (only these two versions are supported).

The default is 1.1.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Examples

Examples using methods of the com.HTTPRequest class.

Example 1: HTTP GET request

```
IMPORT com

MAIN
  DEFINE req com.HTTPRequest
  DEFINE resp com.HTTPResponse
  TRY
    LET req = com.HTTPRequest.Create("http://localhost:8090/MyPage")
    # Set additional HTTP header with name 'MyHeader', and value 'High
 Priority'
    CALL req.setHeader("MyHeader","High Priority")
    CALL req.doRequest()
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
      DISPLAY "HTTP Error ("||resp.getStatusCode()||") ",
        resp.getStatusDescription()
    ELSE
      DISPLAY "HTTP Response is : ",resp.getTextResponse()
    END IF
  CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
  END TRY
END MAIN
```

Example 2 : XForms HTTP POST request

```
IMPORT com
IMPORT xml

MAIN
  DEFINE req com.HTTPRequest
  DEFINE resp com.HTTPResponse
  DEFINE doc xml.DomDocument
  TRY
    LET req = com.HTTPRequest.Create("http://localhost:8090/MyProcess")
    CALL req.setMethod("POST") # Perform an HTTP POST method
      # Param1 value is 'hello', Param2 value is 'how are you ?'
    CALL req.doFormEncodedRequest("Param1=hello&Param2=how are
 you ?",FALSE)
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
      DISPLAY  "HTTP Error ("||resp.getStatusCode()||") ",
        resp.getStatusDescription()
    ELSE
       # Expect a returned content type of the form */xml
      LET   doc = resp.getXmlResponse()
      DISPLAY   "HTTP XML Response is : ",doc.saveToString()
    END IF
  CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
  END TRY
END MAIN
```

Example 3 : Streaming HTTP PUT request

```
IMPORT com
IMPORT xml

MAIN
  DEFINE req com.HTTPRequest
  DEFINE resp com.HTTPResponse
  DEFINE writer xml.StaxWriter
  TRY
    LET req = com.HTTPRequest.Create("http://localhost:8090/MyXmlProcess")
    CALL req.setMethod("PUT") # Perform an HTTP PUT method
    CALL req.setHeader("MyHeader","Value of my header")
      # Retrieve an xml.StaxWriter to start xml streaming
    LET writer = req.beginXmlRequest()
    CALL writer.startDocument("utf-8","1.0",true)
    CALL writer.comment("My first XML document sent in streaming with
 genero")
    CALL writer.startElement("root")
    CALL writer.attribute("attr1","value1")
    CALL writer.endElement()
    CALL writer.endDocument()
    CALL req.endXmlRequest(writer) # End streaming request
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 201 OR resp.getStatusCode() != 204 THEN
      DISPLAY   "HTTP Error ("||resp.getStatusCode()||") ",
        resp.getStatusDescription()
    ELSE
      DISPLAY   "XML document was correctly put on the server"
    END IF
  CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
  END TRY
END MAIN
```

Example 4 : Asynchronous HTTP DELETE request

```
IMPORT com

MAIN
  DEFINE req com.HTTPRequest
  DEFINE resp com.HTTPResponse
  DEFINE url STRING
  DEFINE quit CHAR(1)
  DEFINE questionStr STRING
  DEFINE timeout INTEGER
  TRY
    WHILE TRUE
      PROMPT "Enter http url you want to delete ? "
         FOR url ATTRIBUTES (CANCEL=FALSE)
      LET req = com.HTTPRequest.Create(url)
      CALL req.setMethod("DELETE")
      CALL req.doRequest()
      # Retrieve asynchronous response for the first time
      LET resp = req.getAsyncResponse()
      CALL Update(resp) RETURNING questionStr,timeout
      WHILE quit IS NULL OR ( quit!="Y" AND quit!="N" )
        PROMPT questionStr FOR CHAR quit
          ATTRIBUTES (CANCEL=FALSE,ACCEPT=FALSE,SHIFT="up")
          ON IDLE timeout
          IF resp IS NULL THEN # If no response at first try,
                               # retrieve it again
            LET resp = req.getAsyncResponse() # as we now have time
```

```
            CALL Update(resp) RETURNING questionStr,timeout
          END IF
        END PROMPT
      END WHILE
      IF quit == "Y" THEN
        EXIT PROGRAM
      ELSE
        LET quit = NULL
      END IF
    END WHILE
  CATCH

```

The HTTPResponse class

The `com.HTTPResponse` class provides an interface to perform XML and TEXT responses over HTTP, with additional XML streaming possibilities, on the client side.

The `STATUS` variable is set to zero after a successful method call.

com.HTTPResponse methods

Methods for the `com.HTTPResponse` class.

Table 467: Object methods

Name	Description
`beginXmlResponse()` `  RETURNING` *`writer`* `xml.StaxWriter`	Starts a streaming HTTP response.
`endXmlResponse(` `  ` *`writer`* `xml.StaxWriter )`	Performs the HTTP request.
`getDataResponse(` `  ` *`data`* `BYTE )`	Returns the entire HTTP response in a BYTE.
`getFileResponse( )`	Returns the entire HTTP response in a file on the disk.

Name	Description
RETURNING *filename* STRING	
getHeader(*name* STRING) RETURNING *result* STRING	Returns the value of an HTTP header.
getHeaderCount() RETURNING *result* INTEGER	Returns the number of headers.
getHeaderName(*index* INTEGER) RETURNING *result* STRING	Returns the name of a header by position.
getHeaderValue(*index* INTEGER) RETURNING *result* STRING	Returns the value of a header by position.
getStatusCode() RETURNING *result* INTEGER	Returns the HTTP status code.
getStatusDescription() RETURNING *result* STRING	Returns the HTTP status description.
getTextResponse() RETURNING *data* STRING	Returns the entire HTTP response in a string.
getXmlResponse() RETURNING *data* xml.DomDocument	Returns the entire HTTP response in a DOM document.

Table 468: Object methods: Multipart methods

Name	Description
getMultipartType() RETURNING *result* STRING	Returns whether a response is multipart or not, and the kind of multipart if any.
getPart(*index* INTEGER) RETURNING *part-object* com.HTTPPart	Returns the HTTP part object at the specified index of the current HTTP response.
getPartCount() RETURNING *count* INTEGER	Returns the number of additional parts in the HTTP response.
getPartFromContentID(*id* STRING)	Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

Name	Description
RETURNING *part-object* com.HTTPPart	

com.HTTPResponse.beginXmlResponse

Starts a streaming HTTP response.

Syntax

```
beginXmlResponse()
  RETURNING writer xml.StaxWriter
```

1. *writer* is the `xml.StaxWriter` to be used to write the HTTP request.

Usage

The `beginXmlResponse()` method the streaming HTTP response and returns a `xml.StaxReader` object ready to read XML from the server.

The Content-Type header must be of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPResponse.endXmlResponse

Performs the HTTP request.

Syntax

```
endXmlResponse(
   writer xml.StaxWriter )
```

1. *writer* is the `xml.StaxWriter` used to write the HTTP response.

Usage

The `endXmlResponse()` method ends the streaming HTTP response by closing the the `xml.StaxWriter` object that was created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPResponse.getDataResponse

Returns the entire HTTP response in a BYTE.

Syntax

```
getDataResponse(
   data BYTE )
```

1. *data* is a `BYTE` variable receiving the HTTP response data.

Usage

The `getDataResponse()` method returns the body of an HTTP response into a BYTE variable.

The BYTE variable must be located in memory, otherwise operation fails.

Returns binary data as response from a server into a BYTE.

Previous content is discarded.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPResponse.getFileResponse

Returns the entire HTTP response in a file on the disk.

Syntax

```
getFileResponse( )
   RETURNING filename STRING
```

1. *filename* is the absolute path to the file containing the HTTP response.

Usage

Reads an HTTP response and creates a file from it.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form : `/tmp/ABC/filename_index.ext`, where *index* represents the number of files with the same name on disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPResponse.getHeader

Returns the value of an HTTP header.

Syntax

```
getHeader( name STRING )
  RETURNING result STRING
```

1. *name* is the name of the HTTP header.

Usage

The `getHeader()` method returns the value of the HTTP header specified by the *name* parameter, or `NULL` if not found.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getHeaderCount

Returns the number of headers.

Syntax

```
getHeaderCount()
  RETURNING result INTEGER
```

Usage

The `getHeaderCount()` method returns the number of headers of the HTTP response.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getHeaderName

Returns the name of a header by position.

Syntax

```
getHeaderName(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the ordinal position of the header.

Usage

The `getHeaderName()` method returns the name of the HTTP response header according to the position passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getHeaderValue

Returns the value of a header by position.

Syntax

```
getHeaderValue(
   index INTEGER )
  RETURNING result STRING
```

1. *index* is the ordinal position of the header.

Usage

The `getHeaderValue()` method returns the value of the HTTP response header according to the position passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getMultipartType

Returns whether a response is multipart or not, and the kind of multipart if any.

Syntax

```
getMultipartType()
  RETURNING result STRING
```

Usage

Returns whether a response is multipart or not, and the kind of multipart if any.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getPartCount

Returns the number of additional parts in the HTTP response.

Syntax

```
getPartCount()
  RETURNING count INTEGER
```

Usage

Returns the number of additional parts in the HTTP response. The root part element must be handled via `getXmlResponse()`, `getTextResponse()`, `getDataResponse()` and `beginXmlResponse()`. In other words, there are `getPartCount()` +1 parts if `getMultipartType()` does not return NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getPart

Returns the HTTP part object at the specified index of the current HTTP response.

Syntax

```
getPart(
   index INTEGER )
  RETURNING part-object com.HTTPPart
```

1. *index* is the index number.

Usage

Returns the HTTP part object at the specified index of the current HTTP response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Can raise error -15554 (Index is out of bounds).

com.HTTPResponse.getPartFromContentID

Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

Syntax

```
getPartFromContentID(
   id STRING )
  RETURNING part-object com.HTTPPart
```

1. *name* is the name of the HTTP header.

Usage

Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getStatusCode

Returns the HTTP status code.

Syntax

```
getStatusCode()
  RETURNING result INTEGER
```

Usage

The `getStatusCode()` method returns the status code for the HTTP response.

When the returned HTTP status code is 401 or 407, authorization is required.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getStatusDescription

Returns the HTTP status description.

Syntax

```
getStatusDescription()
  RETURNING result STRING
```

Usage

The `getStatusDescription()` method returns a description of the HTTP reponse status.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPResponse.getTextResponse

Returns the entire HTTP response in a string.

Syntax

```
getTextResponse()
  RETURNING data STRING
```

Usage

The `getTextResponse()` method returns a HTTP reponse as a entire string.

- The Content-Type header can be of the form ***/***. For example: application/json.
- Automatic conversion to the locale charset is performed when possible, otherwise throws an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.HTTPResponse.getXmlResponse

Returns the entire HTTP response in a DOM document.

Syntax

```
getXmlResponse()
  RETURNING data xml.DomDocument
```

Usage

The `getXmlResponse()` method returns an HTTP response in a `xml.DomDocument` object.

The Content-Type header must be of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

Examples

Examples using methods of the `com.HTTPResponse` class.

For examples, see Examples on page 2068.

The HTTPPart class

The `com.HTTPPart` class provides an interface to manage the HTTP attachment sent or received in HTTP.

The `STATUS` variable is set to zero after a successful method call.

com.HTTPPart methods

Methods for the `com.HTTPPart` class.

Table 469: Class methods of com.HTTPPart

Name	Description

`CreateAttachment(`
`  filename STRING)`
`RETURNING part-object com.HTTPPart`
	Creates a new HTTPPart object based on given filename located on disk.

`CreateFromData(` `  b BYTE)`	Creates a new HTTPPart object based on given BYTE located in memory.

Name	Description
`RETURNING part-object com.HTTPPart`	
`CreateFromDomDocument( x xml.DomDocument) RETURNING part-object com.HTTPPart`	Creates a new HTTPPart object based on given XML document.
`CreateFromString( s STRING) RETURNING part-object com.HTTPPart`	Creates a new HTTPPart object based on given string.

Table 470: Object methods of com.HTTPPart

Name	Description
`getAttachment() RETURNING filename STRING`	Returns the absolute path to the HTTP part.
`getContentAsData( b BYTE )`	Returns the HTTP part as a BYTE.
`getContentAsDomDocument() RETURNING domDocument xml.DomDocument`	Returns the HTTP part as a XML document.
`getHeader( name STRING ) RETURNING value STRING`	Setter to handle HTTP multipart headers.
`getContentAsString() RETURNING str STRING`	Returns the HTTP part as a string.
`setHeader( name STRING, value STRING)`	Setter to handle HTTP multipart headers.

com.HTTPPart.CreateFromString

Creates a new HTTPPart object based on given string.

Syntax

```
CreateFromString(
   s STRING)
  RETURNING part-object com.HTTPPart
```

1. *s* is a string

Usage

Creates a new HTTPPart object based on given string. To be used via the addPart() method.

Defaults HTTP multipart headers:

- Content-Type: text/plain
- Content-Transfer-Encoding: 8bits

Notice that the string will be converted during request sending into ISO-8859-1 by default, unless a different charset has been set via setHeader("Content-Type","text/plain; charset=UTF-8") for instance.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPPart.CreateFromDomDocument

Creates a new HTTPPart object based on given XML document.

Syntax

```
CreateFromDomDocument(
   x xml.DomDocument)
  RETURNING part-object com.HTTPPart
```

1. *x* is an XML document.

Usage

Creates a new HTTPPart object based on given XML document. To be used via the addPart() method.

Defaults HTTP multipart headers:

- Content-Type: text/xml; charset=UTF-8
- Content-Transfer-Encoding: 8bits

A different charset can be set with the setHeader method. For example, `setHeader("Content-Type","text/plain; charset=ISO-8859-1")` sets the charset to ISO-8859-1.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPPart.CreateFromData

Creates a new HTTPPart object based on given BYTE located in memory.

Syntax

```
CreateFromData(
   b BYTE)
  RETURNING part-object com.HTTPPart
```

1. *b* is a BYTE object located in memory.

Usage

Creates a new HTTPPart object based on given BYTE located in memory. To be used via the addPart() method.

Defaults HTTP headers:

- Content-Type: application/octet-stream
- Content-Transfer-Encoding: base64

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPPart.CreateAttachment

Creates a new HTTPPart object based on given filename located on disk.

Syntax

```
CreateAttachment(
   filename STRING)
  RETURNING part-object com.HTTPPart
```

1. *filename* is the name of a file.

Usage

Creates a new HTTPPart object based on given filename located on disk. To be used via the addPart() method.

The com.HTTPPart.CreateAttachment() method automatically sets the following headers for the created HTTPPart object:

- Content-Type is defined according to the file name extension. If the file extension is not recognized, Content-Type defaults to application/octet-stream.

  Note: File extensions to Content-Type mapping can be customized in the file FGLDIR/lib/wse/mime.cfg.
- Content-Transfer-Encoding is set to "binary".
- Content-Disposition is set with the base name of the given *filename* as follows: attachment; filename="*basename*".

For example, when calling the method as follows:

```
LET part = com.HTTPPart.CreateAttachment( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP part headers will look like:

```
Content-Type: image/jpeg
Content-Transfer-Encoding: binary
Content-Disposition: attachment; filename="logo.jpg"
```

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPPart.getAttachment

Returns the absolute path to the HTTP part.

Syntax

```
getAttachment()
  RETURNING filename STRING
```

Usage

Returns the absolute path location of the received part file.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the

filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form : `/tmp/ABC/filename_`*`index`*`.ext`, where *index* represents the number of files with the same name on disk.

If the file is encoded in base64, you can use the Genero Web Services `fglpass -dec64` command to convert it back to binary.

It is up to programmer to remove file from the disk when it is no longer needed.

To be used via methods: com.HTTPResponse.getPart on page 2075, com.HTTPResponse.getPartCount on page 2075, and com.HTTPResponse.getPartFromContentID on page 2075

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.HTTPPart.getContentAsData

Returns the HTTP part as a `BYTE`.

Syntax

```
getContentAsData(
   b BYTE )
```

1. *b* is a variable holding the `BYTE` data.

Usage

Returns the HTTP part as a `BYTE`. `BYTE` data cannot be returned from a function with a `RETURN` statement. Therefore, the `BYTE` parameter must be handled by reference.

To be used via methods: com.HTTPResponse.getPart on page 2075, com.HTTPResponse.getPartCount on page 2075, and com.HTTPResponse.getPartFromContentID on page 2075

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The error -15573 is raised if the part cannot be converted to a Genero `BYTE`.

com.HTTPPart.getContentAsDomDocument

Returns the HTTP part as a XML document.

Syntax

```
getContentAsDomDocument()
  RETURNING domDocument xml.DomDocument
```

Usage

Returns the HTTP part as a XML document.

To be used via methods: com.HTTPResponse.getPart on page 2075, com.HTTPResponse.getPartCount on page 2075, and com.HTTPResponse.getPartFromContentID on page 2075

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The error -15573 is raised if the part cannot be converted to a XML DomDocument.

com.HTTPPart.getContentAsString

Returns the HTTP part as a string.

Syntax

```
getContentAsString()
  RETURNING str STRING
```

Usage

Returns the HTTP part as a string.

To be used via methods: com.HTTPResponse.getPart on page 2075, com.HTTPResponse.getPartCount on page 2075, and com.HTTPResponse.getPartFromContentID on page 2075

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The error -15573 is raised if the part cannot be converted to a Genero string or if the charset is not supported.

com.HTTPPart.getHeader

Setter to handle HTTP multipart headers.

Syntax

```
getHeader(
   name STRING )
  RETURNING value STRING
```

1. *name* is the name of the header part.
2. *value* is the value for the header part specified by *name*.

Usage

Getter to handle HTTP multipart headers.

> **Note:** In case of related multipart (i.e., the part is multipart/related and set via the com.HTTPRequest.setMultipartType("related",NULL,NULL)), it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the security.RandomGenerator.CreateUUIDString on page 2280 method for that.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Example

```
LET val = req.getHeader("MyClientHeader")
```

com.HTTPPart.setHeader

Setter to handle HTTP multipart headers.

Syntax

```
setHeader(
   name STRING,
   value STRING)
```

1. *name* is the multipart header name.
2. *value* is the multipart header value (such as HTTP headers).

Usage

Setter to handle HTTP multipart headers.

For instance, when you send a multipart image, you should specify the image mime type with this header method. If the image is a `png`, you have to do `part.setHeader("Content-Type","image/png")`, which lets the peer know the format of the attached file it has to process.

> **Note:** In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`), it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the security.RandomGenerator.CreateUUIDString on page 2280 method for that.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

Example

```
CALL req.setHeader("MyClientHeader","Hello")
```

Example
Examples using methods of the `com.HTTPPart` class.

This example consists of two applications: a client and server exchanging an XML document in multipart with a image as an attachment.

Client Application

```
IMPORT com
IMPORT xml

CONSTANT SERVER_URL = "http://localhost:8090/MultipartMixed/Sample"

MAIN

  DEFINE req      com.HTTPRequest
  DEFINE resp     com.HTTPResponse
  DEFINE doc      xml.DomDocument
  DEFINE root     xml.DomNode
  DEFINE p        com.HTTPPart
  DEFINE type     STRING
  DEFINE count    INTEGER
  DEFINE ind      INTEGER

  FOR ind = 1 TO req.getRequestPartCount()
    LET p = req.getRequestPart(ind)
    IF p.getAttachment() IS NOT NULL THEN
      DISPLAY "Attached file at :",p.getAttachment()
    ELSE
      DISPLAY "Attached part is :",p.getContentAsString()
    END IF
  END FOR
  # Set multipart response type
  CALL req.setResponseMultipartType("mixed",NULL,NULL)
  # Add XML Part
  LET p = com.HTTPPart.CreateAttachment("my_other_picture.jpg")
  CALL p.setHeader("Content-Type","image/jpg")
  CALL req.addResponsePart(p)
  LET doc = xml.DomDocument.CreateDocument("MyResponse")
  CALL req.sendXmlResponse(200,NULL,doc)
END MAIN
```

TCP classes
The TCP classes manage TCP client network operations.

- CLASS TCPRequest
- CLASS TCPResponse

The TCPRequest class
The `com.TCPRequest` class provides an interface to perform asynchronous XML and TEXT requests over TCP, with additional XML streaming possibilities.

> **Important:** This Web Services class is not supported on GMI mobile devices.

com.TCPRequest methods
Methods of the `com.TCPRequest` class.

Table 471: Class methods of com.TCPRequest

Name	Description

`com.TCPRequest.Create(`
`  url STRING )`
`  RETURNING result com.TCPRequest`
	Creates a new TCP request object.

Table 472: Object methods of com.TCPRequest

Name	Description
`beginXmlRequest()` `  RETURNING writer xml.StaxWriter`	Starts a streaming XML request.
`doDataRequest(` `  data BYTE )`	Performs the request by sending binary data.
`doRequest()`	Performs a TCP request.
`doTextRequest(` `  data STRING )`	Persforms a request with a string.
`doXmlRequest(` `  document xml.DomDocument )`	Persforms a request with a DOM document.
`endXmlRequest(` `  writer xml.StaxWriter )`	Terminates a streaming TCP request.
`getAsyncResponse()` `  RETURNING response com.TCPResponse`	Returns the response after performing a TCP request, asynchronously.
`getResponse()` `  RETURNING response com.TCPResponse`	Returns the response after performing a TCP request.
`setConnectionTimeOut(` `  seconds INTEGER )`	Defines the connection time out.
`setKeepConnection(` `  on BOOLEAN )`	Defines if the TCP connection is kept open after sending a request.
`setMaximumResponseLength(`	Defines the time out for read/write operations.

Name	Description
`length INTEGER )`	
`setTimeOut( seconds INTEGER )`	Defines the time out for read/write operations.

com.TCPRequest.beginXmlRequest

Starts a streaming XML request.

Syntax

```
beginXmlRequest()
  RETURNING writer xml.StaxWriter
```

Usage

The `beginXmlRequest()` method begins a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

After sending all the XML data to the server, you must call the `endXmlRequest()` method with the `xml.StaxWriter` object created by the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.Create

Creates a new TCP request object.

Syntax

```
com.TCPRequest.Create(
   url STRING )
  RETURNING result com.TCPRequest
```

1. *url* is the URL of the TCP request.

Usage

This class method creates a new `com.TCPRequest` object according to the URL passed as parameter.

The URL must use the TCP or TCPS protocol. Examples of valid URLs include:

- `tcp://localhost:4242/`
- `tcps://localhost:4343/`

The URL can be an identifier of an URL mapping with an optional **alias://** prefix. See FGLPROFILE configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.TCPRequest.doDataRequest

Performs the request by sending binary data.

Syntax

```
doDataRequest(
   data BYTE )
```

1. *data* is the binary data to be send for a TCP request. The `BYTE` variable must be located `IN MEMORY`.

Usage

Performs the TCP request by sending binary data contained in the `BYTE` variable.

> **Note:** The `BYTE` variable must be located `IN MEMORY`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.TCPRequest.doRequest

Performs a TCP request.

Syntax

```
doRequest()
```

Usage

The `doRequest()` method performs the TCP request.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

Example

```
IMPORT com
IMPORT XML

MAIN
  DEFINE url STRING
  LET url = "tcp://localhost:4242"
  CALL an_example(url)
END MAIN

FUNCTION an_example(url)
DEFINE url STRING
DEFINE req com.TCPRequest
DEFINE resp com.TCPResponse
DEFINE ret xml.DomDocument

TRY
  LET  req = com.TCPRequest.create(url)
  CALL req.doRequest()
  LET  resp = req.getResponse()
  LET  ret = resp.getXmlResponse()
```

```
CATCH
  DISPLAY "ERROR : ", STATUS, SQLCA.SQLERRM
  EXIT PROGRAM(-1)
END TRY

END FUNCTION
```

com.TCPRequest.doXmlRequest

Persforms a request with a DOM document.

Syntax

```
doXmlRequest(
   document xml.DomDocument )
```

1. *document* is the DOM document describing the request.

Usage

The `doXmlRequest()` method performs the TCP request by using the information defined in the `xml.DomDocument` object passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.doTextRequest

Persforms a request with a string.

Syntax

```
doTextRequest(
   data STRING )
```

1. *data* is a string describing the request.

Usage

The `doTextRequest()` method performs the TCP request by using the information defined in string passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.endXmlRequest

Terminates a streaming TCP request.

Syntax

```
endXmlRequest(
```

```
  writer xml.StaxWriter )
```

1. *writer* is the Stax writer object used for streaming.

Usage

The `endXmlRequest()` method terminates a streaming TCP request performed with the `xml.StaxWriter` object that what created by the `beginXmlRequest()` method.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.getResponse

Returns the response after performing a TCP request.

Syntax

```
getResponse()
  RETURNING response com.TCPResponse
```

Usage

The `getResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

A call to this methid will stop the program flow until the response is received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.getAsyncResponse

Returns the response after performing a TCP request, asynchronously.

Syntax

```
getAsyncResponse()
  RETURNING response com.TCPResponse
```

Usage

The `getAsyncResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

Unlike `getResponse()`, the `getAsyncResponse()` method does not stop the program flow: The method returns `NULL` if the response was not yet received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPRequest.setTimeOut

Defines the time out for read/write operations.

Syntax

```
setTimeOut(
   seconds INTEGER )
```

1. *seconds* is the time out in seconds.

Usage

This method defines the time value in seconds to wait for a reading or writing operation, before a break.

If the time out is -1, waits infinitely.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.TCPRequest.setConnectionTimeOut

Defines the connection time out.

Syntax

```
setConnectionTimeOut(
   seconds INTEGER )
```

1. *seconds* is the time out in seconds.

Usage

This method defines the time value in seconds to wait for a connection, before a break.

If the time out is -1, waits infinitely.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.TCPRequest.setKeepConnection

Defines if the TCP connection is kept open after sending a request.

Syntax

```
setKeepConnection(
   on BOOLEAN )
```

1. *on* indicates if the TCP connection must be kept open.

Usage

This method can be used to force the TCP socket to remain open after a send operation, in order to perform subsequent `do*Request()` calls, without closing the connection (in write mode).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

com.TCPRequest.setMaximumResponseLength

Defines the time out for read/write operations.

Syntax

```
setMaximumResponseLength(
   length INTEGER )
```

1. *length* is the max size of a reponse, in Kbytes.

Usage

This method sets the maximum authorized size in Kbyte of the whole response, before a break.

A length of -1 defines no limit.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The TCPResponse class

The com.TCPResponse class provides an interface to perform XML and TEXT responses over TCP, with additional XML streaming possibilities.

> **Important:** This Web Services class is not supported on GMI mobile devices.

com.TCPResponse methods

Methods of the com.TCPResponse class.

Table 473: Object methods

Name	Description
`beginXmlResponse()` `  RETURNING reader xml.StaxReader`	Starts a streaming TCP response.
`endXmlResponse(` `  reader xml.StaxReader )`	Ends a streaming TCP response.
`getDataResponse(` `  data BYTE )`	Returns a TCP response in binary format.
`getTextResponse()` `  RETURNING result STRING`	Returns a TCP response in string format.
`getXmlResponse()` `  RETURNING doc xml.DomDocument`	Returns an entire DOM document as TCP response.

com.TCPResponse.beginXmlResponse

Starts a streaming TCP response.

Syntax

```
beginXmlResponse()
```

```
   RETURNING reader xml.StaxReader
```

Usage

Begins the streaming TCP response and returns an `xml.StaxReader` object ready to read XML from the server.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPResponse.endXmlResponse

Ends a streaming TCP response.

Syntax

```
endXmlResponse(
   reader xml.StaxReader )
```

1. *reader* is the STAX reader object created with `beginXmlResponse()`.

Usage

Terminates the streaming TCP response identified by the `xml.StaxReader` object passed as parameter. This object must have been created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPResponse.getDataResponse

Returns a TCP response in binary format.

Syntax

```
getDataResponse(
   data BYTE )
```

1. *data* is the `BYTE` variable that will hold the response data in binary format. The `BYTE` variable must be located `IN MEMORY`.

Usage

This method retrieves the TCP reponse in binary format into the `BYTE` variable passed as parameter. The method will read the TCP stream, until the peer closes the connection.

> **Note:** The `BYTE` variable must be located `IN MEMORY`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPResponse.getTextResponse
Returns a TCP response in string format.

Syntax

```
getTextResponse()
  RETURNING result STRING
```

Usage

This method returns a complete streaming TCP response from the server as a string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

com.TCPResponse.getXmlResponse
Returns an entire DOM document as TCP response.

Syntax

```
getXmlResponse()
  RETURNING doc xml.DomDocument
```

Usage

This method returns a complete xml.DomDocument as streaming TCP response from the server.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2546

Helper classes
The Helper classes provide utility classes.

- The Util class on page 2094

The Util class
The com.Util class provides static helper methods.

This class does not have to be instantiated.

> **Important:** This Web Services class is not supported on GMI mobile devices.

com.Util methods
Methods of the com.Util class.

Table 474: Class methods

Name	Description
com.Util.UniqueApplicationInstance(path STRING)	Checks that the calling application is the only one to run.

Name	Description
RETURNING *result* INTEGER	

com.Util.UniqueApplicationInstance

Checks that the calling application is the only one to run.

Syntax

```
com.Util.UniqueApplicationInstance(
   path STRING)
  RETURNING result INTEGER
```

1. *path* is the path to the lock file.

Usage

This method checks that the calling application is the only one to run, by trying to get an exclusive lock on the given file.

If the lock could be set, the method returns 0. Otherwise, returns 1 and updates STATUS with an error code.

Specific classes

Several classes support specific features.

- The APNS class on page 2095

The APNS class

The com.APNS class implements Apple Push Notification Service APIs.

The com.APNS class implements a set of methods to build and handle push messages to be broadcasted by the Apple Push Notification service.

APNs SSL certificate

Get and configure an SSL certificate to establish secure connections to the Apple Push Notification service.

Basics

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

You can create two type of APNs certificates for a given App ID:

- Sandbox (for development and test purpose)
- Production (for deployment)

An APNS push notification provider or an APNS feedback handler needs to establish a secure connection to Apple's APNs server.

Get an APNs certificate for your app

In this section we will produce the **myapp.cer** file and **myapp-key.p12** file.

To create an Apple Push Notification Certificate:

1. Log to Apple's Member Center with you iOS developer or enterprise account,
2. Select Certificates, Identifiers & Profiles,
3. Under Certificates, select the + symbol,

4. Select Apple Push Notification service SSL (Sandbox) for development, or Apple Push Notification service SSL (Production) for production,
5. You need to choose the explicit app ID you want to use for push notifications. Verify before that you enable Push Notification Service for this app ID (go to App IDs section and edit your app ID),
6. Follow the instructions on the page to create a CSR file then click Continue,
7. Your certificate request is now available. Now you can go back to the Development Certificate section still active in your browser and click Choose file,
8. Navigate to the file you just saved and choose that file,
9. Click Generate,
10. Once the certificate is generated, click Download. The certificate will download into your Downloads folder, as a `.cer` file (for ex: **`myapp.cer`**).
11. Double-click this file to install it into Keychain,
12. When done, your new certificate should be listed in the Certificates list,
13. Open your Keychain app and locate the certificate you created, export the private key in p12 format (for ex **`myapp-key.p12`**). Note that you will be asked for a password to encode the `.p12` file, and for your session password, to exported Keychain files.

Configure Genero to use the APNs certificate

On the Genero push provider server, you will need the public certificate (`myapp.crt` file) and the private key (`myapp-key.pem` file) for you app. These files will be referenced in the `security.global.certificate` and `security.global.privatekey` entries of FGLPROFILE.

In order to authenticate the APNs server, you will also need the root certificate authority (`apple_entrust_root_certification_authority.pem`), that can be downloaded from Apple's web site. This file will be referenced by the `security.global.ca` entry in FGLPROFILE.

> **Note:** When executing on a Mac, the root certificate (`security.global.ca` entry) is not required: The Web Services library reads the Keystore of the Mac computer, to authenticate the APNs server.

Create the `myapp.crt` file (public certificate) from the `myapp.cer` file, with the `openssl x509` command:

```
$ openssl x509 -in myapp.cer -inform der -out myapp.crt
```

Convert the `myapp-key.p12` file (containing the private key) to a `myapp-key.pem` format, with the `openssl pkcs12` command:

```
$ openssl pkcs12 -nocerts -in myapp-key.p12 -out myapp-key.pem
```

> **Note:** You need to enter the passphrase for the `.p12` file so that `openssl` can read it. Then you need to enter a new passphrase that will be used to encrypt the `.pem` file.

FGLPROFILE entries require encrypted private key files, therefore you need to remove the passphrase from the `myapp-key.pem` file, with the `openssl rsa` command:

```
$ openssl rsa -in myapp-key.pem -out myapp-key-noenc.pem
```

Set up your FGLPROFILE with the appropriate `security.*` entries:

```
security.global.ca           =
 "apple_entrust_root_certification_authority.pem"
security.global.certificate  = "myapp.crt"
security.global.privatekey   = "myapp-key-noenc.pem"
```

In the above example:

1. `apple_entrust_root_certification_authority.pem` is the HTTPS root certificate authenticating the APNs server (if the computer is not a Mac).
2. `myapp.crt` is the public certificate for your app.
3. `myapp-key-noenc.pem` is the private key for your app.

> **Note:** If you want to keep the private key encrypted, you need to configure a password agent, as described in Using the password agent

com.APNS methods
Methods of the `com.APNS` class.

Table 475: Class methods

Name	Description
`com.APNS.DecodeError( data BYTE) RETURNING uuid STRING, error INTEGER`	Decodes content of BYTE data returned from the APNS server in case of error.
`com.APNS.DecodeFeedback( data BYTE, unregs DYNAMIC ARRAY OF RECORD timestamp INTEGER, deviceToken STRING END RECORD )`	Decodes content of BYTE data returned from the APNS feedback service.
`com.APNS.EncodeMessage( data BYTE, deviceToken STRING, json STRING, uuid STRING, expiration INTEGER, priority SMALLINT) RETURNING result INTEGER`	Encodes an APNS specific push notification message into a BYTE.

com.APNS.DecodeError

Decodes content of BYTE data returned from the APNS server in case of error.

Syntax

```
com.APNS.DecodeError(
   data BYTE)
  RETURNING uuid STRING, error INTEGER
```

1. *data* is the `BYTE` variable containing the error data. This `BYTE` variable must be located `IN MEMORY`.
2. *uuid* is a Base64 encoded string containing the push notification identifier.
3. *error* is the APNS error code returned by the server.

Usage

This method decodes the content of the `BYTE` variable passed as a parameter and received as response for a push notification message in the event of an error from the APNs server.

> **Note:** This `BYTE` variable must be located `IN MEMORY`.

The *uuid* is a binary value that identifies the push notification message. It is returned as a Base64-encoded string.

The *error* returned value defines the APNs error code. For example, error will be set to 10 if the APNs server was shutdown. See the Apple Push Notification Service error reference for more details.

In the case of a decoding error, the method will raise the exception -15566, with details in the `SQLCA.SQLERRM` register.

Example

```
DEFINE error_data BYTE,
       uuid STRING,
       error INTEGER

    LOCATE error_data IN MEMORY

    -- Send push notification message TCP request
    ...
    CALL req.doDataRequest(data)
    LET resp = req.getResponse()
    TRY
        CALL resp.getDataResponse(error_data)
        CALL com.APNS.DecodeError(error_data)
             RETURNING uuid, ecode
    ...
```

For a complete example, see APNs push provider on page 2101.

com.APNS.DecodeFeedback

Decodes content of BYTE data returned from the APNS feedback service.

Syntax

```
com.APNS.DecodeFeedback(
   data BYTE,
   unregs DYNAMIC ARRAY OF RECORD
          timestamp INTEGER,
          deviceToken STRING
       END RECORD
   )
```

1. *data* is the `BYTE` variable containing the feedback data. This `BYTE` variable must be located `IN MEMORY`.
2. *unregs* is a structured dynamic array that will contain the list of unregistered device tokens.
   a. *timestamp* is the number of seconds since Unix Epoch (in UTC)
   b. *deviceToken* is a APNS device token that has been unregistered (encoded in Base-64)

Usage

Apple recommends to connect frequently to the APNS feedback server in order to verify that your applications are still registered for push notifications.

To get APNS feedback, you must perform a TCP request (using SSL), to the following specific URI:

```
tcps://feedback.push.apple.com:2196
```

The `DecodeFeedback()` method decodes the content of the `BYTE` variable, which was passed as a parameter and received as response for the TCP request to the APNS feedback server.

Note: This BYTE variable must be located IN MEMORY.

For the second parameter, this method takes a structured dynamic array that will be filled with the list of unregistered APNS device tokens. It is up to the push program to stop sending push notification messages for these unregistered device tokens.

The *timestamp* member of an *unregs* dynamic array element can be used to verify that device tokens have not been re-registered since the feedback entry was generated. This timestamp is returned as a number of seconds since the Unix epoch, in UTC. Use the util.Datetime.fromSecondsSinceEpoch on page 1950 utility API to convert timestamp to a DATETIME value in the current local time.

The *deviceToken* member of an *unregs* dynamic array element identifies iOS devices that have been unregistered from the APNS server. Note that these identifier is encoded in Base64.

In the event of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

Example

```
DEFINE feedback_data BYTE,
       unregs DYNAMIC ARRAY OF RECORD
              timestamp   INTEGER,
              deviceToken STRING
           END RECORD,
       i INTEGER

LOCATE feedback_data IN MEMORY

... TCP request to APNS feedback server ...

CALL com.APNS.DecodeFeedback(feedback_data, unregs)

FOR i=1 TO unregs.getLength()
    DISPLAY i, " ", unrefs[i].deviceToken
END FOR
```

For a complete example, see APNs feedback handler on page 2102.

com.APNS.EncodeMessage

Encodes an APNS specific push notification message into a BYTE.

Syntax

```
com.APNS.EncodeMessage(
   data BYTE,
   deviceToken STRING,
   json STRING,
   uuid STRING,
   expiration INTEGER,
   priority SMALLINT)
  RETURNING result INTEGER
```

1. *data* is the BYTE variable holding the APNS message. This BYTE variable must be located IN MEMORY.
2. *deviceToken* is an APNS device token (encoded in Base-64).
3. *json* is a JSON string containing the APNS push message data.
4. *uuid* is the 4 bytes-long push message identifier (encoded in Base64).
5. *expiration* is a number of seconds since Unix Epoch defining the expiration date of the message.
6. *priority* is an integer defining the priority of the message.

Usage

This method builds the APNS push notification message into a BYTE variable, for a given device token.

> **Note:** This BYTE variable must be located IN MEMORY.

> **Note:** The size of an APNS notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The APNS push notification message protocol requires some binary data to be encoded in the message content before it is sent to the APNS server with a TCP (over SSL) request, to specific URIs, namely:

- `"tcps://gateway.sandbox.apple.com:2195"` (for development)
- `"tcps://gateway.push.apple.com:2195"` (for production)

You need to provide several parameters in order to build the push notification message:

The *deviceToken* parameter is an APNS device token encoded in Base-64. It's used to identify the target device that must receive the push message. The device token identifies a single iOS device: If you have N devices registered to your push notification provider, you will have N different device tokens. If you want to send one push notification message to all the devices, you must send N different messages, where the only difference between the messages is the device token.

> **Note:** It's in your hands to handle the list of registered device tokens. A device token is assigned to a physical iOS device when the mobile app issues a registerForRemoteNotifications on page 1934 front call. The app must then provide its device token to the push provider program using a method such as a web service mechanism.

Fill the *json* parameter with a JSON string containing the APNS push message data. For example:

```
LET json = '{"aps":{"alert":"Hello,
 world","sound":"default","badge":1,"content-available":1}}'
```

See APNS documentation for more details about the JSON content of a message.

The *uuid* parameter is the 4 bytes-long push message identifier, encoded in Base64. This parameter can used later to identify the message in push notification errors (com.APNS.DecodeError on page 2097). This parameter can be NULL. To create the *uuid* parameter, use the security.RandomGenerator.CreateRandomString on page 2279 API, with a size of 4:

```
LET uuid = security.RandomGenerator.createRandomString(4)
```

The *expiration* parameter is a number of seconds since Unix Epoch. It defines the expiration date of the message if it can not be sent by the APNS server to the target devices. This parameter can be NULL, to indicate that there is no expiration date:

```
LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)
```

The *priority* parameter can be used to define a priority for the push notification message. Typically, use a value of 10 for immediate, 5 for delayed. This parameter can be NULL. See APNS documentation for more details.

If there's an encoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

Example

```
DEFINE push_data BYTE,
       deviceTokenHexa STRING,
```

```
        dt DATETIME YEAR TO FRACTION(3),
        expiration INTEGER,
        json_data STRING,
        uuid STRING

LOCATE push_data IN MEMORY

LET deviceTokenHexa = "84e3................."

LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)

LET json_date = util.JSON.stringify(...)

LET uuid = security.RandomGenerator.createRandomString(4)

CALL com.APNS.EncodeMessage(
             push_data,
             security.HexBinary.ToBase64(deviceTokenHexa),
             json_data,
             uuid,
             expiration,
             10
       )

IF LENGTH(push_data) > 2000 THEN
   -- Must reduce the message content...
   RETURN FALSE
END IF

-- Do the TCP request with the push_data variable
...
```

For a complete example, see APNs push provider on page 2101.

APNs examples

APNs push provider

The `com.APNS` class can be used to implement an APNs push provider.

The following code example implements a push program using the `com.APNS` API to send a notification message to devices by using the TCP request API. See also com.APNS methods on page 2097 for more details about the APNs API.

> **Note:** An SSL certificate needs to be defined in FGLPROFILE, as described in APNs SSL certificate on page 2095.
>
> **Note:** The size of the resulting BYTE variable containing the APNS payload cannot exceed 2 Kilobytes.
>
> **Important:** In order to check that the push message was properly handled by the APNs server, you need to define a TCP request timeout (2 seconds in this example). In case of error, the APNs server will return a response immediately. In case of success, there is not a response from the APNs server. For more details about this protocol, see Apple's APNs documentation.

```
IMPORT com
IMPORT security
IMPORT util

MAIN
  DEFINE json STRING
  DEFINE deviceTokenHexa STRING
  DEFINE req com.TCPRequest
  DEFINE resp com.TCPResponse
```

```
  DEFINE uuid STRING
  DEFINE ecode INTEGER
  DEFINE dt DATETIME YEAR TO SECOND
  DEFINE exp INTEGER
  DEFINE data, err BYTE

  LOCATE data IN MEMORY
  LOCATE err IN MEMORY

  LET deviceTokenHexa = "84e3................."
  LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
  LET exp = util.Datetime.toSecondsSinceEpoch(dt)
  TRY
    LET req = com.TCPRequest.create( "tcps://gateway.push.apple.com:2195" )
    CALL req.setKeepConnection(true)
    CALL req.setTimeout(2) # Wait 2 seconds for APNs to return an error code
    LET uuid = security.RandomGenerator.createRandomString(4)
    LET json = '{"aps":{"alert":"Hello,
 world","sound":"default","badge":1,"content-available":1}}'
    CALL com.APNS.EncodeMessage(
                  data,
                  security.HexBinary.ToBase64(deviceTokenHexa),
                  json,
                  uuid,
                  exp,
                  10
              )
    IF LENGTH(data) > 2000 THEN
       DISPLAY "APNS payload cannot exceed 2 kilobytes"
       EXIT PROGRAM 1
    END IF
    DISPLAY "Sending notif with ID:",uuid," and expiring at ",dt
    CALL req.doDataRequest(data)
    LET resp = req.getResponse()
    TRY
        CALL resp.getDataResponse(err)
        CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
        DISPLAY "ERROR code :",ecode
        DISPLAY "ERROR uuid :",uuid
    CATCH
        CASE STATUS
          WHEN -15553 DISPLAY "Timeout Push sent without error"
          WHEN -15566 DISPLAY "Operation failed :", SQLCA.SQLERRM

        END CASE
    END TRY
  CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
  END TRY

END MAIN
```

APNs feedback handler

The `com.APNS` class can be used to implement a server application to query the APNs feedback service.

Implement an APNs feedback handler to get a list of unregistered device tokens in order to stop sending push notification messages to these apps.

> **Note:** An SSL certificate needs to be defined in FGLPROFILE, as described in APNs SSL certificate on page 2095.

```
IMPORT com
```

```
IMPORT security
IMPORT util

MAIN
  DEFINE req com.TCPRequest
  DEFINE resp com.TCPResponse
  DEFINE feedback DYNAMIC ARRAY OF RECORD
                      timestamp INTEGER,
                      deviceToken  STRING
                  END RECORD
  DEFINE timestamp DATETIME YEAR TO SECOND
  DEFINE i INTEGER
  DEFINE data BYTE

  LOCATE data IN MEMORY

    CALL req.setKeepConnection(true)
    CALL req.setTimeout(2)
    CALL req.doRequest()
    LET resp = req.getResponse()
    CALL resp.getDataResponse(data)
    DISPLAY "Feedback service has responded"
    CALL com.APNS.DecodeFeedback(data,feedback)
    FOR i=1 TO feedback.getLength()
      LET timestamp =
 util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
      DISPLAY "Device Token :",feedback[i].deviceToken, " Timestamp :",
 timestamp
    END FOR
  CATCH
    CASE STATUS
      WHEN -15553 DISPLAY "Timeout: No feedback message"
      WHEN -15566 DISPLAY "Operation failed :", SQLCA.SQLERRM
      WHEN -15564 DISPLAY "Server has shutdown"
      OTHERWISE   DISPLAY "ERROR :",STATUS
    END CASE
  END TRY

END MAIN
```

The xml package

The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

The library provides a W3C-compatible DOM API, integrating additional XML Schema and DTD validation methods. There is also an API compatible with StAX for writing or reading XML documents where performance and speed are important.

Use the `IMPORT` statement at the top of the module using this library:

```
IMPORT xml
```

> **Note:** The DOM API of the `om` package is designed to handle specific FGL files or to manipulate the user interface tree (the AUI tree). For all other cases/scenarios, we recommend that you use the DOM API of the Web Services `xml` package.

- The Document Object Modeling (DOM) classes on page 2104
- The streaming API for XML (StAX) classes on page 2170
- XML serialization classes on page 2202

- XML security classes on page 2208
- OM to XML Migration on page 2276

The Document Object Modeling (DOM) classes
The Document Object Modeling (DOM) classes manage XML documents entirely in memory with support of XML Schema and DTD validation.

- CLASS DomDocument
  - Features
- CLASS DomNode
  - Types
- CLASS DomNodeList

The DomDocument class
The `xml.DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

The `STATUS` variable is set to zero after a successful method call.

xml.DomDocument methods
Methods for the `xml.DomDocument` class.

Table 476: Class methods: Creation

Name	Description
`xml.DomDocument.create()` `  RETURNING object xml.DomDocument`	Constructor of an empty DomDocument object.

`xml.DomDocument.createDocument(`
`  name STRING )`
`  RETURNING object xml.DomDocument`
	Constructor of a DomDocument with an XML root element.

`xml.DomDocument.createDocumentNS(`
`  prefix STRING,`
`  name STRING,`
`  ns STRING )`
`  RETURNING object xml.DomDocument`
	Constructor of a DomDocument with a root namespace-qualified XML root element

Table 477: Object methods: Navigation

Name	Description
`getDocumentElement()` `  RETURNING object xml.DomNode`	Returns the root XML Element DomNode object for this DomDocument object.
`getDocumentNodesCount()` `  RETURNING count INTEGER`	Returns the number of child DomNode objects for a DomDocument object.
`getDocumentNodeItem(` `  pos INTEGER )`	Returns the child DomNode object at a given position for this DomDocument object.

Name	Description
`RETURNING object xml.DomNode`	
`getElementById( id STRING ) RETURNING object xml.DomNode`	Returns the element that has an attribute of type ID with the given value
`getElementsByTagName( name STRING ) RETURNING object xml.DomNodeList`	Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document.
`getElementsByTagNameNS( name STRING, ns STRING ) RETURNING list xml.DomNodeList`	Returns a DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document
`getFirstDocumentNode() RETURNING object xml.DomNode`	Returns the first child DomNode object for a DomDocument object.
`getLastDocumentNode() RETURNING object xml.DomNode`	Returns the last child DomNode object for a DomDocument object.
`selectByXPath( expr STRING, nslist ... ) RETURNING list xml.DomNodeList`	Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Table 478: Object methods: Management

Name	Description
`appendDocumentNode( node xml.DomNode )`	Adds a child DomNode object to the end of the DomNode children for this DomDocument object.
`clone() RETURNING object xml.DomDocument`	Returns a copy of a DomDocument object.
`declareNamespace( node xml.DomNode, alias STRING, ns STRING )`	Forces namespace declaration to an XML Element DomNode for a DomDocument object.
`insertAfterDocumentNode( node xml.DomNode,`	Inserts a child DomNode object after another child DomNode for a DomDocument object.

Name	Description
ref xml.DomNode)	
insertBeforeDocumentNode(*node* xml.DomNode, *ref* xml.DomNode)	Inserts a child DomNode object before another child DomNode for this DomDocument object.
importNode(*node* xml.DomNode *deep* INTEGER) RETURNING *object* xml.DomNode	Imports a DomNode from a DomDocument object into its new context (attached to a DomDocument object).
prependDocumentNode(*node* xml.DomNode)	Adds a child DomNode object to the beginning of the DomNode children for a DomDocument object
removeDocumentNode(*node* xml.DomNode)	Removes a child DomNode object from the DomNode children for this DomDocument object.

Table 479: Object methods: Node Creation

Name	Description
createAttribute(*name* STRING) RETURNING *object* xml.DomNode	Creates an XML Attribute DomNode object for a DomDocument object.
createAttributeNS(*prefix* STRING, *name* STRING, *ns* STRING) RETURNING *object* xml.DomNode	Creates an XML namespace-qualified Attribute DomNode object for a DomDocument object.
createCDATASection(*cdata* STRING) RETURNING *object* xml.DomNode	Creates an XML CData DomNode object for a DomDocument object.
createComment(*comment* STRING) RETURNING *object* xml.DomNode	Creates an XML Comment DomNode object for a DomDocument object.
createDocumentFragment() RETURNING *object* xml.DomNode	Creates an XML Document Fragment DomNode object for a DomDocument object.
createDocumentType(*name* STRING, *publicID* STRING, *systemID* STRING, *internalDTD* STRING)	Creates an XML Document Type (DTD) DomNode object for a DomDocument object.

Name	Description
RETURNING *object* xml.DomNode	
createElement(*name* STRING) RETURNING *object* xml.DomNode	Creates an XML Element DomNode object for a DomDocument object
createElementNS(*prefix* STRING, *name* STRING, *ns* STRING) RETURNING *object* xml.DomNode	Creates an XML namespace-qualified Element DomNode object for a DomDocument object.
createEntityReference(*ref* STRING) RETURNING *object* xml.DomNode	Creates an XML EntityReference DomNode object for a DomDocument object
createNode(*str* STRING) RETURNING *object* xml.DomNode	Creates an XML DomNode object from a string for a DomDocument object.
createProcessingInstruction(*target* STRING, *data* STRING) RETURNING *object* xml.DomNode	Creates an XML Processing Instruction DomNode object for this DomDocument object.
createTextNode(*text* STRING) RETURNING *object* xml.DomNode	Creates an XML Text DomNode object for a DomDocument object.

Table 480: Object methods: Load and Save

Name	Description
load(*url* STRING)	Loads an XML Document into a DomDocument object from a file or an URL.
loadFromPipe(*cmd* STRING)	Loads an XML Document into a DomDocument object from a PIPE.
loadFromString(*str* STRING)	Loads an XML Document into a DomDocument object from a string.
normalize()	Normalizes the entire Document.
save(	Saves a DomDocument object as an XML Document to a file or URL.

Name	Description
url STRING)	
saveToPipe(*cmd* STRING)	Saves a DomDocument object as an XML Document to a PIPE.
saveToString() RETURNING *result* STRING	Saves a DomDocument object as an XML Document to a string.

Table 481: Object methods: Configuration

Name	Description
getFeature(*feature* STRING) RETURNING *result* STRING	Gets a feature for a DomDocument object.
getXmlEncoding() RETURNING *result* STRING	Returns the document encoding as defined in the XML document declaration.
getXmlVersion() RETURNING *result* STRING	Returns the document version as defined in the XML document declaration.
isXmlStandalone() RETURNING *result* INTEGER	Returns whether the XML standalone attribute is set in the XML declaration.
setFeature(*feature* STRING, *value* STRING)	Sets a feature for a DomDocument object.
setXmlEncoding(*enc* STRING)	Sets the XML document encoding in the XML declaration.
setXmlStandalone(*alone* INTEGER)	Sets the XML standalone attribute in the XML declaration to yes or no in the XML declaration.

Table 482: Object methods: Validation

Name	Description
validate() RETURNING *result* INTEGER	Performs a DTD or XML Schema validation for a DomDocument object.
validateOneElement(*node* xml.DomNode)	Performs a DTD or XML Schema validation of an XML Element DomNode object.

Name	Description
`RETURNING result INTEGER`	

Table 483: Object methods: Error Management

Name	Description
`getErrorsCount()` `RETURNING count INTEGER`	Returns the number of errors encountered during the loading, saving or validation of an XML document.

`getErrorDescription(`
`pos INTEGER )`
`RETURNING desc STRING`
	Returns the error description at given position.

xml.DomDocument.appendDocumentNode

Adds a child DomNode object to the end of the DomNode children for this DomDocument object.

Syntax

```
appendDocumentNode(
   node xml.DomNode )
```

1. *node* is the node to add.

Usage

Adds a child DomNode object to the end of the DomNode children for this DomDocument object, where *node* is the node to add.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

> **Note:** A fragment is a structure created to receive xml nodes that are not always valid. Once a fragment is added to a valid node, the fragment becomes empty as all nodes are moved from the fragment as a child to the valid node. So developpers can work on the fragment until it is added to another node. At that time developers should no more work on the fragment but rather on the valid node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.clone

Returns a copy of a DomDocument object.

Syntax

```
clone()
  RETURNING object xml.DomDocument
```

Usage

Returns a copy of this DomDocument object, or `NULL`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.create

Constructor of an empty DomDocument object.

Syntax

```
xml.DomDocument.create()
  RETURNING object xml.DomDocument
```

Usage

Constructor of an empty DomDocument object.

Returns a DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Example

Create a DomDocument without a root node:

```
xml.domDocument.create()
```

Create a DomDocument with an initial root node named **ARoot**:

```
xml.domDocument.create("ARoot")
```

xml.DomDocument.createAttribute

Creates an XML Attribute DomNode object for a DomDocument object.

Syntax

```
createAttribute(
   name STRING )
  RETURNING object xml.DomNode
```

1. *name* is the name of the XML attribute.

Usage

Creates an XML Attribute DomNode object for a DomDocument object, where *name* is the name of the XML attribute, cannot be NULL.

Returns a DomNode object, or NULL.

To create a default namespace declaration attribute use **xmlns** as the name. (Using declareNamespace instead is recommended)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createAttributeNS

Creates an XML namespace-qualified Attribute DomNode object for a DomDocument object.

Syntax

```
createAttributeNS(
   prefix STRING,
   name STRING,
   ns STRING )
  RETURNING object xml.DomNode
```

1. *prefix* is the prefix of the XML attribute.
2. *name* is the name of the XML attribute.
3. *ns* is the namespace URI of the XML attribute.

Usage

Creates an XML namespace-qualified Attribute DomNode object for this DomDocument object, where *prefix* is the prefix of the XML attribute, cannot be `NULL`; *name* is the name of the XML attribute, cannot be `NULL`; *ns* is the namespace URI of the XML attribute, cannot be `NULL`.

Returns a DomNode object, or `NULL`.

To create a namespace declaration attribute use **xmlns** as the prefix and **http://www.w3.org/XML/1998/namespace** as the namespace. Using `declareNamespace` instead is recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createCDATASection

Creates an XML CData DomNode object for a DomDocument object.

Syntax

```
createCDATASection(
   cdata STRING )
  RETURNING object xml.DomNode
```

1. *cdata* is the data of the XML CData node.

Usage

Creates an XML CData DomNode object for this DomDocument object, where *cdata* is the data of the XML CData node, or `NULL`. Returns a DomNode object, or `NULL`.

Only the characters **#x9**, **#xA**, **#xD**, [**#x20-#xD7FF**], [**#xE000-#xFFFD**] and [**#x10000-#x10FFFF**] are allowed in the content of an XML CDATASection node.

The character sequence (Double-Hyphen) '--' is not allowed in the content of an XML CDATASection node. The `saveToFile()` and `normalize()` methods will fail if this sequence or characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createComment

Creates an XML Comment DomNode object for a DomDocument object.

Syntax

```
createComment(
   comment STRING )
  RETURNING object xml.DomNode
```

1. *comment* is the data of the XML Comment node.

Usage

Creates an XML Comment DomNode object for this DomDocument object, where *comment* is the data of the XML Comment node, or `NULL`.

Returns a DomNode object, or `NULL`.

Only the characters **#x9**, **#xA**, **#xD**, [**#x20-#xD7FF**], [**#xE000-#xFFFD**] and [**#x10000-#x10FFFF**] are allowed in the content of an XML Comment node.

The character sequence (Double-Hyphen) '--' is not allowed in the content of an XML Comment node. The `saveToFile()` and `normalize()` methods will fail if this sequence or characters other than those allowed exist in a Comment node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createDocument

Constructor of a DomDocument with an XML root element.

Syntax

```
xml.DomDocument.createDocument(
   name STRING )
  RETURNING object xml.DomDocument
```

1. *name* is the name of the XML Element.

Usage

Constructor of a xml.DomDocument with an XML root element; where *name* is the name of the XML Element.

Returns a DomDocument object or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createDocumentFragment

Creates an XML Document Fragment DomNode object for a DomDocument object.

Syntax

```
createDocumentFragment()
  RETURNING object xml.DomNode
```

Usage

Creates an XML Document Fragment DomNode object for this DomDocument object.

Returns a DomNode object, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createDocumentNS

Constructor of a DomDocument with a root namespace-qualified XML root element

Syntax

```
xml.DomDocument.createDocumentNS(
   prefix STRING,
   name STRING,
   ns STRING )
  RETURNING object xml.DomDocument
```

1. *prefix* is the prefix of the XML Element or NULL.
2. *name* is the name of the XML Element.
3. *ns* is the namespace of the XML Element.

Usage

Constructor of a xml.DomDocument with a root namespace-qualified XML root element where *prefix* is the prefix of the XML Element or `NULL`, *name* is the name of the XML Element, and *ns* is the namespace of the XML Element. Returns a DomDocument object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

Example

Create a DomDocument with an initial root node named `"List"` with `abc` as the prefix and `http://www.mysite.com/xmlapi` as the namespace:

```
xml.domdocument.createDocumentNS("abc","List","http://
www.mysite.com/xmlapi")
```

Produces:

```
<abc:List xmlns:abc="http://www.mysite.com/xmlapi">
[...]
</abc:List>
```

xml.DomDocument.createDocumentType

Creates an XML Document Type (DTD) DomNode object for a DomDocument object.

Syntax

```
createDocumentType(
   name STRING,
   publicID STRING,
   systemID STRING,
   internalDTD STRING )
```

```
   RETURNING object xml.DomNode
```

1. *name* is the name of the document type.
2. *publicID* is the URI of the public identifier.
3. *systemID* is the URL of the system identifier (Specifies the file location of the external DTD subset).
4. *internalDTD* is the internal DTD subset.

Usage

Creates an XML Document Type (DTD) DomNode object for this DomDocument object; *name* is the name of the document type; *publicID* is the URI of the public identifier or `NULL`; *systemID* is the URL of the system identifier or `NULL` (Specifies the file location of the external DTD subset); *internalDTD* is the internal DTD subset or `NULL`.

Returns a DomNode object, or `NULL` if *internalDTD* is malformed.

Caution: Not part of W3C API.

Only internal DTDs are supported.

The public identifier cannot be set without the system identifier.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createElement

Creates an XML Element DomNode object for a DomDocument object

Syntax

```
createElement(
   name STRING )
  RETURNING object xml.DomNode
```

1. *name* is the name of the XML element.

Usage

Creates an XML Element DomNode object for this DomDocument object, where *name* is the name of the XML element, cannot be `NULL`.

Returns a DomNode object, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createElementNS

Creates an XML namespace-qualified Element DomNode object for a DomDocument object.

Syntax

```
createElementNS(
   prefix STRING,
   name STRING,
   ns STRING )
  RETURNING object xml.DomNode
```

1. *prefix* is the prefix of the XML element, or `NULL` to use the default namespace.

2. *name* is the name of the XML element.
3. *ns* is the namespace URI of the XML element.

Usage

Creates an XML namespace-qualified Element DomNode object for this DomDocument object, where *prefix* is the prefix of the XML element, or `NULL` to use the default namespace; *name* is the name of the XML element, cannot be `NULL`; *ns* is the namespace URI of the XML element, cannot be `NULL`.

Returns a DomNode object, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createEntityReference

Creates an XML EntityReference DomNode object for a DomDocument object

Syntax

```
createEntityReference(
   ref STRING )
  RETURNING object xml.DomNode
```

1. *ref* is the name of the entity reference.

Usage

Creates an XML EntityReference DomNode object for this DomDocument object, where *ref* is the name of the entity reference.

Returns a DomNode object, or `NULL`.

An Entity Reference node is read-only and cannot be modified.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createNode

Creates an XML DomNode object from a string for a DomDocument object.

Syntax

```
createNode(
   str STRING )
  RETURNING object xml.DomNode
```

1. *str* is the string representation of the DomNode to be created.

Usage

Creates an XML DomNode object from a string for this DomDocument object; *str* is the string representation of the DomNode to be created.

Returns a xml.DomNode object, or `NULL`.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createProcessingInstruction

Creates an XML Processing Instruction DomNode object for this DomDocument object.

Syntax

```
createProcessingInstruction(
   target STRING,
   data STRING )
  RETURNING object xml.DomNode
```

1. *target* is the target part of the XML Processing Instruction.
2. *data* is the data part of the XML Processing Instruction.

Usage

Creates an XML Processing Instruction DomNode object for this DomDocument object, where *target* is the target part of the XML Processing Instruction, cannot be NULL; *data* is the data part of the XML Processing Instruction, or NULL.

Returns a DomNode object, or NULL.

Only the characters **#x9**, **#xA**, **#xD**, [**#x20-#xD7FF**], [**#xE000-#xFFFD**] and [**#x10000-#x10FFFF**] are allowed in the content of an XML Processing Instruction node.

The character sequence (Double-Hyphen) '--' is not allowed in the content of an XML Processing Instruction. The save() and normalize() methods will fail if this sequence or characters other than those allowed exist in a Processing Instruction node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.createTextNode

Creates an XML Text DomNode object for a DomDocument object.

Syntax

```
createTextNode(
   text STRING )
  RETURNING object xml.DomNode
```

1. *text* is the data of the XML Text node.

Usage

Creates an XML Text DomNode object for this DomDocument object, where *text* is the data of the XML Text node, or NULL.

Returns a DomNode object, or NULL.

Only the characters **#x9**, **#xA**, **#xD**, [**#x20-#xD7FF**], [**#xE000-#xFFFD**] and [**#x10000-#x10FFFF**] are allowed in the content of an XML Text node. The save() and normalize() methods will fail if characters other than those allowed exist in a Text node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.declareNamespace

Forces namespace declaration to an XML Element DomNode for a DomDocument object.

Syntax

```
declareNamespace(
   node xml.DomNode,
   alias STRING,
   ns STRING )
```

1. *node* is the XML Element DomNode that carries the namespace definition.
2. *alias* is the alias of the namespace to declare.
3. *ns* is the URI of the namespace to declare.

Usage

Forces namespace declaration to an XML Element DomNode for this DomDocument object ; *node* is the XML Element DomNode that carries the namespace definition; *alias* is the alias of the namespace to declare, or `NULL` to declare the default namespace; *ns* is the URI of the namespace to declare (can only be `NULL` if alias is `NULL`).

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getDocumentElement

Returns the root XML Element DomNode object for this DomDocument object.

Syntax

```
getDocumentElement()
  RETURNING object xml.DomNode
```

Usage

Returns the root XML Element DomNode object for this DomDocument object.

Returns a DomNode object, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getDocumentNodesCount

Returns the number of child DomNode objects for a DomDocument object.

Syntax

```
getDocumentNodesCount()
  RETURNING count INTEGER
```

Usage

Returns the number of child DomNode objects for this DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getDocumentNodeItem

Returns the child DomNode object at a given position for this DomDocument object.

Syntax

```
getDocumentNodeItem(
   pos INTEGER )
  RETURNING object xml.DomNode
```

1. *pos* is the position of the node to return (index starts at 1).

Usage

Returns the child DomNode object at a given position for this DomDocument object where *pos* is the position of the node to return (Index starts at 1), or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getElementById

Returns the element that has an attribute of type ID with the given value

Syntax

```
getElementById(
   id STRING )
  RETURNING object xml.DomNode
```

1. *id* is the Id value.

Usage

Returns the xml.DomNode element that has an attribute of type ID with the given value, or NULL if there is none.

Attributes with the name "ID" or "id" are not of type ID unless so defined with setIdAttribute or setIdAttributeNS. However, there is a specific attribute called **xml:id** and belonging to the namespace **http://www.w3.org/XML/1998/namespace** that is always of type ID even if not set with setIdAttributeNS.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getElementsByTagName

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document.

Syntax

```
getElementsByTagName(
   name STRING )
  RETURNING object xml.DomNodeList
```

1. *name* is the name of the XML Element tag to match or "*" to match all tags.

Usage

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document; *name* is the name of the XML Element tag to match, or "*" to match all tags.

Returns a DomNodeList object, or `NULL`.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getElementsByTagNameNS

Returns a DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document

Syntax

```
getElementsByTagNameNS(
   name STRING,
   ns STRING )
  RETURNING list xml.DomNodeList
```

1. *name* is the name of the XML Element tag to match or "*" to match all tags.
2. *ns* is the namespace URI of the XML Element tag to match, or "*" to match all namespaces.

Usage

Returns a xml.DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document; *name* is the name of the XML Element tag to match, or "*" to match all tags; *ns* is the namespace URI of the XML Element tag to match, or "*" to match all namespaces. Returns a DomNodeList object, or `NULL`.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getErrorDescription

Returns the error description at given position.

Syntax

```
getErrorDescription(
   pos INTEGER )
  RETURNING desc STRING
```

1. *pos* is the position of the error description (index starts at 1).

Usage

Returns the error description at given position. *pos* is the position of the error description (index starts at 1). Returns a string with an error description.

Caution: Not part of W3C API

Example

```
FOR i=1 TO doc.getErrorsCount()
```

```
  DISPLAY "[", i, "] ", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load or validate of doc DomDocument.

To display other errors, use the global variable STATUS to get the error code and err_get(status) or sqlca.sqlerrm to get the description of the error. See error code for more details.

xml.DomDocument.getErrorsCount

Returns the number of errors encountered during the loading, saving or validation of an XML document.

Syntax

```
getErrorsCount()
  RETURNING count INTEGER
```

Usage

Returns the number of errors encountered during the loading, the saving or the validation of an XML document.

Returns the number of errors, or zero if there are none.

Caution: Not part of W3C API

Example

```
FOR i=1 TO doc.getErrorsCount()
  DISPLAY "[", i, "] ", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load or validate of doc DomDocument.

To display other errors, use the global variable STATUS to get the error code and err_get(status) or sqlca.sqlerrm to get the description of the error. See error code for more details.

xml.DomDocument.getFirstDocumentNode

Returns the first child DomNode object for a DomDocument object.

Syntax

```
getFirstDocumentNode()
  RETURNING object xml.DomNode
```

Usage

Returns the first child DomNode object for this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getFeature

Gets a feature for a DomDocument object.

Syntax

```
getFeature(
   feature STRING)
```

```
  RETURNING result STRING
```

1. *feature* is the name of the DomDocument feature.

Usage

Gets a feature for the DomDocument object, where *feature* is the name of the DomDocument feature.

Returns the value of the feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getLastDocumentNode

Returns the last child DomNode object for a DomDocument object.

Syntax

```
getLastDocumentNode()
  RETURNING object xml.DomNode
```

Usage

Returns the last child DomNode object for this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getXmlEncoding

Returns the document encoding as defined in the XML document declaration.

Syntax

```
getXmlEncoding()
  RETURNING result STRING
```

Usage

Returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.getXmlVersion

Returns the document version as defined in the XML document declaration.

Syntax

```
getXmlVersion()
  RETURNING result STRING
```

Usage

Returns the document version as defined in the XML document declaration, which is **1.0**. No other versions are supported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.importNode

Imports a DomNode from a DomDocument object into its new context (attached to a DomDocument object).

Syntax

```
importNode(
   node xml.DomNode
   deep INTEGER )
  RETURNING object xml.DomNode
```

1. *node* is the node to import.
2. *deep* is a boolean identifying whether to import the node only or the node and all its child nodes.

Usage

Imports a DomNode from a DomDocument object into its new context (attached to this DomDocument object), where *node* is the node to import. When *deep* is FALSE only the node is imported; when TRUE the node and all its child nodes are imported.

Returns the DomNode object that has been imported to this DomDocument, or NULL.

Document and Document Type nodes cannot be imported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.insertBeforeDocumentNode

Inserts a child DomNode object before another child DomNode for this DomDocument object.

Syntax

```
insertBeforeDocumentNode(
   node xml.DomNode,
   ref xml.DomNode )
```

1. *node* is the node to insert.
2. *ref* is the reference node (the node before which the new node must be inserted).

Usage

Inserts a child DomNode object before another child DomNode for this DomDocument object; *node* is the node to insert, *ref* is the reference node (the node before which the new node must be inserted).

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.insertAfterDocumentNode

Inserts a child DomNode object after another child DomNode for a DomDocument object.

Syntax

```
insertAfterDocumentNode(
   node xml.DomNode,
   ref xml.DomNode )
```

1. *node* is the node to insert.
2. *ref* is the reference node (the node after which the new node must be inserted).

Usage

Inserts a child DomNode object after another child DomNode for this DomDocument object ; *node* is the node to insert; *ref* is the reference node (the node after which the new node must be inserted).

Caution: Not part of W3C API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.isXmlStandalone

Returns whether the XML standalone attribute is set in the XML declaration.

Syntax

```
isXmlStandalone()
  RETURNING result INTEGER
```

Usage

Returns whether the XML standalone attribute is set in the XML declaration.

Returns TRUE if the standalone attribute in the XML declaration is set to yes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.load

Loads an XML Document into a DomDocument object from a file or an URL.

Syntax

```
load(
   url STRING )
```

1. *url* is a valid URL or the name of the file.

Usage

Loads an XML Document into a DomDocument object from a file or an URL, where *url* is a valid URL or the name of the file.

Only the following kinds of URLs are supported: **http://** , **https://** , **tcp://** , **tcps://** , **file:///** and **alias://** . See Web services configuration on page 2509 for more details about URL mapping with aliases, and for proxy and security configuration.

See `setFeature()` to specify how the document can be loaded. **HTML** parsing is possible when enable-html-compliancy is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

> **Important:** On Mac OS X versions prior to 10.9, the libxml library (used by Genero Web Services classes) has a bug when parsing HTML documents. If you set the HTML compliancy option with `CALL doc.setFeature("enable-html-compliancy",TRUE)`, loading an HTML document with `xml.DomDocument.load()` may produce additional blank TEXT nodes, because the libxml library loads some ignorable whitespace nodes from the HTML document. Starting with Mac OS X 10.9, the libxml library of the system has fixed this bug.

xml.DomDocument.loadFromPipe

Loads an XML Document into a DomDocument object from a PIPE.

Syntax

```
loadFromPipe(
   cmd STRING )
```

1. *cmd* is the command to read from the PIPE.

Usage

Loads an XML Document into a DomDocument object from a PIPE where *cmd* is the command to read from the PIPE.

> **Caution:** Not part of W3C API.

See `setFeature()` to specify how the document can be loaded. **HTML** parsing is possible when enable-html-compliancy is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.loadFromString

Loads an XML Document into a DomDocument object from a string.

Syntax

```
loadFromString(
   str STRING )
```

1. *str* is the string to load.

Usage

Loads an XML Document into a DomDocument object from a string, where *str* is the string to load.

Caution: Not part of W3C API.

See `setFeature()` to specify how the document can be loaded. **HTML** parsing is possible when enable-html-compliancy is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.normalize

Normalizes the entire Document.

Syntax

```
normalize()
```

Usage

Normalizes the entire Document. This method merges adjacent Text nodes, removes empty Text nodes and sets namespace declarations as if the document had been saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document normalization.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.prependDocumentNode

Adds a child DomNode object to the beginning of the DomNode children for a DomDocument object

Syntax

```
prependDocumentNode(
   node xml.DomNode )
```

1. *node* is the node to add.

Usage

Adds a child DomNode object to the beginning of the DomNode children for this DomDocument object; *node* is the node to add.

Caution: Not part of W3C API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.removeDocumentNode

Removes a child DomNode object from the DomNode children for this DomDocument object.

Syntax

```
removeDocumentNode(
   node xml.DomNode )
```

1. *node* is the node to remove.

Usage

Removes a child DomNode object from the DomNode children for this DomDocument object, where *node* is the node to remove.

Only Text nodes, Processing Instruction nodes, Element nodes and Document Type nodes allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.save

Saves a DomDocument object as an XML Document to a file or URL.

Syntax

```
save(
   url STRING )
```

1. *url* is a valid URL or the name of a file.

Usage

Saves a DomDocument object as an XML Document to a file or URL, where *url* is a valid URL or the name of the file.

Only the following kinds of URLs are supported: **http://** , **https://** , **tcp://** , **tcps://** , **file:///** and **alias://** . See Web services configuration on page 2509 for more details about URL mapping with aliases, and for proxy and security configuration.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.saveToPipe

Saves a DomDocument object as an XML Document to a PIPE.

Syntax

```
saveToPipe(
   cmd STRING )
```

1. *cmd* is the command to start the pipe.

Usage

Saves a DomDocument object as an XML Document to a PIPE, where *cmd* is the command to start the pipe.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.saveToString

Saves a DomDocument object as an XML Document to a string.

Syntax

```
saveToString()
  RETURNING result STRING
```

Usage

Saves a DomDocument object as an XML Document to a string. Returns the string that will contain the resulting document.

Caution: Not part of W3C API.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.selectByXPath

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Syntax

```
selectByXPath(
   expr STRING,
   nslist ... )
  RETURNING list xml.DomNodeList
```

1. *expr* is the XPath1.0 expression
2. *nslist* is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression.

Usage

Returns a xml.DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.*expr* is the XPath1.0 expression, *nslist* is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and its corresponding namespace.

Caution: Not part of W3C API.

Valid example:

```
selectByXPath(
  "//d:Record",
  "d",
  "http://defaultnamespace")
selectByXPath(
  "//ns1:Record",
  NULL)
selectByXPath(
  "//ns1:Records/ns2:Record",
  "ns1",
  "http://namespace1",
  "ns2",
  "http://namespace2")
```

Invalid example:

```
selectByXPath(
  "//ns1:Record",
  "ns1")
```

This example is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.setFeature

Sets a feature for a DomDocument object.

Syntax

```
setFeature(
   feature STRING,
   value STRING)
```

1. *feature* is the name of a DomDocument feature.
2. *value* is the value of a feature.

Usage

Sets a feature for the DomDocument object, where *feature* is the name of a DomDocument feature, and *value* is the value of a feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.setXmlEncoding

Sets the XML document encoding in the XML declaration.

Syntax

```
setXmlEncoding(
   enc STRING )
```

1. *enc* is the XML document encoding.

Usage

Sets the XML document encoding in the XML declaration, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.setXmlStandalone

Sets the XML standalone attribute in the XML declaration to yes or no in the XML declaration.

Syntax

```
setXmlStandalone(
   alone INTEGER )
```

1. *alone* is a boolean flag.

Usage

Sets the XML standalone attribute in the XML declaration to yes or no in the XML declaration, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.validate

Performs a DTD or XML Schema validation for a DomDocument object.

Syntax

```
validate()
  RETURNING result INTEGER
```

Usage

Performs a DTD or XML Schema validation for this DomDocument object. Returns the number of validation errors, or zero if there are none.

Caution: Not part of W3C API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to validation errors.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomDocument.validateOneElement

Performs a DTD or XML Schema validation of an XML Element DomNode object.

Syntax

```
validateOneElement(
   node xml.DomNode )
  RETURNING result INTEGER
```

1. *node* is the XML Element DomNode to validate.

Usage

Performs a DTD or XML Schema validation of an XML Element DomNode object; *node* is the XML Element DomNode to validate.

Returns the number of validation errors, or zero if there are none.

> **Caution:** Not part of W3C API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to validation errors.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

Navigation methods usage examples
Examples using the navigation methods of the `xml.DomDocument` class.

DomDocument navigation functions deal with nodes immediately under the DomDocument object, except for search features. To navigate through all the nodes, you can refer to the navigation functions of the class xml.DomNode.

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" >[...]
</CardList>
```

The first node of the document is `xml-stylesheet`. Use **getFirstDocumentNode** to get the node. The element at position 2 is the comment `<!-- demo card -->`. Use **getDocumentNodeItem** function to get the node.

The last node of the document is `CardList`. Use **getLastDocumentNode** to get the node.

The number of node of the document is 3. This is result of function **getDocumentNodeCount**. This function only count the number of children immediately under the DomDocument.

Note that the first line of the example, `<?xml version="1.0" encoding="ISO-8859-1"?>`, is not considered as a node. To access to the information of the first line, use `getXmlVersion()` and `getXmlEncoding` functions.

Caution, if the example is in pretty printed format, the results are not the same. There are addition text nodes representing the carriage returns.

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" > [...]
</CardList>
```

See Cautions section for more details.

You can select nodes using their tag names, by XPath, or by their attributes value (if of type ID, xml:id for example). The `getElementsbyTagName` and `getElementsbyTagNameNS` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is

restricted to contain objects with the same tag name and/or namespace. The`selectByXPath` method also returns a DomNodeList object, but each node can have a different name.

```
getElementsByTagNameNS("message","http://schemas.xmlsoap.org/wsdl/")
```

Get the *message* nodes that have *http://schemas.xmlsoap.org/wsdl/* as the namespace.

```
getElementsByTagNameNS("message","*")
```

Get all the *message* nodes, regardless of the namespace they have.

```
getElementsByTagName("message")
```

Get all the *message* nodes that do not have any namespace.

```
selectByXPath("//xs:element",NULL)
```

Get all the xs:element nodes that has a namespace corresponding to prefix *xs* .

```
selectByXPath("//Card",NULL)
```

Get all the Card nodes that do not have any namespace.

```
getElementById("1")
```

Get the unique node whose attribute of type ID has a value of "1".

Node creation methods usage examples
Node creation methods usage examples for the `xml.DomDocument` class.

Creating a node for the DomDocument is done in two steps:

- Create the node.
- Add the node to the DomDocument.

Each time you create a node, you need to append it at the right place in the DomDocument. To add a node the document use the DomDocument management methods or the DomNode manipulation methods.

```
createNode("<LastName>PATTERSON</LastName><FirstName>Andrew</FirstName>")
```

Creates a structure of nodes.

```
createElement("CardList")
```

Produces

```
<CardList>
```

```
createElementNS("cny", "Company", "http://www.mysite.com/")
```

Produces `<cny:Company xmlns:cny="http://www.mysite.com/"/>` or `<cny:Company />`. See Cautions for more details.

```
createAttribute("Country")
```

Creates a *Country* attribute node.

- To set a value to the attribute, use the method setNodeValue of the xml.DomNode class.

- To add the attribute to an element node, use the method setAttributeNode of the xml.DomNode class.

```
createAttributeNS("tw","Town","http://www.mysite.com/cities")
```

Produces `xmlns:tw="http://www.mysite.com/cities" tw:Town=""`

- To set a value to the attribute use the method setNodeValue of the xml.DomNode class.
- To add the attribute to an element node use the method setAttributeNodeNS of the xml.DomNode class.
- For optimization reasons, the namespace is not written aside the attribute until the saving of the DomDocument.
- When accessing the element node, the namespace is not listed in the list of children. In the example above, `tw:Town=""` is in the list of children, not `xmlns:tw="http://www.mysite.com/cities"`.
- To access the namespace during the DomDocument building use the method normalize first. Normalize write the namespace declaration at the appropriate place. If there is no previous declaration, it will be accessible as an attribute of this element, otherwise it will be an attribute of one of the ancestors of the element.

```
createTextNode("My Company")
```

Creates a text node.

```
createComment("End of the card")
```

Produces`<!--End of the card-->`

```
createCDATASection("<website><a href=\"www.mysite.com\">My
Company</a></website>")
```

Produces`<![CDATA[<website><a href="www.mysite.com">My Company</a></website>]]>`

```
createEntityReference("title")
```

Creates the entity reference `&title`.

```
createProcessingInstruction("xml-stylesheet", "type=\"text/xsl\"
href=\"card.xsl\"")
```

Produces`<?xml-stylesheet type="text/xsl"href="card.xsl"?>`

```
createDocumentType("Card", NULL, NULL,"<!ELEMENT
Card (lastname, firstname, company, location)>")
```

Produces `<!DOCTYPE Card [ <!ELEMENT Card (lastname , firstname , company , location)>]>`

- Only inline DTD are supported. The DTD has to been inserted in the DomDocument at an appropriate place.

```
createDocumentFragment
```

Is a method that creates a lightweight DomDocument. It represents a subtree of nodes that do not need to conform to well-formed XML rules. This makes DocumentFragment easier to manipulate than a DomDocument.

```
for i=1 to 5
  let node = doc.createelement("Card")
  call root.appendchild(node) end for
```

This produces a subtree with 5 Card nodes that do not have any root node. Once the subtree is completed, it can be added to the DomDocument object like any other node.

HTML document usage example
The HTML language provides tags that allow the user to provide an embedded style sheet (the "`style`" tag) and to write embedded client side script (the "`script`" tag). According to the HTML 4.0 specification, the content of these tags must be managed as CDATA section.

> **Note:** For more information, see the HTML 4.0 specification.

Because HTML document management via the xml.DomDocument object provides HTML compliancy only (and not strict HTML management), there is a specific way to add these nodes inside a loaded HTML document:

1. Create an element node with the name of the tag to be created.
2. Append that element node to its parent.
3. Create a CDATASection node with the wanted embedded piece of style sheet or piece of script content.
4. Append the CDATASection to the previously created element node.

By following this procedure, the "`script`" and "`style`" tags content are recognized as `CDATA` section content and not `TEXT` section content and will be preserved. Other methods for adding nodes to the document manage text and therefore will not treat these types of content properly, resulting in invalid HTML code.

Example

```
IMPORT XML

MAIN

  DEFINE myDoc XML.DomDocument
  DEFINE myEltNode, myAttrNode, bodyNode, myCdataNode
 XML.DomNode
  DEFINE nodeLst XML.DomNodeList
  DEFINE i INTEGER

  TRY
    LET myDoc = XML.DomDocument.create()
    CALL myDoc.setFeature("enable-html-compliancy", 1)
    CALL myDoc.load("testHtml.html")

    LET myEltNode = myDoc.CreateElement("script")
    LET myCdataNode =
 myDoc.CreateCDATASection("document.write(\"CDATA\");")
    LET myAttrNode = myDoc.CreateAttribute("type")
    CALL myAttrNode.setNodeValue("text/javascript")

    LET nodeLst = myDoc.getElementsByTagName("body")
    LET docNode = nodeLst.getItem(1)

    CALL docNode.appendChild(myEltNode)
    CALL myEltNode.setAttributeNode(myAttrNode)
    CALL myEltNode.appendChild(myCdataNode)

  CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY

END MAIN
```

Load and save methods usage examples
Load and save methods usage examples for the `xml.DomDocument` class.

You can load an existing xml document. Before loading an xml document you need to create the DomDocument object.

A DomDocument can load files using different URI: http://, https://, tcp://, tcps://, file://and alias://. Use `getErrorsCount()` and `getErrorDescription()` to display errors about the document loading.

```
load("data.xml")
load("http://www.w3schools.com/xml/cd_catalog.xml")
load("https://localhost:6394/ws/r/calculator?WSDL")
load("file:///data/cd_catalog.xml")
load("tcp://localhost:4242/")
load("tcps://localhost:4243/")
load("alias://demo")
```

where demo alias is defined in fglprofile as `ws.demo.url = "http://www.w3schools.com/xml/cd_catalog.xml"`

```
loadfromstring("<List> <elt>First element</elt>
 <elt>Second element</elt> <elt>Third element</elt> </List>")
```

Produces a subtree with a root node `List` and three nodes `elt` and three `textnode`.

A DomDocument can be saved at different URI beginning with: http://, https://, tcp://, tcps://,file:// and alias://. Use `getErrorsCount()` and `getErrorDescription()`to display errors about the document saving.

```
save("myfile.xml")
save("http://myserver:8080/data/save1.xml")
save("file:///data/save.xml")
save("tcp://localhost:4242/")
save("alias://test")
```

where `test` alias is defined in fglprofile as `ws.test.url = "http://localhost:8080/data/save3.xml"`

`saveToString` saves the DomDocument in a string. Use `getErrorsCount()` and `getErrorDescription()` to display errors about the document saving

`normalize` function emulates a DomDocument save and load. It can be called at any stage of the DomDocument building. This removes empty Text nodes and sets namespace declarations as if the document had been saved.

Cautions
Cautions when working with the `xml.DomDocument` class.

Whitespaces, line feeds and carriage returns between elements are represented as text nodes in memory. An XML document written in a single line and a human readable (pretty printed format) do not have the same representation in the DomDocument. Take this under account when navigating in the document.

If a DomNode is not attached to a DomDocument and not referenced by any variable it can be destroyed. If one child of this node is still referenced, this child is not destroyed but its parent and the others node of the subtree are destroyed. To check if a node is attached to a DomDocument use isAttached method.

DomDocument remains in memory if any of its node is still referenced in a variable.

DomDocument Features
A list of features for the `xml.DomDocument` class.

DomDocument features

Table 484: DomDocument Features

Name	Description
format-pretty-print	Formats the output by adding white space to produce a pretty-printed, indented, human-readable form. Possible values are TRUE or FALSE. Default value is FALSE.
comments	Defines whether the XML comments are kept during the load of a document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.
whitespace-in-element-content	Defines whether XML Text nodes that can be considered "Ignorable" are kept during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.
cdata-sections	Defines whether XML CData nodes are kept or replaced by XML Text nodes during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.
expand-entity-references	Defines whether XML EntityReference nodes are kept or replaced during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE. **Note:** See security issues with expand-entity-references.
validation-type	Defines what kind of validation should be performed. Possible values are: DTD, Schema. Default is Schema.
external-schemaLocation	Defines a list of namespace-qualified XML schemas to use for validation on a DomDocument object.

Name	Description
	Value is a space-separated string of one or several pairs of strings representing the namespace URI of the schema, followed by its location. Example: "http://tempuri/org/NS mySchema1.xsd http://www.mycompany.com mySchema2.xsd"
external-noNamespaceSchemaLocation	Defines a list of XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several strings representing the location of a schema. Example: "mySchema1.xsd mySchema2.xsd"
schema-uriRecovery	Changes the schema location of an XML schema referenced by import tags in other schemas. Value is a space-separated string of one or several pairs of strings representing the original schema location followed by the new schema location Example: "http://www.w3.org/2001/xml.xsd myXML.xsd http://www.mycompany.com/GWS.xsd myGWS.xsd"
load-save-base64-string	Changes methods loadFromString() and saveToString() to handle Base64 strings. Parsing an XML document is done from a BASE64 encoded string, and saving an XML document results in a BASE64 encoded string. Possible values are TRUE or FALSE. Default is FALSE.
auto-id-attribute	Changes the parsing of an XML document in order to set all unqualified attributes named ID, Id, iD or id to be of type ID. They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttribute(). Possible values are TRUE or FALSE. Default is FALSE.
auto-id-qualified-attribute	Changes the parsing of an XML document in order to set all qualified attributes named ID, Id, iD or id to be of type ID. They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttributeNS().

Name	Description
	Possible values are TRUE or FALSE. Default is FALSE.
enable-html-compliancy	Changes methods to parse, normalize and save HTML document via the DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE. The HTML parsing isn't namespace qualified, and document is considered as an XML document after loading. **Note:** This feature works only for HTML 4, it is not supported for HTML 5.

Security issues with expand-entity-references

When the `expand-entity-references` document feature is set to TRUE, XML entities referencing sensitive data may be included when loading the XML document with xml.DomDocument.load on page 2123, xml.DomDocument.loadFromPipe on page 2124, xml.DomDocument.loadFromString on page 2124, or xml.DomDocument.normalize on page 2125.

For example, in its DTD, the following XML file defines the `myref ENTITY` element referencing the `/etc/passwd` file:

```
<?xml version="1.0" encoding="ISO-8859-1"?>
 <!DOCTYPE foo [
      <!ELEMENT foo ANY >
      <!ENTITY myref SYSTEM "file:///etc/passwd" >
   ]>
<foo>&myref;</foo>
```

When loading this XML file with `expand-entity-references` set to TRUE, the resulting DOM document will have a `<foo>` node containing a text node with the content of `/etc/passwd`.

Examples
Examples involving the `xml.DomDocument` class.

Example 1 : Create a namespace qualified document with processing instructions

To create the following XML document on disk:

```
<?Target1 This is my first PI ?>
<MyPre:RootNode xmlns:MyPre="http://www.tempuri.org" >
<MyPre:Element />
</MyPre:RootNode>
<?Target2 This is my last PI ?>
```

Write the following code:

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE pi xml.DomNode
  DEFINE node xml.DomNode
  DEFINE elt xml.DomNode
```

```
  # Create a document with an initial namespace qualified root node
  LET doc = xml.DomDocument.CreateDocumentNS("MyPre", "RootNode", "http://
www.tempuri.org")
  # Create a Processing instruction
  LET pi = doc.createProcessingInstruction("Target1", "This is my first PI")
  # And add it at the begining of the document
  CALL doc.prependDocumentNode(pi)
  # Create another Processing instruction
  LET pi = doc.createProcessingInstruction("Target2", "This is my last PI")
  # And add it at the end of the document
  CALL doc.appendDocumentNode(pi)
  # Retrieve initial root node of the document
  LET elt = doc.getDocumentElement()
  # Create a new Element node
  LET node = doc.createElementNS("MyPre", "Element", "http://
www.tempuri.org")
  # And add it as child of the RootNode
  CALL elt.appendChild(node)
  # Then save the document on disk
  CALL doc.save("MyFile.xml")
END MAIN
```

Example 2 : Validating a document against XML schemas or a DTD

This code example loads one or more XML schemas or uses an embedded DTD to validate against a XML document:

```
IMPORT xml

MAIN
  DEFINE location STRING
  DEFINE xmlfile STRING
  DEFINE doc xml.DomDocument
  DEFINE ind INTEGER

  IF num_args()<2 THEN
    # Checks the number of arguments
    CALL ExitHelp()
  ELSE
    LET doc = xml.DomDocument.Create()
    LET xmlfile = arg_val(num_args())
    IF num_args() == 2 AND arg_val(1) == "-dtd" THEN
      # User choosed DTD validation
      CALL doc.setFeature("validation-type", "DTD")
    ELSE
      # User choosed XML Schema validation
      IF arg_val(1) == "-ns" THEN
        # Handle namespace qualified XML schemas
        IF num_args() MOD 2 != 0 THEN
          CALL ExitHelp()
        END IF
        FOR ind = 2 TO num_args()-1 STEP 2
          IF location IS NULL THEN
            LET location = arg_val(ind) || " " || arg_val(ind+1)
          ELSE
            LET location = location || " " || arg_val(ind) ||
                 " " || arg_val(ind+1)
          END IF
        END FOR
        TRY
          CALL doc.setFeature("external-schemaLocation", location)
        CATCH
          FOR ind = 1 TO doc.getErrorsCount()
```

```
            DISPLAY "Schema error ("||
ind||") :",doc.getErrorDescription(ind)
          END FOR
          EXIT PROGRAM (-1)
        END TRY
      ELSE
        # Handle unqualified XML schemas
        FOR ind = 1 TO num_args()-1
          IF location IS NULL THEN
            LET location = arg_val(ind)
          ELSE
            LET location = location || " " || arg_val(ind)
          END IF
        END FOR
        TRY
          CALL doc.setFeature("external-noNamespaceSchemaLocation",
 location)
        CATCH
          FOR ind = 1 TO doc.getErrorsCount()
            DISPLAY "Schema error ("||
ind||") :",doc.getErrorDescription(ind)
          END FOR
          EXIT PROGRAM (-1)
        END TRY
      END IF
    END IF
  END IF
  TRY
    # Load XML document from disk
    CALL doc.load(xmlfile)
  CATCH
    # Display errors if loading failed
    IF doc.getErrorsCount()>0 THEN
      FOR ind = 1 TO doc.getErrorsCount()
        DISPLAY "LOADING ERROR #"||ind||" :",doc.getErrorDescription(ind)
      END FOR
      EXIT PROGRAM(-1)
    ELSE
      DISPLAY "Unable to load file :",xmlfile
      EXIT PROGRAM(-1)
    END IF
  END TRY
  TRY
    # Validate loaded document
    LET ind = doc.validate()
    IF ind == 0 THEN
      # Successful validation
      DISPLAY "OK"
    ELSE
      # Display validation errors
      FOR ind = 1 TO doc.getErrorsCount()
        DISPLAY "VALIDATING ERROR #"||ind||" :",doc.getErrorDescription(ind)
      END FOR
      EXIT PROGRAM(-1)
    END IF
  CATCH
    DISPLAY "Unable to validate file :",xmlfile
    EXIT PROGRAM(-1)
  END TRY
END MAIN

# Display help

FUNCTION ExitHelp()
```

```
  DISPLAY "Validator < -dtd | -ns [namespace schema]+ | [schema]+ > xmlfile"
  EXIT PROGRAM
END FUNCTION
```

Example

```
$ fglrun Validator -dtd MyFile.xml
```

Validates XML file using DTD embedded in the XML file.

```
$ fglrun Validator Schema1.xsd Schema2.xsd MyFile.xml
```

Validates unqualified XML file using two unqualified XML schemas.

```
$ fglrun Validator -ns http://tempuri.org/one Schema1.xsd
   http://tempuri.org/two Schema2.xsd MyFile.xml
```

Validates namespace qualified XML file using two namespace qualified XML schemas.

The DomNode class

The `xml.DomNode` class provides methods to manipulate a node of a DomDocument object.

You can create a DomNode object using creation methods in the DomDocument class.

The `STATUS` variable is set to zero after a successful method call.

xml.DomNode methods
Methods for the `xml.DomNode` class.

Table 485: Object methods: Navigation

Name	Description
`getChildrenCount()` `  RETURNING cnt INTEGER`	Returns the number of child DomNode objects for a DomNode object.

`getChildNodeItem(`
`  pos INTEGER )`
`  RETURNING object xml.DomNode`
	Returns the child DomNode object at a given position for a DomNode object.

`getFirstChild()` `  RETURNING object xml.DomNode`	Returns the first child DomNode object for this XML Element DomNode object.
`getFirstChildElement()` `  RETURNING object xml.DomNode`	Returns the first XML Element child DomNode object for this DomNode object.
`getLastChild()` `  RETURNING object xml.DomNode`	Returns the last child DomNode object for a XML Element DomNode object.
`getLastChildElement()`	Returns the last child XML element DomNode object for this DomNode object.

Name	Description
RETURNING *object* xml.DomNode	
getNextSibling() RETURNING *object* xml.DomNode	Returns the DomNode object immediately following a DomNode object.
getNextSiblingElement() RETURNING *object* xml.DomNode	Returns the XML Element DomNode object immediately following a DomNode object.
getParentNode() RETURNING *object* xml.DomNode	Returns the parent DomNode object for this DomNode object.
getOwnerDocument() RETURNING *object* xml.DomDocument	Returns the DomDocument object containing this DomNode object.
getPreviousSibling() RETURNING *object* xml.DomNode	Returns the DomNode object immediately preceding a DomNode object.
getPreviousSiblingElement() RETURNING *object* xml.DomNode	Returns the XML Element DomNode object immediately preceding a DomNode object.
hasChildNodes() RETURNING *flag* INTEGER	Returns TRUE if a node has child nodes.

Table 486: Object methods: Manipulation

Name	Description
clone(*deep* INTEGER) RETURNING *object* xml.DomNode	Returns a duplicate DomNode object of a node.
appendChild(*node* xml.DomNode)	Adds a child DomNode object to the end of the child list for a DomNode object
appendChildElement(*name* STRING) RETURNING *object* xml.DomNode	Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object.
appendChildElementNS(*prefix* STRING, *name* STRING, *ns* STRING)	Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object.

Name	Description
RETURNING *object* xml.DomNode	
addNextSibling(*node* xml.DomNode)	Adds a DomNode object as the next sibling of a DomNode object.
addPreviousSibling(*node* xml.DomNode)	Adds a DomNode object as the previous sibling of a DomNode object.
insertBeforeChild(*node* xml.DomNode, *ref* xml.DomNode)	Inserts a DomNode object before an existing child DomNode object.
insertAfterChild(*node* xml.DomNode, *ref* xml.DomNode)	Inserts a DomNode object after an existing child DomNode object.
prependChild(*node* xml.DomNode)	Adds a child DomNode object to the beginning of the child list for a DomNode object.
prependChildElement(*name* STRING) RETURNING *object* xml.DomNode	Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.
prependChildElementNS(*prefix* STRING, *name* STRING, *ns* STRING) RETURNING *object* xml.DomNode	Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object.
removeAllChildren()	Removes all child DomNode objects from a DomNode object.
removeChild(*node* xml.DomNode)	Removes a child DomNode object from the list of child DomNode objects.
replaceChild(*new* xml.DomNode, *old* xml.DomNode)	Replaces an existing child DomNode with another child DomNode object.

Table 487: Object methods: Access

Name	Description
getLocalName()	Gets the local name for a DomNode object.

Name	Description
RETURNING *str* STRING	
getNamespaceURI() RETURNING *str* STRING	Returns the namespace URI for a DomNode object.
getNodeName() RETURNING *str* STRING	Gets the name for a DomNode object.
getNodeType() RETURNING *str* STRING	Gets the XML type for this DomNode object.
getNodeValue() RETURNING *str* STRING	Returns the value for a DomNode object.
getPrefix() RETURNING *str* STRING	Returns the prefix for a DomNode object.
isAttached() RETURNING *num* INTEGER	Returns whether the node is attached to the XML document.

Table 488: Object methods: Modifier

Name	Description
setNodeValue(*val* STRING)	Sets the node value for a DomNode object.
setPrefix(*prefix* STRING)	Sets the prefix for a DomNode object.
toString() RETURNING STRING	Returns a string representation of a DomNode object.

Table 489: Object methods: Attribute

Name	Description
hasAttribute(*name* STRING) RETURNING *flag* INTEGER	Checks whether an XML Element DomNode object has the XML Attribute specified by a specified name.
hasAttributeNS(*name* STRING, *ns* STRING)	Checks whether a namespace qualified XML Attribute of a given name is carried by an XML Element DomNode object.

Name	Description
`RETURNING flag INTEGER`	
`getAttributesCount()` `RETURNING num INTEGER`	Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

`getAttributeNode(`
`name STRING )`
`RETURNING object xml.DomNode`
	Returns an XML Attribute DomNode object for an XML Element DomNode object

`getAttributeNodeItem(`
`pos INTEGER )`
`RETURNING object xml.DomNode`
	Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object.

`getAttributeNodeNS(`
`name STRING,`
`ns STRING )`
`RETURNING object xml.DomNode`
	Returns a namespace-qualified XML Attribute DomNode object for an XML Element DomNode object

`getAttribute(`
`name STRING )`
`RETURNING value STRING`
	Returns the value of an XML Attribute for an XML Element DomNode object

`getAttributeNS(`
`name STRING,`
`ns STRING )`
`RETURNING value STRING`
	Returns the value of a namespace qualified XML Attribute for an XML Element DomNode object

`hasAttributes()` `RETURNING flag INTEGER`	Identifies whether a node has XML Attribute nodes.

`setAttribute(`
`name STRING,`
`value STRING )`
	Sets (or resets) an XML Attribute for an XML Element DomNode object.

`setAttributeNode(` `node xml.DomNode )`	Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object.
`setAttributeNodeNS(` `node xml.DomNode )`	Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object.

`setAttributeNS(`
`prefix STRING,`
`name STRING,`
`ns STRING,`
	Sets (or resets) a namespace-qualified XML Attribute for an XML Element DomNode object.

Name	Description
value STRING)	
setIdAttribute(*name* STRING, *isId* INTEGER)	Declare (or undeclare) the XML Attribute of given name to be of type ID.
setIdAttributeNS(*name* STRING, *ns* STRING, *isId* INTEGER)	Declare (or undeclare) the namespace-qualified XML Attribute of given name and namespace to be of type ID.
removeAttribute(*name* STRING)	Removes an XML Attribute for an XML Element DomNode object.
removeAttributeNS(*name* STRING, *ns* STRING)	Removes a namespace qualified XML Attribute for an XML Element DomNode object

Table 490: Object methods: Search

Name	Description
getElementsByTagName(*name* STRING) RETURNING *list* xml.DomNodeList	Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name.
getElementsByTagNameNS(*name* STRING, *ns* STRING) RETURNING *list* xml.DomNodeList	Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace.
isDefaultNamespace(*ns* STRING) RETURNING *flag* INTEGER	Checks whether the specified namespace URI is the default namespace.
lookupNamespaceURI(*prefix* STRING) RETURNING *ns* STRING	Looks up the namespace URI associated to a prefix, starting from a specified node.
lookupPrefix(*ns* STRING) RETURNING *prefix* STRING	Looks up the prefix associated to a namespace URI, starting from the specified node.
selectByXPath(*expr* STRING, *NamespacesList* ...)	Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Name	Description
RETURNING *list* xml.DomNodeList	

xml.DomNode.addPreviousSibling

Adds a DomNode object as the previous sibling of a DomNode object.

Syntax

```
addPreviousSibling(
   node xml.DomNode )
```

1. *node* is the node to add.

Usage

Adds a DomNode object as the previous sibling of this DomNode object; *node* is the node to add.

Caution: Not part of W3C API.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.addNextSibling

Adds a DomNode object as the next sibling of a DomNode object.

Syntax

```
addNextSibling(
  node xml.DomNode )
```

1. *node* is the node to add.

Usage

Adds a DomNode object as the next sibling of this DomNode object; *node* is the node to add.

Caution: Not part of W3C API.

The DomNode object node must be the child of an element or document node, otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.appendChild

Adds a child DomNode object to the end of the child list for a DomNode object

Syntax

```
appendChild(
  node xml.DomNode )
```

1. *node* is the node to add

Usage

Adds a child DomNode object to the end of the child list for this DomNode object.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.appendChildElement

Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object.

Syntax

```
appendChildElement(
   name STRING )
  RETURNING object xml.DomNode
```

1. *name* is the XML Element name.

Usage

Creates and adds a child XML Element node to the end of the list of child nodes for this XML Element DomNode object.

> **Caution:** Not part of W3C API.

Returns the XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.appendChildElementNS

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object.

Syntax

```
appendChildElementNS(
   prefix STRING,
   name STRING,
   ns STRING )
  RETURNING object xml.DomNode
```

1. *prefix* is the prefix of the XML Element to add.
2. *name* is the name of the XML Element to add.
3. *ns* is the namespace URI of the XML Element to add.

Usage

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for this XML Element DomNode object.

> **Caution:** Not part of W3C API.

Returns the XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.clone

Returns a duplicate DomNode object of a node.

Syntax

```
clone(
   deep INTEGER )
  RETURNING object xml.DomNode
```

1. *deep* is a boolean. If *deep* is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

Usage

Returns a duplicate DomNode object of this node. If *deep* is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

Returns a copy of this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttribute

Returns the value of an XML Attribute for an XML Element DomNode object

Syntax

```
getAttribute(
   name STRING )
  RETURNING value STRING
```

1. *name* is the name of the XML attribute to retrieve.

Usage

Returns the value of an XML Attribute for this XML Element DomNode object. where *name* is the name of the XML attribute to retrieve.

Returns the XML Attribute value, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttributeNode

Returns an XML Attribute DomNode object for an XML Element DomNode object

Syntax

```
getAttributeNode(
   name STRING )
  RETURNING object xml.DomNode
```

1. *name* is the name of the attribute to retrieve.

Usage

Returns an XML Attribute DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttributeNodeItem

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object.

Syntax

```
getAttributeNodeItem(
   pos INTEGER )
  RETURNING object xml.DomNode
```

1. *pos* is the position of the node to return.

Usage

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object, where *pos* is the position of the node to return (Index starts at 1).

Returns the XML Attribute DomNode object at the given position, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttributeNodeNS

Returns a namespace-qualified XML Attribute DomNode object for an XML Element DomNode object

Syntax

```
getAttributeNodeNS(
   name STRING,
   ns STRING )
  RETURNING object xml.DomNode
```

1. *name* is the name of the XMLAttribute to retrieve.
2. *ns* is the namespace URI of the XML Attribute to retrieve.

Usage

Returns a namespace-qualified XML Attribute DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttributeNS

Returns the value of a namespace qualified XML Attribute for an XML Element DomNode object

Syntax

```
getAttributeNS(
   name STRING,
   ns STRING )
```

```
   RETURNING value STRING
```

1. *name* is the name.
2. *ns* is the namespace URI of the XML Attribute to retrieve

Usage

Returns the value of a namespace qualified XML Attribute for this XML Element DomNode object, where *name* is the name and *ns* is the namespace URI of the XML Attribute to retrieve.

Returns the XML Attribute value, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getAttributesCount

Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

Syntax

```
getAttributesCount()
  RETURNING num INTEGER
```

Usage

Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getChildNodeItem

Returns the child DomNode object at a given position for a DomNode object.

Syntax

```
getChildNodeItem(
   pos INTEGER )
  RETURNING object xml.DomNode
```

1. *pos* is the position of the child node in the collection.

Usage

Returns the child DomNode object at a given position for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getChildrenCount

Returns the number of child DomNode objects for a DomNode object.

Syntax

```
getChildrenCount()
  RETURNING cnt INTEGER
```

Usage

Returns the number of child DomNode objects for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getElementsByTagName

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name.

Syntax

```
getElementsByTagName(
   name STRING )
  RETURNING list xml.DomNodeList
```

1. *name* is the name of the XML Element tag to match or "*" to match all tags.

Usage

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name, or NULL; *name* is the name of the XML Element tag to match, or "*" to match all tags.

The `getElementsByTagName` and `getElementsByTagNameNS` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getElementsByTagNameNS

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace.

Syntax

```
getElementsByTagNameNS(
   name STRING,
   ns STRING )
  RETURNING list xml.DomNodeList
```

1. *name* is the name of the XML Element tag to match or "*" to match all tags.
2. *ns* is the namespace URI of the XML Element tag to match or "*" to match any namespace.

Usage

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace, or NULL. *name* is the name of the XML Element tag to match, or "*" to match all tags; *ns* is the namespace URI of the XML Element tag to match, or "*" to match any namespace.

The `getElementsByTagName` and `getElementsByTagNameNS` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getFirstChild

Returns the first child DomNode object for this XML Element DomNode object.

Syntax

```
getFirstChild()
  RETURNING object xml.DomNode
```

Usage

Returns the first child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getFirstChildElement

Returns the first XML Element child DomNode object for this DomNode object.

Syntax

```
getFirstChildElement()
  RETURNING object xml.DomNode
```

Usage

Returns the first XML Element child DomNode object for this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getLastChild

Returns the last child DomNode object for a XML Element DomNode object.

Syntax

```
getLastChild()
  RETURNING object xml.DomNode
```

Usage

Returns the last child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getLastChildElement

Returns the last child XML element DomNode object for this DomNode object.

Syntax

```
getLastChildElement()
  RETURNING object xml.DomNode
```

Usage

Returns the last child XML element DomNode object for this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getLocalName

Gets the local name for a DomNode object.

Syntax

```
getLocalName()
  RETURNING str STRING
```

Usage

Gets the local name for this DomNode object. If DomNode has a qualified name, only the local part is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNamespaceURI

Returns the namespace URI for a DomNode object.

Syntax

```
getNamespaceURI()
  RETURNING str STRING
```

Usage

Returns the namespace URI for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNextSibling

Returns the DomNode object immediately following a DomNode object.

Syntax

```
getNextSibling()
  RETURNING object xml.DomNode
```

Usage

Returns the DomNode object immediately following this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNextSiblingElement

Returns the XML Element DomNode object immediately following a DomNode object.

Syntax

```
getNextSiblingElement()
  RETURNING object xml.DomNode
```

Usage

Returns the XML Element DomNode object immediately following this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNodeName

Gets the name for a DomNode object.

Syntax

```
getNodeName()
  RETURNING str STRING
```

Usage

Gets the name for this DomNode object; returns the qualified name of this DomNode object, or NULL. If DomNode does not have a qualified name, the local part is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNodeType

Gets the XML type for this DomNode object.

Syntax

```
getNodeType()
  RETURNING str STRING
```

Usage

Gets the XML type for this DomNode object; returns one of the XML DomNode types, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getNodeValue

Returns the value for a DomNode object.

Syntax

```
getNodeValue()
  RETURNING str STRING
```

Usage

Returns the value for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getOwnerDocument

Returns the DomDocument object containing this DomNode object.

Syntax

```
getOwnerDocument()
  RETURNING object xml.DomDocument
```

Usage

Returns the DomDocument object containing this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getParentNode

Returns the parent DomNode object for this DomNode object.

Syntax

```
getParentNode()
  RETURNING object xml.DomNode
```

Usage

Returns the parent DomNode object for this DomNode object, or NULL. In the case of a DomDocument node, this method will return NULL (parent is not a DomNode object) but isAttached() will return TRUE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getPrefix

Returns the prefix for a DomNode object.

Syntax

```
getPrefix()
  RETURNING str STRING
```

Usage

Returns the prefix for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getPreviousSibling

Returns the DomNode object immediately preceding a DomNode object.

Syntax

```
getPreviousSibling()
  RETURNING object xml.DomNode
```

Usage

Returns the DomNode object immediately preceding this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.getPreviousSiblingElement

Returns the XML Element DomNode object immediately preceding a DomNode object.

Syntax

```
getPreviousSiblingElement()
  RETURNING object xml.DomNode
```

Usage

Returns the XML Element DomNode object immediately preceding this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.hasAttribute

Checks whether an XML Element DomNode object has the XML Attribute specified by a specified name.

Syntax

```
hasAttribute(
   name STRING )
  RETURNING flag INTEGER
```

1. *name* is the object name to check.

Usage

Checks whether this XML Element DomNode object has the XML Attribute specified by *name*. Returns TRUE if an XML Attribute with the given name is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.hasAttributeNS

Checks whether a namespace qualified XML Attribute of a given name is carried by an XML Element DomNode object.

Syntax

```
hasAttributeNS(
   name STRING,
   ns STRING )
  RETURNING flag INTEGER
```

1. *name* the name of the XMLAttribute to check
2. *ns* the namespace URI of the XML Attribute to check.

Usage

Checks whether a namespace qualified XML Attribute of a given name is carried by this XML Element DomNode object, where *name* the name of the XMLAttribute to check; *ns* the namespace URI of the XML Attribute to check. Returns TRUE if an XML Attribute with the given name and namespace URI is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.hasAttributes

Identifies whether a node has XML Attribute nodes.

Syntax

```
hasAttributes()
  RETURNING flag INTEGER
```

1. *flag* acts as a boolean.

Usage

Returns TRUE if this node has XML Attribute nodes; otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.hasChildNodes

Returns TRUE if a node has child nodes.

Syntax

```
hasChildNodes()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if this node has child nodes;otherwise, returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.insertAfterChild

Inserts a DomNode object after an existing child DomNode object.

Syntax

```
insertAfterChild(
   node xml.DomNode,
   ref xml.DomNode )
```

1. *node* is the node to insert.
2. *ref* is the reference node (the node before which the new node must be inserted).

Usage

Inserts a DomNode object after an existing child DomNode object; *node* is the node to insert, *ref* is the reference node (the node before which the new node must be inserted).

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.insertBeforeChild

Inserts a DomNode object before an existing child DomNode object.

Syntax

```
insertBeforeChild(
   node xml.DomNode,
   ref xml.DomNode )
```

1. *node* is the node to insert.
2. *ref* is the reference node (the node before which the new node must be inserted).

Usage

Inserts a DomNode object before an existing child DomNode object; *node* is the node to insert, *ref* is the reference node (the node before which the new node must be inserted).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.isAttached

Returns whether the node is attached to the XML document.

Syntax

```
isAttached()
  RETURNING num INTEGER
```

Usage

Returns whether the node is attached to the XML document.

Caution: Not part of W3C API.

Returns TRUE if this DomNode object is attached to a DomDocument object as a child and was not removed later on; otherwise it returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.isDefaultNamespace

Checks whether the specified namespace URI is the default namespace.

Syntax

```
isDefaultNamespace(
   ns STRING )
  RETURNING flag INTEGER
```

1. *ns* is the namespace URI to look for.

Usage

Checks whether the specified namespace URI is the default namespace, where *ns* is the namespace URI to look for. Returns TRUE if the given namespace is the default namespace, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.lookupNamespaceURI

Looks up the namespace URI associated to a prefix, starting from a specified node.

Syntax

```
lookupNamespaceURI(
   prefix STRING )
  RETURNING ns STRING
```

1. *prefix* is the prefix to look for.

Usage

Looks up the namespace URI associated to a prefix, starting from this node, where *prefix* is the prefix to look for; if NULL, the default namespace URI will be returned. Returns a namespace URI, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.lookupPrefix

Looks up the prefix associated to a namespace URI, starting from the specified node.

Syntax

```
lookupPrefix(
   ns STRING )
  RETURNING prefix STRING
```

1. *ns* is the namespace URI to look for.

Usage

Looks up the prefix associated to a namespace URI, starting from this node, where *ns* is the namespace URI to look for. Returns the prefix associated to this namespace URI, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.prependChild

Adds a child DomNode object to the beginning of the child list for a DomNode object.

Syntax

```
prependChild(
   node xml.DomNode )
```

1. *node* is the node to add.

Usage

Adds a child DomNode object to the beginning of the child list for this DomNode object ; *node* is the node to add.

Caution: Not part of W3C API.

The DomNode object node must be the child of an element or document node, otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.prependChildElement

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

Syntax

```
prependChildElement(
   name STRING )
  RETURNING object xml.DomNode
```

1. *name* is the name of the XML element to add.

Usage

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object; *name* is the name of the XML element to add.

Returns the XML Element DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.prependChildElementNS

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object.

Syntax

```
prependChildElementNS(
```

```
    prefix STRING,
    name STRING,
    ns STRING )
  RETURNING object xml.DomNode
```

1. *prefix* is the prefix of the XML Element to add.
2. *name* is the name of the XML Element to add.
3. *ns* is the namespace URI of the XML Element to add.

Usage

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

Returns the XML Element DomNode object, or NULL.

Note: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.removeAllChildren

Removes all child DomNode objects from a DomNode object.

Syntax

```
removeAllChildren()
```

Usage

Removes all child DomNode objects from this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.removeAttribute

Removes an XML Attribute for an XML Element DomNode object.

Syntax

```
removeAttribute(
  name STRING )
```

1. *name* is the name of the XML attribute to remove.

Usage

Removes an XML Attribute for this XML Element DomNode object, where *name* is the name of the XML attribute to remove. Status is updated with an error code.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.removeAttributeNS

Removes a namespace qualified XML Attribute for an XML Element DomNode object

Syntax

```
removeAttributeNS(
   name STRING,
   ns STRING )
```

1. *name* is the name of the XML Attribute to remove.
2. *ns* is the namespace URI of the XML Attribute to remove.

Usage

Removes a namespace qualified XML Attribute for this XML Element DomNode object, where *name* is the name and *ns* is the namespace URI of the XML Attribute to remove.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.removeChild

Removes a child DomNode object from the list of child DomNode objects.

Syntax

```
removeChild(
   node xml.DomNode )
```

1. *node* is the node to remove.

Usage

Removes a child DomNode object from the list of child DomNode objects, where *node* is the node to remove.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.replaceChild

Replaces an existing child DomNode with another child DomNode object.

Syntax

```
replaceChild(
   new xml.DomNode,
   old xml.DomNode )
```

1. *new* is the replacement child.
2. *old* is the child to be replaced.

Usage

Replaces an existing child DomNode with another child DomNode object, where *old* is the child to be replaced and *new* is the replacement child.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.selectByXPath

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Syntax

```
selectByXPath(
   expr STRING,
   NamespacesList ...)
  RETURNING list xml.DomNodeList
```

1. *expr* is the XPath 1.0 expression.
2. *NamespacesList* is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression.

Usage

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression; *expr* is the XPath 1.0 expression, *NamespacesList* is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and it corresponding namespace.

Caution: Not part of W3C API.

Example

```
selectByXPath(
  "../../d:Record/*[last()]",
  "d",
  "http://defaultnamespace")
selectByXPath(
  "ns:Record",
  NULL)
selectByXPath(
  "ns1:Records/ns2:Record",
  "ns1",
   "http://namespace1",
   "ns2",
   "http://namespace2")
```

`selectByXPath("ns1:Record", "ns1")` is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setAttribute

Sets (or resets) an XML Attribute for an XML Element DomNode object.

Syntax

```
setAttribute(
   name STRING,
   value STRING )
```

1. *name* is the name of the XML Attribute.
2. *val* is the value of the XML Attribute.

Usage

Sets (or resets) an XML Attribute for this XML Element DomNode object, where *name* is the name of the XML Attribute and *val* is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setAttributeNode

Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object.

Syntax

```
setAttributeNode(
   node xml.DomNode )
```

1. *node* is the XML Attribute DomNode object to set.

Usage

Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object, where *node* is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setAttributeNodeNS

Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object.

Syntax

```
setAttributeNodeNS(
   node xml.DomNode )
```

1. *node* is the XML Attribute DomNode object to set.

Usage

Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object, where *node* is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setAttributeNS

Sets (or resets) a namespace-qualified XML Attribute for an XML Element DomNode object.

Syntax

```
setAttributeNS(
   prefix STRING,
   name STRING,
   ns STRING,
```

```
   value STRING )
```

1. *prefix* is the prefix of the XMLAttribute.
2. *name* is the name of the XML Attribute.
3. *ns* is the namespace URI of the XML Attribute.
4. *val* is the value of the XML Attribute.

Usage

Sets (or resets) a namespace-qualified XML Attribute for this XML Element DomNode object, where *prefix* is the prefix of the XMLAttribute, *name* is the name of the XML Attribute, *ns* is the namespace URI of the XML Attribute, and *val* is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setIdAttribute

Declare (or undeclare) the XML Attribute of given name to be of type ID.

Syntax

```
setIdAttribute(
   name STRING,
   isId INTEGER )
```

1. *name* is the name of the XML Attribute to set.
2. *isId* declares whether the attribute is a user-determined ID attribute.

Usage

Declare (or undeclare) the XML Attribute of given name to be of type ID. Use the value TRUE for the parameter *isID* to declare that attribute for being a user-determined ID attribute, otherwise returns FALSE.

This affects the behavior of getElementById.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setIdAttributeNS

Declare (or undeclare) the namespace-qualified XML Attribute of given name and namespace to be of type ID.

Syntax

```
setIdAttributeNS(
   name STRING,
   ns STRING,
   isId INTEGER )
```

1. *name* is the name of the XML Attribute to set.
2. *ns* is the namespace URI of the XML Attribute to set.
3. *isId* declares whether the attribute is a user-determined ID attribute.

Usage

Declare (or undeclare) the namespace-qualified XML Attribute of given name and namespace to be of type ID. Use the value TRUE for the parameter *isID* to declare that attribute for being a user-determined ID attribute, otherwise returns FALSE.

This affects the behavior of getElementById.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setNodeValue

Sets the node value for a DomNode object.

Syntax

```
setNodeValue(
   val STRING )
```

1. *val* is the node value.

Usage

Sets the node value for this DomNode object, where *val* is the node value.

This method should only be used for nodes that are not parent of other nodes, which means it can be sued for a node of type:

- ATTRIBUTE_NODE
- TEXT_NODE
- CDATA_SECTION_NODE
- PROCESSING_INSTRUCTION_NODE
- COMMENT_NODE

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.setPrefix

Sets the prefix for a DomNode object.

Syntax

```
setPrefix(
  prefix STRING )
```

1. *prefix* is the prefix for this DomNode object.

Usage

Sets the *prefix* for this DomNode object.

This method is only valid on namespace qualified Element or Attribute nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNode.toString

Returns a string representation of a DomNode object.

Syntax

```
toString()
  RETURNING STRING
```

Usage

Returns a string representation of this DomNode object, or NULL

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

DomNode types
List of types for the `xml.DomNode` class.

Table 491: DomNode types

Type	Description
ELEMENT_NODE	The DomNode is an XML Element node.
ATTRIBUTE_NODE	The DomNode is an XML Attribute node.
TEXT_NODE	The DomNode is an XML Text node.
CDATA_SECTION_NODE	The DomNode is an XML CData Section node.
ENTITY_REFERENCE_NODE	The DomNode is an XML Entity Reference node.
PROCESSING_INSTRUCTION_NODE	The DomNode is an XML Processing Instruction node.
COMMENT_NODE	The DomNode is an XML Comment node.
DOCUMENT_TYPE_NODE	The DomNode is an XML DTD node.
DOCUMENT_FRAGMENT_NODE	The DomNode is an XML Document Fragment node.

Examples
Examples involving the `xml.DomNode` class.

Example Counting the number of nodes in an XML document

This code example counts the number of nodes of each type.

```
IMPORT XML

DEFINE nbElt INTEGER
DEFINE nbAttr INTEGER
DEFINE nbComment INTEGER
DEFINE nbPI INTEGER
DEFINE nbTxt INTEGER
DEFINE nbCData INTEGER

MAIN
  DEFINE document xml.DomDocument
  DEFINE ind INTEGER
```

```
  # Handle arguments
  IF num_args() !=1 THEN
    CALL ExitHelp()
  END IF
  # Create document, load it, and count the nodes
  LET document = xml.DomDocument.Create()
  CALL document.load(arg_val(1))
  CALL CountDoc(document)
  # Display result
  DISPLAY "Results: "
  DISPLAY " Elements: ",nbElt
  DISPLAY " Attributes:",nbAttr
  DISPLAY " Comments: ",nbComment
  DISPLAY " PI: ",nbPI
  DISPLAY " Texts: ",nbTxt
  DISPLAY " CData: ",nbCData
END MAIN

FUNCTION CountDoc(d)
  DEFINE d xml.DomDocument
  DEFINE n xml.DomNode
  LET n = d.getFirstDocumentNode()
  WHILE (n IS NOT NULL )
    CALL Count(n)
    LET n = n.getNextSibling()
  END WHILE
END FUNCTION

FUNCTION Count(n)
  DEFINE n xml.DomNode
  DEFINE child xml.DomNode
  DEFINE next xml.DomNode
  DEFINE node xml.DomNode
  DEFINE ind INTEGER
  DEFINE name STRING
  IF n IS NOT NULL THEN
    IF n.getNodeType() == "COMMENT_NODE" THEN
      LET nbComment = nbComment + 1
    END IF
    IF n.getNodeType() == "ATTRIBUTE_NODE" THEN
      LET nbAttr = nbAttr + 1
    END IF
    IF n.getNodeType() == "PROCESSING_INSTRUCTION_NODE " THEN
      LET nbPI = nbPI + 1
    END IF
    IF n.getNodeType() == "ELEMENT_NODE" THEN
      LET nbElt = nbElt + 1
    END IF
    IF n.getNodeType() == "TEXT_NODE" THEN
      LET nbTxt = nbTxt +1
    END IF
    IF n.getNodeType() == "CDATA_SECTION_NODE" THEN
      LET nbCData = nbCData + 1
    END IF
    IF n.hasChildNodes() THEN
      LET name = n.getLocalName()
      LET child = n.getFirstChild()
      WHILE (child IS NOT NULL )
        CALL Count(child)
        LET child = child.getNextSibling()
      END WHILE
    END IF
    IF n.hasAttributes() THEN
      FOR ind = 1 TO n.getAttributesCount()
```

```
        LET node = n.getAttributeNodeItem(ind)
        CALL Count(node)
      END FOR
    END IF
  END IF
END FUNCTION

FUNCTION ExitHelp()
  DISPLAY "DomCount <xml>"
  EXIT PROGRAM
END FUNCTION
```

The DomNodeList class

The `xml.DomNodeList` class provides methods to manipulate a list of DomNode objects.

You can create a DomNodeList object using selection methods in the DomDocument and DomNode classes. The relationship between the DomNode objects in the list depends on the method used to create the DomNodeList object.

The `STATUS` variable is set to zero after a successful method call.

xml.DomNodeList methods

Methods for the `xml.DomNodeList` class.

Table 492: Object methods

Name	Description
`getCount()` `  RETURNING num INTEGER`	Returns the number of DomNode objects in a DomNodeList object.

`getItem(`
`  pos INTEGER)`
`  RETURNING object xml.DomNode`
	Returns the DomNode object at a given position in a DomNodeList object.

xml.DomNodeList.getCount

Returns the number of DomNode objects in a DomNodeList object.

Syntax

```
getCount()
  RETURNING num INTEGER
```

Usage

Returns the number of DomNode objects in a DomNodeList object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.DomNodeList.getItem

Returns the DomNode object at a given position in a DomNodeList object.

Syntax

```
getItem(
  pos INTEGER)
```

```
  RETURNING object xml.DomNode
```

1. *pos* is the position of the DomNode object to return (index starts at 1).

Usage

Returns the DomNode object at the given position in this DomNodeList object, where *pos* is the position of the DomNode object to return (Index starts at 1).

Returns NULL when no DomNode object is at the given position.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The streaming API for XML (StAX) classes

The streaming API for XML (StAX) classes use streaming while managing XML documents.

- CLASS StaxWriter
  - Features
  - Example
- CLASS StaxReader
  - Event types
  - Features
  - Example

The StaxWriter class

The xml.StaxWriter class provides methods compatible with StAX (Streaming API for XML) for writing XML documents.

The STATUS variable is set to zero after a successful method call.

xml.StaxWriter methods

Methods for the xml.StaxWriter class.

Table 493: Class methods: Creation

Name	Description
`xml.StaxWriter.create()` `  RETURNING object xml.StaxWriter`	Constructor of a StaxWriter object.

Table 494: Object methods: Configuration

Name	Description

`getFeature(`
`  feature STRING )`
`  RETURNING str STRING`
	Gets a feature of a StaxWriter object.

`setFeature(`
`  feature STRING,`
`  value STRING )`
	Sets a feature of a StaxWriter object.

Table 495: Object methods: Output

Name	Description
`close()`	Closes the StaxWriter streaming, and releases all associated resources.
`writeTo(` `  url STRING )`	Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.
`writeToDocument(` `  doc xml.DomDocument )`	Sets the output stream of the StaxWriter object to an xml.DomDocument object, and starts the streaming.
`writeToPipe(` `  cmd STRING )`	Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.
`writeToText(` `  txt TEXT )`	Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.

Table 496: Object methods: Document

Name	Description
`dtd(` `  data STRING )`	Writes a DTD to the StaxWriter stream.
`endDocument()`	Closes any open tags and writes corresponding end tags.

`startDocument(`
`  encoding STRING,`
`  version STRING,`
`  standalone INTEGER )`
	Writes an XML declaration to the StaxWriter stream.

Table 497: Object methods: Namespace

Name	Description
`declareDefaultNamespace(` `  defaultNS STRING )`	Binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.

`declareNamespace(`
`  prefix STRING,`
`  ns STRING )`
	Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

`setDefaultNamespace(`	Binds a namespace URI to the default namespace.

Name	Description
defaultNS STRING)	
setPrefix(*prefix* STRING, *ns* STRING)	Binds a namespace URI to a prefix.

Table 498: Object methods: Node

Name	Description
attribute(*name* STRING, *value* STRING)	Writes an XML attribute to the StaxWriter stream.
attributeNS(*name* STRING, *ns* STRING, *value* STRING)	Writes an XML namespace qualified attribute to the StaxWriter stream.
cdata(*data* STRING)	Writes an XML CData to the StaxWriter stream.
characters(*text* STRING)	Writes an XML text to the StaxWriter stream.
comment(*data* STRING)	Writes an XML comment to the StaxWriter stream.
emptyElement(*name* STRING)	Writes an empty XML element to the StaxWriter stream.
emptyElementNS(*name* STRING, *ns* STRING)	Writes an empty namespace qualified XML element to the StaxWriter stream.
endElement()	Writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last START_ELEMENT.
entityRef(*name* STRING)	Writes an XML EntityReference to the StaxWriter stream.
processingInstruction(*target* STRING,	Writes an XML ProcessingInstruction to the StaxWriter stream

Name	Description
data STRING)	
startElement(*name* STRING)	Writes an XML start element to the StaxWriter stream.
startElementNS(*name* STRING, *ns* STRING)	Writes a namespace-qualified XML start element to the StaxWriter stream.

xml.StaxWriter.attribute

Writes an XML attribute to the StaxWriter stream.

Syntax

```
attribute(
   name STRING,
   value STRING )
```

1. *name* is the local name of the XML attribute. It cannot be NULL.
2. *value* is the value of the XML attribute. It cannot be NULL.

Usage

Attributes can only be written on the StaxWriter stream if it points to a `START_ELEMENT` or an `EMPTY_ELEMENT`, otherwise the operation fails with an exception; that is, this method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.attributeNS

Writes an XML namespace qualified attribute to the StaxWriter stream.

Syntax

```
attributeNS(
   name STRING,
   ns STRING,
   value STRING )
```

1. *name* is the local name of the XML attribute, cannot be NULL.
2. *ns* is the namespace URI of the XML attribute, cannot be NULL.
3. *value* is the value of the XML attribute, cannot be NULL.

Usage

Attributes can only be written on the StaxWriter stream if it points to a `START_ELEMENT` or an `EMPTY_ELEMENT`, otherwise the operation fails with an exception; that is, this method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`.

If namespace URI has not been bound to a prefix with one of the methods `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.cdata

Writes an XML CData to the StaxWriter stream.

Syntax

```
cdata(
   data STRING )
```

1. *data* is the data contained in the CData section, or NULL.

Usage

This method writes XML character data passed as parameter as a CData.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.characters

Writes an XML text to the StaxWriter stream.

Syntax

```
characters(
   text STRING )
```

1. *text* is the value to write.

Usage

This method writes the character string passed as parameter as a text element.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.close

Closes the StaxWriter streaming, and releases all associated resources.

Syntax

```
close()
```

Usage

This method closes the stream.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.comment

Writes an XML comment to the StaxWriter stream.

Syntax

```
comment(
   data STRING )
```

1. *data* is the data in the XML comment, or NULL.

Usage

This method write and XML comment to the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.create

Constructor of a StaxWriter object.

Syntax

```
xml.StaxWriter.create()
  RETURNING object xml.StaxWriter
```

Usage

Returns a new StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.declareDefaultNamespace

Binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.

Syntax

```
declareDefaultNamespace(
   defaultNS STRING )
```

1. *defaultNS* is the URI to bind to the default namespace. It cannot be NULL.

Usage

The stream must point to a START_ELEMENT, and the prefix scope is the current START_ELEMENT / END_ELEMENT pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.declareNamespace

Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

Syntax

```
declareNamespace(
   prefix STRING,
   ns STRING )
```

1. *prefix* is the prefix to be bind to the URI, cannot be NULL.
2. *ns* is the URI to bind to the default namespace, cannot be NULL.

Usage

The stream must point to a `START_ELEMENT`, and the prefix scope is the current `START_ELEMENT` / `END_ELEMENT` pair.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.dtd

Writes a DTD to the StaxWriter stream.

Syntax

```
dtd(
   data STRING )
```

1. *data* is a string representing a valid DTD, cannot be NULL.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.emptyElement

Writes an empty XML element to the StaxWriter stream.

Syntax

```
emptyElement(
   name STRING )
```

1. *name* is the local name of the XML empty element, cannot be NULL.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.emptyElementNS

Writes an empty namespace qualified XML element to the StaxWriter stream.

Syntax

```
emptyElementNS(
```

```
   name STRING,
   ns STRING )
```

1. *name* is the local name of the XML empty element, cannot be NULL.
2. *ns* is the namespace URI of the XML empty element, cannot be NULL.

Usage

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.endDocument

Closes any open tags and writes corresponding end tags.

Syntax

```
endDocument()
```

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.endElement

Writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last `START_ELEMENT`.

Syntax

```
endElement()
```

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.entityRef

Writes an XML EntityReference to the StaxWriter stream.

Syntax

```
entityRef(
   name STRING )
```

1. *name* is the name of the entity, cannot be NULL.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.getFeature

Gets a feature of a StaxWriter object.

Syntax

```
getFeature(
   feature STRING )
  RETURNING str STRING
```

1. *feature* is the name of a feature.

Usage

Returns the feature value. See StaxWriter Features on page 2182.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.processingInstruction

Writes an XML ProcessingInstruction to the StaxWriter stream

Syntax

```
processingInstruction(
   target STRING,
   data STRING )
```

1. *target* is the target of the Processing Instruction, cannot be NULL.
2. *data* is the data of the Processing Instruction, or NULL.

Usage

Writes an XML ProcessingInstruction to the StaxWriter stream, where *target* is the target of the Processing Instruction, cannot be NULL; *data* is the data of the Processing Instruction, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.setDefaultNamespace

Binds a namespace URI to the default namespace.

Syntax

```
setDefaultNamespace(
   defaultNS STRING )
```

1. *defaultNS* is the URI to bind to the default namespace, cannot be NULL.

Usage

Binds a namespace URI to the default namespace. The default namespace scope is the current START_ELEMENT / END_ELEMENT pair; *defaultNS* is the URI to bind to the default namespace, cannot be NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.setFeature

Sets a feature of a StaxWriter object.

Syntax

```
setFeature(
   feature STRING,
   value STRING )
```

1. *feature* is the name of a feature.
2. *value* is the value of the feature.

Usage

Sets a feature of a StaxWriter object, where *feature* is the name of a feature, and *value* is the value of the feature. The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `writeTo` or `writeToDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.setPrefix

Binds a namespace URI to a prefix.

Syntax

```
setPrefix(
   prefix STRING,
   ns STRING )
```

1. *prefix* is the prefix to be bind to the URI, cannot be NULL.
2. *ns* is the namespace URI to be bind to the prefix, cannot be NULL.

Usage

The prefix scope is the current `START_ELEMENT` / `END_ELEMENT` pair.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.startDocument

Writes an XML declaration to the StaxWriter stream.

Syntax

```
startDocument(
   encoding STRING,
   version STRING,
   standalone INTEGER )
```

1. *encoding* is the encoding of the XML declaration, or NULL to use the default UTF-8 encoding.
2. *version* is the XML version of the XML declaration, or NULL to use the default 1.0 version
3. *standalone* when TRUE sets the standalone of the XML declaration to "yes", when FALSE sets it to "no" or NULL.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Example

This call:

```
startDocument("utf-8","1.0",true)
```

Produces:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
dtd("note [<!ENTITY writer \"Donald Duck.\">]")
```

xml.StaxWriter.startElement

Writes an XML start element to the StaxWriter stream.

Syntax

```
startElement(
   name STRING )
```

1. *name* is the local name of the XML start element, cannot be NULL.

Usage

All startElement methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding endElement causes the scope to be closed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.startElementNS

Writes a namespace-qualified XML start element to the StaxWriter stream.

Syntax

```
startElementNS(
   name STRING,
   ns STRING )
```

1. *name* is the local name of the XML start element, cannot be NULL.
2. *ns* is the namespace URI of the XML start element, cannot be NULL.

Usage

All startElementNS methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding endElement causes the scope to be closed.

If namespace URI has not been bound to a prefix with one of the functions setPrefix, declareNamespace, setDefaultNamespace or declareDefaultNamespace, the operation fails with an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.writeTo

Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.

Syntax

```
writeTo(
   url STRING )
```

1. *url* is a valid URL or the name of the file that will contain the resulting XML document.

Usage

Only the following kinds of URLs are supported:

- http://
- https://
- tcp://
- tcps://
- file:///
- alias://

See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Examples

```
writeTo("printerList.xml")
```

```
writeTo("http://myserver:1100/documents/printerList.xml")
```

```
writeTo("https://myserver:1100/documents/printerList.xml")
```

```
writeTo("alias://printerlist")
```

where printerlist alias is defined in fglprofile as ws.printerlist.url = "http://myserver:1100/documents/ptinterList.xml".

xml.StaxWriter.writeToDocument

Sets the output stream of the StaxWriter object to an xml.DomDocument object, and starts the streaming.

Syntax

```
writeToDocument(
   doc xml.DomDocument )
```

1. *doc* is the empty xml.DomDocument object that will contain the resulting XML document.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.writeToPipe

Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.

Syntax

```
writeToPipe(
   cmd STRING )
```

1. *cmd* is the command to start the PIPE that will get the resulting XML document.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxWriter.writeToText

Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.

Syntax

```
writeToText(
   txt TEXT )
```

1. *txt* must be a TEXT lob located in memory that will contain the resulting XML document.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

StaxWriter Features

Features of the `xml.StaxWriter` class.

Table 499: StaxWriter features

Feature	Description
format-pretty-print	Formats the output by adding whitespace to produce a pretty-printed, indented, human-readable form. Default value is FALSE.
smart-ending-elements	Outputs each tag closed with an `endElement()` call as empty elements if they have no children. Default value is FALSE.

Example
This example uses methods from the `xml.StaxWriter` class.

```
IMPORT xml

FUNCTION save(file)
  DEFINE file STRING
  DEFINE writer xml.StaxWriter
  TRY
    LET writer = xml.StaxWriter.Create()
    CALL writer.setFeature("format-pretty-print",TRUE)
    CALL writer.writeTo(file)
    CALL writer.startDocument("utf-8","1.0",true)
    CALL writer.comment("This is my first comment using a stax writer")
    CALL writer.setPrefix("c","http://www.mycompany.com/c")
    CALL writer.setPrefix("d","http://www.mycompany.com/d")
    CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
    CALL writer.startElementNS("root", "http://www.mycompany.com/d")
    CALL writer.attribute("attr1","value1")
    CALL writer.attribute("attr2","value2")
    CALL writer.attributeNS("attr3", "http://www.mycompany.com/d","value3")
    CALL writer.comment("This is a comment using a stax writer")
    CALL writer.startElementNS("eltA", "http://www.mycompany.com/d")
    CALL writer.CData("<this is a CData section>")
    CALL writer.endElement()
    CALL writer.startElementNS("eltB", "http://www.mycompany.com/c")
    CALL writer.characters("Hello world, I'm from the development team")
    CALL writer.entityRef("one")
    CALL writer.endElement()
    CALL writer.processingInstruction("command1","do what you want")
    CALL writer.endElement()
    CALL writer.comment("This is my last comment using a stax writer")
    CALL writer.endDocument()
    CALL writer.close()
    RETURN TRUE
  CATCH
    DISPLAY "StaxWriter ERROR :",STATUS, SQLCA.SQLERRM
    RETURN FALSE
  END TRY
END FUNCTION
```

The StaxReader class
The StaxReader class provides methods compatible with StAX (Streaming API for XML) for reading XML documents.

The `STATUS` variable is set to zero after a successful method call.

Syntax

```
xml.StaxReader
```

xml.StaxReader methods
Methods for the `xml.StaxReader` class.

Table 500: Class methods: Creation

Name	Description
`xml.StaxReader.Create()` `  RETURNING` *`object`* `xml.StaxReader`	Constructor of a StaxReader object.

Table 501: Object methods: Configuration

Name	Description
`setFeature( feature STRING, value STRING )`	Sets a feature of a StaxReader object.
`getFeature( feature STRING ) RETURNING str STRING`	Gets a feature of a StaxReader object.

Table 502: Object methods: Input

Name	Description
`readFrom( url STRING )`	Sets the input stream of the StaxReader object to a file or an URL and starts the streaming
`readFromDocument( doc xml.DomDocument )`	Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming
`readFromText( txt TEXT )`	Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.
`readFromPipe( cmd STRING )`	Sets the input stream of the StaxReader object to a PIPE and starts the streaming.
`close()`	Closes the StaxReader streaming and releases all associated resources.

Table 503: Object methods: Access

Name	Description
`getEventType() RETURNING eventtype STRING`	Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.
`hasName() RETURNING flag INTEGER`	Checks whether the StaxReader cursor points to a node with a name.
`hasText() RETURNING flag INTEGER`	Checks whether the StaxReader cursor points to a node with a text value.
`isEmptyElement()`	Checks whether the StaxReader cursor points to an empty element node.

Name	Description
RETURNING *flag* INTEGER	
isStartElement() RETURNING *flag* INTEGER	Checks whether the StaxReader cursor points to a start element node.
isEndElement() RETURNING *flag* INTEGER	Checks whether the StaxReader cursor points to an end element node.
isCharacters() RETURNING *flag* INTEGER	Checks whether the StaxReader cursor points to a text node.
isIgnorableWhitespace() RETURNING *flag* INTEGER	Checks whether the StaxReader cursor points to ignorable whitespace.

Table 504: Object methods: Document

Name	Description
getEncoding() RETURNING *docenc* STRING	Returns the document encoding defined in the XML Document declaration, or NULL.
getVersion() RETURNING *version* STRING	Returns the document version defined in the XML Document declaration, or NULL.
isStandalone() RETURNING *flag* STRING	Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.
standaloneSet() RETURNING *flag* STRING	Checks whether the document standalone attribute is defined in the XML Document declaration.

Table 505: Object methods: Nodes

Name	Description
getPrefix() RETURNING *prefix* STRING	Returns the prefix of the current XML node, or NULL.
getLocalName() RETURNING *localname* STRING	Returns the local name of the current XML node, or NULL.
getName()	Returns the qualified name of the current XML node, or NULL.

Name	Description
`RETURNING name STRING`	
`getNamespace()` `RETURNING nsuri STRING`	Returns the namespace URI of the current XML node, or NULL.
`getText()` `RETURNING value STRING`	Returns as a string the value of the current XML node, or NULL.

Table 506: Object methods: Processing Instructions

Name	Description
`getPITarget()` `RETURNING target STRING`	Returns the target part of an XML ProcessingInstruction node, or NULL.
`getPIData()` `RETURNING data STRING`	Returns the data part of an XML ProcessingInstruction node, or NULL.

Table 507: Object methods: Attributes

Name	Description
`getAttributeCount()` `RETURNING num INTEGER`	Returns the number of XML attributes defined on the current XML node, or zero.

`getAttributeLocalName(`
`pos INTEGER )`
`RETURNING localname STRING`
	Returns the local name of an XML attribute defined at a given position on the current XML node, or NULL.

`getAttributeNamespace(`
`pos INTEGER )`
`RETURNING nsuri STRING`
	Returns the namespace URI of an XML attribute defined at a given position on the current XML node, or NULL.

`getAttributePrefix(`
`pos INTEGER )`
`RETURNING prefix STRING`
	Returns the prefix of an XML attribute defined at a given position on the current XML node, or NULL.

`getAttributeValue(`
`pos INTEGER )`
`RETURNING value STRING`
	Returns the value of an XML attribute defined at a given position on the current XML node, or NULL.

`findAttributeValue(`
`name STRING,`
`ns STRING )`
`RETURNING value STRING`
	Returns the value of an XML attribute of a given name and/or namespace on the current XML node, or NULL.

Table 508: Object methods: Namespace

Name	Description
`lookupNamespace( prefix STRING ) RETURNING nsuri STRING`	Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.
`lookupPrefix( ns STRING ) RETURNING prefix STRING`	Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.
`getNamespaceCount() RETURNING num INTEGER`	Returns the number of namespace declarations defined on the current XML node, or zero.
`getNamespacePrefix( pos INTEGER ) RETURNING prefix STRING`	Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.
`getNamespaceURI( pos INTEGER ) RETURNING nsuri STRING`	Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.

Table 509: Object methods: Navigation

Name	Description
`hasNext() RETURNING flag INTEGER`	Checks whether the StaxReader cursor can be moved to a XML node next to it.
`next()`	Moves the StaxReader cursor to the next XML node.
`nextTag()`	Moves the StaxReader cursor to the next XML open or end tag
`nextSibling()`	Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.

xml.StaxReader.close

Closes the StaxReader streaming and releases all associated resources.

Syntax

```
close()
```

Usage

This method closes the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.Create

Constructor of a StaxReader object.

Syntax

```
xml.StaxReader.Create()
  RETURNING object xml.StaxReader
```

Usage

Returns a StaxReader object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.findAttributeValue

Returns the value of an XML attribute of a given name and/or namespace on the current XML node, or NULL.

Syntax

```
findAttributeValue(
   name STRING,
   ns STRING )
  RETURNING value STRING
```

1. *name* is the name of the attribute to retrieve. It cannot be NULL.
2. *ns* is the namespace URI of the attribute to retrieve, or NULL if the attribute is not namespace-qualified.

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getAttributeCount

Returns the number of XML attributes defined on the current XML node, or zero.

Syntax

```
getAttributeCount()
  RETURNING num INTEGER
```

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getAttributeLocalName

Returns the local name of an XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```
getAttributeLocalName(
   pos INTEGER )
  RETURNING localname STRING
```

1. *pos* is the position of the attribute to return (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getAttributeNamespace

Returns the namespace URI of an XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```
getAttributeNamespace(
   pos INTEGER )
  RETURNING nsuri STRING
```

1. *pos* is the position of the attribute to return (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getAttributePrefix

Returns the prefix of an XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```
getAttributePrefix(
   pos INTEGER )
  RETURNING prefix STRING
```

1. *pos* is the position of the attribute to return (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getAttributeValue

Returns the value of an XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```
getAttributeValue(
   pos INTEGER )
  RETURNING value STRING
```

1. *pos* is the position of the attribute to return (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getEncoding

Returns the document encoding defined in the XML Document declaration, or NULL.

Syntax

```
getEncoding()
  RETURNING docenc STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getEventType

Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.

Syntax

```
getEventType()
  RETURNING eventtype STRING
```

Usage

See StaxReader Event Types on page 2200 for the full list of StaxReader event types.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getFeature

Gets a feature of a StaxReader object.

Syntax

```
getFeature(
   feature STRING )
  RETURNING str STRING
```

1. *feature* is the name of a feature.

Usage

See StaxReader Features on page 2200 for the full list of StaxReader features.

Returns the feature value.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getLocalName

Returns the local name of the current XML node, or NULL.

Syntax

```
getLocalName()
  RETURNING localname STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getName

Returns the qualified name of the current XML node, or NULL.

Syntax

```
getName()
  RETURNING name STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getNamespace

Returns the namespace URI of the current XML node, or NULL.

Syntax

```
getNamespace()
  RETURNING nsuri STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getNamespaceCount

Returns the number of namespace declarations defined on the current XML node, or zero.

Syntax

```
getNamespaceCount()
```

```
  RETURNING num INTEGER
```

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getNamespacePrefix

Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```
getNamespacePrefix(
   pos INTEGER )
  RETURNING prefix STRING
```

1. *pos* is the position of the namespace declaration (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getNamespaceURI

Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```
getNamespaceURI(
   pos INTEGER )
  RETURNING nsuri STRING
```

1. *pos* is the position of the namespace declaration (Index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getPIData

Returns the data part of an XML ProcessingInstruction node, or NULL.

Syntax

```
getPIData()
  RETURNING data STRING
```

Usage

This method is only valid on a `PROCESSING_INSTRUCTION` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getPITarget

Returns the target part of an XML ProcessingInstruction node, or NULL.

Syntax

```
getPITarget()
  RETURNING target STRING
```

Usage

This method is only valid on a `PROCESSING_INSTRUCTION` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getPrefix

Returns the prefix of the current XML node, or NULL.

Syntax

```
getPrefix()
  RETURNING prefix STRING
```

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getText

Returns as a string the value of the current XML node, or NULL.

Syntax

```
getText()
  RETURNING value STRING
```

Usage

This method is only valid on `CHARACTERS`, `CDATA`, `SPACE`, `COMMENT`, `DTD` and `ENTITY_REFERENCE` nodes. For an `ENTITY_REFERENCE`, this method returns the replacement value, or NULL if none.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.getVersion

Returns the document version defined in the XML Document declaration, or NULL.

Syntax

```
getVersion()
  RETURNING version STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.hasName

Checks whether the StaxReader cursor points to a node with a name.

Syntax

```
hasName()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node has a name, FALSE otherwise. This method returns TRUE for START_ELEMENT and END_ELEMENT, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.hasNext

Checks whether the StaxReader cursor can be moved to a XML node next to it.

Syntax

```
hasNext()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if there is still an XML node in the stream, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.hasText

Checks whether the StaxReader cursor points to a node with a text value.

Syntax

```
hasText()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node has a text value, FALSE otherwise. This method returns TRUE for `CHARACTERS`, `SPACE`, `CDATA`, `COMMENT`, `ENTITY_REFERENCE` and `DTD`, FALSE for all other nodes.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isCharacters

Checks whether the StaxReader cursor points to a text node.

Syntax

```
isCharacters()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is a text node, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isEmptyElement

Checks whether the StaxReader cursor points to an empty element node.

Syntax

```
isEmptyElement()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML element node has no children, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isEndElement

Checks whether the StaxReader cursor points to an end element node.

Syntax

```
isEndElement()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is an end element node, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isIgnorableWhitespace

Checks whether the StaxReader cursor points to ignorable whitespace.

Syntax

```
isIgnorableWhitespace()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is an ignorable text node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isStandalone

Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.

Syntax

```
isStandalone()
  RETURNING flag STRING
```

Usage

Returns TRUE if the standalone attribute in the XML declaration is set to yes, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.isStartElement

Checks whether the StaxReader cursor points to a start element node.

Syntax

```
isStartElement()
  RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is a start element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.lookupNamespace

Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.

Syntax

```
lookupNamespace(
   prefix STRING )
  RETURNING nsuri STRING
```

1. *prefix* is the prefix to look for; if NULL the default namespace URI will be returned..

Usage

Returns the namespace URI associated with the prefix, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.lookupPrefix

Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.

Syntax

```
lookupPrefix(
   ns STRING )
  RETURNING prefix STRING
```

1. *ns* is the namespace URI to look for. It cannot be NULL.

Usage

Returns the prefix associated with this namespace URI, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.next

Moves the StaxReader cursor to the next XML node.

Syntax

```
next()
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.nextSibling

Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.

Syntax

```
nextSibling()
```

Usage

The cursor points to the parent end tag if there are no siblings.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.nextTag

Moves the StaxReader cursor to the next XML open or end tag

Syntax

```
nextTag()
```

Usage

The cursor points to the end of the document if there is no next XML open or end tag.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.readFrom

Sets the input stream of the StaxReader object to a file or an URL and starts the streaming

Syntax

```
readFrom(
   url STRING )
```

1. *url* is a valid URL or the name of the file to read.

Usage

Only the following kinds of URLs are supported:

- http://
- https://
- tcp://
- tcps://
- file:///
- alias://

See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.readFromDocument

Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming

Syntax

```
readFromDocument(
   doc xml.DomDocument )
```

1. *doc* is an XML/DomDocument object that contains an XML document.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.readFromPipe

Sets the input stream of the StaxReader object to a PIPE and starts the streaming.

Syntax

```
readFromPipe(
   cmd STRING )
```

1. *cmd* is the command to start the PIPE and where the reader will get the XML from.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.readFromText

Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.

Syntax

```
readFromText(
   txt TEXT )
```

1. *txt* must be a TEXT lob located in memory and containing the XML to read.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.setFeature

Sets a feature of a StaxReader object.

Syntax

```
setFeature(
   feature STRING,
   value STRING )
```

1. *feature* is the name of a feature.
2. *value* is the value of the feature.

Usage

See StaxReader Features on page 2200 for the full list of StaxReader features.

The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `readFrom` or `readFromDocument`).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.StaxReader.standaloneSet

Checks whether the document standalone attribute is defined in the XML Document declaration.

Syntax

```
standaloneSet()
  RETURNING flag STRING
```

Usage

Returns TRUE if the standalone attribute in the XML declaration is set, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

StaxReader Features
Features of the xml.StaxReader class.

Table 510: StaxReader Features

Feature	Description
expand-entity-references	Defines whether XML EntityReference nodes are kept or replaced during the parsing of an XML document. Default value is TRUE.

StaxReader Event Types
Event types of the xml.StaxReader class.

Table 511: StaxReader event types

Type	Description	XML sample
START_DOCUMENT	StaxReader cursor points to the beginning of the XML document.	<?xml version="1.0" standalone="no"?>
END_DOCUMENT	StaxReader cursor has reached the end of the XML document. No additional parsing operation will succeed.	
START_ELEMENT	StaxReader cursor points to an XML start element or empty element node.	<p:elt attr="val"> or <p:elt attr="val"/>
END_ELEMENT	StaxReader cursor points to an XML end element node.	</p:elt>
CHARACTERS	StaxReader cursor points to an XML text node.	... eltA/>This is text<eltB ...

Type	Description	XML sample
CDATA	StaxReader cursor points to an XML CData node.	`<![CDATA[<Hello, world!>]]>`
SPACE	StaxReader cursor points to an XML text node containing only whitespaces.	`... eltA/> <eltB ...`
COMMENT	StaxReader cursor points to an XML comment node.	`<!-- a comment -->`
DTD	StaxReader cursor points to a DTD string.	`<!DOCTYPE A [ <!ELEMENT B (C +)> ]>`
ENTITY_REFERENCE	StaxReader cursor points to an XML entity reference node.	`&ref;`
PROCESSING_INSTRUCTION	StaxReader cursor points to an XML processing instruction node.	`<?target data?>`
ERROR	StaxReader cursor points to an unexpected XML node.	

Example
Example using methods of the `xml.StaxReader` class.

```
IMPORT  xml

FUNCTION  parse(file  )
  DEFINE  file     STRING
  DEFINE  event    STRING
  DEFINE  ret      INTEGER
  DEFINE  ind      INTEGER
  DEFINE  reader   xml.StaxReader

END FUNCTION
```

XML serialization classes

The XML serialization classes convert BDL variables to XML and XML to BDL variables.

- CLASS Serializer
  - Option flags

The Serializer class

The `xml.Serializer` class provides methods to manage options for the serializer engine, and to use the serializer engine to serialize variables and XML element nodes.

This class is a static class and does not have to be instantiated.

The STATUS variable is set to zero after a successful method call.

xml.Serializer methods
Methods for the `xml.Serializer` class.

Table 512: Class methods

Name	Description
`xml.Serializer.CreateXmlSchemas( var fgl-type, ar DYNAMIC ARRAY OF xml.DomDocument )`	Creates XML schemas corresponding to the given variable *var*, and fills the dynamic array *ar* with xml.DomDocument objects each representing an XML schema.
`xml.Serializer.DomToStax( node xml.DomNode, stax xml.StaxWriter )`	Serializes an XML node object to a StaxWriter object.
`xml.Serializer.DomToVariable( node xml.DomNode, var fgl-type )`	Serializes an XML element node into a BDL variable using a DomNode object.
`xml.Serializer.GetOption( flag STRING ) RETURNING value STRING`	Gets a global option value from the serializer engine.
`xml.Serializer.SetOption( flag STRING, value STRING )`	Sets a global option value for the serializer engine
`xml.Serializer.SoapSection5ToVariable( node xml.DomNode, var fgl-type )`	Serializes an XML element node into a BDL variable in Soap Section 5 encoding.
`xml.Serializer.StaxToVariable( stax xml.StaxReader, var fgl-type )`	Serializes an XML element node into a BDL variable using a StaxReader object.
`xml.Serializer.StaxToDom( stax xml.StaxReader, node xml.DomNode )`	Serializes an XML element node into a DomNode object using a StaxReader object.
`xml.Serializer.VariableToDom( var fgl-type, node xml.DomNode )`	Serializes a BDL variable into an XML element node using a DomNode object.
`xml.Serializer.VariableToSoapSection5( var fgl-type,`	Serializes a BDL variable into an XML element node in Soap Section 5 encoding.

Name	Description
node xml.DomNode)	
xml.Serializer.VariableToStax(*var fgl-type*, *stax* xml.StaxWriter)	Serializes a BDL variable into an XML element node using a StaxWriter object.

xml.Serializer.CreateXmlSchemas

Creates XML schemas corresponding to the given variable *var*, and fills the dynamic array *ar* with xml.DomDocument objects each representing an XML schema.

Syntax

```
xml.Serializer.CreateXmlSchemas(
   var fgl-type,
   ar DYNAMIC ARRAY OF xml.DomDocument )
```

1. *var* is a given variable.
2. *ar* is a dynamic array of xml.DomDocument objects, each representing an XML schema.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.DomToStax

Serializes an XML node object to a StaxWriter object.

Syntax

```
xml.Serializer.DomToStax(
   node xml.DomNode,
   stax xml.StaxWriter )
```

1. *node* is an XML DomNode object.
2. *stax* is a StaxWriter object.

Usage

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.DomToVariable

Serializes an XML element node into a BDL variable using a DomNode object.

Syntax

```
xml.Serializer.DomToVariable(
   node xml.DomNode,
   var fgl-type )
```

1. *node* is a DomNode object of type `ELEMENT_NODE`.
2. *var* is any BDL variable with optional XML mapping attributes.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.getOption

Gets a global option value from the serializer engine.

Syntax

```
xml.Serializer.GetOption(
   flag STRING )
  RETURNING value STRING
```

1. *flag* is the option flag.

Usage

Returns the value of the flag.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.setOption

Sets a global option value for the serializer engine

Syntax

```
xml.Serializer.SetOption(
   flag STRING,
   value STRING )
```

1. *flag* is the option flag.
2. *value* is the value of the flag.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.SoapSection5ToVariable

Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

Syntax

```
xml.Serializer.SoapSection5ToVariable(
   node xml.DomNode,
   var fgl-type )
```

1. *node* is a DomNode object of type `ELEMENT_NODE`.
2. *var* is any BDL variable with optional XML mapping attributes.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.StaxToDom

Serializes an XML element node into a DomNode object using a StaxReader object.

Syntax

```
xml.Serializer.StaxToDom(
   stax xml.StaxReader,
   node xml.DomNode )
```

1. *stax* is a StaxReader object where the cursor points to an XML Element node,
2. *node* is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.

Usage

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.StaxToVariable

Serializes an XML element node into a BDL variable using a StaxReader object.

Syntax

```
xml.Serializer.StaxToVariable(
   stax xml.StaxReader,
   var fgl-type )
```

1. *stax* is a StaxReader object where the cursor points to an XML Element node.
2. *var* is any BDL variable with optional XML mapping attributes.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.VariableToDom

Serializes a BDL variable into an XML element node using a DomNode object.

Syntax

```
xml.Serializer.VariableToDom(
   var fgl-type,
   node xml.DomNode )
```

1. *var* is any BDL variable with optional XML mapping attributes.
2. *node* is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.

Usage

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.VariableToSoapSection5

Serializes a BDL variable into an XML element node in Soap Section 5 encoding.

Syntax

```
xml.Serializer.VariableToSoapSection5(
   var fgl-type,
   node xml.DomNode )
```

1. *var* is any BDL variable with optional XML mapping attributes.
2. *node* is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.

Usage

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Serializer.VariableToStax

Serializes a BDL variable into an XML element node using a StaxWriter object.

Syntax

```
xml.Serializer.VariableToStax(
   var fgl-type,
   stax xml.StaxWriter )
```

1. *var* is any BDL variable with optional XML mapping attributes.
2. *stax* is a StaxWriter object.

Usage

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Serialization option flags

Serialization option flags for the xml.Serializer class.

Table 513: Serialization option flags

Flag	Description
xml_ignoretimezone	Defines whether, during the marshalling and un-marshalling process of a BDL DATETIME data

Flag	Description
	type, the Serializer should ignore the time zone information. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.
xml_usetypedefinition	Defines whether the Serializer must specify the type of data during serialization. This will add an "xsi:type" attribute to each XML data type. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.
xml_useutctime	Defines whether, during the marshalling process of a BDL DATETIME data type, the Serializer should convert it into UTC time. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.
xs_processcontents	Defines the way to generate wildcard elements and attributes in XML schemas via the XML schema **processContents** tag. See Table 514: Values for xs_processcontents on page 2208 Throws an exception in case of errors, and updates status with an error code.

Table 514: Values for xs_processcontents

Value	Description
0	No processContents tag will be generated. **(default)**
1	Generation of **processContents="skip"**.
2	Generation of **processContents="lax"**.
3	Generation of **processContents="strict"**.

XML security classes

XML Security classes handle encryption and signature of XML documents entirely in memory with keys and certificates.

Important: The XML security classes are not supported on GMI mobile devices.

- CLASS CryptoKey
  - Keys
- CLASS CryptX509

- CLASS Encryption
- CLASS Signature
  - Digests
  - Transformations
- CLASS KeyStore

The CryptoKey class
The `xml.CryptoKey` class provides methods to manipulate HMAC, symmetric and asymmetric keys needed for signing, verifying, encrypting and decrypting XML documents or document fragments.

It follows the XML-Signature and XML-Encryption specifications.

The `STATUS` variable is set to zero after a successful method call.

> **Important:** This class is not supported on GMI mobile devices.

xml.CryptoKey methods
Methods for the `xml.CryptoKey` class.

Table 515: Class methods: Creation

Name	Description

`xml.CryptoKey.Create(`
`  url STRING )`
`RETURNING object xml.CryptoKey`
	Initializes an xml.CryptoKey object. Constructor of an empty CryptoKey object depending on a url.

`xml.CryptoKey.CreateDerivedKey(`
`  url STRING )`
`RETURNING object xml.CryptoKey`
	Constructor of an empty CryptoKey object intended to be derived before use, and depending on a url.

`xml.CryptoKey.CreateFromNode(`
`  url STRING,`
`  node xml.DomNode )`
`RETURNING object xml.CryptoKey`
	Constructor of a new CryptoKey object depending on a url and from a XML node, according to the XML-Signature and XML-Encryption specification.

Table 516: Object methods: Access

Name	Description

`compareTo(`
`  secondKey xml.CryptoKey )`
`RETURNING flag INTEGER`
	Compares a CryptoKey object to a second key.

`getSHA1()` `RETURNING keyId STRING`	Returns the SHA1 encoded key identifier in a base64 encoded STRING.
`getSize()` `RETURNING size INTEGER`	Returns the size of the key in bits.
`getType()`	Returns the type of key.

Name	Description
RETURNING *type* STRING	
getUsage() RETURNING *usage* STRING	Returns the usage of the key.
getUrl() RETURNING *keyId* STRING	Returns the key identifier as an URL, as defined in the XML-Signature and XML-Encryption specification.

See also The Diffie-Hellman key agreement algorithm on page 2447.

Table 517: Object methods: Modify

Name	Description
deriveKey(*method* STRING, *label* STRING, *seed* STRING, *created* STRING, *offset* INTEGER, *size* INTEGER)	Derives the symmetric or HMAC CryptoKey object using the given *method* identifier and concatenating the optional *label*, the mandatory *seed* value and the optional *created* date as initial random value.
generateKey(*size* INTEGER)	Generates a random key of given size (in bits).
setKey(*key* STRING)	Defines the value of a HMAC or Symmetric key.

Table 518: Object methods: Load, save, and compute

Name	Description
computeKey(*otherPubKey* xml.CryptoKey, *url* STRING) RETURNING *sharedSecret* xml.CryptoKey	Computes the shared secret based on the given modulus, generator, the private key and the other peer's public key. The returned key can be any of symmetric/HMAC or symmetric/encryption key type. It can be used for symmetric signature or symmetric encryption.
loadBIN(*file* STRING)	Loads a symmetric or HMAC key from a file in raw format.
loadDER(*file* STRING)	Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in DER format.
loadFromString(	Loads the given key in BASE64 string format into a CryptoKey object.

Name	Description
str STRING)	
loadPEM(*file* STRING)	Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in PEM format.
loadPrivate(*xml* xml.DomDocument)	Loads the private asymmetric RSA key in the given XML document into the private part of this CryptoKey object, according to the XKMS2.0 specification.
loadPublic(*xml* xml.DomDocument)	Loads the public asymmetric RSA or DSA key in the given XML document into the public part of this CryptoKey object, according to the XML-Signature specification for DSA and RSA key value.
loadPublicFromString(*pubKeyStr* STRING)	Populate the current CryptoKey object with the passed public key.
savePrivate() RETURNING *object* xml.DomDocument	Saves the private part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.
savePublic() RETURNING *object* xml.DomDocument	Saves the public part of an asymmetric RSA or DSA CryptoKey object or the parameters and the public key of the Diffie-Hellman object into a XML document according to the XML-Signature specification for DSA and RSA and Diffie-Hellman key values.
savePublicToString() RETURNING *str* STRING	Save the current `xml.CryptoKey`'s public part in the returned base64 string.
saveToString() RETURNING *str* STRING	Saves the CryptoKey object into a BASE64 string format.

Table 519: Object methods: Feature

Name	Description
getFeature(*feature* STRING) RETURNING *value* STRING	Returns the value of the given feature for this CryptoKey object, or NULL.
setFeature(*feature* STRING, *value* STRING)	Sets or resets the value of a feature for a CryptoKey object.

Compares a CryptoKey object to a second key.

Syntax

```
compareTo(
   secondKey xml.CryptoKey )
  RETURNING flag INTEGER
```

1. *secondKey* is the xml.CryptoKey object to use for comparison to the current CryptoKey object.

Usage

The method verifies if the keys URL, type, size, usage and value are the same. If they are the same, the two identical keys will produce the same encryption cipher.

The key features are not taken into account during comparison.

Returns TRUE if they are identical, FALSE if they are not identical.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.computeKey

Computes the shared secret based on the given modulus, generator, the private key and the other peer's public key. The returned key can be any of symmetric/HMAC or symmetric/encryption key type. It can be used for symmetric signature or symmetric encryption.

Syntax

```
computeKey(
   otherPubKey xml.CryptoKey,
   url STRING )
  RETURNING sharedSecret xml.CryptoKey
```

1. *otherPubKey* is the other peer's public key (xml.CryptoKey).
2. *url* is the shared secret key type as an url identifier (STRING)..

Usage

> **Important:** This method is for Diffie-Hellman key-agreement algorithm only.

Returns an xml.CryptoKey sharedSecret: An xml.CryptoKey object of the specified type.

In the 3DES case, no key weakness test is done. If the compound shared secret is week, the other peer inovled in the communication may raise an error. It depends on the language used on the other side.

In order to be able to compute an AES256 shared secret of the Java™ side, you need to add or relace the files local_policy.jar and US_export_policy.jar located in $JDK_HOME/jre/lib/security by the Java™ Cryptographic Extension correspoinding to your JDK version. You can find this extension at http://www.oracle.com/technetwork/java/javase/downloads/index.html.

If the shared secret key length is less than the Diffie-Hellman key length, only the first needed bytes will be taken. For example, if the Diffie-Hellman is 512 bits length and the shared secret is a 3DES key, then only the first 192 bits will be used by the computation. In a 3DES shared secret case, xml.CryptoKey.computeKey() is calculated, where in AES shared secret case, the Diffie-Hellman key is truncated.

If the shared secret key length is bigger than the Diffie-Hellman key length, an error is raised.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.Create

Initializes an xml.CryptoKey object. Constructor of an empty CryptoKey object depending on a url.

Syntax

```
xml.CryptoKey.Create(
   url STRING )
  RETURNING object xml.CryptoKey
```

1. *url* defines a key identifier according to the XML-Signature and XML-Encryption specification or the Diffie-Hellman specification.

Usage

Returns a CryptoKey object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.CreateDerivedKey

Constructor of an empty CryptoKey object intended to be derived before use, and depending on a url.

Syntax

```
xml.CryptoKey.CreateDerivedKey(
   url STRING )
  RETURNING object xml.CryptoKey
```

1. *url* defines a key identifier according to the XML-Signature and XML-Encryption specification.

Usage

Returns a CryptoKey object or NULL. Only symmetric and HMAC keys can be derived.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.CreateFromNode

Constructor of a new CryptoKey object depending on a url and from a XML node, according to the XML-Signature and XML-Encryption specification.

Syntax

```
xml.CryptoKey.CreateFromNode(
   url STRING,
   node xml.DomNode )
  RETURNING object xml.CryptoKey
```

1. *url* defines a key identifier restricted to PUBLIC/PRIVATE keys.
2. *node* is an ELEMENT node whose local name is either:
   - **DSAKeyValue** or **RSAKeyValue** and belonging to the XML-Signature namespace **http://www.w3.org/2000/09/xmldsig#**
   - **RSAKeyPair** and belonging to the XKMS 2.0 namespace**http://www.w3.org/2002/03/xkms#**

Usage

Returns a CryptoKey object or NULL.

If the local name is RSAKeyValue or RSAKeyPair, the URL must be a RSA key. If the local name is DSAKeyValue, the URL must be a DSA key.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.deriveKey

Derives the symmetric or HMAC CryptoKey object using the given *method* identifier and concatenating the optional *label*, the mandatory *seed* value and the optional *created* date as initial random value.

Syntax

```
deriveKey(
   method STRING,
   label STRING,
   seed STRING,
   created STRING,
   offset INTEGER,
   size INTEGER )
```

1. *method* is the identifier of the algorithm to apply to the password and its inputs.
2. *label* is the optional label input.
3. *seed*, the mandatory seed input, is the a valid Base64 string representing a random binary data you can obtain with the security.RandomGenerator.CreateRandomNumber on page 2279 helper method.
4. *created* is the optional created date input.
5. *offset* is the number of bytes the resulting octet stream must be shifted to obtain the derived key.
6. *size* defines the number of bytes of the resulting derived key.

Usage

If it is a symmetric key, the size can be 0, or must match the original key according to key identifier.

See Derived keys on page 2224 for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.generateKey

Generates a random key of given size (in bits).

Syntax

```
generateKey(
   size INTEGER )
```

1. *size* is the size of the key to generate.

Usage

For symmetric keys, the size is fixed by the key identifier and cannot be changed. The only authorized values are the real key size or NULL.

For Diffie-Hellman, the input parameter (size INTEGER) is the size of the Diffie-Hellman modulus. If the given size is greater than zero (0), it populates the Diffie-Hellman object by randomly generating a modulus

of the given size and a private key, and computes the public key. The used generator is two (2). If the given size is zero (0), it completes the Diffie-Hellman object by choosing a private key and computing the public key according to the previously loaded parameters. For more details on loading parameters, see Table 526: Object methods: Load and save on page 2228.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getFeature

Returns the value of the given feature for this CryptoKey object, or NULL.

Syntax

```
getFeature(
   feature STRING )
  RETURNING value STRING
```

1. *feature* is the CryptoKey feature.

Usage

Returns NULL if the feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getSHA1

Returns the SHA1 encoded key identifier in a base64 encoded STRING.

Syntax

```
getSHA1()
  RETURNING keyId STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getSize

Returns the size of the key in bits.

Syntax

```
getSize()
  RETURNING size INTEGER
```

Usage

For a Diffie-Hellman key, returns the size of the key; the size of a Diffie-Hellman key is actually the size of the modulus. If the modulus is not available (null or equal to zero), the method returns zero. In this situation, a return of zero does NOT mean the key is corrupt or unusable.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getType
Returns the type of key.

Syntax

```
getType()
  RETURNING type STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getUrl
Returns the key identifier as an URL, as defined in the XML-Signature and XML-Encryption specification.

Syntax

```
getUrl()
  RETURNING keyId STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.getUsage
Returns the usage of the key.

Syntax

```
getUsage()
  RETURNING usage STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadBIN
Loads a symmetric or HMAC key from a file in raw format.

Syntax

```
loadBIN(
   file STRING )
```

1. *file* is the file name or an entry in the FGLPROFILE file.

Usage

Raw format means that the data in the file are read without any transformation, and will be stored as it in the key.

For instance, if you file contains **hello**, it has the same effect as calling setKey() with **hello** as parameter.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadDER

Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in DER format.

Syntax

```
loadDER(
   file STRING )
```

1. *file* is the file name or an entry in the FGLPROFILE file.

Usage

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the `openssl` tool and to put the key file on a restricted file system. However, you can use a script or the `fglpass` agent to provide the password to the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadFromString

Loads the given key in BASE64 string format into a CryptoKey object.

Syntax

```
loadFromString(
   str STRING )
```

1. *str* is the string to load.

Usage

For Diffie-Hellman, the input parameter is a base64 encoded string containing the Diffie-Hellman parameters. This method populates the Diffie-Hellman key with the modulus and generator in the base64 encoded string. This is useful for the parameters exchange step between two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadPEM

Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in PEM format.

Syntax

```
loadPEM(
   file STRING )
```

1. *file* is the file name or an entry in the FGLPROFILE file.

Usage

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the `openssl` tool and to put the key file on a restricted file system. However, you can use a script or the `fglpass` agent to provide the password to the application.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadPrivate

Loads the private asymmetric RSA key in the given XML document into the private part of this CryptoKey object, according to the XKMS2.0 specification.

Syntax

```
loadPrivate(
   xml xml.DomDocument )
```

1. *xml* is a DomDocument object.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadPublic

Loads the public asymmetric RSA or DSA key in the given XML document into the public part of this CryptoKey object, according to the XML-Signature specification for DSA and RSA key value.

Syntax

```
loadPublic(
   xml xml.DomDocument )
```

Usage

For Diffie-Hellman, the input parameter is an xml.DomDocument object containing a representation of the Diffie-Hellman key. This method populates the Diffie-Hellman object with the parameters and the public key contained in the given xml.DomDocument according to the XML-Signature specification for the Diffie-Hellman key values. If the public key node exists in the xml document but is empty, it won't be possible to use the key unless the document contains valid modulus and generator parameters and you call `generateKey` with a size of zero (0). In this case, you won't be in possession of the other peer's public key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.loadPublicFromString

Populate the current CryptoKey object with the passed public key.

Syntax

```
loadPublicFromString(
   pubKeyStr STRING )
```

1. *pubKeyStr* is the public part of the key in base64 form.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.savePrivate

Saves the private part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.

Syntax

```
savePrivate()
  RETURNING object xml.DomDocument
```

Usage

Returns an DomDocument object containing the private part of an asymmetric RSA key.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.savePublic

Saves the public part of an asymmetric RSA or DSA CryptoKey object or the parameters and the public key of the Diffie-Hellman object into a XML document according to the XML-Signature specification for DSA and RSA and Diffie-Hellman key values.

Syntax

```
savePublic()
  RETURNING object xml.DomDocument
```

Usage

For Diffie-Hellman, it is useful for the public key exchange between the two peers.

See also the RetrievalMethod feature.

Returns an DomDocumentobject.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.savePublicToString

Save the current xml.CryptoKey's public part in the returned base64 string.

Syntax

```
savePublicToString()
  RETURNING str STRING
```

Usage

Returns the public part of the key in base64 form (STRING).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.saveToString

Saves the CryptoKey object into a BASE64 string format.

Syntax

```
saveToString()
  RETURNING str STRING
```

Usage

For Diffie-Hellman, returns the Diffie-Hellman key's modulus and generator in a base64 encoded string. This is useful for the parameters exchange step between the two peers.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.setFeature

Sets or resets the value of a feature for a CryptoKey object.

Syntax

```
setFeature(
   feature STRING,
   value STRING )
```

1. *feature* is the name of the feature.
2. *value* is the value to set for the named feature.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoKey.setKey

Defines the value of a HMAC or Symmetric key.

Syntax

```
setKey(
   key STRING )
```

1. *key* is the value.

Usage

The value can be a password and must be of the size corresponding to the key identifier.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

Supported kind of keys
Supported kind of keys for the `xml.CryptoKey` class.

Table 520: Supported kind of keys

Identifier	Description	Usage	Type
http://www.w3.org/2000/09/xmldsig#dsa-sha1	Asymmetric DSA key with SHA1 for signature purposes. Uses a private DSA key for signature and needs an associated public DSA key or X509 certificate containing it, to verify it. See specification for details.	SIGNATURE	PUBLIC or PRIVATE
http://www.w3.org/2000/09/xmldsig#rsa-sha1	Asymmetric RSA key with SHA1 for signature purposes. Uses a private RSA key for signature and needs an associated public RSA key or X509 certificate containing it, to verify it. See specification for details.	SIGNATURE	PUBLIC or PRIVATE
http://www.w3.org/2001/04/xmldsig-more#rsa-sha256	Asymmetric RSA key with SHA256 for signature purposes. Uses a private RSA key for signature and needs an associated public RSA key or X509 certificate containing it, to verify it. See specification for details.	SIGNATURE	PUBLIC or PRIVATE
http://www.w3.org/2000/09/xmldsig#hmac-sha1	Message Authentication Code key with SHA1 for signature purposes. Uses a same password for signature and to verify it, and key size is free. See specification for details.	SIGNATURE	HMAC

Identifier	Description	Usage	Type
http://www.w3.org/2001/04/xmldsig-more#hmac-sha256	Message Authentication Code key with SHA256 for signature purposes. Uses a same password for signature and to verify it, and key size is free. See specification for details.	SIGNATURE	HMAC
http://www.w3.org/2001/04/xmlenc#aes128-cbc	Symmectric AES128 key for encryption purposes. Uses a common key of 128bits for encrypting and decrypting XML documents. See specification for details.	ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#aes192-cbc	Symmetric AES192 key for encryption purposes. Uses a common key of 192bits for encrypting and decrypting XML documents. See specification for details.	ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#aes256-cbc	Symmetric AES256 key for encryption purposes. Uses a common key of 256bits for encrypting and decrypting XML documents. See specification for details.	ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#tripledes-cbc	Symmetric TripleDes key for encryption purposes. Uses a common key of 192bits for encrypting and decrypting XML documents. See specification for details.	ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#kw-aes128	Symmetric AES128 key wrap for key encryption purposes.	KEY ENCRYPTION	SYMMETRIC

Identifier	Description	Usage	Type
	Uses a common key of 128bits for encrypting and decrypting a symmetric key. See specification for details.		
http://www.w3.org/2001/04/xmlenc#kw-aes192	Symmetric AES192 key wrap for key encryption purposes. Uses a common key of 192bits for encrypting and decrypting a symmetric key. See specification for details.	KEY ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#kw-aes256	Symmetric AES256 key wrap for key encryption purposes. Uses a common key of 256bits for encrypting and decrypting a symmetric key. See specification for details.	KEY ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#kw-tripledes	Symmetric TripleDes key wrap for key encryption purposes. Uses a common key of 192bits for encrypting and decrypting a symmetric key. See specification for details.	KEY ENCRYPTION	SYMMETRIC
http://www.w3.org/2001/04/xmlenc#rsa-1_5	Asymmetric RSA key for key encryption purposes. Uses a public RSA key or a X509 certificate containing it to encrypt a symmetric key, and needs the associated private RSA key to decrypt it. See specification for details.	KEY ENCRYPTION	PUBLIC or PRIVATE

Identifier	Description	Usage	Type
http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p	Asymmetric RSA key for key encryption purposes. Uses a public RSA key or a X509 certificate containing it to encrypt a symmetric key, and needs the associated private RSA key to decrypt it. See specification for details.	KEY ENCRYPTION	PUBLIC or PRIVATE
Diffie-Hellman identifier: http://www.w3.org/2001/04/xmlenc#DHKeyValue	Diffie-Hellman key agreement algorithm. Derives a shared secret. The resulting shared secret is a HMAC or symmetric key for encryption purposes.	KEY AGREEMENT	PUBLIC or PRIVATE

Derived keys

Key derivation is used on symmetric or HMAC keys to avoid the direct usage of a shared secret password in secured operations. If two parties share a secret password that is successfully hacked by a third party, any future operation becomes unsecure, and the initial two parties do not even realize that their exchanges are unsafe. However, if a different password based on that shared secret password is used for each new secured operation, even if one operation is compromised, it will only unsecure that operation, but not other operations.

The derivation consists of applying an algorithm with some additional inputs (such as a random seed value) to a password in order to obtain another password that is then used in one secured operation. Of course, the algorithm and its additional inputs must also be shared to enable the computation of the same derived key by someone that is intended to decrypt the message.

Note that passwords are often only composed of alphanumeric characters that eases a bit more the job of a hacker, whereas a derived key is composed of any binary data produced by the algorithm used for the derivation.

Table 521: Derived keys methods

Method	Description
http://schemas.xmlsoap.org/ws/2005/02/sc/dk/p_sha1	Only algorithm supported. See specification for details.

CryptoKey Features
Features of the `xml.CryptoKey` class.

Table 522: CryptoKey Features

Name	Description
`KeyName` See specification for details.	Defines or returns whether a user-defined key name is added during a XML**signature**

Name	Description
	or **encryption** in order to identify it to other applications, or by the key store. The default value is NULL, meaning that no key name is used.
`KeyValue` See specification for details.	Defines or returns whether the public part of the asymmetric key is added during a XML **signature** or **encryption**. Only for RSA and DSA keys. The default value is FALSE, meaning that no key value is used.
`RetrievalMethod` See specification for details.	Defines or returns the URL where the XML form of: • a DSA or RSA public key will be set during a XML **signature**, and loaded during a XML **verification** process. • a RSA public key will be set and used to encrypt a XML node during XML encryption • a symmetric key with encryption usage will be used to encrypt a XML node or decrypt it back The default value is NULL, meaning that no retrieval method is used. The XML form of a DSA or RSA public key can be obtain by the `savePublic` method. The XML form of a symmetric key can be obtain by the `encryptKey` method.

Examples
Examples using the `xml.CryptoKey` class.

Examples:

- Loading an asymmetric RSA key on page 2225
- Generating a symmetric AES256 key on page 2226
- Setting a HMAC key on page 2226
- Deriving a HMAC key on page 2226
- Computing the shared secret with Diffie-Hellman on page 2227

Loading an asymmetric RSA key

```
IMPORT xml

MAIN
  DEFINE key xml.CryptoKey
  LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
  TRY
    CALL key.loadPEM("RSA1024Key.pem")
    CALL key.setFeature("KeyName","MyRsaKey")
    DISPLAY "Key size (in bits) : ",key.getSize() # displays 1024 (bits)
    DISPLAY "Key type : ",key.getType() # displays PRIVATE or PUBLIC
    DISPLAY "Key usage : ",key.getUsage() # displays KEYENCRYPTION
  CATCH
    DISPLAY "Unable to load key :",STATUS
```

```
  END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Generating a symmetric AES256 key

```
IMPORT xml

MAIN
  DEFINE key xml.CryptoKey
  LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#aes256-
cbc")
  TRY
    CALL key.generateKey(NULL)
    DISPLAY "Key size (in bits) : ",key.getSize() # displays 256 (bits)
    DISPLAY "Key type : ",key.getType() # displays SYMMETRIC
    DISPLAY "Key usage : ",key.getUsage() # displays ENCRYPTION
  CATCH
    DISPLAY "Unable to generate key :",STATUS
  END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Setting a HMAC key

```
IMPORT xml

MAIN
  DEFINE key xml.CryptoKey
  LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-
sha1")
  TRY
    CALL key.setKey("secretpassword")
    # displays 112 (size of secretpassword in bits)
    DISPLAY "Key size (in bits) : ",key.getSize()
    DISPLAY "Key type : ",key.getType() # displays HMAC
    DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
  CATCH
    DISPLAY "Unable to set key :",STATUS
  END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Deriving a HMAC key

```
IMPORT xml
IMPORT com

MAIN
  DEFINE key xml.CryptoKey
  # will contain a random binary data encoded in Base64
  DEFINE seedBase64 STRING
  LET key = xml.CryptoKey.CreateDerivedKey(
    "http://www.w3.org/2000/09/xmldsig#hmac-sha1")
  TRY
    # Creates a random 24 bytes long binary data encoded into a Base64 form
 string
    CALL key.setKey("secretpassword")
```

```
    # Derives the 14 bytes long "secretpassword" into a 64 bytes long key
    # from a random 24 bytes long seed value and shifting the resulting key
    # from 255 bytes
    LET seedBase64 = com.Util.CreateRandomString(24)
    CALL key.deriveKey(
      "http://schemas.xmlsoap.org/ws/2005/02/sc/dk/p_sha1",
      NULL,seedBase64,NULL,255,64)
    # Displays 512 (size of 'secretpassword' derivation in bits)
    DISPLAY "Key size (in bits) : ",key.getSize()
    # Note: Key is derived and can be used in
    # any encryption or signature function
  CATCH
    DISPLAY "Unable to derive key :",STATUS
  END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Computing the shared secret with Diffie-Hellman

Load the Diffie-Hellman parameters from a PEM file, the other peer's public key from an XML file and compute the shared secret.

Function `generateKey` is called with a 0, parameters are already filled.

```
FUNCTION BuildSharedSecret(DHdoc)
  DEFINE myKey, othersPubKey, sharedSecret xml.CryptoKey
  DEFINE DHdoc xml.DomDocument
  LET myKey =
    xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
  LET othersPubKey =
    xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue " )
  TRY
    CALL othersPubKey.loadPublic(DHdoc)

    # populate myKey with the parameters previously generated by the
    # other peer.
    CALL myKey.loadPEM("DHParam.pem")

    # Randomly generate a private key and compute the public key. Key
    # length is the parameters length.
    CALL myKey.generateKey(0)
    LET sharedSecret = myKey.computeKey(othersPubKey,
      "http://www.w3.org/2000/09/xmldsig#hmac-sha1")

  CATCH
    DISPLAY "ERROR : should not raise exception”
    EXIT PROGRAM (-1)
  END TRY
END FUNCTION
```

The CryptoX509 class

The `xml.CryptoX509` class provides methods to manipulate X509 certificates needed for identification of individual persons, groups or any entities during XML encryption or signature process.

It also provides additional load and save functions to interact with other applications in XML or in BASE64, such as in WS-Security compliant applications. It follows the XML-Signature and XML-Encryption specifications.

The `STATUS` variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.CryptoX509 methods
Methods for the `xml.CryptoX509` class.

Table 523: Class methods: Creation

Name	Description
`xml.CryptoX509.Create()` `  RETURNING object xml.CryptoX509`	Constructor of an empty CryptoX509 object.

`xml.CryptoX509.CreateFromNode(`
`  node xml.DomNode )`
`  RETURNING object xml.CryptoX509`
	Constructor of a new CryptoX509 object from a XML X509 certificate node, according to the XML-Signature specification

Table 524: Object methods: Access

Name	Description
`getIdentifier()` `  RETURNING idpart STRING`	Gets the identification part of an X509 certificate
`getThumbprintSHA1()` `  RETURNING setp STRING`	Gets the SHA1 encoded thumbprint identifying this X509 certificate.

Table 525: Object methods: Modify

Name	Description

`createPublicKey(`
`  url STRING )`
`  RETURNING object xml.CryptoX509`
	Creates a new public CryptoKey object for the given url, from the public key embedded in a certificate.

Table 526: Object methods: Load and save

Name	Description
`load(` `  xml xml.DomDocument )`	Loads the given XML document with ds:X509Data as root node according to the XML-Signature specification, into the CryptoX509 object.
`loadDER(` `  file STRING )`	Loads a X509 certificate from a file in DER format.
`loadFromString(` `  str STRING )`	Loads the given X509 certificate in BASE64 string format into this CryptoX509 object.
`loadPEM(`	Loads a X509 certificate from a file in PEM format.

Name	Description
file STRING)	
save() RETURNING *object* xml.DomDocument	Saves the CryptoX509 certificate into a XML document with ds:X509Data as root node according to the XML-Signature specification.
saveToString() RETURNING *cert* STRING	Saves the CryptoX509 certificate into a BASE64 string format.

Table 527: Object methods: Feature

Name	Description
getFeature(*feature* STRING) RETURNING *value* STRING	Get the value of a given feature of a CryptoX509 object.
setFeature(*feature* STRING, *value* STRING)	Sets or resets the given feature for this CryptoX509 object.

xml.CryptoX509.Create

Constructor of an empty CryptoX509 object.

Syntax

```
xml.CryptoX509.Create()
  RETURNING object xml.CryptoX509
```

Usage

Returns a CryptoX509 object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.CreateFromNode

Constructor of a new CryptoX509 object from a XML X509 certificate node, according to the XML-Signature specification

Syntax

```
xml.CryptoX509.CreateFromNode(
   node xml.DomNode )
  RETURNING object xml.CryptoX509
```

1. *node* is an ELEMENT DomNode node with **X509Data** as local name, and belonging to the XML-Signature namespace **http://www.w3.org/2000/09/xmldsig#**.

Usage

Returns a CryptoX509 object or NULL.

If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of **SubjectName** or **Issuer** matches. (See addCertificate for more details.)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.createPublicKey

Creates a new public CryptoKey object for the given url, from the public key embedded in a certificate.

Syntax

```
createPublicKey(
   url STRING )
  RETURNING object xml.CryptoX509
```

1. *url* is the given url.

Usage

Creates a new public CryptoKey object for the given url, from the public key embedded in this certificate if any; NULL otherwise.

Returns a CryptoX509 object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.getFeature

Get the value of a given feature of a CryptoX509 object.

Syntax

```
getFeature(
   feature STRING )
  RETURNING value STRING
```

1. *feature* is a feature of the CryptoX509 object.

Usage

Returns the value of the given feature for this CryptoX509 object, or NULL if feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.getIdentifier

Gets the identification part of an X509 certificate

Syntax

```
getIdentifier()
  RETURNING idpart STRING
```

Usage

Returns the identification part of this X509 certificate in a STRING.

Example: `/C=FR/ST=France/L=Schiltigheim/O=MC/OU=My Company Name/CN=cert`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.getThumbprintSHA1

Gets the SHA1 encoded thumbprint identifying this X509 certificate.

Syntax

```
getThumbprintSHA1()
  RETURNING setp STRING
```

Usage

Returns the SHA1 encoded thumbprint identifying this X509 certificate in a BASE64 encoded STRING.

Example: `CM4y6z7zzLnTGMe1lE46RKIKAPI=`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.load

Loads the given XML document with ds:X509Data as root node according to the XML-Signature specification, into the CryptoX509 object.

Syntax

```
load(
   xml xml.DomDocument )
```

1. xml is a DomDocument object.

Usage

If the X509 certificate in the XML document is incomplete, the certificate will be loaded from the global certificate list if one of **SubjectName** or **Issuer** matches.

See the w3.org site for more information on ds:X509Data as root node according to the XML-Signature specification.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.loadDER

Loads a X509 certificate from a file in DER format.

Syntax

```
loadDER(
   file STRING )
```

1. *file* is the filename or an entry in the FGLPROFILE file.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.loadFromString

Loads the given X509 certificate in BASE64 string format into this CryptoX509 object.

Syntax

```
loadFromString(
   str STRING )
```

1. *str* is the X509 certificate in BASE64 string format to load.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.loadPEM

Loads a X509 certificate from a file in PEM format.

Syntax

```
loadPEM(
   file STRING )
```

1. *file* is the filename or an entry in the FGLPROFILE file.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.save

Saves the CryptoX509 certificate into a XML document with ds:X509Data as root node according to the XML-Signature specification.

Syntax

```
save()
  RETURNING object xml.DomDocument
```

Usage

See the w3.org site for more information on ds:X509Data as root node according to the XML-Signature specification.

(See also the RetrievalMethod feature)

Returns an xml.DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.saveToString

Saves the CryptoX509 certificate into a BASE64 string format.

Syntax

```
saveToString()
  RETURNING cert STRING
```

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.CryptoX509.setFeature

Sets or resets the given feature for this CryptoX509 object.

Syntax

```
setFeature(
   feature STRING,
   value STRING )
```

1. *feature* is the feature to be set.
2. *value* is the value to set.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

CryptoX509 Features
Features of the `xml.CryptoX509` class.

Table 528: CryptoX509 Features

Feature	Description
`X509Certificate` See specification for details.	Defines or returns whether the complete X509 certificate is added during XML **signature** or **encryption**. Default value is FALSE.
`X509SubjectName` See specification for details.	Defines or returns whether the subject name of the X509 certificate is added during XML **signature** or **encryption**. Default value is FALSE.
`X509IssuerSerial` See specification for details.	Defines or returns whether the issuer name and serial number of the X509 certificate is added during XML **signature** or **encryption**. Default value is FALSE.

Feature	Description
`RetrievalMethod` See specification for details.	Defines or returns the URL where the XML form of the X509 certificate will be set during a XML **signature**, and loaded during a XML **verification** process, and based on that CryptoX509 object. Default value is NULL, meaning that no retrieval method is used. **Note:** The XML form of a X509 certificate can be obtain by the `save()` method.

Examples
Examples using the `xml.CryptoX509` class.

Topics:

- Loading a certificate from a PEM file on page 2234
- Creating a public key for signature verification from a certificate on page 2234
- Saving the subjectName of a certificate in XML on page 2235

Loading a certificate from a PEM file

```
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("Certificate.crt");
    DISPLAY "Id : ",x509.getIdentifier()
  CATCH
    DISPLAY "Unable to load certificate :",STATUS
  END TRY
END MAIN
```

Note: All certificates in PEM format were created with the OpenSSL tool.

Creating a public key for signature verification from a certificate

```
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  DEFINE key xml.CryptoKey
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("RSA1024Certificate.crt");
  CATCH
    DISPLAY "Unable to load certificate :",STATUS
    EXIT PROGRAM
  END TRY
  TRY
    LET key = x509.createPublicKey("http://www.w3.org/2000/09/xmldsig#rsa-
sha1")
    DISPLAY "Key size (in bytes) : ",key.getSize() # displays 1024 (bits)
    DISPLAY "Key type : ",key.getType() # displays PUBLIC
    DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
  CATCH
    DISPLAY "Unable to create public key :",STATUS
  END TRY
```

```
END MAIN
```

Note: All certificates in PEM format were created with the OpenSSL tool.

Saving the subjectName of a certificate in XML

```
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  DEFINE key xml.CryptoKey
  DEFINE doc xml.DomDocument
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("RSA1024Certificate.crt");
  CATCH
    DISPLAY "Unable to load certificate :",STATUS
    EXIT PROGRAM
  END TRY
  TRY
    CALL x509.setFeature("X509SubjectName",TRUE)
    LET doc = x509.save()
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("RSAX509SubjectName.xml")
  CATCH
    DISPLAY "Unable to save certificate :",STATUS
  END TRY
END MAIN
```

Note: All certificates in PEM format were created with the OpenSSL tool.

The Signature class
The `xml.Signature` class provides methods to create detached, enveloped or enveloping XML signatures of one or more references of XML documents or document fragments, and to determine whether a signed referenced document has been modified afterwards.

It follows the XML-Signature specifications.

The `STATUS` variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.Signature methods
Methods for the `xml.Signature` class.

Table 529: Class methods: Creation

Name	Description
`xml.Signature.Create()` `  RETURNING sign xml.Signature`	Constructor of a blank Signature object.

`xml.Signature.CreateFromNode(`
`  signode xml.DomNode )`
`  RETURNING sign xml.Signature`
	Constructor of a new Signature object from a XML Signature node, according to the XML-Signature specification.

Table 530: Class methods: Object access

Name	Description

`xml.Signature.RetrieveObjectDataListFromSignatureNode(`
`  sign xml.DomNode,`
`  ind INTEGER )`
`  RETURNING nodelist xml.DomNodeList`
	Returns a DomNodeList containing all embedded XML nodes related to the signature object of index *ind* in the XML Signature node *sign*.

Note: In addition to this class method categorized under Object Access, there are also object methods. These are listed in Table 537: Object methods: Object access on page 2238.

Table 531: Object methods: Key and certificate

Name	Description
`setCertificate(` `  cert xml.CryptoX509 )`	Defines the X509 certificate to be added to the Signature object when signing a document.
`setKey(` `  key xml.CryptoKey )`	Defines the key used for signing or validation.

Table 532: Object methods: Modifier

Name	Description
`setCanonicalization(` `  url STRING )`	Sets the canonicalization method to use for the signature.
`setID(` `  id STRING )`	Sets an ID value for the signature.

Table 533: Object methods: Access

Name	Description
`getCanonicalization()` `  RETURNING ident STRING`	Returns one of the four canonicalization identifier of the signature.
`getDocument()` `  RETURNING doc xml.DomDocument`	Returns a new DomDocument object representing the signature in XML.
`getID()` `  RETURNING id STRING`	Returns the ID value of the signature.
`getSignatureMethod()`	Returns the algorithm method of the signature.

Name	Description
`RETURNING algo STRING`	
`getType()` `RETURNING str STRING`	Returns a string with the type of the Signature object.

Table 534: Object methods: Reference modifier

Name	Description

`appendReferenceTransformation(`
`ind INTEGER,`
`trans STRING,`
`... )`
	Appends a transformation related to the reference of index *ind*, and is executed before any computation

`createReference(`
`uri STRING,`
`digest STRING )`
`RETURNING ind INTEGER`
	Creates a new reference that will be signed with the `compute()` method

`setReferenceID(`
`ind INTEGER,`
`value STRING )`
	Sets an ID *value* for the signature reference of index *ind*.

Table 535: Object methods: Reference access

Name	Description
`getReferenceCount()` `RETURNING num INTEGER`	Returns the number of references in this Signature object.

`getReferenceDigest(`
`ind INTEGER )`
`RETURNING algo STRING`
	Returns the digest algorithm identifier of the reference of index *ind* in this Signature object.

`getReferenceURI(`
`ind INTEGER )`
`RETURNING uri STRING`
	Returns the URI of the reference of index *ind* in this Signature object.

`getReferenceID(`
`ind INTEGER )`
`RETURNING value STRING`
	Returns the ID value of the reference of index *ind* in this Signature object, or NULL if there is none.

`getReferenceTransformation(`
`ind INTEGER,`
`pos INTEGER )`
	Gets the transformation identifier related to the reference of index *ind* at position *pos* in the list of transformation.

Name	Description
`RETURNING ident STRING`	
`getReferenceTransformationCount( ind INTEGER ) RETURNING num INTEGER`	Returns the number of transformation related to the reference of index *ind*.

Table 536: Object methods: Object modifier

Name	Description
`appendObjectData( ind INTEGER, node xml.DomNode )`	Appends a copy of a XML node *node* to the signature object of index *ind*.
`createObject() RETURNING ind INTEGER`	Creates a new object that will embed additional XML nodes.
`setObjectID( ind INTEGER, value STRING )`	Sets an ID *value* for the signature object of index *ind*.

Table 537: Object methods: Object access

Name	Description
`getObjectCount() RETURNING num INTEGER`	Returns the number of objects in this Signature object.
`getObjectId( ind INTEGER ) RETURNING id STRING`	Returns the ID value of the signature object of index *ind* in this Signature object.

Note: In addition to these object methods categorized under Object Access, there is also a class method. It is listed in Table 530: Class methods: Object access on page 2236.

Table 538: Object methods: Signature computation and verification

Name	Description
`compute( doc xml.DomDocument )`	Computes the signature of all references set in this Signature object.
`signString( key xml.CryptoKey, strToSign STRING )`	Sign the passed string according to the specified key.

Name	Description
`RETURNING sig STRING`	
`verify( doc xml.DomDocument ) RETURNING flag INTEGER`	Verifies whether all references in this Signature object haven't changed.
`verifyString( key xml.CryptoKey, signedStr STRING, signature STRING ) RETURNING flag INTEGER`	Verify the signature is consistent with the given key and the original message.

xml.Signature.appendObjectData

Appends a copy of a XML node *node* to the signature object of index *ind*.

Syntax

```
appendObjectData(
   ind INTEGER,
   node xml.DomNode )
```

1. *ind* is the index in this Signature object.
2. node is the XML node.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.appendReferenceTransformation

Appends a transformation related to the reference of index *ind*, and is executed before any computation

Syntax

```
appendReferenceTransformation(
   ind INTEGER,
   trans STRING,
   ... )
```

1. *ind* is the index in this Signature object.
2. *trans* represents an URL as identifier of the transformation algorithm.

Usage

A transformation modifies the reference URI before signing or validating it. Several transformations are executed one after another, and only once the last transformation was applied, is the reference really signed or verified.

Depending on the transformation identifier, additional parameters are necessary.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.compute

Computes the signature of all references set in this Signature object.

Syntax

```
compute(
   doc xml.DomDocument )
```

1. *doc* is the XML document.

Usage

If the signature type is:

- Enveloping: then *doc* must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then *doc* must be the XML document where the signature must be added afterwards to get a valid enveloped signature
- Detached: then *doc* can be NULL if all references are absolute, otherwise it can be the XML document the fragment references are referencing

See XML Signature concepts for more details.

Also, see Windows™ .NET special recommendation.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.Create

Constructor of a blank Signature object.

Syntax

```
xml.Signature.Create()
  RETURNING sign xml.Signature
```

Usage

Returns a Signature object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.CreateFromNode

Constructor of a new Signature object from a XML Signature node, according to the XML-Signature specification.

Syntax

```
xml.Signature.CreateFromNode(
   signode xml.DomNode )
  RETURNING sign xml.Signature
```

1. *sign* is the XML Signature node.

Usage

Returns a Signature object or NULL.

The *node* must be an ELEMENT node with **Signature** as the local name, and belonging to the XML-Signature namespace **http://www.w3.org/2000/09/xmldsig#**, as defined here.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.createObject

Creates a new object that will embed additional XML nodes.

Syntax

```
createObject()
  RETURNING ind INTEGER
```

Usage

The returned value represents the index for any further manipulation of this signature object.

> **Note:** An object is enveloping additional XML nodes, but is not necessarily signed unless there is a reference on it.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.createReference

Creates a new reference that will be signed with the compute() method

Syntax

```
createReference(
   uri STRING,
   digest STRING )
  RETURNING ind INTEGER
```

1. *uri* represents the data to be signed.
2. *digest* is a URL as identifier for the hash algorithm.

Usage

The returned value represents the index for any further manipulation of this reference.

The *uri* can be:

- An absolute url such as **http://, https://, tcp://, tcps://, file:///** and **alias://** (see FGLPROFILE Configuration for more details about URL mapping with aliases), and where the data can be a XML document or any kind of data such as images or html pages.
- NULL to sign the whole document, but only one NULL is allowed in the entire signature.
- A fragment like **#tobesigned**. Note that a DOM node fragment is identified via the value of an attribute of type ID such as **xml:id** or any attribute whose type was changed to ID with setIdAttribute() or setIdAttributeNS().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getCanonicalization

Returns one of the four canonicalization identifier of the signature.

Syntax

```
getCanonicalization()
  RETURNING ident STRING
```

Usage

Returns the canonicalization identifier of the signature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getDocument

Returns a new DomDocument object representing the signature in XML.

Syntax

```
getDocument()
  RETURNING doc xml.DomDocument
```

Usage

Returns a xml.DomDocument object.

If the type of the signature is **enveloped**, it's up to the user to add it at the right place in the XML document it is intended to sign.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getID

Returns the ID value of the signature.

Syntax

```
getID()
  RETURNING id STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getObjectCount

Returns the number of objects in this Signature object.

Syntax

```
getObjectCount()
  RETURNING num INTEGER
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getObjectId

Returns the ID value of the signature object of index *ind* in this Signature object.

Syntax

```
getObjectId(
   ind INTEGER )
  RETURNING id STRING
```

1. *ind* is the index in this Signature object.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceCount

Returns the number of references in this Signature object.

Syntax

```
getReferenceCount()
  RETURNING num INTEGER
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceDigest

Returns the digest algorithm identifier of the reference of index *ind* in this Signature object.

Syntax

```
getReferenceDigest(
   ind INTEGER )
  RETURNING algo STRING
```

1. *ind* is the index in this Signature object.

Usage

Returns the digest algorithm identifier of the reference of index *ind* in this Signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceID

Returns the ID value of the reference of index *ind* in this Signature object, or NULL if there is none.

Syntax

```
getReferenceID(
   ind INTEGER )
  RETURNING value STRING
```

1. *ind* is the index in this Signature object.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceTransformation

Gets the transformation identifier related to the reference of index *ind* at position *pos* in the list of transformation.

Syntax

```
getReferenceTransformation(
   ind INTEGER,
   pos INTEGER )
  RETURNING ident STRING
```

1. *ind* is the index in this Signature object.
2. *pos* is the position in the list of transformation.

Usage

Returns the transformation identifier related to the reference of index *ind*, and at position *pos* in the list of transformation.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceTransformationCount

Returns the number of transformation related to the reference of index *ind*.

Syntax

```
getReferenceTransformationCount(
   ind INTEGER )
  RETURNING num INTEGER
```

1. *ind* is the index in this Signature object.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getReferenceURI

Returns the URI of the reference of index *ind* in this Signature object.

Syntax

```
getReferenceURI(
   ind INTEGER )
  RETURNING uri STRING
```

1. *ind* is the index in this Signature object.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getSignatureMethod

Returns the algorithm method of the signature.

Syntax

```
getSignatureMethod()
  RETURNING algo STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.getType

Returns a string with the type of the Signature object.

Syntax

```
getType()
  RETURNING str STRING
```

Usage

The string can be Detached, Enveloped, Enveloping or Invalid according to the XML-Signature specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.RetrieveObjectDataListFromSignatureNode

Returns a DomNodeList containing all embedded XML nodes related to the signature object of index *ind* in the XML Signature node *sign*.

Syntax

```
xml.Signature.RetrieveObjectDataListFromSignatureNode(
   sign xml.DomNode,
   ind INTEGER )
  RETURNING nodelist xml.DomNodeList
```

1. *sign* is the XML Signature node.
2. *ind* is the index of the signature object.

Usage

Returns a DomNodeList

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setCanonicalization

Sets the canonicalization method to use for the signature.

Syntax

```
setCanonicalization(
   url STRING )
```

1. *url* is one of the four canonicalization identifier.

Usage

The default value is the c14nmethod.

> **Note:** Windows™ .NET default c14n canonicalization method is not compatible with the W3C standard, therefore it is recommended to use the exc-c14n method when inter-operating with a Windows™ system.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setCertificate

Defines the X509 certificate to be added to the Signature object when signing a document.

Syntax

```
setCertificate(
   cert xml.CryptoX509 )
```

1. *cert* is the X509 certificate to be added.

Usage

If NULL, no certificate is added.

During the computation of the signature, some certificate information can be added according to the feature set on that CryptoX509 object. If no features are set, the complete X509 certificate is automatically added.

During the verification of a signature the certificate set with the setCertificate method isn't used. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setID

Sets an ID value for the signature.

Syntax

```
setID(
   id STRING )
```

1. *id* is the ID value to be set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setKey

Defines the key used for signing or validation.

Syntax

```
setKey(
   key xml.CryptoKey )
```

1. key is the key to be used for signing or validation.

Usage

Only RSA, DSA or HMAC keys intended for SIGNATURE are allowed.

During the computation of the signature, some key information can be added according to the feature set on that CryptoKey object. If no features are set, nothing is added. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setObjectID

Sets an ID *value* for the signature object of index *ind*.

Syntax

```
setObjectID(
   ind INTEGER,
   value STRING )
```

1. *ind* is the index value.
2. *value* is the value to be set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.setReferenceID

Sets an ID *value* for the signature reference of index *ind*.

Syntax

```
setReferenceID(
   ind INTEGER,
   value STRING )
```

1. *ind* is the index value.
2. *value* is the value to be set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.signString

Sign the passed string according to the specified key.

Syntax

```
signString(
  key xml.CryptoKey,
  strToSign STRING
 )
 RETURNING sig STRING
```

1. *key* is the key to be used for the signature.
2. *strToSign* is the string to be sign.

Usage

The key can be a HMAC key, a RSA private key or a DSA private key. The signing process is performed with SHA-1 digest, as recommended by the XmlSec specification.

Returns *sig*, or the signature in base64 format.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.verify

Verifies whether all references in this Signature object haven't changed.

Syntax

```
verify(
   doc xml.DomDocument )
  RETURNING flag INTEGER
```

1. *doc* is the XML document.

Usage

Returns TRUE if valid, FALSE otherwise.

If the signature type is:

- Enveloping: then *doc* must be NULL because all document fragment references are inside the Signature itself,
- Enveloped: then *doc* must be the XML document where the signature was enveloped,
- Detached: then *doc* can be null if all references are absolute, otherwise it can be the XML document the fragment references are referencing.

See XML Signature concepts for more details.

By default, the validation process uses the CryptoKey set with `setKey()` to verify the signature. However, if the signature contains a X509 certificate or a X509 retrieval method, it uses the list of trusted certificate, or if the signature contains a RSA or DSA retrieval method, it uses the RSA or DSA public key automatically loaded.

> **Note:** See Windows™ .NET special recommendation.

Before loading the XML document to verifiy the signature, you might need to set some options to retrieve the "id" nodes with the `xml.DomDocument.setFeature()` method:

```
DEFINE doc xml.DomDocument
...
CALL doc.setFeature(feature, TRUE)
...
```

Here *feature* must be `"auto-id-attribute"` if the `"id"` attribute has no namespace, or `"auto-id-qualified-attribute"`, when `"id"` has a namespace.

This is especially needed when you encounter error messages such as:

```
Xml security operation failed : libxml2 library function failed :
 expr=xpointer(id('id-1436767651')).
```

Meaning that the parser could not find the `"id"` attribute in the XML document.

Note that the `"auto-id-*"` features will declare all XML attributes where the name is `"id"`, `"ID"`, `"Id"` or `"iD"` to be of type `ID`, and thus be usable via `xml.DomDocument.getElementById()` method used during signature validation.

If needed, you can also set features for a specific attribute with the `xml.DomNode.setIdAttribute()` method, or with the `xml.DomNode.setIdAttributeNS()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Signature.verifyString

Verify the signature is consistent with the given key and the original message.

Syntax

```
verifyString(
   key xml.CryptoKey,
   signedStr STRING,
   signature STRING )
  RETURNING flag INTEGER
```

1. *key* is the key to use for verification.
2. *signedStr* is the signed string in its clear form.
3. *signature* is the signature to be verified.

Usage

The key can be a HMAC key, a RSA private key or a DSA private key. The HMAC key must be the same as the one used for signing. The public RSA and DSA key must be the public key corresponding to the private key used for signing.

Returns 1 when verification is successful; 0 (zero) is returned if verification fails.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

XML Signature concepts

The purpose of a signature is to guarantee the integrity of a XML document, that it was not altered, and that it still contains the same data as when it was created. An additional purpose of a signature is to authenticate the author of the document. There are different ways to achieve this guarantee.

Sign and verify with a common shared HMAC key

Use if the sender of the XML document and the receiver share a common secret key.

How to sign

1. Create a HMAC key with the constructor of the CryptoKey class.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a HMAC key with the constructor of the CryptoKey.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with the originator public RSA or DSA key

Use if the receiver of the XML document has the RSA or DSA public key of the sender.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a RSA or DSA key with the constructor of the CryptoKey class.

2. Load the RSA or DSA public key into the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with a RSA or DSA retrieval method

Use if the sender of the XML document provides the public RSA or DSA key in XML form (and via http, tcp or a file protocol).

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Set the RetrievalMethod feature on the CryptoKey object with the URL where the XML form of the public RSA or DSA key is available.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
2. Verify the signature validity.

Note: There is no key nor certificate to set in the Signature object during validation.

Sign with the originator private RSA or DSA key, and verify with the originator X509 certificate associated to the private RSA or DSA key

Use if the receiver of the XML document has the X509 certificate associated to the RSA or DSA private key.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate into the CryptoKey object.
3. Create the RSA or DSA public key from the X509 certificate of the CryptoX509 object.

4. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
5. Assign the CryptoKey object containing the public key to the Signature object.
6. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with trusted X509 certificates

Use if the sender of the XML document adds a X509 certificate that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Load the X509 certificate associated to the RSA or DSA private key into the CryptoKey object.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
5. Verify the signature validity.

Note: Point 1 to 3 can be omitted if entry `xml.application.calist` has been set in FGLPROFILE file with the trusted certificate.

Note: There is no key nor certificate to set in the Signature object during validation.

Sign with the originator private RSA or DSA key, and verify with a X509 certificate retrieval method and trusted X509 certificates

Use if the sender of the XML document adds a X509 retrieval method that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Set the RetrievalMethod feature on the CryptoX509 object with the URL where the XML form of the originator X509 certificate is available.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.

7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
5. Verify the signature validity.

   Note: Steps 1 - 3 can be omitted if entry `xml.application.calist` has been set in FGLPROFILE file with the trusted certificate.

   Note: There is no key or certificate to set in the Signature object during validation.

Sign with a named key and verify using the keystore

Use if the sender and the receiver exchange multiple XML documents signed with different keys.

How to sign

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey class.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Register the key to be used by key name for any signature verification.
5. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
6. Verify the signature validity.

   Note: Steps 1 - 4 should be done once at application startup for each key used in the application. Steps 5 - 6 can then quickly be executed for any XML signature to be checked.

Digest identifier

Table 539: Digest identifiers

Identifier	Description
http://www.w3.org/2000/09/xmldsig#sha1 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a SHA algorithm of 160 bits.

Identifier	Description
	Note: It is the only digest algorithm recommended by the W3C.
http://www.w3.org/2001/04/xmlenc#sha512 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a SHA algorithm of 512 bits.
http://www.w3.org/2001/04/xmldsig-more#sha384 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a SHA algorithm of 384 bits.
http://www.w3.org/2001/04/xmlenc#sha256 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a SHA algorithm of 256 bits.
http://www.w3.org/2001/04/xmldsig-more#sha224 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a SHA algorithm of 224 bits.
http://www.w3.org/2001/04/xmldsig-more#md5 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a MD5 algorithm.
http://www.w3.org/2001/04/xmlenc#ripemd160 See specification for details.	Computes the digest of the reference set with createReference(), by applying a hash operation using a RIPEMD algorithm.

Transformation identifier

Table 540: Transformation identifiers

Identifier	Description	Additional Parameters
http://www.w3.org/2000/09/xmldsig#base64 See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into the raw data associated to a BASE64 encoded form. This is intended to sign the raw data associated with the BASE64 encoded content of an element. See specification for details.	No
http://www.w3.org/TR/2001/REC-xml-c14n-20010315 See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a canonicalized XML document without any XML comments. This is intended to transform two equivalent XML documents into a standardized XML representation in order to obtain the same hash value. For instance: The following two XML nodes are equivalent but would produce different hash values if not canonicalized. • `<tag Attr1="hello" Attr2="world"/>` • `<tag Attr2="world" Attr1="hello" />`	No

Identifier	Description	Additional Parameters
	See specification for details.	
http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a canonicalized XML document keeping all XML comments. This is intended to transform two equivalent XML documents into a standardized XML representation in order to obtain the same hash value. For instance: The following two XML nodes are equivalent but would produce different hash values if not canonicalized. • `<tag Attr1="hello" Attr2="world"/>` • `<tag Attr2="world" Attr1="hello" />` See specification for details.	No
http://www.w3.org/2001/10/xml-exc-c14n# See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a canonicalized XML document without any XML comments, and removing all unused namespaces declaration. This is intended to transform two equivalent XML documents into a standardized XML representation in order to obtain the same hash value. For instance: The following two XML nodes are equivalent but would produce different hash values if not canonicalized. • `<tag Attr1="hello" Attr2="world"/>` • `<tag Attr2="world" Attr1="hello" />` See specification for details.	No
http://www.w3.org/2001/10/xml-exc-c14n#WithComments See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a canonicalized XML document keeping all XML comments, and removing all unused namespaces declaration. This is intended to transform two equivalent XML documents into a standardized XML representation in order to obtain the same hash value. For instance: Following two XML nodes are equivalent but would produce different hash values if not canonicalized. • `<tag Attr1="hello" Attr2="world"/>` • `<tag Attr2="world" Attr1="hello" />` See specification for details.	No

Identifier	Description	Additional Parameters
http://www.w3.org/2000/09/xmldsig #enveloped-signature See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into the same XML document or fragment, but without the Signature node. This is intended to create **enveloped** signatures where the**<dsig:Signature>** node is inside the document, but without taking it into account during signature computation or verification. See specification for details.	No

http://www.w3.org/TR/1999/REC-xpath-19991116
 	
See specification for details.
	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a XML document according to a XPath filtering expression applied to each node of the input document, where the expression represents a predicate to the XPath expression`(//. | //@* | //namespace::*)`.
	
	In other words: **`(//. | //@* | //namespace::*)[expr]`**
	
	This is intended to identify the nodes to be signed using a XPath expression instead of an attribute of type ID.
	
	For instance: The following samples output only the **MyCode** node of the input document:
	
	`CALL s.appendReferenceTransformation( i, "http://www.w3.org/TR/1999/REC-xpath-19991116", "ancestor-or-self::MyCode", NULL`
	
	`CALL s.appendReferenceTransformation( i, "http://www.w3.org/TR/1999/REC-xpath-19991116", "ancestor-or-self::p:MyCode", "p", "http://www.tempuri.org")`
	
	See specification for details.
		XPath expression, followed by NULL or a list of prefix, namespace matching the XPath expression.

http://www.w3.org/2002/06/xmldsig-filter2 See specification for details.	Transforms the output from the previous transformation (or the reference if there is no previous transformation), into a XML document according to a XPath filtering 2.0 expression applied to the entire document at once.	XPathFilter2.0 type (**intersect**, **subtract** or **union**), followed by the XPath expression, followed by NULL or a list of prefix, namespace

Identifier	Description	Additional Parameters

	This is intended to identify the nodes to be signed using a XPath expression instead of an attribute of type ID, and to perform fast and more complex operations such as **intersect**, **subtract** or **union**.
	
	For instance: The following samples output the entire document without the **MyCode** node child of the **MyElement** root node:
	
	`CALL s.appendReferenceTransformation( i, "http://www.w3.org/2002/06/xmldsig-filter2", "subtract", "/MyElement/MyCode")`
	
	`CALL s.appendReferenceTransformation( i, "http://www.w3.org/2002/06/xmldsig-filter2", "subtract", "/p1:MyElement/p2:MyCode", "p2", "http://www.tempuri.org/ns2", "p1", "http://www.tempuri.org/ns1")`
	
	See specification for details.
		matching the XPath expression.

Examples
Examples using the XML Signature class.

- Create a detached signature using a HMAC key on page 2257
- Verify a detached signature using a HMAC key on page 2258
- Create an enveloping signature using a DSA key on page 2259
- Verify an enveloping signature using a X509 certificate on page 2260
- Create an enveloped signature using a RSA key on page 2260
- Verify an enveloped signature using a RSA key on page 2261

Create a detached signature using a HMAC key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE root xml.DomNode
  DEFINE sig xml.Signature
  DEFINE key xml.CryptoKey
  DEFINE index INTEGER
  # Create DomDocument object
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significant in crytography,
  # therefore it is recommended that you remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
```

```
    # Load document to be signed
    CALL doc.load("MyDocument.xml")
    # Create HMAC key
    LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-
sha1")
    CALL key.setKey("secretpassword")
     # Create signature object with the key to use
    LET sig = xml.Signature.Create()
    CALL sig.setKey(key)
    # Set XML node to be signed. In our case, the node with attribute
    # 'xml:id="code"'
    LET index = sig.createReference("#code",
      "http://www.w3.org/2000/09/xmldsig#sha1")
    # Set canonicalization method on the XML fragment to be signed.
    CALL sig.appendReferenceTransformation(index,
      "http://www.w3.org/2001/10/xml-exc-c14n#")
    # Compute detached signature
    CALL sig.compute(doc)
    # Retrieve signature document
    LET doc=sig.getDocument()
    # Save signature on disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("MyDocumentDetachedSignature.xml")
  CATCH
    DISPLAY "Unable to create a detached signature :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Verify a detached signature using a HMAC key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE node xml.DomNode
  DEFINE sig xml.Signature
  DEFINE key xml.CryptoKey
  DEFINE isVerified INTEGER
  # Create DomDocument object
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significants in crytography,
  # therefore it is recommended to remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load Signature into a DomDocument object
    CALL doc.load("MyDocumentDetachedSignature.xml")
    # Create signature object from DomDocument root node
    LET sig = xml.Signature.CreateFromNode(doc.getDocumentElement())
    # Create HMAC key and assign it to the signature object
    LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-
sha1")
    CALL key.setKey("secretpassword")
    CALL sig.setKey(key)
    # Load original XML document into a DomDocument object

The Encryption class

The `xml.Encryption` class provides methods to encrypt and decrypt XML documents, nodes or symmetric keys.

It follows the XML-Encryption specifications.

The STATUS variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.Encryption methods

Methods for the `xml.Encryption` class.

Table 541: Class methods: Creation

Name	Description
`xml.Encryption.Create()` `  RETURNING` *enc* `xml.Encryption`	Constructor of an Encryption object.

Table 542: Class methods: String encryption and decryption

Name	Description
`xml.Encryption.DecryptString( key xml.CryptoKey , str STRING ) RETURNING rstr STRING`	Decrypts the encrypted string *str* encoded in BASE64, using the symmetric key *key*, and returns the string in clear text.
`xml.Encryption.EncryptString( key xml.CryptoKey, str STRING ) RETURNING rstr STRING`	Encrypts the string *str* using the symmetric key *key*, and returns the encrypted string encoded in BASE64.
`xml.Encryption.RSADecrypt( key STRING, enc STRING ) RETURNING rstr STRING`	Decrypts the BASE64 encrypted string *enc* using the RSA key *key* and returns it in clear text
`xml.Encryption.RSAEncrypt( key STRING, str STRING ) RETURNING rstr STRING`	Encrypts the string *str* using the RSA key *key* and returns it encoded in BASE64.

The methods listed in Table 542: Class methods: String encryption and decryption on page 2263 do not belong to the XML encryption specification, but are helper functions to allow BDL application to encrypt and decrypt short passwords with RSA keys, or big strings by using symmetric keys. Notice that a common way to encrypt data is to use symmetric keys, and to use RSA keys to encrypt the symmetric key value.

Table 543: Object methods: Key and certificate setting

Name	Description
`getEmbeddedKey() RETURNING key xml.CryptoKey`	Get a copy of the embedded symmetric key that was used in the last decryption operation.
`setCertificate( cert xml.CryptoX509 )`	Assigns a copy of the X509 certificate to this Encryption object.
`setKey( key xml.CryptoKey )`	Assigns a copy of the symmetric key to this Encryption object.
`setKeyEncryptionKey( key xml.CryptoKey )`	Assigns a copy of the **key-encryption** key to this Encryption object.

Table 544: Object methods: XML elements encryption and decryption

Name	Description
`decryptElement( enc xml.DomNode )`	Decrypts the EncryptedData DomNode *enc* using the symmetric key.
`decryptElementContent( enc xml.DomNode )`	Decrypts the EncryptedData DomNode *enc* using the symmetric key.
`encryptElement( node xml.DomNode )`	Encrypts the ELEMENT DomNode *node* and all its children using the symmetric key.
`encryptElementContent( node xml.DomNode )`	Encrypts all child nodes of the ELEMENT DomNode *node* using the symmetric key.

Table 545: Object methods: Detached XML elements encryption and decryption

Name	Description
`decryptElementDetached( enc xml.DomNode ) RETURNING node xml.DomNode`	Decrypts the EncryptedData DomNode *enc* using the symmetric key, and returns it in a new ELEMENT node
`decryptElementContentDetached( enc xml.DomNode ) RETURNING node xml.DomNode`	Decrypts the EncryptedData DomNode *enc* using the symmetric key, and returns all its children in one new DOCUMENT_FRAGMENT_NODE node.
`encryptElementDetached( node xml.DomNode ) RETURNING rnode xml.DomNode`	Encrypts the ELEMENT DomNode *node* and all its children using the symmetric key, and returns them as one new EncryptedData node.
`encryptElementContentDetached( node xml.DomNode ) RETURNING rnode xml.DomNode`	Encrypts all child nodes of the ELEMENT DomNode *node* using the symmetric key, and returns them as one new EncryptedData node.

Table 546: Object methods: Key encryption and decryption

Name	Description
`decryptKey( xml xml.DomDocument, url STRING ) RETURNING key xml.CryptoKey`	Decrypts the EncryptedKey as root in the given XML document, and returns a new CryptoKey of the given kind.
`encryptKey( key xml.CryptoKey )`	Encrypts the given symmetric or HMAC key as an EncryptedKey node and returns it as root node of a new XML document .

Name	Description
RETURNING *doc* xml.DomDocument	

xml.Encryption.Create

Constructor of an Encryption object.

Syntax

```
xml.Encryption.Create()
  RETURNING enc xml.Encryption
```

Usage

Returns a Encryption object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.decryptElement

Decrypts the EncryptedData DomNode *enc* using the symmetric key.

Syntax

```
decryptElement(
   enc xml.DomNode )
```

1. *enc* is the encrypted DomNode.

Usage

The encrypted DomNode *enc* is replaced at the same place in the XML document with the resulting ELEMENT DomNode and its children.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.decryptElementContent

Decrypts the EncryptedData DomNode *enc* using the symmetric key.

Syntax

```
decryptElementContent(
   enc xml.DomNode )
```

1. *enc* is the encrypted DomNode.

Usage

The encrypted DomNode *enc* is replaced at the same place in the XML document with the resulting child nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.decryptElementContentDetached

Decrypts the EncryptedData DomNode *enc* using the symmetric key, and returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

Syntax

```
decryptElementContentDetached(
   enc xml.DomNode )
  RETURNING node xml.DomNode
```

1. *enc* is the encrypted DomNode.

Usage

Returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

The resulting child nodes aren't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.decryptElementDetached

Decrypts the EncryptedData DomNode *enc* using the symmetric key, and returns it in a new ELEMENT node

Syntax

```
decryptElementDetached(
   enc xml.DomNode )
  RETURNING node xml.DomNode
```

1. *enc* is the encrypted DomNode.

Usage

The resulting DomNode and its children aren't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.decryptKey

Decrypts the EncryptedKey as root in the given XML document, and returns a new CryptoKey of the given kind.

Syntax

```
decryptKey(
   xml xml.DomDocument,
   url STRING )
  RETURNING key xml.CryptoKey
```

1. xml is the DomDocument object.
2. url is the string.

Usage

Returns a new CryptoKey of the given kind.

Only symmetric or HMAC keys are allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.DecryptString

Decrypts the encrypted string *str* encoded in BASE64, using the symmetric key *key*, and returns the string in clear text.

Syntax

```
xml.Encryption.DecryptString(
   key xml.CryptoKey ,
   str STRING )
  RETURNING rstr STRING
```

1. *key* is the symmetric key to use for decryption.
2. *str* is the encrypted string for decryption.

Usage

The key must be of usage: **encryption**.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.encryptElement

Encrypts the ELEMENT DomNode *node* and all its children using the symmetric key.

Syntax

```
encryptElement(
   node xml.DomNode )
```

Usage

The ELEMENT DomNode *node* and all its children are replaced at the same place in the XML document with the resulting EncryptedData node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.encryptElementContent

Encrypts all child nodes of the ELEMENT DomNode *node* using the symmetric key.

Syntax

```
encryptElementContent(
   node xml.DomNode )
```

Usage

The child nodes of the ELEMENT DomNode *node* are replaced at the same place in the XML document with the resulting EncryptedData node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.encryptElementContentDetached

Encrypts all child nodes of the ELEMENT DomNode *node* using the symmetric key, and returns them as one new EncryptedData node.

Syntax

```
encryptElementContentDetached(
   node xml.DomNode )
  RETURNING rnode xml.DomNode
```

1. node is the ELEMENT DomNode to encrypt.

Usage

Encrypts all child nodes of the ELEMENT DomNode *node* using the symmetric key, and returns them as one new EncryptedData node.

The resulting DomNode isn't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.encryptElementDetached

Encrypts the ELEMENT DomNode *node* and all its children using the symmetric key, and returns them as one new EncryptedData node.

Syntax

```
encryptElementDetached(
   node xml.DomNode )
  RETURNING rnode xml.DomNode
```

1. *node* is the ELEMENT DomNode to encrypt.

Usage

Encrypts the ELEMENT DomNode *node* and all its children using the symmetric key, and returns them as one new EncryptedData node.

The resulting DomNode isn't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.encryptKey

Encrypts the given symmetric or HMAC key as an EncryptedKey node and returns it as root node of a new XML document .

Syntax

```
encryptKey(
   key xml.CryptoKey )
```

```
   RETURNING doc xml.DomDocument
```

1. *key* is the given symmetric or HMAC key as an EncryptedKey node.

Usage

Returns it as root node of a new XML document. The key-encryption key must been set otherwise it will fail.

Depending on the feature set on the key-encryption key, the returned XML document will contain an additional KeyInfo node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.EncryptString

Encrypts the string *str* using the symmetric key *key*, and returns the encrypted string encoded in BASE64.

Syntax

```
xml.Encryption.EncryptString(
   key xml.CryptoKey,
   str STRING )
  RETURNING rstr STRING
```

1. *key* is the key.
2. *str* is the string to be encrypted.

Usage

The key must be of usage: **encryption**.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.getEmbeddedKey

Get a copy of the embedded symmetric key that was used in the last decryption operation.

Syntax

```
getEmbeddedKey()
  RETURNING key xml.CryptoKey
```

Usage

Returns a copy of the embedded symmetric key that was used in the last decryption operation, or NULL if there is none.

An embedded symmetric key is always encrypted, and needs therefore a **key-encryption** key to be set in order to decrypt it.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.RSADecrypt

Decrypts the BASE64 encrypted string *enc* using the RSA key *key* and returns it in clear text

Syntax

```
xml.Encryption.RSADecrypt(
   key STRING,
   enc STRING )
  RETURNING rstr STRING
```

1. *key* is the file name of a RSA private key in PEM format or an entry in the FGLPROFILE file.
2. *enc* is a string that was encrypted with the fglpass tool or with the `xml.Encryption.RSAEncrypt` method.

Usage

RSA decryption is only intended to short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, you password cannot exceed 512/8-12 = 52 bytes. If you need to handle big strings, you must use symmetric keys and the `DecryptString` method. However, you can use RSA keys to decrypt symmetric key values.

> **Important:** YOU MUST PAY ATTENTION TO RESTRICT ACCESS TO THAT RSA PRIVATE KEY FILE ONLY TO THE PERSON OR GROUP OF PERSON AUTHORIZED.

If the RSA private key is protected with a password the recommended way is to unprotect it with the openssl tool and to put the key file on a restricted file system. But you can also use a script or the fglpass agent to provide the password to the application.

For example, you can encrypt a database password with the fglpass tool and store it in the FGLPROFILE file, then you can decrypt it with the `base.Application.getResourceEntry` and the `xml.Encryption.RSADecrypt` method to connect to the database.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.RSAEncrypt

Encrypts the string *str* using the RSA key *key* and returns it encoded in BASE64.

Syntax

```
xml.Encryption.RSAEncrypt(
   key STRING,
   str STRING )
  RETURNING rstr STRING
```

1. *key* is the file name of a RSA public or private key in PEM format or an entry in the FGLPROFILE file.
2. *str* is the string to be encrypted.

Usage

RSA encryption is only intended to short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, you password cannot exceed 512/8-12 = 52 bytes. If you need to handle big strings, you must use symmetric keys and the `EncryptString` method. However, you can use RSA keys to encrypt symmetric key values.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.setCertificate

Assigns a copy of the X509 certificate to this Encryption object.

Syntax

```
setCertificate(
   cert xml.CryptoX509 )
```

1. *cert* is the copy of the X509 certificate.

Usage

The certificate will then be added to any further XML document or node encryption.

- NULL is allowed to avoid the certificate being added.
- To encrypt using a certificate, you must use the `createPublicKey` method of the X509 class to obtain the public key embedded in the certificate, and then provide it to the encryption object with above `setKeyEncryptionKey` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.setKey

Assigns a copy of the symmetric key to this Encryption object.

Syntax

```
setKey(
   key xml.CryptoKey )
```

1. key is the symmetric key.

Usage

Any further XML document or node encryption or decryption will use that symmetric key.

When decrypting a XML document that has an embedded symmetric key, the embedded key will be used instead.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.Encryption.setKeyEncryptionKey

Assigns a copy of the **key-encryption** key to this Encryption object.

Syntax

```
setKeyEncryptionKey(
   key xml.CryptoKey )
```

1. *key* is the **key-encryption** key.

Usage

Any further XML encryption will use that **key-encryption** key to encrypt the symmetric key set with `setKey()` within the resulting XML, and any further XML decryption will use that **key-encryption** key to decrypt the embedded symmetric key.

- NULL is allowed, meaning that embedded symmetric keys will not be encrypted nor decrypted anymore, assuming that they have been exchanged in another way.
- Only public or private RSA keys, or key-wrap keys are allowed.
- Public RSA keys can encrypt but not decrypt.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Examples

Examples using the xml.Encryption class.

Encrypt a XML node with a symmetric AES128 key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE root xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  LET doc = xml.DomDocument.Create()
  # Notice that white spaces are significant in crytography,
  # therefore it is recommended that you remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load XML file to be encrypted
    CALL doc.load("XMLFileToBeEncrypted.xml")
    LET root = doc.getDocumentElement()
    # Create symmetric AES128 key for XML encryption purposes
    LET symkey = xml.CryptoKey.Create(
                    "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
    CALL symkey.setKey(">secretpassword<") # password of 128 bits
    CALL symKey.setFeature("KeyName","MySecretKey") # Name the password
                      # in order to identify the key (Not mandatory)
    # Encrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKey(symkey) # Set the symmetric key to be used
    CALL enc.encryptElement(root) # Encrypt
    # Save encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("EncryptedXMLFile.xml")
  CATCH
    DISPLAY "Unable to encrypt XML file :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node with a symmetric AES128 key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE node xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  DEFINE list xml.DomNodeList
  DEFINE str String
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significants in crytography,
  # therefore it is recommended to remove unnecessary ones
```

```
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load encrypted XML file
    CALL doc.load("EncryptedXMLFile.xml")
    # Retrieve encrypted node (if any) from the document
    LET list = doc.getElementsByTagNameNS(
               "EncryptedData","http://www.w3.org/2001/04/xmlenc#")
    IF list.getCount()==1 THEN
      LET node = list.getItem(1)
    ELSE
      DISPLAY "No encrypted node found"
      EXIT PROGRAM
    END IF
    # Check if symmetric key name matches the expected "MySecretKey"
        (Not mandatory)
    LET list = node.selectByXPath(
                  "dsig:KeyInfo/dsig:KeyName[position()=1 and
                  text()=\"MySecretKey\"]","dsig",
                  "http://www.w3.org/2000/09/xmldsig#")
    IF list.getCount()!=1 THEN
      DISPLAY "Key name doesn't match"
      EXIT PROGRAM
    END IF
    # Create symmetric AES128 key for XML decryption purpose
    LET symkey = xml.CryptoKey.Create(
                    "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
    CALL symkey.setKey(">secretpassword<") # password of 128 bits
    # Decrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKey(symkey) # Set the symmetric key to be used
    CALL enc.decryptElement(node) # Decrypt
    # Save encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("DecryptedXMLFile.xml")
  CATCH
    DISPLAY "Unable to decrypt XML file :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Encrypt a XML node with a generated symmetric key protected with the public RSA key within a X509 certificate

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE root xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  DEFINE kek xml.CryptoKey
  DEFINE cert xml.CryptoX509
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significants in crytography,
  # therefore it is recommended to remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load XML file to be encrypted
    CALL doc.load("XMLFileToBeEncrypted.xml")
    LET root = doc.getDocumentElement()
    # Load the X509 certificate and retrieve the public RSA key
    # for key-encryption purpose
    LET cert = xml.CryptoX509.Create()
```

```
    CALL cert.loadPEM("RSA1024Certificate.crt")
    LET kek = cert.createPublicKey(
      "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
    # Generate symmetric key for XML encryption purpose
    LET symkey = xml.CryptoKey.Create(
      "http://www.w3.org/2001/04/xmlenc#aes256-cbc")
    CALL symkey.generateKey(NULL)
    # Encrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKey(symkey) # Set the symmetric key to be used
    CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to
                           # be used for protecting the symmetric key
    CALL enc.setCertificate(cert) # Set the certificate to be added
                                  # (not mandatory)
    CALL enc.encryptElement(root) # Encrypt
    # Save encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("EncryptedXMLFile.xml")
  CATCH
    DISPLAY "Unable to encrypt XML file :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node encrypted with a symmetric key protected with a private RSA key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE node xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  DEFINE kek xml.CryptoKey
  DEFINE list xml.DomNodeList
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significants in crytography,
  # therefore it is recommended to remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load encrypted XML file
    CALL doc.load("EncryptedXMLFile.xml")
    # Retrieve encrypted node (if any) from the document
    LET list = doc.getElementsByTagNameNS("EncryptedData",
      "http://www.w3.org/2001/04/xmlenc#")
    IF list.getCount()==1 THEN
      LET node = list.getItem(1)
    ELSE
      DISPLAY "No encrypted node found"
      EXIT PROGRAM
    END IF
    # Load the private RSA key
    LET kek = xml.CryptoKey.create(
      "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
    CALL kek.loadPEM("RSA1024Key.pem")
    # Decrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to
                                # decrypted the protected symmetric key
    CALL enc.decryptElement(node) # Decrypt
    # Retrieve the embedded symmetric key for futher usage and display
    # info about it
```

```
    LET symkey = enc.getEmbeddedKey()
    DISPLAY "Key size (in bytes) : ",symkey.getSize() # displays 1024
    DISPLAY "Key type : ",symkey.getType() # displays SYMMETRIC
    DISPLAY "Key usage : ",symkey.getUsage() # displays ENCRYPTION
    # Encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("DecryptedXMLFile.xml")
  CATCH
    DISPLAY "Unable to decrypt XML file :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

The KeyStore class

The `xml.KeyStore` class provides static methods to handle a key store global to the entire application. It enables to register X509 and trusted certificates, and any kind of key by name for automatic XML signature validation or XML decryption.

The `STATUS` variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.KeyStore methods

Methods for the `xml.KeyStore` class.

Table 547: Class methods

Name	Description
`xml.KeyStore.AddCertificate( cert xml.CryptoX509 )`	Registers the given X509 certificate as a certificate for the application. It will be used when an incomplete X509 certificate is detected during signature or encryption to complete the process by checking the certificate issuer name and serial number.
`xml.KeyStore.AddKey( key xml.CryptoX509 )`	Registers the given key by name to the application. It is used for XML signature verification or XML decryption when a key name was specified in the XML KeyInfo node and no other key was set in the Signature or Encryption object.
`xml.KeyStore.AddTrustedCertificate( cert xml.CryptoX509 )`	Registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

xml.KeyStore.AddCertificate

Registers the given X509 certificate as a certificate for the application. It will be used when an incomplete X509 certificate is detected during signature or encryption to complete the process by checking the certificate issuer name and serial number.

Syntax

```
xml.KeyStore.AddCertificate(
   cert xml.CryptoX509 )
```

1. *cert* is the X509 certificate to register.

Usage

The method has the same effect as the `FGLPROFILE` entry `xml.keystore.x509list`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.KeyStore.AddKey

Registers the given key by name to the application. It is used for XML signature verification or XML decryption when a key name was specified in the XML KeyInfo node and no other key was set in the Signature or Encryption object.

Syntax

```
xml.KeyStore.AddKey(
   key xml.CryptoX509 )
```

1. *key* is the key object xml.CryptoX509 to add to the keystore.

Usage

Registers the given key by name to the application. It is used for XML signature verification or XML decryption when a key name was specified in the XML KeyInfo node and no other key was set in the Signature or Encryption object.

The CryptoKey must have the KeyName feature set, and the name must be unique in the application.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

xml.KeyStore.**AddTrustedCertificate**

Registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

Syntax

```
xml.KeyStore.AddTrustedCertificate(
   cert xml.CryptoX509 )
```

1. *cert* is the X509 certificate to register.

Usage

Registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

Has the same effect as the `FGLPROFILE` entry `xml.keystore.calist`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

OM to XML Migration

Information to migrate code that uses the language build-in `om` package, to the Web Services extensions `xml` package.

Before you migrate, make sure that you are using the classes from the appropriate package:

- Classes from the `om` package exist to manipulate the AUI tree.

- Classes from the `xml` package provide full support for XML document processing, and should be used to manipulate XML documents.

Why would you migrate from `om` to `xml` classes and methods?

- You need to be able to utilize a feature (such as a StyleSheet) that requires use of methods from the `xml` library classes.

OM - XML Mapping

Table 548: OM - XML Mapping

OM class method	XML class method(s)
om.DomDocument.create	xml.DomDocument.createDocument
om.DomDocument.createFromXmlFile	xml.DomDocument.load
om.DomDocument.createFromString	xml.DomDocument.loadFromString
om.DomDocument.copy	xml.DomNode.clone
om.DomDocument.createChars	xml.DomDocument.createTextNode
om.DomDocument.createEntity	xml.DomDocument.createEntityReference
om.DomDocument.createElement	xml.DomDocument.createElement
om.DomDocument.getDocumentElement	xml.DomDocument.getFirstDocumentNode
om.DomDocument.getElementById	xml.DomDocument.getElementById + xml.DomNode.setIdAttribute or xml.DomNode.setIdAttributeNS
om.DomDocument.removeElement	xml.DomDocument.removeDocumentNode
om.DomNode.appendChild	xml.DomDocument.createNode + xml.DomNode.appendChild
om.DomNode.createChild	xml.DomDocument.createNode + xml.DomNode.appendChild
om.DomNode.insertBefore	xml.DomNode.insertBeforeChild
om.DomNode.removeChild	xml.DomNode.removeChild
om.DomNode.replaceChild	xml.DomNode.replaceChild
om.DomNode.loadXml	xml.DomDocument.loadFromString
om.DomNode.parse	xml.DomDocument.createNode + add it to the DomDocument
om.DomNode.toString	xml.DomNode.toString
om.DomNode.writeXml	xml.DomDocument.save
om.DomNode.write	xml.DomNode.toString
om.DomNode.getId	N/A
om.DomNode.getTagName	xml.DomNode.getLocalName
om.DomNode.setAttribute	xml.DomNode.setAttribute
om.DomNode.getAttribute	xml.DomNode.getAttribute

OM class method	XML class method(s)
om.DomNode.getAttributeInteger	xml.DomNode.getAttribute + condition for the default value and the cast
om.DomNode.getAttributeString	xml.DomNode.getAttribute + condition for the default value and the cast
om.DomNode.getAttributeName	xml.DomNode.getAttributeNodeItem + xml.DomNode.getLocalName
om.DomNode.getAttributesCount	xml.DomNode.getAttributesCount
om.DomNode.getAttributeValue	xml.DomNode.getAttributeNodeItem + xml.DomNode.getNodeValue
om.DomNode.removeAttribute	xml.DomNode.removeAttribute
om.DomNode.getChildCount	xml.DomNode.getChildrenCount
om.DomNode.getChildByIndex	xml.DomNode.getChildNodeItem
om.DomNode.getFirstChild	xml.DomNode.getFirstChild
om.DomNode.getLastChild	xml.DomNode.getLastChild
om.DomNode.getNext	xml.DomNode.getNextSibling
om.DomNode.getParent	xml.DomNode.getParentNode
om.DomNode.getPrevious	xml.DomNode.getPreviousSibling
om.DomNode.selectByTagName	xml.DomNode.getElementsByTagName
om.DomNode.selectByPath	xml.DomNode.selectByXPath
om.NodeList.item	xml.DomNodeList.getItem
om.NodeList.getLength	xml.DomNodeList.getCount

For more information on Genero built-in classes (such as the OM class), refer to Built-in packages on page 1687.

The security package

The Genero Web Services `security` package provides classes and methods to support basic cryptographic features.

Use the `IMPORT` statement at the top of the module using this library:

```
IMPORT security
```

- The RandomGenerator class on page 2279
- The Base64 class on page 2280
- The HexBinary class on page 2286
- The Digest class on page 2291

The RandomGenerator class
The `security.RandomGenerator` class includes methods for creating random strings or numbers.
security.RandomGenerator methods
Methods of the `security.RandomGenerator` class.

Table 549: Class methods

Name	Description
`security.RandomGenerator.CreateRandomNumber()` `  RETURNING result BIGINT`	Generates a 8-byte strong random number.

`security.RandomGenerator.CreateRandomString(`
`  size INTEGER )`
`  RETURNING result STRING`
	Creates a random base64 string.

`security.RandomGenerator.CreateUUIDString()` `  RETURNING result STRING`	Creates a new universal unique identifier (UUID).

security.RandomGenerator.CreateRandomNumber
Generates a 8-byte strong random number.

Syntax

```
security.RandomGenerator.CreateRandomNumber()
  RETURNING result BIGINT
```

1. *result* is a random big integer.

Usage

Generates a 8-byte strong random number and returns it as a `BIGINT`.

The generated number can then be used for advanced cryptographic features.

This method is based on openssl, using `/dev/random` on Unix and `CryptGenRandom()` on Microsoft Windows, which are following CSPRNG specifications.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.RandomGenerator.CreateRandomString
Creates a random base64 string.

Syntax

```
security.RandomGenerator.CreateRandomString(
   size INTEGER )
  RETURNING result STRING
```

1. *size* is the size of the random string.
2. *result* is the generated random string in Base64.

Usage

Generates a random binary data of *size* bytes long and returns it in a `STRING` encoded in a Base64 form.

The size must be greater than 0.

Use this function when randomness is required, such as in `xml.CryptoKey.deriveKey()` or `security.Digest.CreateDigestString()`.

This method is based on openssl, using `/dev/random` on Unix and `CryptGenRandom()` on Microsoft Windows, which are following CSPRNG specifications.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.RandomGenerator.CreateUUIDString
Creates a new universal unique identifier (UUID).

Syntax

```
security.RandomGenerator.CreateUUIDString()
  RETURNING result STRING
```

1. *result* is the new generated UUID string.

Usage

Generates an universal unique identifier and returns the value as `STRING`.

The generated strings follows the UUID version 4 specification. Version 4 UUIDs have the form `xxxxxxxx-xxxx-4xxx-yxxx-xxxxxxxxxxxx` where `x` is any hexadecimal digit and `y` is one of 8, 9, A, or B.

> **Note:** This method replaces `com.Util.CreateUUIDString()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The Base64 class
The `security.Base64` class includes methods for encoding to base64 or decoding from base64.
security.Base64 methods
Methods of the `security.Base64` class.

Table 550: Class methods

Name	Description
`security.Base64.FromByte( source BYTE ) RETURNING result STRING`	Encodes the given BYTE data in base64.
`security.Base64.FromHexBinary( source STRING ) RETURNING result STRING`	Decodes the given hexadecimal string to base64.
`security.Base64.FromString( source STRING )`	Encodes the given string in base64.

Name	Description
`RETURNING result STRING`	
`security.Base64.FromStringWithCharset( source STRING, charset STRING ) RETURNING result STRING`	Encodes the given string in base64, according to a given charset.
`security.Base64.LoadBinary( path STRING ) RETURNING result STRING`	Reads data from a file and encodes to base64.
`security.Base64.SaveBinary( path STRING, data STRING )`	Decodes the given base64 string and writes the data to a file.
`security.Base64.ToByte( source STRING, destination BYTE )`	Decodes the given base64 string into a BYTE.
`security.Base64.ToHexBinary( source STRING ) RETURNING result STRING`	Decodes the given base64 string to hexadecimal.
`security.Base64.ToString( source STRING ) RETURNING result STRING`	Decodes the given base64 string.
`security.Base64.ToStringWithCharset( source STRING, charset STRING ) RETURNING result STRING`	Decodes the given base64 string, according to a given charset.
`security.Base64.Xor( b64str1 STRING, b64str2 STRING ) RETURNING result STRING`	Computes the exclusive disjunction between two base64 encoded strings.

security.Base64.FromByte
Encodes the given BYTE data in base64.

Syntax

```
security.Base64.FromByte(
   source BYTE )
  RETURNING result STRING
```

1. *source* is the BYTE to be encoded.
2. *result* is the base64 encoded string.

Usage

Encodes the given BYTE data in base64 and returns the string.

> **Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.FromHexBinary
Decodes the given hexadecimal string to base64.

Syntax

```
security.Base64.FromHexBinary(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string in its hexadecimal form
2. *result* is a string encoded in base64

Usage

Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.FromString
Encodes the given string in base64.

Syntax

```
security.Base64.FromString(
   source STRING )
  RETURNING result STRING
```

1. *source* is the string to be encoded.
2. *result* is the base64 encoded string.

Usage

Encodes the given string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.FromStringWithCharset
Encodes the given string in base64, according to a given charset.

Syntax

```
security.Base64.FromStringWithCharset(
   source STRING,
   charset STRING )
  RETURNING result STRING
```

1. *source* is the string to be encoded.
2. *charset* is the character set to be used.
3. *result* is the base64 encoded string.

Usage

Encodes the given string and returns it in base64.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.LoadBinary
Reads data from a file and encodes to base64.

Syntax

```
security.Base64.LoadBinary(
   path STRING )
  RETURNING result STRING
```

1. *path* is the path to the binary file.
2. *result* is a string encoded in base64.

Usage

Reads the file located at `path` and encodes these binary data in Base64 format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.SaveBinary
Decodes the given base64 string and writes the data to a file.

Syntax

```
security.Base64.SaveBinary(
   path STRING,
   data STRING )
```

1. *path* is the path to the binary file
2. *data* is a base64 string to be written.

Usage

Decodes the given Base64 string and writes the binary data to the file defined by *path*.

This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.ToHexBinary
Decodes the given base64 string to hexadecimal.

Syntax

```
security.Base64.ToHexBinary(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string encoded in base64.
2. *result* is a string decoded in hexadecimal.

Usage

Decodes the given base64 string and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.ToByte
Decodes the given base64 string into a BYTE.

Syntax

```
security.Base64.ToByte(
   source STRING,
   destination BYTE )
```

1. *source* is a string in base64.
2. *destination* is the BYTE to fill with data.

Usage

Decodes the given base64 string and fills the BYTE variable with binary data.

> **Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.ToString
Decodes the given base64 string.

Syntax

```
security.Base64.ToString(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string encoded in base64.
2. *result* is the decoded string.

Usage

Decodes the given base64 string and returns it in its clear (human readable) form.

If the base64 string does not contain a human readable data, the method will raise an exception.

If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.ToStringWithCharset
Decodes the given base64 string, according to a given charset.

Syntax

```
security.Base64.ToStringWithCharset(
   source STRING,
   charset STRING )
  RETURNING result STRING
```

1. *source* is a string encoded in base64.
2. *charset* is the character set to be used.
3. *result* is the decoded string.

Usage

Decodes the given base64 string and returns it in its clear human readable form, according to a given charset.

The original base64 encoded string is first decoded to a string that will be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the base64 string does not contain a human readable data, the method will raise an exception.

If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Base64.Xor
Computes the exclusive disjunction between two base64 encoded strings.

Syntax

```
security.Base64.Xor(
   b64str1 STRING,
   b64str2 STRING )
  RETURNING result STRING
```

1. *b64str1* is a first string encoded in base64.
2. *b64str2* is a second string encoded in base64.
3. *result* is the xor result encoded in base64.

Usage

Decodes the two given strings and does an exclusive disjunction between the two binary and returns the result encoded in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

The HexBinary class

The `security.HexBinary` class includes methods for encoding to hexadecimal or decoding from hexadecimal.

security.HexBinary methods

Methods of the `security.HexBinary` class.

Table 551: Class methods

Name	Description
`security.HexBinary.FromBase64( source STRING ) RETURNING result STRING`	Converts a base64 string to the hexadecimal equivalent.
`security.HexBinary.FromByte( source BYTE ) RETURNING result STRING`	Encodes BYTE data in hexadecimal.
`security.HexBinary.FromString( source STRING ) RETURNING result STRING`	Encodes a given string in hexadecimal.
`security.HexBinary.FromStringWithCharset( source STRING, charset STRING ) RETURNING result STRING`	Encodes a given string in hexadecimal, according to a given charset.
`security.HexBinary.LoadBinary( path STRING ) RETURNING result STRING`	Reads binary data from a file and converts it to hexadecimal.
`security.HexBinary.SaveBinary( path STRING, data STRING )`	Decodes an hexadecimal strings and writes the binary data to a file.
`security.HexBinary.ToBase64( source STRING ) RETURNING result STRING`	Converts an hexadecimal string to the base64 equivalent
`security.HexBinary.ToByte( source STRING, destination BYTE )`	Decodes an hexadecimal string into a BYTE variable.
`security.HexBinary.ToString( source STRING ) RETURNING result STRING`	Decodes an hexadecimal string to a clear, human-readable string.
`security.HexBinary.ToStringWithCharset( source STRING, charset STRING )`	Decodes an hexadecimal string to a clear, human-readable string, according to a given charset.

Name	Description
`RETURNING result STRING`	
`security.HexBinary.Xor( hexstr1 STRING, hexstr2 STRING ) RETURNING result STRING`	Computes the exclusive disjunction between two hexadecimal encoded strings.

security.HexBinary.FromBase64
Converts a base64 string to the hexadecimal equivalent.

Syntax

```
security.HexBinary.FromBase64(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string encoded in base64.
2. *result* is a string decoded in hexadecimal.

Usage

Decodes the given base64 string and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.FromByte
Encodes BYTE data in hexadecimal.

Syntax

```
security.HexBinary.FromByte(
   source BYTE )
  RETURNING result STRING
```

1. *source* is the BYTE to be encoded in hexadecimal.
2. *result* is the encoded hexadecimal string.

Usage

Encodes the given BYTE data in hexadecimal and returns the string.

> **Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.FromString
Encodes a given string in hexadecimal.

Syntax

```
security.HexBinary.FromString(
```

```
    source STRING )
  RETURNING result STRING
```

1. *source* is the source string to be encoded in hexadecimal.
2. *result* is the encoded hexadecimal string.

Usage

Encodes the given string and returns it in hexadecimal.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.FromStringWithCharset
Encodes a given string in hexadecimal, according to a given charset.

Syntax

```
security.HexBinary.FromStringWithCharset(
  source STRING,
  charset STRING )
  RETURNING result STRING
```

1. *source* is the source string to be encoded in hexadecimal.
2. *charset* is the character set to be used.
3. *result* is the encoded hexadecimal string.

Usage

Encodes the given string and returns it in hexadecimal.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.LoadBinary
Reads binary data from a file and converts it to hexadecimal.

Syntax

```
security.HexBinary.LoadBinary(
   path STRING )
  RETURNING result STRING
```

1. *path* is the path to the binary file.
2. *result* is the string in hexadecimal format.

Usage

Reads the file located at *path* and returns these binary data in hexadecimal format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.SaveBinary
Decodes an hexadecimal strings and writes the binary data to a file.

Syntax

```
security.HexBinary.SaveBinary(
   path STRING,
   data STRING )
```

1. *path* is the path to the binary file.
2. *data* is the hexadecimal string to be written.

Usage

Decodes the given hexadecimal string and writes the binary data to the file defined by *path*.

This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.ToBase64
Converts an hexadecimal string to the base64 equivalent

Syntax

```
security.HexBinary.ToBase64(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string in its hexadecimal form.
2. *result* is a string encoded in base64.

Usage

Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.ToByte
Decodes an hexadecimal string into a BYTE variable.

Syntax

```
security.HexBinary.ToByte(
   source STRING,
   destination BYTE )
```

1. *source* is a string in hexadecimal.
2. *destination* is the BYTE to fill with data.

Usage

Decodes the given hexadecimal string and fills the BYTE variable with binary data.

Important: The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.ToString
Decodes an hexadecimal string to a clear, human-readable string.

Syntax

```
security.HexBinary.ToString(
   source STRING )
  RETURNING result STRING
```

1. *source* is a string in hexadecimal.
2. *result* is a human readable string.

Usage

Decodes the given hexadecimal string and returns it in its clear, human readable, form. If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.ToStringWithCharset
Decodes an hexadecimal string to a clear, human-readable string, according to a given charset.

Syntax

```
security.HexBinary.ToStringWithCharset(
   source STRING,
   charset STRING )
  RETURNING result STRING
```

1. *source* is a string in hexadecimal.
2. *charset* is the character set to be used.
3. *result* is a human readable string.

Usage

Decodes the given hexadecimal string and returns it in its clear human readable form, according to a given charset.

The original hexadecimal encoded string is first decoded to a string that will then be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.HexBinary.Xor
Computes the exclusive disjunction between two hexadecimal encoded strings.

Syntax

```
security.HexBinary.Xor(
   hexstr1 STRING,
```

```
   hexstr2 STRING )
  RETURNING result STRING
```

1. *hexstr1* is a first string in hexadecimal.
2. *hexstr1* is a second string in hexadecimal.
3. *result* is the xor result encoded in hexadecimal.

Usage

Decodes the two given string and does an exclusive disjunction between the two binary and returns the result in hexadecimal.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

The Digest class

The `security.Digest` class implements digest algorithms to process data.

The class implements several methods that allow you to add data by pieces and process these data with a specified digest algorithm.

Steps to process data with a digest algorithm:

1. Define the digest algorithm with the `security.Digest.CreateDigest` method.
2. Add data to the digest buffer with methods such as `security.Digest.AddData`, `security.Digest.AddBase64Data`, `security.Digest.AddHexBinaryData`, `security.Digest.AddStringData`.
3. When all data pieces are added, the buffer can be processed by calling methods like `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

Alternatively, a simple data string can be processed with the `security.Digest.CreateDigestString` method.

security.Digest methods

Methods of the `security.Digest` class.

Table 552: Class methods

Name	Description
`security.Digest.AddData( data BYTE )`	Adds a data from a BYTE variable to the digest buffer.
`security.Digest.AddBase64Data ( data STRING )`	Adds a data in base64 format to the digest buffer.
`security.Digest.AddHexBinaryData( data STRING )`	Adds a data in hexadecimal format to the digest buffer.
`security.Digest.AddStringData( data STRING )`	Adds a data string to the digest buffer.
`security.Digest.AddStringDataWithCharset( data STRING,`	Adds a data string to the digest buffer, after converting to the specified character set.

Name	Description
charset STRING)	
security.Digest.CreateDigest(*algo* STRING)	Defines a new digest context by specifying the algorithm to be used.
security.Digest.CreateDigestString(*password* STRING, *randBase64* STRING) RETURNING *result* STRING	Creates a SHA1 digest from the given string.
security.Digest.DoBase64Digest() RETURNING *b64Digest* STRING	Creates a digest of the buffered data and returns the result in base64 format.
security.Digest.DoHexBinaryDigest() RETURNING *hexBinDigest* STRING	Creates a digest of the buffered data and returns the result in hexadecimal format.

security.Digest.AddData
Adds a data from a BYTE variable to the digest buffer.

Syntax

```
security.Digest.AddData(
   data BYTE )
```

1. *data* is binary data to be added to the digest buffer.

Usage

Adds the binary data contained in the given BYTE to the digest context.

After adding all data pieces, the buffer can be processed by calling security.Digest.DoBase64Digest or security.Digest.DoHexBinaryDigest.

> **Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.AddBase64Data
Adds a data in base64 format to the digest buffer.

Syntax

```
security.Digest.AddBase64Data (
   data STRING )
```

1. *data* is the base64 data string to be added to the digest buffer.

Usage

Decodes the given base64 string and adds the binary data to the digest buffer.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.AddHexBinaryData
Adds a data in hexadecimal format to the digest buffer.

Syntax

```
security.Digest.AddHexBinaryData(
   data STRING )
```

1. *data* is the hexadecimal data string to be added to the digest buffer.

Usage

Decodes the given hexadecimal string and adds the binary data to the digest buffer.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.AddStringData
Adds a data string to the digest buffer.

Syntax

```
security.Digest.AddStringData(
   data STRING )
```

1. *data* is a human-readable character string to be added to the digest buffer.

Usage

Adds the specified string data to the digest buffer.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.AddStringDataWithCharset
Adds a data string to the digest buffer, after converting to the specified character set.

Syntax

```
security.Digest.AddStringDataWithCharset(
   data STRING,
   charset STRING )
```

1. *data* is a human-readable character string to be added to the digest buffer.
2. *charset* is the charset to be used.

Usage

Adds the specified string data to the digest buffer.

Before adding the string, it is converted from the local DVM charset to the specified encoding.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.CreateDigest
Defines a new digest context by specifying the algorithm to be used.

Syntax

```
security.Digest.CreateDigest(
   algo STRING )
```

1. *algo* is the digest algorithm to be used.

Usage

Creates and initializes a digest context to compute data digest according to the given algorithm.

Available digest algorithms are:

- `"SHA1"`
- `"SHA224"`
- `"SHA256"`
- `"SHA384"`
- `"SHA512"`
- `"MD5"`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.CreateDigestString
Creates a SHA1 digest from the given string.

Syntax

```
security.Digest.CreateDigestString(
   password STRING,
   randBase64 STRING )
  RETURNING result STRING
```

1. *password* is the password to be digested.
2. *randBase64* is a random string in Base64.
3. *result* is a base64 encoded string.

Usage

Computes the SHA1 digest from a *password* value and an optional *randBase64* random Base64 form string, and returns it into a string encoded in Base64 form.

The random value must be a valid Base64 String. You typically generate this value with the `security.RandomGenerator.CreateRandomString()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Example

```
DEFINE password, digest STRING
...
LET digest =
    security.Digest.CreateDigestString(
       password,
       security.RandomGenerator.CreateRandomString(16) )
```

security.Digest.DoBase64Digest
Creates a digest of the buffered data and returns the result in base64 format.

Syntax

```
security.Digest.DoBase64Digest()
  RETURNING b64Digest STRING
```

1. *b64Digest* is the digest in base64

Usage

Processes the digest on all data previously added to the context and encodes it in base64.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

security.Digest.DoHexBinaryDigest
Creates a digest of the buffered data and returns the result in hexadecimal format.

Syntax

```
security.Digest.DoHexBinaryDigest()
  RETURNING hexBinDigest STRING
```

1. *hexBinDigest* is the hexadecimal digest.

Usage

Processes the digest on all data previously added to the context and returns it in hexadecimal.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2546.

Example
Computing a hash value of a string.

Program example ComputeHash.4gl :

```
IMPORT SECURITY

MAIN
```

```
  DEFINE result STRING

  IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY "  string: the string to digest"
    DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
  ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
      DISPLAY "Hash value is :",result
    ELSE
      DISPLAY "Error"
    END IF
  END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

  DEFINE toDigest, algo, result STRING
  DEFINE dgst security.Digest

  TRY
    LET dgst = security.Digest.CreateDigest(algo)
    CALL dgst.AddStringData(toDigest)
    LET result = dgst.DoBase64Digest()
  CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY

  RETURN result
END FUNCTION
```

Example execution:

```
$ fglrun ComputeHash "Hello World" SHA1
```

Hash value is :Ck1VqNd45QIvq3AZd8XYQLvEhtA=

File extensions

This page describes the file extensions used by the language.

Table 553: File extensions

Extension	Type	Description
`.4gl`	Text	Source module
`.42m`	Binary	Compiler p-code module
`.per`	Text	Form specification file
`.42f`	XML	Compiled form specification file
`.42s`	Binary	Localized strings compiled file
`.4st`	XML	Presentation styles resource file
`.4sm`	XML	Startmenu resource file

Extension	Type	Description
`.4tm`	XML	Topmenu resource file
`.4tb`	XML	Toolbar resource file
`.4ad`	XML	Action defaults resource file
`.sch`	Text	Database schema file - column types
`.42d`	Binary (development only)	Database schema file index (for .sch)
`.str`	Text	Localized strings source file
`.val`	Text	Database schema file - form field attributes
`.att`	Text	Database schema file - video attributes
`.42r`	Binary	Compiled program
`.42x`	Binary	Compiled p-code library
`.msg`	Text	Message definition source file
`.iem`	Binary	Compiled message definition file

Genero BDL errors

System error messages sorted by error number.

Table 554: Genero system error messages

Number	Description
-201	`A syntax error has occurred.` This general SQL error message indicates mistakes in the syntax of an SQL statement. Look for missing or extra punctuation; keywords misspelled, misused, or out of sequence, or a reserved word used as an identifier.
-204	`An illegal floating point number has been found in the statement.` A numeric constant that is punctuated like a floating-point number (with a decimal point and/or an exponent starting with e) is unacceptable. Possibly the exponent is larger than can be processed.
-206	`The specified table table-name is not in the database.` The database server cannot find a table or view specified in the statement. The table or view might have been renamed or dropped from the database.
-213	`Statement interrupted by user.` The database server received an interrupt signal from the user. The statement ended early. A program should roll back the current transaction and terminate gracefully.
-217	`Column column-name not found in any table in the query.` The column specified does not exist in the database tables used in this SQL statement.

Number	Description
-235	`Character column size is too big.` The SQL statement specifies a width for a character data type that is greater than 65,534 bytes. If you need a column of this size, use the TEXT data type, which allows unlimited lengths. Otherwise, inspect the statement for typographical errors.
-236	`Number of columns in INSERT does not match number of VALUES.` Each column that is named or implied in an INSERT statement must have a separate value expression. If the statement does not list specific columns, review the definition of the table for the number of columns and their data types. Also check that the list of expressions in the VALUES clause has no extra or missing comma that might result in an incorrect number of values. Be especially careful of long character strings and expressions with parentheses.
-239	`Could not insert new row - duplicate value in a UNIQUE INDEX column.` The row that is being inserted (or being updated to have a new primary key) contains a duplicate value of some row that already exists, in a column or columns that are constrained to have unique values.
-244	`Could not do a physical-order read to fetch next row.` The database server cannot read the data block for this SQL client program. The database server returns this error when a record is locked by another process, and the lock timeout defined by the current program has expired. Consider using the `SET LOCK MODE TO WAIT` instruction to define a lock timeout. By default, with most databases, this timeout is zero and error -244 is returned immediately when a lock conflict occurs. If all programs do short transactions (holding locks for a short period of time), it is usually safe to define a lock timeout of 5 to 10 seconds to avoid this SQL error.
-250	`Cannot read record from file for update.` The database server cannot get a row of a table prior to update.
-251	`ORDER BY or GROUP BY column number is too big.` The ORDER BY or GROUP BY clause uses column-sequence numbers, and at least one of them is larger than the count of columns in the select list.
-253	`Cannot read record from file for update.` The database server cannot get a row of a table prior to update.
-254	`Too many or too few host variables given.` The number of host variables that you named in the INTO clause of this statement does not match the number of columns that you referenced in the SQL statement.
-255	`Not in transaction.`

Number	Description
	The database server cannot execute this COMMIT WORK or ROLLBACK WORK statement because no BEGIN WORK was executed to start a transaction. Because no transaction was started, you cannot end one.
-256	`Transaction not available.` The database server does not support transactions.
-257	`System limit on maximum number of statements exceeded, maximum is count.` The database server can handle only a fixed number of prepared SQL statements for each user. This limit includes statements that were prepared with the PREPARE statement and cursors that were declared with the DECLARE statement.
-259	`Cursor not open.` The current statement refers to a cursor that has not been opened. Review the logic of the program to see how it failed to execute the OPEN statement before it reached this point.
-263	`Could not lock row for UPDATE.` This statement, probably a FETCH statement that names a cursor declared FOR UPDATE, failed because the row it should have fetched could not be locked.
-266	`There is no current row for UPDATE/DELETE cursor.` The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement.
-268	`Unique constraint constraint-name violated.` The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement.
-272	`No SELECT permission for table/column.` The person who created this table has not granted SELECT privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can select data from the table or column.
-273	`No UPDATE permission for table/column.` The person who created this table has not granted UPDATE privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can update a row in this table or update the column.
-274	`No DELETE permission for table.`

Number	Description
	The person who created this table has not granted DELETE privilege to your account name or to the public. The owner of the table or the DBA must grant this privilege before you can delete a row in this table.
-275	`The Insert privilege is required for this operation.` The Insert access privilege on this table or column is not currently held by your account name, nor by the PUBLIC group, nor by your current role. The owner of the table or the DBA must grant the Insert privilege before you can insert a row into this table.
-280	`A quoted string exceeds 256 bytes.` A character literal in this statement exceeds the maximum length. Check the punctuation and length of all quoted strings in the statement. Possibly two missing quotes make a long string out of two short ones. You must revise the statement to use a shorter character string.
-282	`Found a quote for which there is no matching quote.` Inspect the current statement, examining the punctuation of all quoted strings.
-284	`A subquery has returned not exactly one row.` A subquery that is used in an expression in the place of a literal value must return only a single row and a single column. In this statement, a subquery has returned more than one row, and the database server cannot choose which returned value to use in the expression. You can ensure that a subquery will always return a single row. Use a WHERE clause that tests for equality on a column that has a unique index. Or select only an aggregate function. Review the subqueries, and check that they can return only a single row. This error can also occur when you use a singleton SELECT statement to retrieve multiple rows. You must use the DECLARE/OPEN/FETCH series of statements or the EXECUTE INTO statement to retrieve multiple rows.
-285	`Invalid cursor received by sqlexec.` The cursor that this statement uses has not been properly declared or prepared, or the FREE statement has released it, or an automatic re-prepare has been attempted while opening the cursor but that operation failed, leaving the cursor unavailable. Review the program logic to ensure that the cursor has been declared. If it has, and if the DECLARE statement refers to a statement identifier, check that the referenced statement has been prepared.
-290	`Cursor not declared with FOR UPDATE clause.` This statement attempts to update with a cursor that was not declared for update. To use a cursor with the UPDATE or DELETE statements, you must declare it FOR UPDATE. Review the program logic to make sure that this statement uses the intended cursor.
-294	`The column column-name must be in the GROUP BY list.` In a grouping SELECT, you must list every nonaggregate column in the GROUP BY clause to ensure that a well-defined value exists for each selected column in each grouped row. A column contains either a single aggregate value or a value unique to that group. If a selected column were neither an aggregate nor in the list, two or more values for that column might possibly exist in some group, and the database server

Number	Description
	could not choose which value to display. Revise the query to include either the column name or its positional number in the clause.
-307	`Illegal subscript.` The substring values (two numbers in square brackets) of a character variable are incorrect. The first is less than zero or greater than the length of the column, or the second is less than the first. Review all uses of square brackets in the statement to find the error. Possibly the size of a column has been altered and makes a substring fail that used to work.
-309	`ORDER BY column or expression must be in SELECT list.` An expression or column name is in the ORDER BY clause of this SELECT statement, but the expression or column name is not in the select list (the list of values that follows the word SELECT). This action is not supported when a UNIQUE or DISTINCT operator is being used in a query.
-316	`Index index-name already exists in database.` This statement tries to create an index with the name shown, but an index of that name already exists. Only one index of a given name can exist in a single database.
-324	`Ambiguous column column-name.` The column name appears in more than one of the tables that are listed in the FROM clause of this query. The database server needs to know which columns to use. Revise the statement so that this name is prefixed by the name of its table (table-name.column) wherever it appears in the query.
-329	`Database not found or no system permission.` The database you tried to connect to is not known by the db server. Check database client configuration settings and make sure that there is no spelling error in the name of the database
-330	`Cannot create or rename the database.` Possibly you tried to create a database with the same name as one that already exists or rename a database to a name that already exists; if so, choose a different name.
-349	`Database not selected yet.` The SQL statement cannot be executed because no current database exists. You must issue a DATABASE or CONNECT TO instruction before executing other SQL statements.
-350	`Index already exists on the column (or on the set of columns).` This CREATE INDEX statement cannot be executed because an index on the same column or combination of columns already exists. For a given collation order, at most two indexes can exist on any combination of columns, one ascending and one descending.
-354	`Incorrect database or cursor name format.`

Number	Description
	This statement contains the name of a database or a cursor in some invalid format. If the statement is part of a program, the name might have been passed in a host variable.
-360	`Cannot modify a table or view that is also used in subquery.` The UPDATE, INSERT, or DELETE statement uses data taken from the same table in a subquery. Because of the danger of entering an endless loop, this action is not allowed, except in the case of an uncorrelated subquery in the WHERE clause of the DELETE or UPDATE statement.
-363	`CURSOR not on SELECT statement.` The cursor named in this statement (probably an OPEN) has been associated with a prepared statement that is not a SELECT statement. Review the program logic, especially the DECLARE for the cursor, the statement id specified in it, and the PREPARE that set up that statement. If you intended to use a cursor with an INSERT statement, you can only do that when the INSERT statement is written as part of the DECLARE statement. If you intended to execute an SQL statement, do that directly with the EXECUTE statement, not indirectly through a cursor.
-366	`The scale exceeds the maximum precision specified.` A problem exists with the precision or scale of a DECIMAL or a MONEY data type usage, for example in a DEFINE statement. The first should be declared as DECIMAL(p) or DECIMAL(p,s) where p, the precision (total number of digits) is between 1 and 32, and s, the scale (number of digits to the right of the decimal point) is greater or equal to zero and not greater than p. The MONEY type follows the same rules. Review the DECIMAL or MONEY type definition, and make sure that the precision is in the range [1,32] and that the scale is in the range [0,precision].
-371	`Cannot create unique index on column with duplicate data.` This CREATE UNIQUE INDEX statement cannot be completed because the column (or columns) contains one or more duplicate rows.
-387	`No connect permission.` You cannot access the database that this statement requests because you have not been granted CONNECT privilege to it. Contact a person who has Database Administrator privilege to that database and ask to be granted CONNECT privileges to it.
-388	`No resource permission.` If you issued a CREATE TABLE, CREATE INDEX, or CREATE PROCEDURE statement, you cannot execute this statement because your account has not been granted the RESOURCE privilege for this database. You need the RESOURCE privilege to create permanent tables, indexes on permanent tables, and procedures.
-389	`No DBA permission.`

Number	Description
	This statement cannot be executed because you have not been granted DBA privilege for this database. Contact a person who has DBA privilege for the database and ask to be granted DBA privilege (or simply ask to have this statement executed for you).
-391	`Cannot insert a null into column column-name.` This statement tries to put a null value in the noted column. However, that column has been defined as NOT NULL. Roll back the current transaction. If this is a program, review the definition of the table, and change the program logic to not use null values for columns that cannot accept them.
-400	`Fetch attempted on unopen cursor.` This FETCH statement names a cursor that has never been opened or has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. Unless a cursor is declared WITH HOLD, it is automatically closed by a COMMIT WORK or ROLLBACK WORK statement.
-404	`The cursor or statement is not available.` You used a statement that names a cursor that is was destroyed. Review the program logic and check that the cursor specified is declared and opened, but not freed, prior to reaching this statement.
-410	`Prepare statement failed or was not executed.` This EXECUTE statement refers to a statement id that has not been prepared. Either no PREPARE statement was done, or one was done but returned an error code. Review the program logic to ensure that a statement is prepared and the PREPARE return code is checked. A negative error code from PREPARE usually reflects an error in the statement being prepared.
-412	`Command pointer is NULL.` This statement (probably an EXECUTE or DECLARE) refers to a dynamic SQL statement that has never been prepared or that has been freed. Review the program logic to ensure that the statement has been prepared, the PREPARE did not return an error code, and the FREE statement has not been used to release the statement before this point.
-413	`Insert attempted on unopen cursor.` This INSERT statement names a cursor that has never been opened or that has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK statement.
-422	`Flush attempted on unopen cursor.` This FLUSH statement names a cursor that has never been opened or has been closed. Review the program logic to ensure that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK.
-450	`Illegal ESQL locator, or uninitialized blob variable in BDL.` An SQL statement is using a TEXT or BYTE variable that was not initialized with LOCATE IN FILE or MEMORY.

Number	Description
	LOCATE the TEXT or BYTE variable before using it in SQL statements.
-458	`Long transaction aborted.` The database server ran out of log space in which to record this transaction. A transaction that is not fully recorded cannot be rolled back. To preserve database integrity, the operating system ended the transaction and rolled it back automatically. All changes made since the start of the transaction have been removed. Terminate the application, and replan it so that it modifies fewer rows per transaction. Alternatively, contact the database server administrator to discuss increasing the number or the size of the logical logs. Be prepared to talk about the number of rows being updated or inserted and the size of each row.
-481	`Invalid statement name or statement was not prepared.` The statement has not been prepared, or the format of the statement name is not valid. A valid statement name does not exceed the maximum length, begins with a letter or underscore, does not contain any blanks or nonalphanumeric characters except underscores.
-482	`Invalid operation on a non-SCROLL cursor.` You cannot issue a FETCH PRIOR, FETCH FIRST, FETCH LAST, FETCH CURRENT, FETCH RELATIVE n, or FETCH ABSOLUTE n statement with a non-scroll cursor. To do so, you must first declare the cursor as a scroll cursor.
-507	`Cursor cursor-name not found.` The cursor that is named in the WHERE CURRENT OF clause in this UPDATE or DELETE statement does not exist. Review the spelling of the name. If it is as you intended, check the DECLARE statement to ensure that it has been executed. Also make sure that the cursor has not been freed with the FREE statement or during a failed automatic re-prepare attempt.
-513	`Statement not available with this database server.` The SQL statement used by the program is not valid for the target database server. Review the code, the SQL instruction cannot be used.
-517	`The total size of the index is too large or too many parts in index.` All database servers have limits on the number of columns that can be included in an index and on the total number of bytes in a key (the sum of the widths of the columns). This CREATE INDEX statement would exceed that limit for this database server.
-522	`Table table-name not selected in query.` The table name used in an expression (for example, in the WHERE clause) has not been listed in the clause defininig the tables to be used in the query (typically the FROM clause in SELECT statements).
-526	`Updates are not allowed on a scroll cursor.` For a DECLARE statement, the clause FOR UPDATE is not allowed in conjunction with the SCROLL keyword.

Number	Description
-530	`Check constraint constraint-name failed.` The check constraint placed on the table column was violated.
-535	`Already in transaction.` This BEGIN WORK statement is redundant; a transaction is already in progress. If this is a program, review its logic to make sure it has not accidentally failed to end the previous transaction.
-551	`The constraint contains too many columns.` The total number of columns listed in a UNIQUE, PRIMARY KEY, or FOREIGN KEY clause is limited. The limit depends on the database server in use.
-674	`Routine routine-name cannot be resolved.` You called a routine that does not exist in the database, you do not have permission to execute the routine, or you called the routine with too few or too many arguments.
-681	`Column specified more than once in the INSERT list.` The error occurs if the user specifies a column name more than once in the INSERT column list.
-691	`Missing key in referenced table for referential constraint constraint-name.` A referential constraint has been violated. This condition usually occurs when you are trying to insert a value into or update the value of a column that is part of a referential constraint. The value you are trying to enter does not exist in the referenced (parent-key) column.
-743	`Object object_name already exists in database.` You are trying to define an object that already exists in the database.
-768	`Internal error in routine routine-name.` If this internal error recurs, note all circumstances and contact your technical support.
-805	`Cannot open file for load.` The input file that is specified in this LOAD statement could not be opened. Check the statement. Possibly a more complete pathname is needed, the file does not exist, or your account does not have read permission for the file or a directory in which it resides.
-806	`Cannot open file for unload.` The output file that is specified in this UNLOAD statement could not be opened. Check the statement. Possibly a more complete pathname is needed; the file exists, but your account does not have write permission for it; or the disk is full.
-809	`SQL Syntax error has occurred.` The INSERT statement in this LOAD/UNLOAD statement has invalid syntax.

Number	Description
	Review it for punctuation and use of keywords.
-846	`Number of values in load file is not equal to number of columns.` The LOAD processor counts the delimiters in the first line of the file to determine the number of values in the load file. One delimiter must exist for each column in the table, or for each column in the list of columns if one is specified. Check that you specified the file that you intended and that it uses the correct delimiter character. An empty line in the text can also cause this error. If the LOAD statement does not specify a delimiter, verify that the default delimiter matches the delimiter that is used in the file. If you are in doubt about the default delimiter, specify the delimiter in the LOAD statement.
-930	`Cannot connect to database server servername.` The application is trying to access the database server but failed.
-942	`Transaction commit failed - transaction will be rolled back.` This error can occur at transaction-commit time if the database server could not commit the transaction.
-1102	`Field name not found in form.` A field name listed in an INPUT, INPUT ARRAY, CONSTRUCT, SCROLL or DISPLAY statement does not appear in the form specification of the screen form that is currently displayed. Review the program logic to ensure that the intended window is current, the intended form is displayed in it, and all the field names in the statement are spelled correctly.
-1107	`Field subscript out of bounds.` The subscript of a screen array in an INPUT, DISPLAY, or CONSTRUCT statement is either less than 1 or greater than the number of fields in the array. Review the program source in conjunction with the form specification to see where the error lies.
-1108	`Record name not in form.` The screen record that is named in an INPUT ARRAY or DISPLAY ARRAY statement does not appear in the screen form that is now displayed. Review the program source in conjunction with the form specification to see if the screen record names match.
-1109	`List and record field counts differ.` The number of program variables does not agree with the number of screen fields in a CONSTRUCT, INPUT, INPUT ARRAY, DISPLAY, or DISPLAY ARRAY statement. Review the statement in conjunction with the form specification to see where the error lies. Common problems include a change in the definition of a screen record that is not reflected in every statement that uses the record, and a change in a program record that is not reflected in the form design.
-1110	`Form file (file-name) not found.`

Number	Description
	The form file that is specified in an OPEN FORM or OPEN WINDOW WITH FORM statement was not found. Inspect the form name used in the statement. It should not include the form file suffix. If the form is not in the current directory, verify that FGLRESOURCEPATH / DBPATH environment variables contain the path to the form file.
-1112	`A form is incompatible with the current BDL version. Rebuild your form.` The form file that is specified in an OPEN FORM statement is not acceptable. Possibly it was corrupted in some way, or it was compiled with a version of the Form Compiler that is not compatible with the version of the BDL compiler that compiled this program. Use a current version of the Form Compiler to recompile the form specification.
-1114	`No form has been displayed.` The current statement requires the use of a screen form. For example, DISPLAY...TO or an INPUT statement must use the fields of a form. However, the DISPLAY FORM statement has not been executed since the current window was opened. Review the program logic to ensure that it opens and displays a form before it tries to use a form.
-1119	`NEXT FIELD name not found in form.` This statement (INPUT or INPUT ARRAY) contains a NEXT FIELD clause that names a field that is not defined in the form. Review the form and program logic. Perhaps the form has been changed, but the program has not.
-1129	`Field ( field-name ) in BEFORE/AFTER clause not found in form.` This statement includes a BEFORE FIELD clause or an AFTER FIELD clause that names a field that is not defined in the form that is currently displayed. Review the program to ensure that the intended form was displayed, and review this statement against the form specification to ensure that existing fields are named.
-1133	`The NEXT OPTION name is not in the menu.` This MENU statement contains a NEXT OPTION clause that names a menu-option that is not defined in the statement. The string that follows NEXT OPTION must be identical to one that follows a COMMAND clause in the same MENU statement. Review the statement to ensure that these clauses agree with each other.
-1140	`NEXT OPTION is a hidden option.` The option that is named in this NEXT OPTION statement has previously been hidden with the HIDE OPTION statement. Because it is not visible to the user, it cannot be highlighted as the next choice. Use the SHOW OPTION statement to unhide the menu option.
-1141	`Cannot close window with active INPUT, DISPLAY ARRAY, or MENU statement.`

Number	Description
	This CLOSE WINDOW statement cannot be executed because an input operation is still active in that window. The CLOSE WINDOW statement must have been contained in, or called from within, the input statement itself. Review the program logic, and revise it so that the statement completes before the window is closed.
-1143	`Window is already open.` This OPEN WINDOW statement names a window that is already open. Review the program logic, and see whether it should contain a CLOSE WINDOW statement, or whether it should simply use a CURRENT WINDOW statement to bring the open window to the top.
-1146	`PROMPT message is too long to fit in the window.` Although BDL truncates the output of MESSAGE and COMMENT to fit the window dimensions, it does not do so for PROMPT and the user's response. Reduce the length of the prompt string, or make the window larger. You could display most of the prompting text with DISPLAY and then prompt with a single space or colon.
-1150	`Window is too small to display this menu.` The window must be at least two rows tall, and it must be wide enough to display the menu title, the longest option name, two sets of three-dot ellipses, and six spaces. Revise the program to make the window larger or to give the menu a shorter name and shorter options. Review the OPEN WINDOW statement for the current window in conjunction with this MENU statement.
-1168	`Command does not appear in the menu.` The SHOW OPTION, HIDE OPTION, or NEXT OPTION statement cannot refer to an option (command) that does not exist. Check the spelling of the name of the option.
-1170	`The type of your terminal is unknown to the system.` Check the setting of your TERM environment variable and the setting of your TERMCAP or TERMINFO environment variable. Check with your system administrator if you need help with this action.
-1202	`An attempt was made to divide by zero.` Zero cannot be a divisor. Check that the divisor is not zero. In some cases, this error arises because the divisor is a character value that does not convert properly to numeric.
-1204	`Invalid year in date.` The year in a DATE value or literal is invalid. For example, the number 0000 is not acceptable as the year. Check the value of year.

Number	Description
-1205	`Invalid month in date.` The month in a DATE value or literal must be a one- or two-digit number from 1 to 12. Check the value of month.
-1206	`Invalid day in date.` The day number in a DATE value or literal must a one- or two-digit number from 1 to 28 (or 29 in a leap year), 30, or 31, depending on the month that accompanies it. Check the value of day.
-1210	`Date could not be converted to month/day/year format.` The DATE type is compatible with the INTEGER type, but not all integer values are valid dates. The range of valid integer values for dates is from -693,594 to +2,958,464. Numbers that are outside this range have no representation as dates. Check the value of the number used to assign the date variable.
-1212	`Date conversion format must contain a month, day, and year component.` When a date value is converted between internal binary format and display or entry format, a pattern directs the conversion. When conversion is done automatically, the pattern comes from the environment variable DBDATE. When it is done with an explicit call to the rfmtdate(), rdefmtdate(), or USING functions, a pattern string is passed as a parameter. In any case, the pattern string (the format of the message) must include letters that show the location of the three parts of the date: 2 or 3 letters d; 2 or 3 letters m; and either 2 or 4 letters y. Check the pattern string and the value of DBDATE.
-1213	`A character to numeric conversion process failed.` A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number. Check the character string. It must not contain characters other than white space, digits, a sign, a decimal, or the letter e. Verify the parts are in the right order. If you are using NLS, the decimal character or thousands separator might be wrong for your locale.
-1214	`Value too large to fit in a SMALLINT.` The SMALLINT data type can accept numbers with a value range from -32,767 to +32,767. To store numbers that are outside this range, redefine the column or variable to use INTEGER or DECIMAL type.
-1215	`Value too large to fit in an INTEGER.` The INTEGER data type can accept numbers with a value range from -2,147,483,647 to +2,147,483,647. Check the other data types available, such as DECIMAL.
-1218	`String to date conversion error.`

Number	Description
	The data value does not properly represent a date: either it has non-digits where digits are expected, an unexpected delimiter, or numbers that are too large or are inconsistent. Check the value being converted.
-1222	`Value will not fit in a SMALLFLOAT.` A statement tries to assign a value that exceeds the limits of the SMALLFLOAT data type. Review the code and consider using a FLOAT or DECIMAL type.
-1223	`Value will not fit in a FLOAT.` A statement tries to assign a value that exceeds the limits of the FLOAT data type. Review the code and consider using a DECIMAL type.
-1226	`Decimal or money value exceeds maximum precision.` The data value has more digits to the left of the decimal point than the declaration of the variable allows. Revise the program to define the variable with an appropriate precision.
-1260	`It is not possible to convert between the specified types.` Data conversion does not make sense, or is not supported. Possibly you referenced the wrong variable or column. Check that you have specified the data types that you intended and that literal representations of data values are correctly formatted.
-1261	`Too many digits in the first field of datetime or interval.` The first field of a DATETIME literal must contain 1 or 2 digits (if it is not a YEAR) or else 2 or 4 digits (if it is a YEAR). The first field of an INTERVAL literal represents a count of units and can have up to 9 digits, depending on the precision that is specified in its qualifier. Review the DATETIME and INTERVAL literals in this statement, and correct them.
-1262	`Non-numeric character in datetime or interval.` A DATETIME or INTERVAL literal can contain only decimal digits and the allowed delimiters: the hyphen between year, month, and day numbers; the space between day and hour; the colon between hour, minute, and second; and the decimal point between second and fraction. Any other characters, or these characters in the wrong order, produce an error. Check the value of the literal.
-1263	`A field in a datetime or interval is out of range.` At least one of the fields in a datetime or interval is incorrect. Inspect the DATE, DATETIME, and INTERVAL literals in this statement. In a DATE or DATETIME literal, the year might be zero, the month might be other than 1 to 12, or the day might be other than 1 to 31 or inappropriate for the month. Also in a DATETIME

Number	Description
	literal, the hour might be other than 0 to 23, the minute or second might be other than 0 to 59, or the fraction might have too many digits for the specified precision.
-1264	`Extra characters at the end of a datetime or interval.` Only spaces can follow a DATETIME or INTERVAL literal. Inspect this statement for missing or incorrect punctuation.
-1265	`Overflow occurred on a datetime or interval operation.` An arithmetic operation involving a DATETIME and/or INTERVAL produced a result that cannot fit in the target variable. Check if the data type can hold the result of the operation. For example, extend the INTERVAL precision by using YEAR(9) or DAY(9).
-1266	`Intervals or datetimes are incompatible for the operation.` An arithmetic operation mixes DATETIME and/or INTERVAL values that do not match. Check the data types of the variable used in the operation.
-1267	`The result of a datetime computation is out of range.` In this statement, a DATETIME computation produced a value that cannot be stored. This situation can occur, for example, if a large interval is added to a DATETIME value. This error can also occur if the resultant date does not exist, such as Feb 29, 1999. Review the expressions in the statement and see if you can change the sequence of operations to avoid the overflow.
-1268	`Invalid datetime or interval qualifier.` This statement contains a DATETIME or INTERVAL qualifier that is not acceptable. These qualifiers can contain only the words YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, FRACTION, and TO. A number from 1 to 5 in parentheses can follow FRACTION. Inspect the statement for missing punctuation and misspelled words. A common error is adding an s, as in MINUTES.
-1279	`Value exceeds string column length.` You attempted to insert into a CHAR, NCHAR, VARCHAR, NVARCHAR or LVARCHAR column using a string host variable, but the string is too long.
-1284	`Value will not fit in a BIGINT or INT8.` The BIGINT data type can accept numbers with a value range from -9223372036854775807 to +9223372036854775807. To store numbers that are outside this range, redefine the column or variable to use the DECIMAL type.
-1301	`This value is not among the valid possibilities.` A list or range of acceptable values has been established for this column in the form-specification file. You must enter a value within the acceptable range.

Number	Description
-1302	`The two entries were not the same -- please try again.` To guard against typographical errors, this field has been designated VERIFY in the form-specification file. You must enter the value in this field twice, identically. Carefully reenter the data. Alternatively, you can cancel the form entry with the Interrupt key.
-1303	`You cannot use this editing feature because a picture exists.` This field is defined in the form-specification file with a PICTURE attribute to specify its format. You cannot use certain editing keys (for example, CTRL-A, CTRL-D, and CTRL-X) while you are editing such a field. Use only printable characters and backspace to enter the value.
-1304	`Error in field.` You entered a value in this field that cannot be stored in the program variable that is meant to receive it. Possibly you entered a decimal number when the application provided only an integer variable, or you entered a character string that is longer than the application expected.
-1305	`This field requires an entered value.` The cursor is in a form field that has been designated REQUIRED. You must enter some value before the cursor can move to another field. To enter a null value, type any printable character and then backspace. Alternatively, you can cancel the form entry with the Interrupt key.
-1306	`Please type again for verification.` The cursor is in a form field that has been designated VERIFY. This procedure helps to ensure that no typographical errors occur during data entry. You must enter the value twice, identically, before the cursor can move to another field. Alternatively, you can cancel the form entry with the Interrupt key.
-1307	`Cannot insert another row - the input array is full.` You are entering data into an array of records that is represented in the program by a static array of program variables. That array is now full; no place is available to store another record. Press the ACCEPT key to process the records that you have entered.
-1308	`Cannot delete row - it has no data.` You try to delete a row in an empty row. Nothing was deleted.
-1309	`There are no more rows in the direction you are going.` You are attempting to scroll an array of records farther than it can go, either scrolling up at the top or scrolling down at the bottom of the array. Further attempts will have the same result.
-1312	`FORMS statement error number error-num.`

Number	Description
	An error occurred in the form at runtime. Edit your source file: go to the specified line, correct the error, and recompile the file.
-1313	`SQL statement error number error-num.` The current SQL statement returned this error code number.
-1314	`Program stopped at 'filename', line number line-number.` At runtime an error occurred in the specified file at the specified line. No .err file is generated. Edit your source file, go to the specified line, correct the error, and recompile the file.
-1318	`A parameter count mismatch has occurred between the calling function and the called function.` Either too many or too few parameters were given in the call to the function. The call is probably in a different source module from the called functions. Inspect the definition of the function, and check all places where it is called to ensure that they use the number of parameters that it declares.
-1320	`A function has not returned the correct number of values expected.` A function that returns several variables has not returned the correct number of parameters. Check your source code and recompile.
-1321	`A validation error has occurred as a result of the VALIDATE command.` The VALIDATE LIKE statement tests the current value of variables against rules that are stored in the syscolval table. It has detected a mismatch. Ordinarily, the program would use the WHENEVER statement to trap this error and display or correct the erroneous values. Inspect the VALIDATE statement to see which variables were being tested and find out why they were wrong.
-1322	`A report output file cannot be opened: description` The file that the REPORT TO statement specifies cannot be opened. See the description for more details. Check that your account has permission to write such a file, that the disk is not full, and that you have not exceeded some limit on the number of open files.
-1323	`A report output pipe cannot be opened.` The pipe that the REPORT TO PIPE statement specifies could not be started. Check that all programs that are named in it exist and are accessible from your execution path. Also look for operating-system messages that might give more specific errors.
-1324	`A report output file cannot be written to.`

Number	Description
	The file that the REPORT TO statement specifies was opened, but an error occurred while writing to it. Possibly the disk is full. Look for operating- system messages that might give more information.
-1326	`An array variable has been referenced outside of its specified dimensions.` The subscript expression for an array has produced a number that is either less than one or greater than the number of elements in the array. Review the program logic that leads up to this statement to determine how the error was made.
-1327	`An insert statement could not be prepared for inserting rows into a temporary table used for a report.` Within the report function, BDL generated an SQL statement to save rows into a temporary table. The dynamic preparation of the statement (see the reference material on the PREPARE statement) produced an error. Probably the database tables are not defined now, at execution time, as they were when the program was compiled. Either the database has been changed, or the program has selected a different database than the one that was current during compilation. Possibly the database administrator has revoked SELECT privilege from you for one or more of the tables that the report uses. Look for other error messages that might give more details.
-1328	`A temporary table needed for a report could not be created in the selected database.` Within the report definition, BDL generated an SQL statement to save rows into a temporary table, but the temporary table could not be created. You must have permission to create tables in the selected database, and there must be sufficient disk space left in the database. You may already have a table in your current database with the same name as the temporary table that the report definition is attempting to create as a sorting table; the sorting table is named "t_ reportname ". Another possible cause with some database servers is that you have exceeded an operating-system limit on open files.
-1329	`A database index could not be created for a temporary database table needed for a report.` Within the report definition, BDL generated SQL statements to save rows into a temporary table. However, an index could not be created on the temporary table. Probably an index with the same name already exists in the database. (The sorting index is named "i_reportname"; for example, "i_order_rpt".) Possibly no disk space is available in the file system or dbspace. Another possibility with some database servers is that you have exceeded an operating-system limit on open files.
-1330	`A row could not be inserted into a temporary report table.` Within the report definition, BDL generated SQL statements that would save rows into a temporary table. However, an error occurred while rows were being inserted.

Number	Description
	Probably no disk space is left in the database. Look for other error messages that might give more details.
-1331	`A row could not be fetched from a temporary report table.` Within the report definition, BDL generated SQL statements to select rows from a temporary table. The table was built successfully but now an error occurred while rows were being retrieved from it. Almost the only possible cause is a hardware failure or an error in the database server. Check for operating-system messages that might give more details.
-1332	`A character variable has referenced subscripts that are out of range.` In the current statement, a variable that is used in taking a substring of a character value contains a number less than one or a number greater than the size of the variable, or the first substring expression is larger than the second. Review the program logic that leads up to this statement to find the cause of the error.
-1335	`A report is accepting output or being finished before it has been started.` The program executed an OUTPUT TO REPORT or FINISH REPORT statement before it executed a START REPORT. Review the program logic that leads up to this statement to find the cause of the error.
-1337	`The variable variable-name has been redefined with a different type or length, definition in module-name-1.4gl, redefinition in module-name-2.4gl.` The variable that is shown is defined in the GLOBALS section of two or more modules, but it is defined differently in some modules than in others. Possibly modules were compiled at different times, with some change to the common GLOBALS file between. Possibly the variable is declared as a module variable in some module that does not include the GLOBALS file.
-1338	`The function 'function-name' has not been defined in any module in the program.` The named function is called from at least one module of the program, but it is defined in none. Verify that the module containing the function is a part of the program, and that the function name is correctly spelled.
-1340	`The error log has not been started.` The program called the errorlog() function without first calling the startlog() function. Review the program logic to find out the cause of this error.
-1349	`Character to numeric conversion error.` A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number. It

Number	Description
	contains some characters other than white space, digits, a sign, a decimal, or the letter e, or else the parts are in the wrong order so that the number cannot be deciphered.
-1353	`Use '!' to edit TEXT and BYTE fields.` This is a normal message text used outside an error context.
-1355	`Cannot build temporary file.` A TEXT or BYTE variable has been located in a temporary file using the LOCATE statement. The current statement assigns a value into that variable, so BDL attempted to create the temporary file, but an error occurred. Possibly no disk space is available, or your account does not have permission to create a temporary file. Look for operating-system error messages that might give more information.
-1359	`Read error on blob file 'file-name'.` The operating system signaled an error during output to a temporary file in which a TEXT or BYTE variable was being saved. Possibly the disk is full, or a hardware failure occurred. For more information, look for operating-system messages.
-1360	`No PROGRAM= clause for this field.` No external program has been designated for this field using the PROGRAM attribute in the form-specification file (For Text User Interface mode on ASCII terminals only)
-1373	`The field 'field-name' is not in the list of fields in the CONSTRUCT/INPUT statement.` The built-in function get_fldbuf() or field_touched() has been called with the field name shown. However, input from that field was not requested in this CONSTRUCT or INPUT statement. As a result, the function cannot return any useful value. Review all uses of these functions, and compare them to the list of fields at the beginning of the statement.
-1374	`SQL character truncation or transaction warning.` The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement involved is a DATABASE statement, the condition is that the database that was just opened uses a transaction log. On any other statement, the condition is that a character value from the database had to be truncated to fit in its destination.
-1375	`SQL NULL value in aggregate or mode ANSI database warning.` The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE statement, the condition is that the database that was just opened is ANSI compliant. On any other statement, the condition is that a null value has been used in the computation of an aggregate value.
-1376	`SQL, database server, or program variable mismatch warning.` The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE or CREATE DATABASE statement, the condition is that the database server opened the database. On any other statement,

Number	Description
	the condition is that a SELECT statement returned more values than there were program variables to contain them.
-1377	`SQL float-to-decimal conversion warning.` The program set WHENEVER WARNING STOP, and a warning condition arose. The condition is that in the database that was just opened, the database server will use the DECIMAL data type for FLOAT values.
-1378	`SQL non-ANSI extension warning.` A database operation was performed that is not part of ANSI SQL, although the current database is ANSI compliant. This message is informational only.
-1396	`A report PRINT FILE source file cannot be opened for reading.` The file that is named in a PRINT FILE statement cannot be opened. Review the file name. If it is not in the current directory, you must specify the full path. If the file exists, make sure your account has permissions to read it.
-2017	`The character data value does not convert correctly to the field type.` You have entered a character value (a quoted string) into a field that has a different data type (for example INTEGER). However, the characters that you entered cannot be converted to the type of the field. Re-enter the data.
-2024	`There is already a record 'record-name' specified.` A screen record is automatically defined for each table that is used in the ATTRIBUTES section to define a field. If you define a record with the name of a table, it is seen as a duplicate. Check that the record-name of every screen record and screen array is unique in the form specification.
-2028	`The symbol 'symbol-name' does not represent a table prefix used in this form.` In a SCREEN RECORD statement, each component must be introduced by the name of the table as defined in the TABLES section or by the word FORMONLY. Review the spelling of the indicated name against the TABLES section, and check the punctuation of the rest of the statement.
-2029	`Screen record array 'record-name' has different component sizes.` The screen record array name has component sizes which either differ from the specified dimension of the array or differ among themselves. This error message appears when one or more of the columns appear a different number of times. The dimension of the screen array is written in square brackets that follow its name. Verify that the dimensions of the screen array match the screen fields.
-2039	`The attributes AUTONEXT, DEFAULT, INCLUDE, VERIFY, RIGHT and ZEROFILL are not supported for BLOB fields.`

Number	Description
	Columns of the data type specified cannot be used in the ways that these attributes imply. Check that the table and column names are as you intended, and verify the current definition of the table in the database that the DATABASE statement names.
-2041	`The form 'form-name' cannot be opened.` The form filename cannot be opened. This is probably because it does not exist, or the user does not have read permission. Check the spelling of filename. Check that the form file exists in your current directory. If it is in another directory, check that the correct pathname has been provided. On a UNIX™ system, if these things are correct, verify that your account has read permission on the file.
-2045	`The conditional attributes of a field cannot depend on the values of other fields.` The boolean expression in a WHERE clause of a COLOR attribute can use only the name of that field and constants. Revise this attribute, and recompile the form.
-2100	`Field 'field-name' has validation string error, String = string.` One of the formatting or validation strings that is stored in the syscolval or syscolatt tables is improperly coded. The string is shown as is the field to which it applies. Update the string in the tables.
-2810	`The name 'database-name' is not an existing database name.` This name, which was found in the DATABASE statement at the start of the form specification, is not a database that can be found. Check the spelling of the database name and the database entries in the fglprofile file.
-2820	`The label name between brackets is incorrectly given or the label is missing.` In the layout section of a form specification, the brackets should contain a simple name. Instead, they contain spaces or an invalid name. Check the layout section of the form for invalid form item labels.
-2830	`A left square bracket has been found on this line, with no right square bracket to match it.` Every left square bracket field delimiter must have a right square bracket delimiter on the same line. Review the form definition file to make sure all fields are properly marked.
-2840	`The field label 'label-name' was not defined in the form.` The indicated name appears at the left of this ATTRIBUTES statement, but it does not appear within brackets in the SCREEN section. Review the field tags that have been defined to see why this one was omitted.

Number	Description
-2843	`The column 'column-name' does not appear in the form specification.` A name in this ATTRIBUTES statement should have been defined previously in the form specification. Check that all names in the statement are spelled correctly and defined properly.
-2846	`The field 'field-name' is not a member of the table 'table-name'.` Something in this statement suggests that the name shown is part of this table, but that is not true in the current database. Review the spelling of the two names. If they are as you intended, check that the correct database is in use and that the table has not been altered.
-2859	`The column 'column-name' is a member of more then one table -- you must specify the table name.` Two or more tables that are named in the TABLES section have columns with the name shown. You must make clear which table you mean. To do this, write the table name as a prefix of the column name, as table.column, wherever this name is used in the form specification.
-2860	`There is a column/value type mismatch for 'column-name'.` This statement assigns a value to the field with the DEFAULT clause or uses its value with the INCLUDE clause, but it does so with data that does not agree with the data type of the field. Review the data type of the field (which comes from the column with which it is associated), and make sure that only compatible values are assigned.
-2862	`The table 'table-name' cannot be found in the database.` The indicated table does not exist in the database that is named in the form. Check the spelling of the table name and database name. If they are as you intended, either you are not using the version of the database that you expected, or the database has been changed.
-2863	`The column 'column-name' does not exist among the specified tables.` The tables that are specified in the TABLES section of the form exist, but column-name, which is named in the ATTRIBUTES section, does not. Check its spelling against the actual table. Possibly the table was altered, or the column was renamed.
-2864	`The table 'table-name' is not among the specified tables.` The indicated table is used in this statement but is not defined in the TABLES section of the form specification. Check its spelling; if it is as you intended, add the table in the TABLES section.

Number	Description
-2865	`The column 'column-name' does not exist in the table 'table-name'.` Something in this statement implies that the column shown is part of the indicated table (most likely the statement refers to table-name.column-name). However, it is not defined in that table. Check the spelling of both names. If they are as you intended, then make sure that the database schema (.sch) is up to date; possibly the table has been altered or the column renamed, and thus needs a new db schema extraction with the fgldbsch tool.
-2892	`The column 'column-name' appears more then once. If you wish a column to be duplicated in a form, use the same display field label.` The same column name is listed in the ATTRIBUTES section more than once. The expected way to display the same column in two or more places is to put two or more fields in the screen layout, each with the same tag-name. Then put a single statement in the ATTRIBUTES section to associate that tag-name with the column name. The current column value will be duplicated in all fields. If you intended to display different columns that happen to have the same column-names, prefix each column with its table-name.
-2893	`The display field label 'label-name' appears more than once in this form, but the lengths are different.` You can put multiple copies of a field in the screen layout (all will display the same column), but all copies must be the same length. Review the form definition to make sure that, if you intended to have multiple copies of one field, all copies are the same.
-2975	`The display field label 'label-name' has not been used.` A field tag has been declared in the screen section of the form- specification file but is not defined in the attributes section. Check your form-specification file.
-2992	`The display label 'label-name' has already been used.` The forms compiler indicates that name has been defined twice. These names must be defined uniquely in the form specification. Review all uses of the name to see if one of them is incorrect.
-2997	`See error number error-num.` The database server returned an error that is shown. Look up the shown error in the database server documentation.
-4303	`A blob variable or cursor name expected .` The argument to the FREE statement must be the name of a cursor or prepared statement or, in BDL, the name of a variable with the BYTE or TEXT data type. Check the name used after the FREE keyword.

Number	Description
-4307	`The number of variables and/or constants in the display list does not match the number of form fields in the display destination.` There must be exactly as many items in the list of values to display as there are fields listed following the TO keyword in this statement. Review the statement.
-4308	`The number of input variables does not match the number of form fields in the screen input list.` Your INPUT statement must specify the same number of variables as it does fields. When checking this, keep in mind that when you refer to a record using an asterisk or THRU, it is the same as listing each record component individually.
-4309	`Printing cannot be done within a loop or CASE statement contained in report headers or trailers.` BDL needs to know how many lines of space will be devoted to page headers and trailers; otherwise, it does not know how many detail rows to allow on a page. Since it cannot predict how many times a loop will be executed, or which branch of a CASE will be execute, it forbids the use of PRINT in these contexts within FIRST PAGE HEADER, PAGE HEADER, and PAGE TRAILER sections. Re-arrange the code to place the PRINT statement where it will always be executed.
-4319	`The symbol 'symbol-name' has been defined more than once.` The variable that is shown has appeared in at least one other DEFINE statement before this one. Review your code. If this DEFINE is within a function or the MAIN section, the prior one is also. If this DEFINE is outside any function, the prior one is also outside any function; however, it might be within the file included by the GLOBALS statement.
-4320	`The symbol 'symbol-name' is not the name of a table in the specified database.` The named table does not appear in the database. Review the statement. The table name may be spelled wrong in the program, or the table might have been dropped or renamed since the last time the program was compiled.
-4322	`The symbol 'symbol-name' is not the name of a column in the specified database.` The preceding statement suggests that the named column is part of a certain table in the specified database. The table exists, but the column does not appear in it. Check the spelling of the column name. If it is spelled as you intended, then either the table has been altered, or the column renamed, or you are not accessing the database you expected.
-4323	`The variable 'variable-name' is too complex to be used in an assignment statement.`

Number	Description
	The named variable is a complex variable like a record or an array, which cannot be used in a LET statement. You must assign groups of components to groups of components using asterisk notation.
-4324	`The variable 'variable-name' is not a character type, and cannot be used to contain the result of concatenation.` This statement attempts to concatenate two or more character strings (using the comma as the concatenation operator) and assign the result to the named variable. Unfortunately, it is not a character variable, and automatic conversion from characters cannot be performed in this case. Assign the concatenated string to a character variable; then, if you want to treat the result as numeric, assign the string as a whole to a numeric variable.
-4325	`The source and destination records in this record assignment statement are not compatible in types and/or length.` This statement uses asterisk notation to assign all components of one record to the corresponding components of another. However, the components do not correspond. Note that BDL matches record components strictly by position, the first to the first, second to second, and so on; it does not match them by name. If the source and destination records do not have the same number and type of components, you will have to write a simple assignment statement for each component.
-4328	`The variable 'variable-name' is too complex to be used as the destination of a return from a function.` The named variable is too complex to be assigned directly in a `RETURNING` clause. Individual members of the complex variable must be returned separately.
-4333	`The function 'function-name' has already been called with a different number of parameters.` Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list. At least one of these calls must be in error. Examine the FUNCTION statement for the named function to find out the correct number of parameters. Then examine all calls to it, and make sure that they are written correctly.
-4334	`The variable 'variable-name' in its current form is too complex to be used in this statement.` The variable has too many component parts. Only simple variables (those that have a single component) can be used in this statement. If variable-name is an array, you must provide a subscript to select just one element. If it is a record, you must choose just one of its components. (However, if this statement permits a list of variables, as in the INITIALIZE statement, you can use asterisk or THRU notation to convert a record name into a list of components)
-4335	`The symbol 'field-name' is not an element of the record 'record-name'.`

Number	Description
	The field name used in a record.field expression is not identified as a member of the record variable. Find the definition of the record (it may be in the GLOBALS file), verify the names of its fields, and correct the spelling of field-name .
-4336	`The parameter 'param-name' has not been defined within the function or report.` The name variable-name appears in the parameter list of the FUNCTION statement for this function. However, it does not appear in a DEFINE statement within the function. All parameters must be defined in their function before use. Review your code. Possibly you wrote a DEFINE statement but did not spell variable-name the same way in both places.
-4338	`The symbol 'symbol-name' has already been defined once as a parameter.` The name that is shown appears in the parameter list of the FUNCTION statement and in at least two DEFINE statements within the function body. Review your code. Only one appearance in a DEFINE statement is permitted.
-4340	`The variable 'variable-name' is too complex a type to be used in an expression.` In an expression, only simple variables (those that have a single component) can be used. If the variable indicated is an array, you must provide a subscript to select just one element. If it is a record or object, you must choose just one of its components.
-4341	`Aggregate functions are only allowed in reports and SELECT statements.` Aggregate functions such as SUM, AVG, and MAX can only appear in SQL statements and within certain statements that you use in the context of a report body. They are not supported in ordinary expressions in program statements. Review the code and check that the aggregate functions are in an SQL statement or in the correct blocks of the REPORT routine.
-4343	`Subscripting cannot be applied to the variable 'variable-name'.` You tried to use a [x,y] subscript expression with a variable that is neither a character data type or an array type. Check the variable data type and make sure it can be used with a subscript expression.
-4347	`The variable 'variable-name' is not a record. It cannot reference record elements.` In this statement variable-name appears followed by a dot, followed by another name. This is the way you would refer to a component of a record variable; however, variable-name is not defined as a record. Either you have written the name of the wrong variable, or else variable-name is not defined the way you intended.

Number	Description
-4353	`The type of this ORDER BY or GROUP item specified for the report is not valid for sorting.` A REPORT routine defines an ORDER BY or GROUP clause using a variable defined with a type such as TEXT and BYTE, that is too complex to be used in comparisons. As result, columns with such types cannot be used to sort or group rows. Review the report and sort or group rows by using items defined with simple data types.
-4356	`A PAGE HEADER has already been specified within this report.` Only one PAGE HEADER control block is allowed in a REPORT. Search for other PAGE HEADER sections and combine all statements in a unique control block.
-4357	`A PAGE TRAILER has already been specified within this report.` Only one PAGE TRAILER control block is allowed in a REPORT. Search for other PAGE TRAILER sections and combine all statements in a unique control block.
-4358	`A FIRST PAGE HEADER has already been specified within this report.` Only one FIRST PAGE TRAILER control block is allowed in a REPORT. Search for other FIRST PAGE TRAILER sections and combine all statements in a unique control block.
-4359	`An ON EVERY ROW clause has already been specified within this report.` Only one ON EVERY ROW control block is allowed in a REPORT. Search for other ON EVERY ROW sections and combine all statements in a unique control block.
-4360	`An ON LAST ROW clause has already been specified within this report.` Only one ON LAST ROW control block is allowed in a REPORT. Search for other ON LAST ROW sections and combine all statements in a unique control block.
-4361	`Group aggregates can occur only in AFTER GROUP clauses.` The aggregate functions that apply to a group of rows (GROUP COUNT/PERCENT/ SUM/AVG/MIN/MAX) can only be used at the point in the report when a complete group has been processed, namely, in the AFTER GROUP control block. Make sure that the AFTER GROUP block exists and was recognized. If you need the value of a group aggregate at another time (for instance, in a PAGE TRAILER control block), you can save it in a module variable with a LET statement in the AFTER GROUP block.

Number	Description
-4363	`The report cannot skip lines while in a loop within a header or trailer.` BDL needs to know how many lines of space will be devoted to the page header and trailer (otherwise it does not know how many detail rows to allow on the page). It cannot predict how many times a loop will be executed, so it has to forbid the use of SKIP statements in loops in the PAGE HEADER, PAGE TRAILER, and FIRST PAGE HEADER sections. Review the report header or trailer to avoid SKIP in loops.
-4369	`The symbol 'symbol-name' does not represent a defined variable.` The name shown appears where a variable would be expected, but it does not match any variable name in a DEFINE statement that applies to this context. Check the spelling of the name. If it is the name you intended, look back and find out why it has not yet been defined. Possibly the GLOBALS statement has been omitted from this source module, or it names an incorrect file. Possibly this code has been copied from another module or another function, but the DEFINE statement was not copied also.
-4371	`Cursors must be uniquely declared within one program module.` In the statement DECLARE cursor-name CURSOR, the identifier cursor-name can be used in only one DECLARE statement in the source file. This is true even when the DECLARE statement appears inside a function. Although a program variable made with the DEFINE statement is local to the function, a cursor within a function is still global to the whole module Search for duplicated cursor names and change the name to have unique identifiers.
-4372	`The cursor 'cursor-name' has not yet been declared in this program.` The name shown appears where the name of a declared cursor or a prepared statement is expected; however, no cursor (or statement) of that name has been declared (or prepared) up to this point in the program. Check the spelling of the name. If it is the name you intended, look back in the program to see why it has not been declared. Possibly the DECLARE statement appears in a GLOBALS file that was not included.
-4374	`This type of statement can only be used within a MENU statement.` This statement only makes sense within the context of a MENU statement. Review the program in this vicinity to see if an END MENU statement has been misplaced. If you intended to set up the appearance of a menu before displaying it, use a BEFORE MENU block within the scope of the MENU.
-4375	`The page length is too short to cover the specified page header and trailer lengths.` A REPORT defines page header and trailer sections with a total number of lines that is not sufficiently less than the specified page length in order to print some detail lines. Review the [FIRST] PAGE HEADER and PAGE TRAILER blocks to use less lines or increase the page length.

Number	Description
-4379	`The input file 'file-name' cannot be opened.` Either the file does not exist, or, on UNIX™, your account does not have permission to read it. Possibly the filename is misspelled, or the directory path leading to the file was specified incorrectly.
-4380	`The listing file 'file-name' cannot be created.` The file cannot be created. Check that the directory path leading to the file is specified correctly and, on UNIX™ systems, that your account has permission to create a file in that directory. Look for other, more explicit, error messages from the operating system. Possibly the disk is full, or you have reached a limit on the number of open files.
-4382	`Record variables that contain array type elements may not be referenced by the ".*" or THROUGH shorthand, or used as a function parameter.` The .* and THROUGH/THRU notation is used to expand a record with an array member. It is allowed to define a record with an array member, but this element must always be used with its full designation of record.array[n]. The .* or THROUGH/THRU notation only expands simple members of the record.
-4383	`The elements 'name-1' and 'name-2' do not belong to the same record.` The two names shown are used where two components of one record are required; however, they are not components of the same record. Check the spelling of both names. If they are spelled as you intended, go back to the definition of the record and see why it does not include both names as component fields.
-4402	`In this type of statement, subscripting may be applied only to array.` The statement contains a name followed by square brackets, but the name is not that of an array variable. Check the punctuation of the statement and the spelling of all names. Names that are subscripted must be arrays. If you intended to use a character substring in this statement, you will have to revise the program.
-4403	`The number of dimensions for the variable 'variable-name' does not match the number of subscripts.` In this statement, the array whose name is shown is subscripted by a different number of dimensions than it was defined to have. Check the punctuation of the subscript. If it is as you intended, then review the DEFINE statement where variable-name is defined.
-4410	`There is a numeric constant in the previous line that is too large or too small.`

Number	Description
	The compiler could not process a numeric constant because it is too big or too small to represent a valid SMALLINT, INTEGER, BIGINT or DECIMAL constant. Check the number of digits and the punctuation of the numeric constant. Make sure you have not typed a letter for a digit for example.
-4414	`The label 'label-name' has been used but has never been defined within the above main program or function.` A GOTO or WHENEVER statement refers to the label shown, but there is no corresponding LABEL statement in the current function or main program. Check the spelling of the label. If it is as you intended it, find and inspect the LABEL statement that should define it. You cannot transfer out of a program block with GOTO; labels must be defined in the same function body where they are used.
-4415	`An ORDER BY or GROUP item specified within a report must be one of the report parameters.` The names used in a ORDER BY, AFTER GROUP OF, or BEFORE GROUP OF statement must also appear in the parameter list of the REPORT statement. It is not possible to order or group based on a global variable or other expression. Check the spelling of the names in the statement and compare them to the REPORT statement.
-4416	`There is an error in the validation string: 'validation-string'.` The validation string in the syscolval table is not correct. Change the appropriate DEFAULT or INCLUDE value in the syscolval table.
-4417	`This type of statement can be used only in a report.` Statements such as PRINT, SKIP, or NEED are meaningful only within the body of a report function, where there is an implicit report listing to receive output. Remove the report specific statement from the code which is not in a report body.
-4418	`The variable used in the INPUT ARRAY or DISPLAY ARRAY statement must be an array.` The name following the words DISPLAY ARRAY or INPUT ARRAY must be that of an array of records. Check the spelling of the name. If it is as you intended, find and inspect the DEFINE statement to see why it is not an array. (If you want to display or input a simple variable or a single element of an array, use the DISPLAY or INPUT statement.)
-4420	`The number of lines printed in the IF part of an IF-THEN-ELSE statement of a header or trailer clause must equal the number of lines printed in the ELSE part.` The runtime system needs to know how many lines will be filled in header and trailer sections (otherwise it could not know how many detail rows to put on the page). Because it cannot tell which part of an IF statement will be executed, it requires that both produce the same number of lines of output. Use the same number of occurrences of PRINT statements in each block of the IF statement.

Number	Description
-4425	`The variable 'variable-name' has not been defined like the table 'table-name'.` The named variable has been used in the SET clause of an UPDATE statement or in the VALUES clause of an INSERT statement, but it was not define LIKE the table being modified. As a result, then runtime system cannot associate record components with table columns. Make sure the schema file is up to date and check that the variable was defined like the table. You can also rewrite the UPDATE or INSERT statement with a different syntax to show the explicit relationship between column names and record components.
-4440	`The field 'field-name-1' precedes 'field-name-2' in the record 'record-name' and must also precede it when used with the THROUGH shorthand.` The THROUGH or THRU shorthand requires you to give the starting and ending fields as they appear in physical sequence in the record. Check the spelling of the names; if they are as you intended, then refer to the VARIABLE statement where the record was defined to see why they are not in the sequence you expected.
-4447	`'key-name' is not a recognized key value.` The key name used in an ON KEY clause is not known by the compiler. Search the documentation for possible key names (F1-F255, Control-?).
-4448	`Cannot open the file 'file-name' for reading or writing.` The file cannot be opened. Verify that the filename is correctly spelled and that your account has permission to read or write to it.
-4452	`The function (or report) 'function-name' has already been defined.` Each function (or report, which is similar to a function) must have a unique name within the program. Change the function or report name.
-4457	`You may have at most 4 keys in the list.` An interactive instruction defines a ON KEY() clause with more that 4 keys. Remove keys from the list.
-4458	`One dimension of this array has exceeded the limit of 65535.` The program is using a static array with a dimension that exceeds the limit. Use a dimension below the 65535 limit.
-4463	`The NEXT FIELD statement can only be used within an INPUT or CONSTRUCT statement.` The NEXT FIELD statement is used outside an INPUT, INPUT ARRAY or CONSTRUCT statement.

Number	Description
	Remove the NEXT FIELD statement from that part of the code.
-4464	`The number of columns must match the number of values in the SET clause of an UPDATE statement.` In an UPDATE statement, the number of values used does not match the number of columns. Check for the table definition, then either add or remove values or columns from the UPDATE statement.
-4476	`Record members may not be used with database column substring.` This statement has a reference of the form name1.name2[...]. This is the form in which you would refer to a substring of a column: table.column[...]. However, the names are not a table and column in the database, so BDL presumes they refer to a field of a record. Inspect the statement and determine what was intended: a reference to a column or to a record. If it is a column reference, verify the names of the table and column in the database. If it is a record reference, verify that the record and component are properly defined.
-4477	`The variable 'variable-name' is an array. You must specify one of its elements in this statement.` You tried to use an array without element specification in a SQL statement. Use one of the members of the array.
-4485	`Only blob variables of type BYTE or TEXT may be used in a LOCATE statement.` The LOCATE statement is using a variable defined with a data type different from BYTE or TEXT. Make sure the variables used with LOCATE are defined as BYTE or TEXT.
-4488	`The program cannot CONTINUE or EXIT statement-type at this point because it is not immediately within statement-type statement.` This CONTINUE or EXIT statement is not appropriate in its context. Review your code. Possibly the statement is misplaced, or the statement type was specified incorrectly.
-4489	`A variable used in the above statement must be a global variable.` A REPORT routine is defining an OUTPUT REPORT TO using a local function variable or report parameter. Review the report clause to use a global or module variable instead.
-4490	`You cannot have multiple BEFORE clauses for the same field.` You cannot specify more than one BEFORE FIELD clause for the same field. Review your code to eliminate multiple BEFORE FIELD clauses.
-4491	`You cannot have multiple AFTER clauses for the same field.`

Number	Description
	You cannot specify more than one AFTER FIELD clause for the same field. Review your code to eliminate multiple AFTER FIELD clauses.
-4534	`Wordwrap may not be used within report headers or trailers.` The report routine uses the WORDWRAP clause in the FIRST PAGE HEADER, PAGE HEADER or PAGE TRAILER sections. Remove the WORDWRAP clause from the expression.
-4631	`Startfield of DATETIME or INTERVAL qualifiers must come earlier in the time-list than its endfield.` The qualifier for a DATETIME or INTERVAL consists of start TO end, where the start and end are chosen from this list: YEAR MONTH DAY HOUR MINUTE SECOND FRACTION. The keyword for the start field must come earlier in the list than, or be the same as, the keyword for the end field. Check the order of the startfield and endfield qualifiers. For example, qualifiers of DAY TO FRACTION and MONTH TO MONTH are valid but one of MINUTE TO HOUR is not.
-4632	`Parenthetical precision of FRACTION must be between 1 and 5. No precision can be specified for other time units.` In a DATETIME qualifier only the FRACTION field may have a precision in parentheses, and it must be a single digit from 1 to 5. Check the DATETIME qualifiers in the current statement; one of them violates these rules. The first field of an INTERVAL qualifier may also have a parenthesized precision from 1 to 5.
-4652	`The function 'function-name' can only be used within an INPUT or CONSTRUCT statement.` The function shown is being used outside of an INPUT or CONSTRUCT statement. However, it returns a result that is only meaningful in the context of INPUT or CONSTRUCT. Review the code to make sure that an END INPUT or END CONSTRUCT statement has not been misplaced. Review the operation and use of the function to make sure you understand it.
-4653	`No more than one BEFORE or AFTER INPUT/CONSTRUCT clause can appear in an INPUT/CONSTRUCT statement.` There may be only one BEFORE block of statements to initialize each of these statement types. Make sure that the scope of all your INPUT, CONSTRUCT and MENU statements is correctly marked with END statements. Then combine all the preparation code into a single BEFORE block for each one.
-4656	`CANCEL INSERT can only be used in the BEFORE INSERT clause of an INPUT ARRAY statement.`

Number	Description
	The CANCEL INSERT statement is being used outside of the BEFORE INSERT clause of an INPUT ARRAY. Review the code to make sure that CANCEL INSERT has not been used anywhere except in the BEFORE INSERT clause.
-4657	`CANCEL DELETE can only be used in the BEFORE DELETE clause of an INPUT ARRAY statement.` The CANCEL DELETE statement is being used outside of BEFORE DELETE clause of an INPUT ARRAY. Review the code to make sure that CANCEL DELETE has not been used anywhere except in the BEFORE DELETE clause.
-4668	`The report output, specified by a START REPORT statement, is not any of file, pipe, screen, printer, pipe in line mode, or pipe in form mode.` The output of a report can be sent only to any of file, pipe (in form or line modes), screen, or printer. Check the START REPORT instruction and make sure that the OUTPUT clause specifies one of the supported values.
-4900	`This syntax is not supported here. Use [screenrecordname.]screenfieldname.` The field name specification in a BEFORE FIELD or AFTER FIELD is not valid. Check for the field name and use [screenrecordname.]screenfieldname syntax.
-4901	`Fatal internal error: description ( line-number ).` This generic error occurs when the fglcomp compiler cannot identify the problem and must stop processing the source. Check the code near the line displayed in the error message.
-6001	`The license manager daemon cannot be started.` This error occurs when a process creation fails during the start of the license manager. Increase the maximum number of processes allowed (ulimit)
-6012	`Cannot get license information. Check your environment and the license (run 'fglWrt -a info').` See error -6015.
-6013	`Time limited version: time has expired.` The license installed is a license with time limit and time has expired. The program can not start. Contact your distributor or support center.
-6014	`Your serial number is not valid for this version.` The license serial number is invalid for this version of the software.

Number	Description
	Contact your distributor or support center.

-6015	`Cannot get license information. Check your environment and the license (run 'fglWrt -a info').`
	It is not possible for the application to check the license validity.
	• License manager:
	  • The license may not have been installed
	  • The license controller can not communicate with the license manager. Check that the license manager is started and check that the fglprofile entries flm.server and flm.service contain valid information.
	  • The directory **$FLMDIR/lock** and all the files below must have read/write permission.
	• License controller:
	  • The license may not have been installed.
	  • The directory **$FGLDIR/lock** and all the files below must have read/write permission.

-6016	`Cannot get information for license (Error error-num). Check your environment and the license (run 'fglWrt -a info').` The application is unable to check the license validity. See error -6015.
-6017	`User limit exceeded. Cannot run this program.` The maximum number of users allowed by the license has been reached. The program can not start. Contact your distributor or support center.
-6018	`Cannot access internal data file. Cannot continue this program. Please, check your environment(variable-name).` When a client computer starts an application on the server, the application stores data in the **$FGLDIR/lock** directory. The client must have permission to create and delete files in this directory. • Do not remove or modify files contained in the directory $FGLDIR/lock • Change the permissions of the **$FGLDIR/lock** directory, or connect to the server with a user name having the correct permissions.
-6019	`This demonstration version allows one user only.` The demonstration version is designed to run with only one user. Another user or another graphical daemon is currently active. Wait until the user stops the current program, or use the same graphical daemon.
-6020	`Installation: Cannot open 'file-name'.` A file is missing or the permissions are not set for the current user. Check that the file permissions are correct for the user trying to execute the application. If the file is missing, re-install the compiler package.

Number	Description
-6022	`Demonstration time has expired. Please, run this program again.` The runtime demonstration version is valid only for a few minutes after you have started a program. Restart the program.
-6025	`Demonstration time has expired. Please, contact your vendor.` The demonstration version of the product has a time limit of 30 days. Either reinstall a new demonstration version, or call your software vendor to purchase a permanent license.
-6026	`Bad link for runner demonstration. Please, retry or rebuild your runner.` The runner is corrupted.
-6027	`Cannot access license server. Please check the following:` - the license server entry in your resource file. (service port) - the license server host. - the license server program. You have not specified a value for the environment variable [fgllic|fls|flm].server in the $FGLDIR/etc/fglprofile file. Check the fglprofile file for the entry point [fgllic|fls|flm].server and specify the name of the computer that runs the License Manager.
-6029	`Unknown parameter 'param-name' for checking.` The command line of the fglWrt or flmprg tool contains an unknown parameter. Check your command-line parameters and retry the command.
-6031	`Temporary license license-number has expired.` Your temporary runtime license has expired. Call your software vendor to get a new license.
-6032	`command-name: illegal option: 'option-name'.` You are not using a valid option for the specified command. Check your command line syntax and try again.
-6033	`command-name: 'option-name' option requires an argument.` You cannot use this option of the tool without a parameter. Check your command line and try again.
-6034	`Warning! This is a temporary license, installation number is 'installation-number'.` You have installed a temporary license of 30 days. You will have to enter an installation key before the end of this period if you want to keep on running the program.

Number	Description
	This is only a warning message.
-6035	`Cannot read in directory` The compiler cannot access the $FGLDIR/lock directory. The current user must have read and write permissions in this directory. Give the current user read and write permissions to the $FGLDIR/lock directory.
-6041	`Can not retrieve network interface information.` An error occurred while retrieving network interface information. Restart your program. If this does not solve your problem, contact your distributor.
-6042	`MAC Address has changed.` The MAC address of the host has changed since the license was first installed. The license must be reinstalled, or restore the old MAC address.
-6043	`The testing period is finished. You must install a new license.` The test time license of has expired. Call your software vendor to purchase a new license.
-6044	`IP Address has changed.` The IP Address of the host has changed. Restore the IP address of the host, or reinstall the license. This is no longer checked by the latest versions of the license controller.
-6045	`Host name has changed.` The host name has changed. Restore the host name or reinstall the license. This is no longer checked by the latest versions of the license controller.
-6046	`Could not get file reference number information.` The license could not get information about the license file. Reinstall the license. Contact your distributor.
-6047	`The device number of the license file has changed.` The license file has been touched. The license is no longer valid. Reinstall the license. Contact your distributor.
-6048	`The file reference number of the license file has changed.` The license file has been touched. The license is no longer valid. Reinstall the license. Contact your distributor.
-6049	`This product is licensed for runtime only. No compilation is allowed.`

Number	Description
	You have a runtime license installed with this package. You cannot compile BDL source code modules with this license. If you want to compile .4gl source code, you must purchase and install a development license. Contact your distributor.
-6050	`Temporary license license-number expired. Please contact your vendor.` A license with a time limit has been installed and the license has expired. Install a new license to activate the product. Contact your distributor.
-6051	`Temporary license license-number expired. Please contact your vendor.` A license with a time limit has been installed and the license has expired. Install a new license to activate the product. Contact your distributor.
-6052	`Temporary license license-number expired. Please contact your vendor.` A license with a time limit has been installed and the license has expired. Install a new license to activate the product. Contact your distributor.
-6053	`Installation path has changed. It must hold the original installation path.` The value of FGLDIR or the location of FGLDIR has been changed. Ask the person who installed the product for the location of the original installation directory and then set the FGLDIR environment variable.
-6054	`Cannot read a license file. Check installation path and your environment. Verify if a license is installed.` The file that contains the license is not readable by the current user. • License controller: Check that the FGLDIR environment variable is correctly set and that the file $FGLDIR/etc/f4gl.sn is readable by the current user. • License manager: Check that the file $FLMDIR/etc/license/lic?????.dat is readable by the current user.
-6055	`Cannot update a license file. Check installation path and your environment. Verify if a license is installed.` The file that contains the license cannot be overwritten by the current user. • License controller: Check that the FGLDIR environment variable is correctly set and that the file $FGLDIR/etc/f4gl.sn is writable by the current user. • License manager: Check that the file $FLMDIR/etc/license/lic?????.dat is writable by the current user.
-6056	`Cannot write into a license file. Please check your rights.` The file that contains the license cannot be overwritten by the current user. • License controller: Check that the FGLDIR environment variable is correctly set and that the file $FGLDIR/etc/f4gl.sn is writable by the current user.

Number	Description
	• License manager: Check that the file $FLMDIR/etc/license/lic?????.dat is writable by the current user.
-6057	`Cannot read a license file. Check installation path and your environment. Verify if a license is installed.` The file that contains the license cannot be read by the current user. Check that the current user can read the file $FGLDIR/etc/f4gl.sn. Also check that the FGLDIR environment variable is set correctly.
-6058	`Incorrect license file format. Verify if a license is installed.` The file that contains the license has been corrupted. Reinstall the license. If you have a backup of the current installation of Genero Business Development Language, restore the files located in the $FGLDIR/etc directory.
-6059	`Incorrect license file format. Verify if a license is installed.` The file that contains the license has been corrupted. Reinstall the license. If you have a backup of the current installation of Genero Business Development Language, restore the files located in the $FGLDIR/etc directory.
-6061	`License 'license-number' not installed.` The license shown is not installed. Reinstall the license.
-6062	`No installed license has been found for 'license-number'.` The add-user license can not be installed. No main license found to add users. Contact your distributor.
-6063	`License 'license-number' is already installed.` The license shown is already installed. No particular action to be taken.
-6064	`The resource 'flm.license.number' is required to use the license manager.` In order to use a license manager, the FGLPROFILE entry described in the error message must exist and define a license number.
-6065	`The resource 'flm.license.key' is required to use the license manager.` In order to use a license manager, the FGLPROFILE entry described in the error message must exist and define a license key.
-6066	`License 'license-number' cannot be installed over 'license-number'.`

Number	Description
	The add-user license does not match the main license. The add-user license can not be installed. Contact your distributor.
-6067	`You need a installed license if you want to add users.` The add-user license must be installed after the main license. Install the main license before the add-user license. If this does not solve your problem, contact your distributor.
-6068	`No license installed.` There is no license installed for Genero Business Development Language. Install a license. If a license is already installed, check that the $FGLDIR environment variable is set correctly.
-6069	`Cannot uninstall the license.` There was a problem during the uninstall of the Genero Business Development Language license. Check whether the FGLDIR environment variable is correctly set in your environment and the current user has permission to delete files in the $FGLDIR/etc directory.
-6070	`The license server entry must be set in your resource file in order to reach the license server.` You are using the remote license process and you have set the value of fgllic.server, in $FGLDIR/etc/fglprofile, to localhost or to the 127.0.0.1 address. You must use the real IP address of the computer even if it is the local computer.
-6071	`Cannot use directory 'directory-name'. Check installation path and verify if access rights are 'drwxrwxrwx'.` The compiler needs to operate in the specified directory. Change the permission of this directory.
-6072	`Cannot create file in 'file-name'. Check installation path and verify if access rights are 'drwxrwxrwx'.` The compiler needs to operate in the specified directory. Change the permission of this directory to 777 mode.
-6073	`Cannot change mode of a file in 'file-name'. Verify if access rights are 'drwxrwxrwx'.` The compiler needs to operate in the specified directory. Change the permission of this directory to 777 mode.
-6074	`'file-name' does not have 'rwxrwxrwx' rights or isn't a directory. Check access rights with 'ls -ld <installation-path>/lock' or execute 'rm -r <installation-path>/lock' if no users are connected.` The compiler needs to operate in the specified directory.

Number	Description
	Change the permission of this directory. The $FGLDIR/lock directory contains only data needed at runtime by BDL applications. When the application is finished, you can remove this directory. If you delete this directory while BDL applications are running, the applications will be stopped immediately.
-6075	`Cannot read from directory 'directory-name'. Check installation path and verify if access rights are 'drwxrwxrwx'.` The compiler needs to operate in the specified directory. Change the permission of this directory.
-6076	`Bad lock tree. Please check your environment.` There is a problem accessing the $FGLDIR/lock directory. Check if the current user has sufficient permission to read and write to the $FGLDIR/lock directory. Check also if the FGLDIR environment variable is correctly set.
-6077	`Bad lock tree. Please check your environment.` There is a problem accessing the $FGLDIR/lock directory. Check if the current user has sufficient permission to read and write to the $FGLDIR/lock directory. Check also if the FGLDIR environment variable is correctly set.
-6079	`Cannot get machine name or network IP address. Each graphical client must have an IP address when using a license server. FGLSERVER must hold the IP address or the host name of the client.` You are using the remote license process and you have set the value of fgllic.server, in $FGLDIR/etc/fglprofile, to localhost or to the 127.0.0.1 address. You must use the real IP address of the computer even if it is the local computer. This is also true for the value used with the FGLSERVER environment variable.
-6080	`Cannot get IP address from 'host-name' host. Check the 'flm.server' resource.` The system cannot find the IP address of the specified host. This is a configuration issue regarding your system. The command ping should not reply as well. Correct your system configuration and then try to execute your program.
-6081	`Cannot reach host 'host-name' with ping. Check license server entry in your resource file. Check your network configuration or increase 'flm.ping' value.` The license server cannot ping the client computer, or it does not get the response in the time limit specified by the fgllic.ping entry in the $FGLDIR/etc/fglprofile file. Try to manually ping the specified computer. If this works, try to increase the value of the fgllic.ping entry in fglprofile. If the ping does not respond, fix the system configuration problem and then try the program again.
-6082	`SYSERROR(error-num) description: Cannot set option TCP_NODELAY on socket. Check the system error message and retry.` There is a problem with the socket of the Windows™ computer.

Number	Description
	Check that the system is correctly configured and retry the program.
-6085	`SYSERROR(error-num) description: Cannot connect to the license server on host 'host-name'. Check following things: - license server entry. - the license server machine. - the license server TCP port.` The application cannot check the license validity. To do so, it tries to communicate with the Genero Business Development Language license service running on the computer where the product is installed. Check that the Genero Business Development Language License Server is running on the computer where the product is installed.
-6086	`SYSERROR(error-num) description: Cannot send data to the license server. Check the system error message and retry.` Theres a problem with the socket of the Windows™ computer. Check that the system is correctly configured and retry the program.
-6087	`SYSERROR(error-num) description: Cannot receive data from license server. Check the system error message and retry.` There is a problem with the socket of the Windows™ computer. Check that the system is correctly configured and retry the program.
-6088	`You are not allowed to be connected for the following reason: description` The program cannot connect to the license server because of the specified reason. Try to fix the problem described and rerun your application.
-6089	`Each graphical client must have an IP address when using a license server. FGLSERVER must hold the IP address or the host name of the client (localhost or 127.0.0.1 are not allowed).` Use the real IP address or hostname of the client.
-6090	`SYSERROR(error-num) description: Cannot create a socket to start the license server. Check the system error message and retry.` There is a problem with the socket of the Windows™ computer. Check that the system is correctly configured and rerun the program.
-6091	`SYSERROR(error-num) description: Cannot bind socket for the license server. Check the system error message and retry.` There is a problem with the socket of the Windows™ computer. Check that the system is correctly configured and rerun the program.
-6092	`SYSERROR(error-num) description: Cannot listen socket for the license server.` There is a problem with the socket of the Windows™ computer.

Number	Description
	Check that the system is correctly configured and rerun the program.
-6093	`SYSERROR(error-num) description: Cannot create a socket to search an active client.` There is a problem with the socket of the Windows™ computer. Check that the system is correctly configured and rerun the program.
-6094	`SYSERROR(error-num) description: This is a WSAStartup error. Check the system error message and retry.` There is a problem with the socket of the Windows™ computer. Check that the system is correctly configured and rerun the program.
-6095	`License problem: description` License type incompatible. You are installing an earlier version, which was not designated for use with the current license server. Reinstall and then contact your vendor.
-6096	`Connection refused by the license server.` There is problem connecting the client computer to the Windows™ license server. There is a configuration problem with the license server computer. Check the configuration of the computers and of the products.
-6100	`Bad format of line sent by the license requester.` The license request sent by the license controller is not understood by the license manager. Upgrade your license software to the latest version available. If the issue is not solved, contact your support center.
-6101	`License number 'license-number' does not correspond to license key 'license-key'.` Either the license number or the license key is invalid. Check the license number and keys entered and try again. If that does not solve the issue, upgrade your license software to the latest version available. If the issue is not solved, contact your support center.
-6102	`Verify if resource 'flm.license.number' and 'flm.license.key' correspond to a valid license.` Either the `flm.license.number` or `flm.license.key` entry in `fglprofile` is incorrectly filled. Ensure these `fglprofile` entries contain valid license numbers.
-6103	`License 'license-number' is no longer available from the license server.` The license has been uninstalled from the license server. It may still appear as some sessions are active, but the license can not be used to start a new session. Reinstall the license, or contact your support center.

Number	Description
-6107	`User limit exceeded. Please retry later.` The maximum number of clients that can be run has been reached (due to the license installed). Retry later (when the number of current users has decreased) or install a new license that allows more users.
-6108	`Environment is incorrect.` There is no local license, or the environment is not set correctly. Check your environment and your FGLDIR environment variable.
-6109	`Cannot add session #session-number.` You do not have the permissions to create the new session (the directory representing the new client). Check the permissions of the dedicated directories.
-6110	`Cannot add program 'program-name' (pid=processid).` You do not have the permissions to create the new application (the file representing the new application) for the current user . Check the permissions of the dedicated directories.
-6112	`Compilation is not allowed: This product is licensed for runtime only.` Buy and install a development license.
-6113	`Compilation is not allowed: Invalid license.` Buy and install a development license.
-6114	`Cannot start program 'program-name' or result of process number is 0.` When fglWrt -u is executed to find the number of users allowed on this installation, the command "ps" may be launched (only on UNIX™). Check the permissions for ps.
-6116	`Wrong number of characters.` The license number, license key, installation number, installation key or maintenance key provided is incomplete. Ensure that provided license numbers are correct and try again.
-6117	`The entry must be 12 characters long.` The license number, license key, installation number, installation key or maintenance key provided is incomplete. Ensure that provided license numbers are correct and try again.
-6118	`Wrong checksum result for this entry.`

Number	Description
	When entering license numbers, the checksum is verified if it is provided. This error occurs if the checksum computed does not match the provided checksum. Either the checksum or the license number is wrong. Ensure that checksum and license numbers are correct and try again.
-6122	`You must specify entry 'flm.server' in the resource file.` The `fglprofile` entry `flm.server` is missing. This entry should contain the host name or IP address of the host running the license manager. Add and configure the fglprofile entry `flm.server`.
-6123	`SYSERROR(error-num) description: Cannot open socket. Check the system error message and retry.` The license controller can not connect to the license manager. Check the error message and fix the issue. Ensure that `fglprofile` entries `flm.server` and `flm.service` are correctly filled. Check your network configuration.
-6129	`License uninstalled.` This is an information message.
-6130	`This license requires a full installation.` The installed license has not be activated, but can not be used in temporary installation mode. Contact your vendor to obtain the activation key.
-6131	`This license number is no more valid. Please, contact your vendor.` The license number is no longer accepted. Contact your vendor to obtain a new license number.
-6132	`Incompatible License Controller (fglWrt/greWrt) version. The minimum version required is min-version.` Upgrade your license controller version to the specified version or higher.
-6133	`This product requires a BDL license. The license number should start with the letter F.` A BDL license is required for this product. Call you support center to get a BDL license.
-6134	`This product requires a Genero license. The license number should start with the letter T.` A Genero license is required for this product. Call you support center to get a Genero license.
-6135	`Invalid license key.` The license key does not correspond to the license number.

Number	Description
	Call you support center to check the license key.
-6136	`The date-limited license has expired.` The time limited license has expired, the product is blocked. Call you support center to get a new license.
-6137	`This product requires a GRW license .` A GRW license is required for this product. Call you support center to get a GRW license.
-6138	`GRW licenses are not accepted by this product .` This product does not accept GRW licenses. Call you support center to check if the license corresponds to the product.
-6140	`Version version-number` This is an information message.
-6142	`Try and buy demonstration time expired. Please, restart your application.` Applications started with a Try and Buy version will stop after few minutes of execution. Restart your application.
-6143	`This license requires a valid maintenance key. Check your environment (run 'fglWrt/greWrt -a info')` Genero 2.20 and higher require a valid maintenance key. Update your maintenance key.
-6144	`The DVM build date is greater than the maintenance key expiration date. Contact your nearest FourJ's sales representative to update the maintenance key.` Update your maintenance key or downgrade your Genero installation to an older version.
-6146	`This product requires a Genero Time-Limited Evaluation license.` You have installed a trial version of the Genero product, but the installed license is not a trial license. Install a trial license for this product. Contact your support to get a trial license.
-6147	`This product requires a GRE Time-Limited Evaluation license.` You have installed a trial version of the GRE product, but the installed license is not a trial license. Install a trial license for this product. Contact your support to get a trial license.
-6148	`Installation path is not known.` You are handling licenses but the FGLDIR environment variable is not set.

Number	Description
	Set the FGLDIR environment variable and retry.
-6149	`Problem while installing license 'license-number'.` A problem occurred while licensing. Note the system-specific error number and contact your Technical Support.
-6150	`Temporary license not found for this version.` While adding a definitive license key, the temporary license has not been found. Re-install the license.
-6151	`Wrong installation key.` While adding a definitive license key, the installation key was not valid. Re-install the license.
-6152	`Problem during license installation.` A problem occurred while installing the license. Could not write information to the disk (either own files or system files). Check the FGLDIR environment variable and the rights of the license files (must be able to change them).
-6153	`License installation failed.` License information could not be written to files. Check the system error message if provided, check the file permissions for the current user.
-6154	`License installation successful.` This is an information message.
-6156	`Too many temporary licenses. You must reinstall a license.` You installed a temporary license too many times. Contact technical support to get a valid license.
-6158	`Cannot store temporary information.` A problem occurred while installing the license. Could not write information to the disk (either own files or system files). Check the FGLDIR environment variable and the rights of the license files (you must be able to change them).
-6159	`This kind of license is not permitted.` The license numbers can not be installed. Contact your support center.
-6160	`You do not have the permissions to be connected.` The host running the license controller (where the DVM is running) is not allowed to connect to this license manager. There is likely a configuration issue.

Number	Description
	Check your license manager configuration.
-6161	`You do not have the permissions to compile.` The compilation request is rejected by the license manager. Contact your support center.
-6162	`Cannot reach the license server. Please check if 'flm.server' is correctly initialized. ('flmprg -a info up' command should answer 'ok'). The license server is running but no autocheck will be done.` While this error is no longer used, it can be raised by older versions of Genero. The license controller can not connect to the license manager. Ensure that `fglprofile` entries `flm.server` and `flm.service` are filled correctly. Ensure that the license manager is running on the specified host and port.
-6168	`Cannot get information from directory 'directory-name'.` Failed to read directory information. Ensure that the user installing a license is the user that installed the product. Ensure that the user installing a license has read/write permissions on the '`etc`' directory of the product.
-6169	`SYSERROR(error-num) description: Cannot set option O_NONBLOCK on socket. Check the system error message and retry.` Failed to configure the socket in non-blocking mode. Check the system error message. Contact your support center.
-6170	`Old request format to license server detected. You must install a license program version 2.99 or higher.` The license controller version is too old for the current license manager version. Requests sent by the license controller are no longer supported by the current license manager. Upgrade the license controller to the latest version available.
-6171	`A license has been installed temporarily. Only the installation key is required. You must run 'fglWrt -k <installation-key>' to install it.` The installed license is temporarily installed, yet it is missing the installation key. Obtain your installation key and install it.
-6172	`Bad parameter: 'parameter' hasn't the right format.` Two issues can raise this error. **1.** The license manager can raise this error if it receives a request from the license controller with unknown commands. Upgrade the license software version to the latest available. Contact your support center. **2.** The license manager `etc/lmprofile` configuration is invalid.

Number	Description
	Check your `lmprofile` entries `flm.license.together` and `flm.license.allow`.
-6173	`Invalid license number or invalid license key.` During the license installation, the license number / license key couple does not match. Ensure that the license numbers are correct. Upgrade the license software to the latest version available and retry.
-6174	`This option is only available for a local license. And resource 'flm.server' was found in your configuration.` A license server is configured and the user tries to install or uninstall a license using `fglWrt`. Install the license on the license manager (`flmprg`) Or remove the license manager configuration from `fglprofile` and install the license locally.
-6175	`License number 'license-number' is invalid.` The license number is not valid. Ensure that the license number provided is correct. Upgrade the license software to the latest version available.
-6176	`In license server, following problem occurs with license number 'license-number': problem-description` This is a generic error containing the text of another error. Check the error. Contact your support center.
-6177	`Following problem occurs with license number 'license-number': description` This is a generic error containing the text of another error. Check the error. Contact your support center.
-6178	`Your machine is not allowed to be connected on any of your authorized licenses.` The CPU license rejects the connection of a new host. All CPU licenses are consumed. Contact your support center.
-6179	`License validity time is reached. The users control is reactivated.` The CPU license is time limit is reached. The CPU license is degraded and user control is reactivated. Contact your support center.
-6180	`CPU limit exceeded. The users control is reactivated.` The CPU license has less CPUs available than the number of CPUs on the connected host, resulting in one or more hosts running in degraded mode. When running in degraded mode, the number of users allowed is the number of available CPUs in the license * 100 users. User control is activated for license request coming from that host.

Number	Description
	For example, say you have a 5 CPU license and are using the license manager. • Host A with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 3 CPUs remain free on the license. • Host B with 2 CPUs connects. It will consume 2 CPUs of the 5 CPU license. 1 CPU remains free on the license. • Host C with 2 CPU connects. It should consume 2 CPUs, but only 1 CPU remains on the license. User control for Host C is enabled, with 1 CPU (the remaining free CPU) * 100 users allowed. • Host D connects with *N* CPU, however there are no CPUs free on the license. Host D is rejected. In summary, Host A and B can have unlimited sessions, Host C is limited to 100 sessions as the license is degraded by CPU, and any other host is rejected. In the case of a single host, user control applies to local licenses as well. If Host A has 6 CPUs, yet has a 5 CPU license, it consumes all of the CPUs for the license and run in degraded mode. That means 5 * 100 users are allowed. Contact your support center.
-6181	`Cannot get license extension information. Check your environment, the license (run 'fglWrt -a info') and the fglWrt version ('fglWrt -V' should give version-number or higher).` License information is invalid. This error is not yet used. Contact your support center.
-6182	`Your license has 'restriction-name' restriction. You are not allowed to run another mode.` The license has restrictions, and the requested use of the license is not compatible with these restrictions. For example, the license may have a text-only restriction, where GUI front-ends are not allowed. Contact your support center to obtain a license matching your needs.
-6183	`Local license controller (fglWrt) may not be compatible with this runner. Check its version ('fglWrt -V' should give version-number or higher).` The license controller is incompatible. Update the license controller to the latest version available.
-6184	`You are not authorized to run this version of runner.` Older licenses do not use the maintenance key. The DVM version that can be used is limited. The DVM version is higher that the allowed DVM version. Contact your support center. Re-licensing is required.
-6185	`Protection file is not compatible with this version of the runner. You must reinstall your license.` This error is no longer used by the current licensing software, however it may occur with older versions. Contact your support center.

Number	Description
-6186	`Demo version initialization.` This is an information message.
-6188	`Your evaluation license period has expired. Contact your support center.` The software you are using has been installed with a demo license that has expired. Contact your software vendor to extend the evaluation period or purchase a permanent license.
-6196	`You are not authorized to delete sessions from the license server 'server-name'.` The command `fglWrt -i` can only be used with local licenses. If a license server is configured, this error is raised. Use the command `flmprg` instead.
-6197	`'extension-name' extension is not allowed with this license type.` Generic error indicating that an extension check is rejected. For example, if you are using a non-Informix database, this error will raise if the ODI extension is not set in the license.
-6198	`Product identifier does not correspond to the license number.` This error indicates that a wrong license is installed in the product, such as when you attempt to use a Genero Report Writer (GRW) license when installing the Genero Business Development Language (BDL). This error should not be raised, as `fglWrt` will reject the installation of a Genero Report Engine (GRE) license when installing Genero BDL, and conversely `greWrt` will not allow the installation of a Genero BDL license. That being said, the installation checks to ensure the license is valid for the product, and raises this error it if is not. Ensure the proper license is used with the proper package.
-6199	`Cannot create directory 'directory-name'. Check installation path and verify your access rights.` The specified directory can not be created or modified.
-6200	`Module 'module-name': The function function-signature-1 will be called as function-signature-2 .` An incorrect number of parameters are used to call a BDL function. Check your source code and recompile your application.
-6201	`Module 'module-name': Bad version: Recompile your sources.` You have compiled your program with an old version. The newly compiled version of your program is not supported. Compile all source files and form files again.

Number	Description
-6202	`filename 'file-name': Bad magic: Code cannot run with this p code machine.` You have compiled your program with an old version. The new compiled version of your program is not supported. You might also have a file with the same name as the .42r. You used the fglrun 42r-Name without specifying the extension. To resolve this problem, call fglrun with the .42r extension or recompile your application.
-6203	`Module 'module-name-1': The function 'function-name' has already been defined in module 'module-name-2'.` The specified function is defined for the second time in the application. The second occurrence of the function is in the specified module. Eliminate one of the two function definitions from your source code.
-6204	`Module 'module-name': Unknown op-code.` An unknown instruction was found in the compiled BDL application. Check that the version of the Genero Business Development Language package executing the compiled application is the same as the one that compiled the application. It is also possible that the compiled module has been corrupted. If so, you will need to recompile your application.
-6205	`INTERNAL ERROR: Alignment.` This error is internal, which should not normally occur. Contact your Technical Support.
-6206	`The 42m module 'module-name' could not be loaded, check FGLLDPATH environment variable.` The 42m module is not in the current directory or in one of the directories specified by the **FGLLDPATH** environment variable. Set the environment variable **FGLLDPATH** with the path to the 42m modules to be loaded.
-6207	`The dynamic loaded module 'module-name' does not contain the function 'function-name'.` A BDL module has been changed and recompiled, but the different modules of the application have not been linked afterward. Link the new modules together before you execute your application.
-6208	`Module 'module-name' already loaded.` A module was loaded twice at runtime. This can occur because one module has been concatenated with another. Recompile and re-link your BDL modules.
-6210	`INTERNAL ERROR: exception 2 raised before invoking the exception handler for exception 1.`

Number	Description
	A module was loaded twice at runtime. This can occur because one module has been concatenated with another. Check for function names, recompile and re-link your BDL modules.
-6211	`Link has failed.` A problem occurred while linking the BDL program. Check for function names, recompile and re-link your BDL modules.
-6212	`Function function-name : local variables size is too large - Allocation failed.` A local function variable is too large and runtime could not allocate memory. Review the variable data types in the function.
-6213	`Module module-name : Module's variable size is too large - Allocation failed.` A module variable is too large and runtime could not allocate memory. Review the variable data types in the module.
-6214	`Global variable variable-name size is too large - Allocation failed.` A global variable is too large and runtime could not allocate memory. Review the variable data types in the globals.
-6215	`Memory allocation failed. Ending program.` Runtime could not allocate memory. Check for system resources and verify if the OS user is allowed to allocate as much memory as the program needs (check for **ulimits** on UNIX™ systems).
-6216	`The global 'constant-name' has been redefined with a different constant-value.` A global constant has been defined twice with a different value. A global constant may have only one value. Review your code.
-6217	`The global 'variable-name' has been defined as a constant and a variable.` The same symbol was used to define a constant and a variable. Use a different name for the constant and the variable. Review your code.
-6218	`No runtime. You must call fgl_start() before calling fgl_call().` This error occurs when a C extension has redefined the main() routine, but then does not call fgl_start() to initialize the BDL runtime environment. Check the C extension and call fgl_start() before any other operation.
-6219	`WHENEVER ERROR CALL: The error-handler recursively calls itself.`

Number	Description
	The function specified with the WHENEVER ERROR CALL instruction raises an error that would call itself recursively. Review the function called by the WHENEVER ERROR CALL and make sure it does not produce a runtime error.
-6220	`Could not load C extension library ' library-name'. Reason: description` Runtime system could not find the shared library for the reason given. Check if the C extension library exists in one of the directories defined by FGLLDPATH. If the C extension module depends from other shared libraries, make sure that these libraries can be found by the library loader of the operating system (check the LD_LIBRARY_PATH environment variable on UNIX™ or the PATH environment variable on Windows™).
-6221	`C extension initialization failed with status number.` C extension failed to initialize and returned the status shown in the error message. Check the C extension source or documentation.
-6222	`class-name class not found.` The program was compiled with the built-in class class-name but at execution time the class is not found. Check you installation, it is possible that you are executing program that was compiled with a younger version as the version used in the execution context, which certainly is missing that class in the runtime library.
-6223	`No such symbol: symbol-name.` The runtime system loads a module dynamically (on demand) and searches the symbol in this module. But the symbol could not be found, for example because of an invalid FGLLDPATH, or because the installed module does no more contain the symbol (after a recompilation).
-6300	`Can not connect to GUI: description` You have run a GUI application but the environment variable FGLSERVER is not set correctly, or the Genero client (graphical front-end) is not running. See the description for more details. The FGLSERVER environment variable should be set to the hostname and port of the graphical front end used by the runtime system to display the application windows. Check that the network connection is still available, make sure no firewall denies access to the workstation, and see whether the front-end is still running.
-6301	`Can not write to GUI: description` You are running a GUI application but for an unknown reason the front-end no longer responds and the runtime system could not write to the GUI socket. Check that the network connection is still available, make sure no firewall denies access to the workstation, and see whether the front-end is still running.
-6302	`Can not read from GUI: description`

Number	Description
	You are running a GUI application but for an unknown reason the front-end no longer responds and the runtime system could not read from the GUI socket. Check that the network connection is still available, make sure no firewall denies access to the workstation, and see whether the front-end is still running.
-6303	`Invalid user interface protocol.` You are trying to execute a program with a runtime system that uses a different AUI protocol version as the front-end. Install either a new front-end or a new runtime environment that matches (2.0x with 2.0x, 1.3x with 1.3x).
-6304	`Invalid abstract user interface definition.` You are trying to execute a program with a runtime system that uses a different AUI protocol version as the front-end. Install either a new front-end or a new runtime environment that matches (2.0x with 2.0x, 1.3x with 1.3x).
-6305	`Can not open char table file. Check your fglprofile.` This error occurs if the conversion file defined by the gui.chartable entry, in the $FGLDIR/etc/fglprofile file, is not readable by the current user. Check if the gui.chartable entry is correctly set and if the specified file is readable by the current user.
-6306	`Can not open server file. Check installation.` A file on the server side cannot be sent to the graphical interface. Check the permissions of the file located in the $FGLDIR/etc directory. These files must have at least read permission for the current user.
-6307	`GUI server autostart: can not identify workstation.` GUI Server autostart configuration is wrong. Either DISPLAY, FGLSERVER or fglprofile settings are invalid. Set the required environment variables and check for fglprofile autostart entries.
-6308	`GUI server autostart: unknown workstation: check gui.server.autostart entries.` The computer described by the X11 DISPLAY environment variable is neither the local host, nor is it listed in the fglprofile entries. Check if the X11 DISPLAY name is correctly set, or review the fglprofile entries.
-6309	`Not connected. Cannot write to GUI.` For unknown reasons there was an attempt to write on the GUI socket before the connection was initiated. Check the program for invalid GUI operations.
-6310	`Not connected. Cannot read from GUI.`

Number	Description
	For unknown reasons there was an attempt to read on the GUI socket before the connection was initiated. Check the program for invalid GUI operations.
-6311	`No current window.` The program tries to issue a MENU instruction with no current window open. Review the program logic and make sure a window is open before MENU.
-6312	`The type of the user interface (FGLGUI) is invalid.` While initiating the user interface, the runtime system did not recognize the GUI type and stopped. Make sure the FGLGUI environment variable has a correct value.
-6313	`The UserInterface has been destroyed.` The error occurs when the front-end sends a DestroyEvent event, indicating some inconsistency with the starting program. This can happen, for example, when multiple StartMenus are used, or when you try to run an MDI child without a parent container, or when two MDI containers are started with the same name, etc. Check for inconsistency and fix it.
-6314	`Wrong connection string. Check client version.` While starting the program, the runtime received a wrong or incorrectly constructed answer from the front-end. Make sure you are using a front-end that is compatible with the runtime system.
-6315	`The form is too complex for the console-ui.` The program tries to display a form with a complex layout that cannot be displayed in text mode. Review the form file and use a simple grid with a SCREEN section instead of LAYOUT.
-6316	`Error error-num returned from client: description` Front end returned the specified error during GUI connection initialization. Check the front-end documentation for more details.
-6317	`Invalid or unsupported client protocol feature.` The GUI protocol feature you are trying to use is not supported by the front-end. For example, you are trying to use protocol compression but the runtime is not able to compress data. Make sure that the front-end component is compatible with the runtime system (versions must be close). Check the runtime system version for supported protocol features. If compression is enabled, check that the zlib library is installed on your system.
-6318	`Choosing the DIALOG implementation by setting the environment variable FGL_USENDIALOG=0 has been desupported since version 2.20.03.`

Number	Description
	You try to use the old dialog implementation by setting FGL_USENDIALOG to zero. The old dialog implementation has been removed, you must unset the FGL_USENDIALOG environment variable.
-6319	`Internal error in the database library. Set FGLSQLDEBUG to get more details.` An unexpected internal error occurred in the database driver. Set the FGLSQLDEBUG environment variable to level 1, 2, 3 or 4 to get detailed debug information.
-6320	`Can't open file 'file-name'.` The runtime system tried to open a resource file in FGLDIR but access is denied or file no longer exists. Check for file permissions and existence in FGLDIR.
-6321	`No such interface capability: 'feature-name'.` The runtime system tried to use a front-end protocol capability, but is not able to use it. Check if the front-end is compatible with the runtime system.
-6322	`version-num-1 wrong version. Expecting version-num-2.` Some resource files of FGLDIR have been identified as too old for the current runtime system. Re-install the runtime system environment.
-6323	`Can't load factory profile 'file-name'.` The default fglprofile file located in FGLDIR/etc is missing or is unreadable. Check the permission of the file. If the file is missing, reinstall the software.
-6324	`Can't load customer profile 'file-name'.` The configuration file defined by the FGLPROFILE environment variable is missing or unreadable. Check if the FGLPROFILE environment variable is correctly set and if the file is readable by the current user.
-6325	`Can't load application resources 'file-name'.` The directory specified by the fglrun.default entry in FGLDIR/etc/fglprofile is missing or not readable for the current user. Check if the entry fglrun.default is correctly set in FGLDIR/etc/fglprofile and if the directory specified is readable by the current user.
-6327	`Internal error in the run time library file library-name.` Something unpredictable has occurred, generating an error. Contact your Technical Support.

Number	Description
-6328	`Bad format of resource 'entry-name' value 'entry-value': you must use the syntax: entry-name='VARNAME=envvar-value'.` The FGLPROFILE file contains an invalid environment variable definition format. Check the content of the profile file.
-6329	`All TABLE columns must be defined with the same height.` The form layout defines a TABLE with field tags using different heights. Review all cells of the table to use the same height in all columns.
-6330	`Syntax error in profile 'file-name', line number lineno , near 'token'.` The FGLPROFILE file shown in the error message contains a syntax error. Check the content of the profile file.
-6331	`Front end module could not be loaded.` A front call failed because the module does not exist. The front end is probably not supporting this module.
-6332	`Front end function could not be found.` A front call failed because the function does not exist. The front end is probably not supporting this function.
-6333	`Front end function call failed. Reason: description` A front call failed for an unknown reason. Call the support and report the problem.
-6334	`Front end function call stack problem.` A front call failed because the number of parameter or returning values does not match. Make sure the number of parameters and return values are correct.
-6340	`Can't open file: description` The channel object failed to open the file specified. Make sure the filename is correct and user has permissions to read/write to the file.
-6341	`Unsupported mode for 'open file'.` You try to open a channel with an unsupported mode. See channel documentation for supported modes.
-6342	`Can't open pipe.` The channel object failed to open a pipe to execute the command. Make sure the command you try to execute is valid.
-6343	`Unsupported mode for 'open pipe'.`

Number	Description
	You try to open a channel with an unsupported mode. See channel documentation for supported modes.
-6344	`Can't write to unopened file, pipe or socket.` You try to write to a channel object which is not open. First open the channel, then write.
-6345	`Channel write error: description` An unexpected error occurred while writing to the channel. See the description for more details.
-6346	`Cannot read from unopened file, pipe or socket.` You try to read from a channel object which is not open. First open the channel, then read.
-6360	`This runner cannot execute any SQL.` The runtime system is not ready for database connections. Check the configuration of BDL.
-6361	`Dynamic SQL: type unknown: type-name .` The database driver does not support this SQL data type. You cannot use this SQL data type, review the code.
-6364	`Cannot connect to sql back end.` The runtime system could not initialize the database driver to establish a database connection. Make sure the database driver exists.
-6365	`Database driver not connected yet.` There is an attempt to execute an SQL statement, but no database connect is established. First connect, then execute SQL statements.
-6366	`Could not load database driver driver-name.` The runtime system failed to load the specified database driver. The database driver shared object (.so or .DLL) or a dependent library could not be found. Make sure that the specified driver name does not have a spelling mistake. If the driver name is correct, there is probably an environment problem. Make sure the database client software is installed. Check the UNIX™ LD_LIBRARY_PATH environment variable or the PATH variable on Windows™. These must point to the database client libraries.
-6367	`Incompatible database driver interface.`

Number	Description
	The database driver interface does not match the interface expected by the runtime system. This can occur if you copy an old database driver into a younger FGLDIR installation. Call the support to get a valid database driver.
-6368	`SQL driver initialization function failed.` The runtime system failed to initialize the database driver, program must stop because no database connection can be established. There is probably an environment problem (for example, INFORMIXDIR or ORACLE_HOME is not set). Check your environment and try to connect with a database vendor tool (dbaccess, sqlplus) to identify the problem.
-6369	`Invalid database connection mode.` You try to mix DATABASE and CONNECT statements, but this is not allowed. Use either DATABASE or CONNECT.
-6370	`Unsupported SQL feature.` This SQL command or statement is not supported with the current database driver. Review the code and use a standard SQL feature instead.
-6371	`SQL statement error number error-num (native-error).` An SQL error has occurred having the specified error number. You can query SQLERRMESSAGE or the SQLCA record to get a description of the error.
-6372	`General SQL error, check SQLCA.SQLERRD[2].` A general SQL error has occurred. You can query SQLERRMESSAGE or the SQLCA record to get a description of the error. The native SQL error code is in SQLCA.SQLERRD[2].
-6373	`Invalid database connection string.` The database connection string that you have used is not valid. Verify the format of the connection string.
-6374	`Wrong database driver context.` You try to EXECUTE, OPEN, FETCH, PUT, FLUSH, CLOSE or FREE a cursor that was declared or prepared in a different connect and driver. Issue a SET CONNECTION before the statement to select the same connection and driver as when the cursor was created.
-6375	`LOAD cannot get describe information for table columns.` The LOAD instructions needs column description to allocate the automatic fetch buffers, but the database driver is not able to describe the table columns used in the INSERT statement.

Number	Description
	If the underlying database client API does not provide result set column description, the LOAD statement cannot be supported.
-6601	`Can not open Database dictionary 'directory-name'. Run database schema extraction tool.` The schema file does not exist or cannot be found. If the schema file exists, verify that the filename is spelled correctly, and that the file is in the current directory or the FGLDBPATH environment variable is set to the correct path. If the file does not exist, run the database schema extraction tool to create a schema file.
-6602	`Can not open globals file 'file-name'.` The globals file does not exist or cannot be found. Verify that the globals file exists. Check the spelling of the filename, and verify that the path is set correctly.
-6603	`The file 'file-name' cannot be created for writing.` The compiler failed to create the file shown in the error message for writing. Check for user permissions to make sure that the **.42m** file can be created.
-6604	`The function 'function-name' can only be used within an INPUT [ARRAY], DISPLAY ARRAY or CONSTRUCT statement.` The language provides built-in functions that can only be used within specific interactive statements. Review your code and make the necessary corrections.Check that the function is within the interactive statement and that appropriate END statements (END INPUT/ARRAY/ DISPLAY ARRAY/CONSTRUCT) have been used.
-6605	`The module 'module-name' does not contain function 'function-name'.` The module shown in the error message does not hold the function name as expected. The specified function needs to be defined in this module.
-6606	`No member function 'function-name' for class 'class-name' defined.` The function name is misspelled or is not a method of the class for which it is called. Review your code and the documentation for the method you are attempting to use. If the function is an object method, make sure the referenced object in your code is of the correct class.
-6608	`Resource error: entry-name :parameter expected` This is a generic error message for resource file problems.
-6609	`A grammatical error has been found at 'seen-token' expecting: expected-token.` A general syntax error message that indicates the location of the problem code and what code was expected.

Number	Description
	Review your code, particularly for missing END statements such as END FUNCTION or END INPUT, etc., and make the necessary corrections.
-6610	`The function 'function-name' has already been called with a different number of parameters.` Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list. Check the correct number of parameters for the specified function. Then examine all calls to it, and make sure that they are written correctly.
-6611	`Function 'function-name': unexpected number of returned values.` The function shown returned a different number of values as expected. Check the body of the function for RETURN instructions.
-6612	`Redeclaration of function 'function-name'.` The function shown was defined multiple times. Change the name of conflicting functions.
-6613	`The library function 'function-name' is not declared.` The function shown was not declared. Change the name of the function.
-6614	`The function 'function-name' may return a different number of values.` The function shown contains multiple RETURN instructions which may return different number of values. Review the RETURN instructions to return the same number of values.
-6615	`The symbol 'symbol-name' is unused.` This is a warning indicating that the shown symbol is defined but never used. Useless definition can be removed.
-6616	`The symbol 'symbol-name' does not represent a defined CONSTANT.` The shown symbol is used as a CONSTANT, but it is not a constant. Review your code and check for this name.
-6617	`The symbol 'symbol-name' is a VARIABLE.` The symbol shown is a VARIABLE which cannot be used in the current context. Review your code and check for this name.
-6618	`The symbol 'symbol-name' is a CONSTANT.` The symbol shown is a CONSTANT which cannot be used in the current context. Review your code and check for this name.
-6619	`The symbol 'symbol-name' is not an INTEGER CONSTANT.`

Number	Description
	The symbol shown is used as if it was an INTEGER constant, but it is not. Review your code and check for this name.
-6620	`The symbol 'symbol-name' is not a REPORT.` The symbol shown is used as a REPORT, but it is not defined as a REPORT. Review your code and check for this name.
-6621	`The symbol 'symbol-name' is not a FUNCTION.` The symbol shown is used as a FUNCTION, but it is not defined as FUNCTION. Review your code and check for this name.
-6622	`The symbol 'symbol-name' does not represent a valid variable type.` The symbol shown is not known as a valid type to define a program variable. Review your code and check for the type name.
-6623	`The method 'method-name' cannot be called without an object.` The specified method is an object method of its class. Review your code. Ensure that the required object of the class has been instantiated and still exists, and that the method is called specifying the object variable as the prefix, with the period character as a separator.
-6624	`The method 'method-name' cannot be called with an object.` The specified method is a class method and cannot be called using an object reference. No object has to be created. Review your code. Ensure that the method is called using the class name as the prefix, with the period character as a separator.
-6625	`The statement is not Informix compatible.` The SQL statement is not Informix® compatible. Change the SQL statement by using Informix® SQL syntax.
-6627	`The symbol 'symbol-name' is not a VARIABLE.` The symbol shown is use as a variable, but is not defined as a variable. Review your code and check for this name.
-6628	`The GLOBALS file does not contain a GLOBALS section.` The filename specified in a GLOBALS statement references a file that does not contain a GLOBALS section. Review your code to make sure that the file specified by the filename is a valid GLOBALS file, containing the required GLOBALS section.
-6629	`The type 'type-name' is too complex to be used within a C-extension.`

Number	Description
	The type of the global variable is too complex to be used in a C extension. This error can occur when the -G option of fglcomp, to generate the C sources to share global variables with C extensions, when a global variable is defined with complex data types without a C equivalent. Review the definition of the global variables and use simple types instead, corresponding to a C data type. The BYTE, TEXT and STRING types are complex types.
-6630	`Memory overflow occurred during p-code generation. Simplify the module.` A memory overflow occurred during compilation to p-code because the .4gl source module is too large. This problem can occur with very large source files. You must split the module into multiple sources.
-6631	`Incompatible types, found: source-type, required: target-type.` A LET or RETURNING tries to assign a value or an object reference to a variable defined with a data type or class that is not compatible to the value type. This occurs usually when using Java™ classes because Java™ is a strongly type language. For example, assigning a Java™ string to a Java™ StringBuffer raises this error. Define the target variable with a type corresponding to the assigned value.
-6632	`Cannot find symbol symbol-name, location: category type-name.` The symbol used does not exist. This occurs typically when referencing a Java™ class with an invalid name in the class path, or when referencing a class member that does not exist. Check the symbol names used in the instruction.
-6633	`primitive-type cannot be dereferenced.` An expression references a method or a field with a primitive Java™ type, but primitive types are not classes and therefore do not have methods or fields. For example, you try to call a method with a symbol defined as integer or short in Java™: DISPLAY java.lang.Short.MAX_VALUE.foo Review the code using the symbol defined with a primitive type.
-6634	`Incompatible or corrupted database dictionary 'database-name'.` The .sch database schema 'database-name' contains incompatible type definitions or is corrupted. Re-generate the .sch file with the fgldbsch tool by using the correct command line options to generate compatible types.
-6636	`Invalid usage of NULL in an expression` The compiler detected an `NULL` constant in an expression that will always evaluate to `NULL` or FALSE. For example, when writing `IF var == NULL THEN`, the program flow will never enter in the `IF` block.
-6774	`The license 'license-num' is no more valid. Please contact your vendor.`

Number	Description
	The license number is no longer valid. Contact your vendor to obtain a new license number.
-6780	`Invalid license request format.` The request sent to the license manager was not recognized. Check that the version of the license manager is compatible with the runtime system.
-6781	`Incompatible License Manager (flmprg) version. The minimum version required is version-num.` The license manager is too old and is not compatible with the current runtime system. Call the support center to get a new version of the license manager.
-6783	`The license number 'license-num' is invalid. Please, contact your vendor.` The license number could not be validated by the license server. Call the support center to get a new license number.
-6784	`The license 'license-num' has expired. Please, contact your vendor.` The license is time limited and it has expired. Call the support center to get a new license number.
-6785	`CPU limit exceeded. Please, contact your vendor.` The license is CPU limited and the system has more CPUs as allowed. Call the support center to get a new license number.
-6786	`Report Writer token creation failed.` Check permissions on the lock/token directory (in FGLDIR or FLMDIR).
-6787	`This GRW license requires a DVM license with a valid maintenance date.` GRW licenses with the option 'DVM under maintenance' require that the DVM maintenance key expiration date not be expired. Update the DVM maintenance key.
-6788	`Cannot get GRW report token information.` Contact your support center.
-6789	`The installed license is invalid and cannot be used by this product.` The current license is not valid for the product you have installed. Contact your support center to get a license corresponding to the current installed product.

Number	Description
-6802	`Can not open Database dictionary 'schema-name'. Run schema extraction tool.` The schema file does not exist or cannot be found. If the schema file exists, verify that the filename is spelled correctly, and that the file is in the current directory or the FGLDBPATH environment variable is set to the correct path. If the file does not exist, run the database schema extraction tool to create a schema file.
-6803	`A grammatical error has been found at 'line-number', expecting token-name.` This is a generic message for errors.
-6804	`'form-name' form compilation was successful.` This is an information message indicating that the form was compiled without problem.
-6805	`Open Form 'form-name', Bad Version: version-1, expecting: version-2.` You have compiled your form with a version of the form compiler that is not compatible with that used for compiling the other source code. Compile your form file and related source code files using the same or compatible versions of the compilers.
-6807	`The label 'label-name' could not be used as column-title.` The form file defines an invalid TABLE column title. Check for column titles which are not corresponding to column positions.
-6808	`The widget 'widget-name' can not be defined as array.` The form file defines an item which is used as a matrix column. Review your form definition.
-6809	`The layout tag 'tag-name' is invalid, expecting: token-name.` The form compiler detected an invalid layout tag specification. Review your form definition.
-6810	`The attribute 'attribute-name' is invalid for item type 'type-name'.` The form compiler detected an invalid attribute definition for this item type. Review your form definition and check for invalid attributes.
-6811	`Syntax error near 'token-1', expecting token-2.` A general syntax error message that indicates the location of the problem code and what code was expected. Review your code and make the necessary corrections.
-6812	`Unterminated char constant.`

Number	Description
	The form compiler detected an unterminated character constant. Review your form definition and check for missing quotes or double-quotes.
-6813	`The element 'element-name' conflicts with group-box 'group-name'.` You have used the same name for an element and for a group-box. Review your form definition and ensure that the names used are unique.
-6814	`All members of the SCREEN RECORD 'screen-record-name' must reference the same Table or ScrollGrid.` The shown screen record references multiple tables or scrollgrids in your form file. Review your form definition and use one unique table for a given screen record.
-6815	`Invalid indentation in between braces.` The LAYOUT section of your form defines an invalid indentation. Review your form definition and check for corresponding indentations.
-6817	`TABLE container defined without a SCREEN RECORD in the INSTRUCTION section.` The minimum value of the defined attribute must be lower than the maximum value. Review your code and make the necessary corrections.
-6818	`Min value must be lower that Max value.` The minimum value of the defined attribute must be lower than the maximum value. Review your code and make the necessary corrections.
-6819	`Number of elements in the SCREEN RECORD must match the number of columns in TABLE container.` The elements defined in the screen record differs from the columns used for the TABLE container. Review your form definition and add missing table columns to the screen record, order does not matter.
-6820	`ScrollGrid and/or Group layout tags cannot be nested.` The form definition has nested ScrollGrid and/or Group layout tags. These tags cannot be nested. Review your form definition and make the necessary corrections.
-6821	`HBOX tags cannot be used for ARRAYS.` The form definition is using an HBOX tag for an array, which is not permitted. Review your form definition and make the necessary corrections.
-6822	`Escaped graphical characters are not accepted in GRID sections.` You try to use Text User Interface graphics in the new GRID container.

Number	Description
	This is not allowed, use GROUPs instead.
-6823	`Close tag does not have a matching tag above.` The form definition has a close tag without a prior matching open tag. Open tags and close tags must match. Review your form definition file and make the necessary corrections.
-6824	`The table 'table-name' is empty.` The form layout defines a table layout tag identified by tablename , but nothing was found directly under this table which could be a column or a column title. Append columns to the table layout region.
-6825	`The tag 'tag-name' overlaps with table 'table-name'.` In the form layout, tagname overlaps the layout region of tablename and makes it invalid. Move or remove tagname , or redefine the layout region of tablename .
-6826	`Checked value must be different from unchecked value for field 'field-name'.` The VALUECHECKED and VALUEUNCHECKED attributes have the same value. This makes no sense because these attributes define the values corresponding to the checked and unchecked states of a checkbox. Use different values for these attributes.
-6827	`Duplicated item key found for field 'field-name'.` The ITEMS attribute of field fieldname defines item keys with the same value. Check ITEMS attribute and use unique key values. Note that '' and NULL are equivalent.
-6828	`The attribute attribute-name must belong to a column of a TABLE.` A form item uses an attribute that references a form field which is not defined or does not belong to the TABLE. Check the ATTRIBUTES section for invalid column references.
-6829	`The column column-name referenced by the attribute-name attribute must belong to the TABLE.` A form item uses an attribute that references a form field which is not defined or does not belong to the TABLE. Check the ATTRIBUTES section for invalid column references.
-6830	`Not implemented (yet): feature-name` The feature or syntax you are using is not implemented yet. This feature cannot be used in the Genero version you have installed.
-6831	`At least one member of the SCREEN RECORD 'screen-record-name' must not be a PHANTOM field.`

Number	Description
	A screen record is defined with form fields that are all defined as PHANTOM fields. At least on screen record field must not be a PHANTOM field.
-6832	`Repeated screen tags 'tag-name' are misaligned, must align on X or Y.` The layout defines multiple tags with the same name, but these are not properly aligned in the X or Y direction. Edit the form file and make sure that repeated tags are correctly aligned.
-6833	`Invalid TREE definition: the field 'field-name' must be an EDIT or LABEL.` The form defines a TREE container with the field column defined with a wrong item type. Replace the item type by EDIT or LABEL.
-6834	`Invalid TREE definition: the field 'field-name' must be defined for the SCREEN RECORD.` The form defines a TREE container with an invalid field set. Check that mandatory fields such as node name, parent id and node id fields are defined.
-6835	`The fields specified in the THRU option appear in the reverse order.` The form defines a screen record by using the THRU or THROUGH keyword, but the first field is defined after the last field in the ATTRIBUTES section. Exchange the field names specified in the screen record definition, or review the declaration order in ATTRIBUTES.
-6836	`Invalid TREE definition: the attribute 'attribute-name' conflicts with id or parentid.` The .per form defines a TREE with invalid configuration. You have probably used the same field for the named attribute and for IDCOLUMN or PARENTIDCOLUMN. Review the form definition and configure the TREE properly. You must use dedicated columns for the attributes mentioned.
-6837	`Invalid AGGREGATE definition: must be located below a table column.` The .per form defines an AGGREGATE form item with a field tag that is not aligned under a table column field tag. Review the table layout and make sure that all aggregate fields are properly aligned and placed below column tags.
-6838	`This area is reserved for AGGREGATEs.` The .per form defines a TABLE with aggregate fields, but not all aggregate fields are declared with the AGGREGATE item type. Review the field definitions in the ATTRIBUTES section.

Number	Description
-6839	`The screen tag 'tag-name' can not be defined in a TABLE.` The .per form defines a TABLE with columns using different field tag names, an no AGGREGATE field is defined. Review columns of the TABLE, each field tag of a given column must use the same tag name, except if you want to define an AGGREGATE field.
-6840	`Columns with AGGREGATE must have type EDIT.` The form field table column corresponding to the aggregate field must be of type EDIT.
-6841	`FORM not contain TOPMENU or TOOLBAR.` The form layout includes an external form specification file containing a TOPMENU or a TOOLBAR. Remove these sections from the included form file.
-6842	`FORM is out of date.` The form layout includes an external form specification file the was compiled with a older version.
-6843	`A resizable SCROLLGRID requires the definition of exactly one template.` A resizable SCROLLGRID (WANTFIXEDPAGESIZE=NO) must define a single row template.
-6844	`None form-field in resizable SCROLLGRID.` Elements in a resizable SCROLLGRID (WANTFIXEDPAGESIZE=NO) can only be form fields.
-6845	`The display field label 'field-name' has already been defined.` The field item tag is defined several times in different containers of the LAYOUT section.
-6846	`The screen tag '`*`tagname`*`' can not be defined in a SCROLLGRID` A SCROLLGRID contains a layout tag such as <TABLE > or <TREE >. This is not allowed.
-6847	`TABINDEX has to be unique` Some elements of the form define the same TABINDEX. Review the ATTRIBUTE section and make sure that all TABINDEX values are unique.
-6848	`All TABLE columns must have the same size.` In a TABLE or TREE container, all columns must be defined with the same width and height in the LAYOUT section.
-8000	`Dom: Node not found.` The node could not be found in the current document. Review your code.
-8001	`Dom: Invalid Document.`

Number	Description
	The document passed to the DOM API is not a valid document. Review your code.
-8002	`Dom: Invalid usage of NULL as parameter.` NULL cannot be used at this place. Review your code.
-8003	`Dom: A node is inserted somewhere it doesn't belong.` You try to insert a node under a parent node which does not allow this type of nodes. Check for the possible nodes and review your code.
-8004	`Sax: Invalid hierarchy.` The SAX handler encountered an invalid hierarchy. Make sure parent/child relations are respected.
-8005	`Deprecated feature: feature-name` The feature you are using will be removed in a next version. A replacement for the feature is normally available.
-8006	`The string resource file 'file-name' cannot be found.` The string file shown could not be found. Check if file exists and if path is valid.
-8007	`The string resource file 'file-name' cannot be read.` The string file shown could not be read. Check if file exists and if user has read permissions.
-8008	`There is no string text defined for the 'key-name' string key.` The runtime system could not find a string resource corresponding to the shown key. Check if the key is defined in one of the resource files.
-8009	`String resource syntax error near 'token-name', expecting token.` The string file compiler detected a syntax error. Check for invalid syntax in the **.str** file.
-8012	`Duplicate string key 'key-name' ( file-name : line ) IGNORE LINE.` The string file compiler detected duplicated string keys. Review the .str file and remove duplicated keys.
-8013	`The string file 'file-name' can not be opened for writing.` The string file compiler could not write to the specified string file. Make sure the user has write permissions and file name is valid.
-8014	`The string file 'file-name' can not be read.`

Number	Description
	The runtime system could not read from the specified string file. Make sure the user has read permissions.
-8015	`Field ( field-name ) in ON CHANGE clause not found in form.` The field used in the ON CHANGE clauses was not found in the form specification file. Make sure the field name of the ON CHANGE clause matches a valid form field.
-8016	`You cannot have multiple ON CHANGE clauses for the same field.` It is not possible to specify multiple ON CHANGE clauses using the same field. Remove unnecessary ON CHANGE clauses.
-8017	`SFMT: Invalid % index used.` The format string is not valid. Check for invalid % positions.
-8018	`SFMT: Format error.` The format string is not valid. Check for invalid % positions.
-8020	`Multiple ON ACTION clauses with the same action name appear in the statement.` It is not possible to specify multiple ON ACTION clauses using the same action name. Remove unnecessary ON ACTION clauses.
-8021	`Multiple ON KEY clauses with the same key name appear in the statement.` It is not possible to specify multiple ON KEY clauses using the same key. Remove unnecessary ON KEY clauses.
-8022	`Dom: Cannot open xml-file.` The file could not be loaded. Check file name and user permissions.
-8023	`Dom: The attribute 'attribute-name' does not belong to node 'node-type'.` You try to set an attribute to a node which does not have such attribute. This is not allowed, review your code.
-8024	`Dom: Character data can not be created here.` You try to create a text node under a node which does not allow such nodes. This is not allowed, review your code.
-8025	`Dom: Cannot set attributes of a character node.` You try to set attributes in a text node.

Number	Description
	This is not allowed, review your code.
-8026	`Dom: The attribute 'attribute-name' can not be removed: the node 'node-type' belongs to the user-interface.` You try to remove a mandatory attribute from an AUI node. You can only change the value of this attribute, try 'none' or an empty string.
-8027	`Sax: can not write.` The SAX handlers could not write to the destination file. Make sure the file path is correct and the user has write permissions.
-8029	`Multiple inclusion of the source file 'file-name'.` The preprocessor detected that the specified file was included several times by the same source. Remove unnecessary file inclusions.
-8030	`The full path to the source file 'file-name' is too long.` The preprocessor does not support very long file names. Rename the file.
-8031	`The source file 'file-name' cannot be read.` The preprocessor could not read the file specified. Make sure the use has read permissions.
-8032	`The source file 'file-name' cannot be found.` The preprocessor could not find the file specified. Make sure the file exists.
-8033	`Extra token found after 'directive-name' directive.` The preprocessor detected an unexpected token after the shown directive. Review your code and make the necessary corrections.
-8034	`feature-name : This feature is not implemented.` This preprocessor feature is not supported. Review your code and make the necessary corrections.
-8035	`The macro 'macro-name' has already been defined.` The preprocessor found a duplicated macro definition. Review your code and make the necessary corrections.
-8036	`A &else directive found without corresponding &if, &ifdef or &ifndef directive.` The preprocessor detected an unexpected **&else** directive.

Number	Description
	Review your code and make the necessary corrections.
-8037	`A &endif directive found without corresponding &if, &ifdef or &ifndef directive.` The preprocessor detected an unexpected **&endif** directive. Review your code and make the necessary corrections.
-8038	`Invalid preprocessor directive & name found.` The preprocessor directive shown in the error message does not exist. Review your code and check valid macros.
-8039	`Invalid number of parameters for macro-name.` The number of parameters of the preprocessor macro shown in the error message does not match de number of parameters in the definition of this macro. Review your code and check for the number of parameters.
-8040	`Lexical error: Unclosed string.` The compiler detected an unclosed string and cannot continue. Review your code and make the necessary corrections.
-8041	`Unterminated condition &if or &else.` The preprocessor found an un-terminated conditional directive. Review the definition of this directive.
-8042	`The operator '##' can only be used with identifiers and numbers. token is not allowed.` The preprocessor found an invalid usage of the ## string concatenation operator. Review the definition of this macro.
-8043	`Could not run FGLPP, command used: command` The compiler could not run the preprocessor command shown in the error message. Make sure the preprocessor command exists.
-8044	`Lexical error: Unclosed comment.` The compiler detected an unclosed comment and cannot continue. Review your code and make the necessary corrections.
-8045	`This type of statement can only be used within an INPUT, INPUT ARRAY, DISPLAY ARRAY, CONSTRUCT or MENU statement.` This statement has not been used within a valid interactive statement, which must be terminated appropriately with END INPUT, END INPUT ARRAY, END DISPLAY ARRAY, END CONSTRUCT, or END MENU. Review your code and make the necessary corrections.

Number	Description
-8046	`This type of statement can only be used within an INPUT, INPUT ARRAY, DISPLAY ARRAY or CONSTRUCT statement.` This statement has not been used within a valid interactive statement, which must be terminated appropriately with END INPUT, END INPUT ARRAY, END DISPLAY ARRAY, or END CONSTRUCT. Review your code and make the necessary corrections.
-8047	`Invalid use of 'dialog'. Must be used within an INPUT, INPUT ARRAY, DISPLAY ARRAY or CONSTRUCT statement.` The predefined keyword DIALOG has not been used within a valid interactive statement, which must be terminated appropriately with END INPUT, END INPUT ARRAY, END DISPLAY ARRAY, or END CONSTRUCT. Review your code and make the necessary corrections.
-8048	`An error occurred while preprocessing the file 'file-name'. Compilation ends.` The Genero BDL preprocessor could not parse the whole source file and stopped compilation. Review the source code and check for not well formed & preprocessor macros.
-8049	`The program cannot ACCEPT (INPUT|CONSTRUCT|DISPLAY) at this point because it is not immediately within (INPUT|INPUT ARRAY|CONSTRUCT|DISPLAY ARRAY) statement.` ACCEPT XXX has not been used within a valid interactive statement, which must be terminated appropriately with END INPUT, END PROMPT, or END INPUT ARRAY. Review your code and make the necessary corrections.
-8050	`Dom: Invalid XML data found in source.` ACCEPT DISPLAY has not been used within a valid DISPLAY ARRAY statement, which must be terminated with END DISPLAY ARRAY. Review your code and make the necessary corrections.
-8051	`Sax: Invalid processing instruction name.` The om.SaxDocumentHandler.processingInstruction() does not allow invalid processing instruction names such as 'xml'. <?xml ..?> is not a processing instruction, it is reserved to define the XML file text declaration. You must use another name.
-8052	`Illegal input sequence. Check LANG.` The compiler encountered an invalid character sequence. The source file uses a character sequence which does not match the locale settings (LANG). Check source file and locale settings.
-8053	`Unknown preprocessor directive 'directive-name'.` The preprocessor directive shown in the error message is not a known directive.

Number	Description
	Check for typo errors and read the documentation for valid preprocessor directives.
-8054	`Unexpected preprocessor directive.` The preprocessor encountered an unexpected directive. Remove the directive.
-8055	`The resource file 'file-name' contains unexpected data.` The XML resource file shown in the error message does not contain the expected nodes. For example, you try to load a ToolBar with ui.Interface.loadActionDefaults(). Check if the XML file contains the node types expected for this type of resource.
-8056	`XPath: Unclosed quote at position integer.` The XPath parser found an unexpected quote at the given position. Review the XPath expression.
-8057	`XPath: Unexpected character 'char' at position pos.` The XPath parser found an unexpected character at the given position. Review the XPath expression.
-8058	`XPath: Unexpected token/string 'token-name' at position pos.` The XPath parser found an unexpected token or string at the given position. Review the XPath expression.
-8059	`SQL statement or language instruction with vendor proprietary syntax.` The compiler found an SQL statement which is using a database specific syntax. This statement will probably not run on other database servers as the current. Review the SQL statement and use standard/common syntax and features.
-8060	`Spacer items are not allowed inside a SCREEN sections.` The form contains spacer items in a SCREEN section, while these are only allowed in LAYOUT. Review the form specification file.
-8061	`A TABLE row should not be defined on multiple lines.` All columns of a row in a TABLE container must be in a single line. Use a SCROLLGRID if you want to show row cells on multiple lines.
-8063	`The client connection timed out, exiting program.` The runtime system could not establish the connection with the front-end after a given time. This can for example happen during a file transfer, when the front-end takes too much time to answer to the runtime system. Check that your network connection is working properly.
-8064	`File transfer interrupted.`

Number	Description
	An interruption was caught during a file transfer. File could not be transferred, you need to redo the operation.
-8065	`Network error during file transfer.` An socket error was caught during a file transfer. Check that your network connection is working properly.
-8066	`Could not write destination file for file transfer.` The runtime system could not write the destination file for a transfer. Make sure the file path is correct and check that user has write permissions.
-8067	`Could not read source file for file transfer.` The runtime system could not read the source file to transfer. Make sure the file path is correct and check that user has read permissions.
-8068	`File transfer protocol error (invalid state).` The runtime system encountered a problem during a file transfer. A network failure has probably raised this error.
-8069	`File transfer not available.` File transfer feature is not supported. Make sure the front-end supports file transfer.
-8070	`The localized string file 'file-name' is corrupted.` The shown string resource file is invalid (probably invalid multibyte characters corrupt the file). Check for locale settings (LANG), make sure the .str source uses valid characters and recompile it.
-8071	`'symbol-name' is already defined.` The form file defines several elements of the same type with the same name. Review the form file and use unique identifiers.
-8072	`Statement must terminate with ';'.` An ESQL/C preprocessor directive is not terminated with a semicolon. Add a semicolon to the end of the directive.
-8073	`Invalid 'include' directive file name.` An include preprocessor directive is using an invalid file name. Check the file name.
-8074	`A &elif directive found without corresponding &if, &ifdef or &ifndef directive.` The preprocessor found an **&elif** directive with no corresponding **&if** .

Number	Description
	Add the **&if** directive before the **&elif**, or remove the **&elif** .
-8075	`The compiler plugin name could not be loaded.` fglcomp could not load the plugin because it was not found. Make sure the plugin exists and can be loaded.
-8076	`The compiler plugin name does not implement the required interface.` fglcomp could not load the plugin because the interface is invalid. Check if the plugin corresponds to the version of the compiler.
-8077	`The attribute 'attribute-name' has been defined more than once.` The variable attribute shown in the error message was defined multiple times. Review the variable definition and remove duplicated attributes.
-8078	`The attribute 'attribute-name' is not allowed.` The variable attribute shown in the error message is not allowed for this type of variable. Review the possible variable attributes.
-8079	`An error occurred while parsing the XML file.` The runtime system could not parse an XML file, which is probably not using a valid XML format. Check for XML format typos and if possible, validate the XML file with a DTD.
-8080	`Could not open xml file.` The specified XML file cannot be opened. Make sure the file exists and has access permissions for the current user.
-8081	`Invalid multibyte character has been encountered.` A compiler found an invalid multibyte character in the source and cannot compile the form or module. Check locale settings (LANG) and verify if there are no invalid characters in your sources.
-8082	`The item 'item-name' is used in an invalid layout context.` The form item name is used in a layout part which does not support this type of form item. This error occurs for example when you try to define a BUTTON as a TABLE column. Review your form definition file and use correct item types.
-8083	`NULL pointer exception.` The program is using calling a method thru an object variable which is NULL. You must assign an object reference to the variable before calling a method.

Number	Description
-8084	`Can't open socket: description` The channel object failed to open a TCP socket. See the description for more details. Make sure the IP address and port are correct.
-8085	`Unsupported mode for 'open socket'.` You try to open a channel with an unsupported mode. See channel documentation for supported modes.
-8086	`The socket connection timed out.` Socket connect could not be established and timeout expired. Check all network layers and try again.
-8087	`File error in BYTE or TEXT readFile or writeFile.` File I/O error occurred while reading from or writing to a file. Verify the file name, content and access permissions.
-8088	`The dialog attribute 'attribute-name' is not supported.` A dialog instruction was declared with an ATTRIBUTES clause containing an unsupported option. Review the ATTRIBUTES clause and remove unsupported option.
-8089	`Action 'action-name' not found in dialog.` You try to use and action name that does not exist in the current dialog. Verify if name of the action is defined by an ON ACTION clause.
-8090	`Field 'field-name' already used in this DIALOG.` The DIALOG instruction binds the same field-name or screen-record multiple times. Review all sub-dialog blocks and check the field-names / screen-records.
-8091	`The clause 'clause-name' appears more than once.` You have defined the same dialog control block multiple times. For example, AFTER ROW was defined twice. Remove the un-necessary control blocks.
-8092	`At least one field for this INPUT ARRAY must be editable.` An INPUT ARRAY is executed on fields that are read-only. At least one field must be editable and active. Review the form specification file or check that at least one field is active.
-8093	`Multi-range selection is not available in this context.` You try to use multi-range selection but it is not possible in the current dialog type. Disable this feature.

Number	Description
-8094	`Multi-range selection is not available in this context.` You try to use multi-range selection but it is not possible in the current dialog type. Disable this feature.
-8095	`Cannot change selection flag for this range of rows.` An attempt of selection flag modification with DIALOG.setSelectionRange() failed because the range is out of bounds or because there is no multi-range selection available in this context. Make sure you can use multi-range selection, and check the start and end index of the range.
-8096	`General SQL Warning, check SQLCA.SQLERRD[2] or SQLSTATE.` The last SQL statement has generated an SQL warning setting the SQLCA.SQLAWARN flags. Program execution can continue. However, you should take care and check the native SQL code and the SQL message in SQLERRMESSAGE.
-8097	`Value too large to fit in a TINYINT.` The TINYINT data type can accept numbers with a value range from -128 to +127. To store numbers that are outside this range, redefine the column or variable to use the SMALLINT or INTEGER type.
-8098	`ON FILL BUFFER conflicts with DISPLAY ARRAY as a tree.` The DISPLAY ARRAY instruction is using a treeview as decoration, but it implements also an ON FILL BUFFER trigger to do paged mode. The paged mode is not possible when using a treeview, because all rows of visible nodes are required (i.e. the dialog cannot display a tree only with a part of the dataset). To populate dynamically the array for a treeview, use the ON EXPAND to add new nodes and ON COLLAPSE to remove nodes.
-8099	`The form 'form-name' is incompatible with the current runtime version. Rebuild you forms.` The .42f form was probably compiled with an earlier version as the current runtime system. Recompile the form with the fglform compiler corresponding to the current fglrun.
-8100	`Attempt to access a closed dialog.` A call to a DIALOG class method is done with a dialog object that has terminated. Review the program logic and call the DIALOG methods only for active running dialogs.
-8101	`The TABLE column tag 'tag-name' appears multiple times in the row definition.` A TABLE column can only be used once in the row definition, you have probably repeated the same screen tag by mistake.

Number	Description
	Modify the TABLE row definition in the layout section in order to use each column only once.
-8102	`Syntax error in preprocessor directive.` The source file contains a preprocessor macro with an invalid syntax. Check the preprocessor manual page and fix the syntax error.
-8103	`The source and destination file name of a file transfer must not be NULL or empty.` The program is doing an fgl_getfile() or fgl_putfile() and the source or destination file name is NULL or empty. Provide a valid file name for both source and destination parameters.
-8104	`Cannot read from TUI: system-error .` A program running in text mode (FGLGUI=0) failed to read from console input stream. Check the console/terminal settings.
-8105	`Not found.` This message displayed by the runtime system when a record was not found. It can be displayed in different contexts, for example when searching a record in a list with the built-in search feature.
-8106	`Field ( field-name ) in ON ACTION INFIELD not found in form.` The field name used in an ON ACTION INFIELD action handle could not be found in the form. Make sure you are using the correct field name and field prefix (table name or screen record name).
-8107	`FGL_LENGTH_SEMANTICS environment variable is invalid. Valid values are BYTE and CHAR` The value specified in the FGL_LENGTH_SEMANTICS environment variable must be BYTE or CHAR.
-8108	`Subdialog dialog-name: already active` The sub-dialog is already in use.
-8109	`JSON parse error: description` Verify the input string passed to the JSON parsing function. See the description for more details.
-8110	`JSON stringify error: description` The JSON serialization failed. See the description for more details.
-8111	`Can not happen: description`

Number	Description
	The runtime system encounters an unexpected situation. The message is displayed to the user, but the program flow will continue. This unexpected situation must be fixed by programmers.
-8112	`Illegal argument.` The runtime system intruction, function or object method does not expect the value passed as argument. This can for example occur when calling the `Array.sort()` method with an invalid array-record member name.
-8113	`The actions DETAILACTION and DOUBLECLICK must be different.` The `DETAILACTION` and `DOUBLECLICK` attributes are used in `DISPLAY ARRAY` to configure a table decoration and behavior. These attributes cannot define the same action.
-8114	`Completer item list too long. The list must not contain more than 50 items.` The array passed to the setCompleterItems() dialog method is too long, reduce the list.
-8115	`Character to boolean conversion error.` The array passed to the setCompleterItems() dialog method is too long, reduce the list.
-8116	`Illegal context.` The current instruction is used on a wrong context.
-8117	`'##' cannot appear at start of macro expansion.` The preprocessor operator ## must join two identifiers (a ## b).
-8118	`'##' cannot appear at end of macro expansion.` The preprocessor operator ## must join two identifiers (a ## b).
-8119	`'#' is not followed by a macro parameter.` The preprocessor operator # must be followed by a parameter of the macro.
-8120	`File transfer: copy file to file-name failed.` The runtime system could not copy the specified file.
-8121	`File transfer: remove file file-name failed.` The runtime system could not delete the specified file.
-8122	`File transfer: touch file file-name failed.` The runtime system could not touch the specified file.
-8123	`\x used with no following hex digits.` The `\xNN` character code is malformed.
-8124	`hex escape sequence out of range.`

Number	Description
	The `\xNN` character code contains an invalid hexadecimal value.
-8125	`File transfer: create symbolic link file-name failed.` The file transfer required a symbolic link that could not be created.
-8126	`Image to font mapping: Font file file-name not found.` The font file could not be found, check FGLIMAGEPATH environment variable.
-8127	`Image to font mapping: Format error in file file-name.` The image to font mapping file contains errors.
-8128	`Image to font mapping: Cannot open file file-name.` The image to font mapping file could not be found, check FGLIMAGEPATH environment variable.
-8200	`apidoc: parameter name 'param-name' is invalid.` The compiler has detected a comment error while extracting the source documentation: The @param variable name is not in the list of parameters in the next FUNCTION definition. Check the function parameter name.
-8201	`apidoc: tag missing: @param param-name.` The compiler has detected a comment error while extracting the source documentation: There is a missing @param tag that should describe a parameter of the next FUNCTION definition. Check the function parameter name.
-8202	`apidoc: invalid tag name @ tag-name.` The compiler has detected a comment error while extracting the source documentation: The @ tag-name tag is not a known tag name. Check for typo errors in the tag name.
-8300	`Cannot load java shared library. Reason: system-error` The runtime system could not load the JVM shared library (or DLL). Make sure that a JRE is installed on the machine and check the environment (LD_LIBRARY_PATH on UNIX™ or PATH on Windows™).
-8301	`Cannot create java VM.` The runtime system could load the JVM shared library (or DLL), but could not initialize the Java™ VM with a call to JNI_CreateJavaVM(). Check that the Java™ requirements and resources needs to create a Java™ VM.
-8302	`Array element type is not a Java type.` The fglcomp compiler detected a Java™ Array definition which is not using a Java™ type for the elements.

Number	Description
	Review the DEFINE statement and use a Java™ type.
-8303	`Java is not supported.` The platform you are using does not support a recent Java™ version required by Genero. You cannot use the Java™ interface in this operating system, you must review your source code and remove all Java™ related parts.
-8304	`Cannot assign a value to final variable 'variable-name'.` The program tries to set a Java™ class variable which is not writable. Review the program logic.
-8305	`The Java variable 'variable-name' can not be used here.` The program tries to use a Java™ class variable in an invalid context. For example, a Java™ class variable is used in an INPUT instruction. Review the program logic and use a regular Genero BDL variable.
-8306	`Java exception thrown: java-exception-text.` A Java™ exception has been thrown while executing Java™ code. Check the exception text and review the code.
-8307	`Java object required.` A Java™ object reference is expected by the instruction. This error typically occurs in a CAST() or INSTANCEOF(). Check the expression used in the instruction and make sure it references a Java object.
-8400	`module.name has private access.` An instruction references a module function or module variable which is declared as private. Make the function or variable public in the imported module.
-8401	`Reference to name is ambiguous.` A function or variable referenced without the module prefix, but exists in several imported modules. This error can also be printed by the compiler for Java™ calls. Add the module prefix before the object name to remove the ambiguity.
-8402	`Cyclic IMPORT FGL involving module.` Some modules are importing each other and introduce a cyclic reference which is impossible to resolve. Extract common language elements into a new module.
-8403	`Module name does not exist.` The module name to be imported could not be found.

Number	Description
	Make sure the module name matches the file name.
-8404	`Module name has not been imported.` A statement is referencing module name which has not been imported. Import the module before usage.
-8405	`category-name qualifier-name.symbol-name has not been defined.` The symbol identified by qualifier-name.symbol-name cannot be found. For example, a START REPORT or SUBDIALOG is referencing a report or sub-dialog symbol with module prefix, but the symbol is not found in the specified module. You must import the module defining the referenced symbol.
-8406	`The function 'function-name' has not been defined. This conflicts with IMPORT FGL.` The function name is referenced in the compiled module, but none of the imported modules define that function. You must import the module containing the function.
-8407	`The type of the parameter 'param-name' is not an SQL type: cannot be inserted into a temporary table used for this report.` The REPORT parameter name is defined with a BDL type that has no SQL equivalent and thus cannot be used to create the temporary table needed to sort rows for a two-pass report. Define the parameter with an SQL-compatible type (CHAR, VARCHAR, INTEGER, DECIMAL, etc).
-8408	`ON ACTION action-name conflicts with ON action-name.` The dialog block defines conflicting ON ACTION and ON triggers, defining the same actions. For example, an ON ACTION delete is defined within a dialog block that is also defining an ON DELETE trigger. Review the dialog actions, if you want to use ON triggers defining actions.
-8409	`The action action-name shadows another action with the same name.` The dialog defines ON ACTION blocks using the same action name at different levels (dialog, sub-dialog and field level). Use different action names when a conflict occurs.
-8410	`The symbol 'symbol-name' is not a DIALOG.` The symbol referenced is not defined as a DIALOG subdialog block.
-8500	`The Genero Mobile pcode size limit has been reached.` Contact your vendor for details.
-8501	`Modules compiled with Genero require a Genero license at runtime.`

Number	Description
	Contact your vendor for details.
-9000	`Value not allowed for this XML attribute.` Remove the value for this attribute or see the "Mapping between simple BDL and XML data types" section.
-9001	`Value mandatory for this XML attribute.` Set a value to the XML attribute. See the "Mapping between simple BDL and XML data types" section.
-9002	`Cannot set the XML attribute, because only one XSD attribute is allowed per definition.` Select the unique appropriate XSD data type.
-9003	`XML Attribute only allowed on a BDL TYPE.` Remove the XML attribute or change your BDL DEFINE instruction into a BDL TYPE definition.
-9004	`XML Attribute is not allowed on a type definition.` Remove the XML attribute or change your BDL TYPE definition into a BDL DEFINE instruction.
-9005	`XML Attribute XSTypeNamespace cannot be set without attribute XSTypeName.` Add a XSTypeName attribute.
-9006	`XML Attribute is only allowed on a simple data type definition.` Remove the XML attribute or change your RECORD or ARRAY into a simple BDL data type.
-9007	`XML Attribute is only allowed on a BDL RECORD definition.` Change your BDL variable definition into a RECORD.
-9008	`XML Attribute is only allowed on a one dimentional array definition.` Remove the XML attribute or use a one dimentional array.
-9009	`Attributes XMLAttribute, XMLElement, XMLAny and XMLBase are exclusives.` Choose only one of the above available choices.
-9010	`Attributes XMLChoice, XMLAll, XMLSequence, XMLSimpleContent and XSComplexType are exclusives.` Choose only one of the above available choices.
-9011	`Attribute XSTypeName has been defined twice with the same value XML attribute and the same XSTypeNamespace value, but not the same definition.`

Number	Description
	Define a unique (XSTypeName,XSTypeNamespace) couple for your program.
-9012	`XMLName or XMLNamespace not allowed on nested XMLChoice variable.` Remove the XMLName and XMLNamespace attributes.
-9013	`XMLName or XMLNamespace not allowed on nested XMLSequence variable.` Remove the XMLName and XMLNamespace attributes.
-9014	`Unrecognized XML attribute value.` Review the available values for this XML attibute.
-9015	`XML Attribute is only supported on a member of a record.` Remove the XML attribute.
-9016	`XML Attribute is only supported on a record's member when XMLChoice is defined.` Remove the XML attribute.
-9017	`XML Attribute is only supported on a record's member when XMLSimpleContent is defined.` Remove the XML attribute.
-9018	`XML Attribute not supported on this simple type.` Remove the XML attribute or change your BDL type definition.
-9019	`Attribute XMLTypeNamespace cannot be set without attribute XMLTypeName.` Set XMLTypeName attribute.
-9020	`XMLSimpleContent attribute supports only XMLAttribute and XMLAnyAttribute attributes.` Remove the unallowed XML attributes.
-9021	`Attribute XMLBase has been defined more than once in the BDL record.` Set only one XMLBase attribute.
-9022	`Attribute XMLSelector has been defined more than once in the BDL record.` Set only one XMLSelector attribute.
-9023	`XML Attribute cannot be set with other attributes.` Remove all the other XML attributes.
-9024	`Attribute XMLSelector is missing in the BDL record.`

Number	Description
	Set the XMLSelector attribute on one of the record member.
-9025	`Attribute XMLBase is missing in the BDL record.` Set the XMLBase attribute on one of the record member.
-9026	`Nested XML attribute cannot be defined on a BDL TYPE.` Remove the Nested XML attribute.
-9027	`Nested XML attribute cannot be defined on root variable.` Remove the Nested XML attribute.
-9028	`Invalid parameter.` See the documentation about the function paramaters.
-9029	`Parameters of a published RPC Web Service operation must be a Record or NULL.` Review your parameters definition.
-9030	`Parameters of a published DOC Web Service operation must be a Record, an Array or NULL.` Review your parameters definition.
-9031	`XML Attribute is not allowed on a BDL record's member.` Remove the XML attribute or set it at the appropriate place.
-9032	`XML Attribute can only be set on a ARRAY defined inside a RECORD.` Remove the XML attribute or set it at the appropriate place.
-9033	`XML Attribute cannot be defined at first level of a variable.` Remove the XML attribute or set it at the appropriate place.
-9034	`Attributes 'XMLAttribute' are not allowed on nested sequence or choice.` Remove the XMLAttribute attribute.
-9035	`RPC Web Functions cannot have XMLList set on one of the parameters.` Put your BDL ARRAY inside a BDL RECORD.
-9036	`Attribute XMLName is mandatory on BDL variable when used as SOAP Header.` Add the XMLName attribute.
-9037	`RPC Web Functions cannot have XMLNamespace set on one of the parameters.`

Number	Description
	Remove the XMLNamespace attribute.
-9038	`XSComplexType attribute allows only attributes with one optional nested list or nested record.` Set only one XMLOptional attribute for all nested record members.
-9039	`XMLName or XMLNamespace not allowed on nested XMLAll.` Remove XMLName and XMLNamespace.
-9040	`Nested XML Attribute is not allowed on an array.` Remove the XML attribute
-9041	`XMLBase Attribute allows only one additional XSD attribute.` Set a unique XSD attribute.
-9042	`XML Attribute value is not allowed on a BDL record's member.` Set the appropriate value to the specified XML attribute.
-9043	`Unsupported facet constraint for the BDL type.` Check the available facet constraint in "Mapping between simple BDL and XML data types" section.
-9044	`Invalid value for facet constraint 'constraint-name'.` Check the available facet constraint value. See XML facet constraint attributes on page 2529.
-9045	`Facet constraint attributes cannot be defined without a XSD simple type attribute.` Add the appropriate XSD attribute.
-9046	`Facet XSDLength and XSDMinLength or XSDMaxLength cannot be used together.` Select only one of the above attributes.
-9047	`XML Attribute not allowed on BDL objects.` Remove the XML attribute.
-9048	`Attribute XMLName cannot be set with XMLAny or XMLAnyAttribute.` Remove the XMLName attribute.
-9049	`XML Attribute not allowed on members of xmlchoice='inherited' records.` Remove the XML attribute.
-9050	`Parameter with public qualifier not allowed.` Remove the PUBLIC instruction.

Number	Description
-9051	`Parameters of published Web Service operations must be variables in global or modular scope.` Move your variables to a GLOBALS instruction or to modular scope.
-9052	`A published Web service header must be a variable in global or modular scope.` Move your Web service header to a GLOBALS instruction or to modular scope.
-9053	`Web service function with private qualifier not allowed.` Remove the PRIVATE instruction.
-9054	`Web service function must be a string literal.` You cannot use a variable for your web service function name.
-9055	`XML Attribute is not allowed on an array definition.` Remove the XML attribute.
-9056	`Attribute XMLAny has been defined more than once per BDL record.` Use only one XMLAny attribute in a BDL RECORD.
-9057	`Attribute XMLAnyAttribute has been defined more than once per BDL record.` Use only one XMLAnyAttribute attribute in a BDL RECORD.
-9058	`Attribute XMLList and XMLAnyAttribute are exclusives.` Use only one of the above XML attributes.
-9059	`Element of BDL array with XMLAnyAttribute must be a BDL record containing three variables for the namespace, name, value of type STRING.` Example: DEFINE arr DYNAMIC ARRAY OF RECORD ns, name, value STRING END RECORD
-9060	`XML Attribute is only allowed on dynamic arrays.` Change your BDL ARRAY into a DYNAMIC ARRAY.
-9061	`XML Attribute cannot be set inside a nested record.` Remove the XML attribute.
-9062	`Attribute XMLAttribute is not allowed after attribute XMLAnyAttribute.` Move the record member with XMLAnyAttribute attribute to the last position.
-9063	`A published Web service fault must be in global or modular scope.` Move your variables to a GLOBALS instruction or to modular scope.

Number	Description
-9064	`Attribute XMLName is mandatory on the BDL variable when used as Fault.` Set the XMLName attribute.
-9065	`Colon not allowed for XML attribute value.` Remove the colon.
-9066	`XML Attribute is only allowed on a root variable.` Remove the attribute or move it to the root variable.

-9067	`Bad W3CEndPointReference definition.`
	Review your RECORD definition. It should match this structure:
	`RECORD ATTRIBUTES(W3CEndpointReference)`
	`  address STRING, -- The location of the Web Service (for ex: URL)`
	`  ref RECORD`
	`  ... (other members defining the state)`
	`  END RECORD`
	`END RECORD`
	See com.WebService.CreateStatefulWebService on page 2012.

-9068	`Invalid state BDL variable, only simple variables or W3CEndpointReference record allowed.` Check that "state" parameter TYPE of function com.WebService.CreateStatefulWebService is correct. Its type must be a simple type definition or a W3CEndPointReference RECORD.
-9069	`Registered HTTP variable error.` Check that the BDL variable match the definition set in com.WebService.registerInputHTTPVariable or com.WebService.registerOutputHTTPVariable.
-10098	`Incorrectly formed hexadecimal value.` You try to load data with LOAD or locate a BYTE variable with a file contained malformed hexadecimal values. Check the file content and fix the typos before loading again.
-10099	`Invalid delimiter. Do not use '\' or hex digits (0-9, A-F, a-f).` You try to LOAD or UNLOAD data with an invalid field delimiter. Change the field delimiter to a valid character such as | (pipe) or ^ (caret).
-15500	`Internal runtime error occurred in WS server program.` Contact your support center.
-15501	`Cannot create WS operation because the given function is not defined.`

Number	Description
	Verify that the name of the BDL function of fgl_ws_server_publishFunction() is correct.
-15502	`Invalid WS-function declaration, no parameters allowed.` Verify that the BDL function has no input and no output parameters.
-15503	`Operation name is already used in the current web service.` You must change the name of the Web-Function operation in the function fgl_ws_server_publishFunction().
-15504	`WS server port already used by another application.` You must change the port number in the function Fgl_ws_server_start().
-15505	`Some BDL data types are not supported by XML.` Verify that all exposed functions don't contain one of the following data types: • DATETIME beginning with MINUTE • DATETIME beginning with SECOND • INTERVAL beginning with YEAR and/or MONTH
-15511	`Invalid fgl_ws_set/getOption() parameter.` Verify that the option flag of the fgl_ws_setOption()/ fgl_ws_getOption() function exists.
-15512	`WS input record not defined.` Verify that the name of the input record on the fgl_ws_server_publishFunction() exists.
-15513	`WS output record not defined.` Verify that the name of the output record on the fgl_ws_server_publishFunction() exists.
-15514	`The port value from the FGLAPPSERVER environment variable or from the parameter of the fgl_ws_server_start() function is not a numeric one.` Verify that the port value contains only digits. See fgl_ws_server_start()
-15515	`No application server has been started at specified host.` Verify that FGLAPPSERVER contains the right host and port where the application server is listening.
-15516	`No more licenses available.` Contact your support center.
-15517	`Current runner version not compatible with the Web Services Extension.` Install the right version of the Genero BDL.
-15518	`The input namespace of your Web function is missing.` Add a valid input namespace in fgl_ws_server_publishFunction().

Number	Description
-15519	`The output namespace >namespace of your Web function is missing.` Add a valid output namespace in fgl_ws_server_publishFunction().
-15520	`Cannot load a certificate or private key file.` Verify that each ws.ident.security FGLPROFILE entries contain a valid security identifier.
-15521	`Cannot find a certificate in the Windows key store.` Verify that each ws.ident.security FGLPROFILE entries contain a valid Windows™ security identifier.
-15522	`Cannot load the Certificate Authorities file.` Verify that the security.global.ca FGLPROFILE entry contains the correct Certificate Authorities filename.
-15523	`Cannot create the Certificate Authorities from the Windows key store.` Verify that you have enough rights to access the Windows™ key store.
-15524	`Cannot set the cipher list.` Verify that all ciphers in the list are valid ones and supported by openssl.
-15525	`Unable to reach the HTTP proxy.` Verify that the proxy.http.location FGLPROFILE entry contains the correct HTTP proxy address.
-15526	`Unable to reach the HTTPS proxy.` Verify that the proxy.https.location FGLPROFILE entry contains the correct HTTPS proxy address.
-15527	`Unknown HTTP proxy authenticate identifier.` Verify that the proxy.http.authenticate FGLPROFILE entry contains a valid HTTP authenticate identifier.
-15528	`Unknown HTTPS proxy authenticate identifier.` Verify that the proxy.https.authenticate FGLPROFILE entry contains a valid HTTP authenticate identifier.
-15529	`Cannot create a HTTP authenticate configuration.` Verify that all authenticate logins and passwords are correctly set.
-15530	`Cannot create an encrypted HTTP authenticate configuration.` Verify that all authenticate logins and encrypted passwords are correctly set.
-15531	`Cannot create a server configuration.` Verify that all ws.ident.url FGLPROFILE entries are correctly set.

Number	Description
-15532	`Unknown server configuration security identifier.` Verify that all ws.ident.security FGLPROFILE entries contain a valid Security identifier.
-15533	`Unknown server configuration authenticate identifier.` Verify that all ws.ident.authenticate FGLPROFILE entries contain a valid HTTP Authenticate identifier.
-15534	`Invalid self object.` Contact your support center.
-15535	`Cannot perform operation due to invalid parameters.` Check all parameters against the built-in classes documentation.
-15536	`Service registration failed, see SQLCA.SQLERRM for more details.` Check the following : • A service of the same name already exists • The namespace of the service is missing • A header cannot have the same name and namespaces as an operation
-15537	`Cannot create web service, see SQLCA.SQLERRM for more details.` Check that the service has a valid name and namespace.
-15538	`Cannot create Web operation, see SQLCA.SQLERRM for more details.` Check that operation name and namespace are valid according to the style (Document or RPC).
-15539	`Cannot publish Web operation, see SQLCA.SQLERRM for more details.` Check that input or output headers have previously been created.
-15540	`Published BDL function not found, see SQLCA.SQLERRM for more details.` Check that BDL function to be publish exists.
-15541	`Published BDL function not correctly defined, see SQLCA.SQLERRM for more details.` Check that BDL function has no input or output parameters.
-15542	`Input parameter of published operation error. See SQLCA.SQLERRM for more details.` Contact your support center.
-15543	`Output parameter of published operation error. See SQLCA.SQLERRM for more details.` Contact your support center.

Number	Description
-15544	`Web Service header configuration error, see SQLCA.SQLERRM for more details.` Verify that a one-way function do not have an output header.
-15545	`Service is already registered. You cannot modify a service after it has been registered.` Check that you do not call a service modifier method on a service after registration.
-15546	`Invalid option.` Check the option name according to documentation.
-15547	`Unsupported web service operation.` Verify if a Document style operation does not perform SOAP Section5 encoding.
-15548	`Bad URI.` Check that URI passed to a HttpRequest or TcpRequest is valid.
-15549	`HTTP runtime exception, see SQLCA.SQLERRM for more details.` Contact your support center.
-15550	`XML runtime exception, see SQLCA.SQLERRM for more details.` Contact your support center.
-15551	`WSDL generation failed.` Contact your support center.
-15552	`Charset conversion exception, see SQLCA.SQLERRM for more details.` Change server charset response via a HTTP accept header or change you application locale.

-15553	`TCP runtime exception, see SQLCA.SQLERRM for more details.`
	If detailed message is 'The TCP connection has been interrupted', then check that your network was working properly and that the INT_FLAG was not set to TRUE.
	When working with a Web Service application, this can the result of a COM error. Check in FGLWSDEBUG to see whether it was shut down on the client or server side.
	For example:
	`WS-DEBUG (IO ERROR)`
	`Class: TCPConnection::atomicReceive()`
	`Msg: TCP input stream shut down.`
	`Code: 104`
	`WS-DEBUG END=`
	You can find the 104 code in `/usr/include/asm-i386/errno.h` (depending on your system).

Number	Description
	In this example it correspond to: `#define ECONNRESET 104 /* Connection reset by peer */` • Review the WSDL and see if what we send to the server is correct • Review the server log and see why it has ended the connection
-15554	`Index is out of bound.` Check your index maximum value.
-15555	`Unsupported request-response feature.` Check the streaming operations order or for invalid usage. For example, in function readTextRequest(), the incoming request can be read only once, so processing the incoming message while sending the response is not allowed.
-15556	`No request was sent.` Check that you called one of the doRequest(), doXmlRequest() or doTextRequest() method before to call getResponse() or getAsyncResponse().
-15557	`Request was already sent.` Check that you do not call twice one of the doRequest(), doXmlRequest() or doTextRequest() method.
-15558	`Waiting for a response.` Check that you do not perform a new request before reading the response of previous one.
-15559	`No stream available.` Check that you do not call a method to read on a stream that has not yet been created.
-15560	`Streaming is over.` Check that you do not read a streaming response that was closed.
-15561	`Streaming in progress.` Check that you do not call twice beginXmlResponse() without a call to endXmlResponse().
-15562	`Streaming not yet started.` Check that you do not call endXmlRequest() or endXmlResponse() without a beginXmlRequest() or beginXmlResponse().
-15563	`Streaming already started.` Check that you do not call twice beginXmlRequest() or beginXmlResponse().
-15564	`Unexpected peer stream was shutdown.` The peer closed connection during reading operation.
-15565	`Cannot return incoming request, see SQLCA.SQLERRM for more details.`

Number	Description
	Check detailed message.
-15566	`Operation failed, see SQLCA.SQLERRM for more details.` Check the parameter for invalid data.
-15567	`Parameter cannot be NULL.` Check that the parameter is not NULL
-15568	`BDL callback function not found, see SQLCA.SQLERRM for more details.` Check that BDL callback function exists.
-15569	`BDL callback function requires one input and one output parameter, see SQLCA.SQLERRM for more details.` Check BDL callback parameters according to documentation.
-15570	`Web Service fault error. See SQLCA.SQLERRM for more detail.` Contact your support center.
-15571	`Stateful Service error. See SQLCA.SQLERRM for more detail.` Contact your support center.
-15572	`Access denied lock error.` Either the file is already locked, or the application does not have the write access right to the given path.
-15573	`HTTP Multipart error : description.` One of the methods of the COM multipart API has failed. See the description for more details. Contact your support center if the error detail does not provide the information needed to fix the error.
-15574	`Cannot load Certificate Authorities from path : path.` The certificate could not be found according to the current FGLPROFILE configuration. Check the certificate authority settings as described in: HTTPS configuration on page 2440.
-15575	`Incoming request has been closed : reason` The GAS has disconnected the web service server, for example while calling the `com.WebServiceEngine.GetHTTPServiceRequest` or `com.WebServiceEngine.HandleRequest` methods. Use a `TRY/CATCH` block to trap this error, as described in com.WebServiceEngine.GetHTTPServiceRequest on page 2027.
-15576	`Invalid TCP IP version.` The FGLPROFILE configuration parameter `ip.global.version` defines a value different from valid possible values (4 and 6).

Number	Description
-15577	`Unknown network interface name : name.` The FGLPROFILE configuration parameter `ip.global.v6.interface.name` defines a network interface that does not exist.
-15578	`Request canceled by user.` The HTTP request initiated by a `com.HTTPRequest.getResponse()` method has been canceled by the user.
-15598	`XML deserialization error.` The WSDL contract does not match the BDL variable definition. Check that BDL variables are correctly generated according to the WSDL.
-15599	`Internal error, should not happen.` Contact your support center.
-15600	`Operation failed.` Check method for invalid parameters according to documentation.
-15601	`Name cannot be NULL.` Check that name parameter is not NULL.
-15602	`Namespace cannot be NULL.` Check that namespace parameter is not NULL.
-15603	`Prefix cannot be NULL.` Check that prefix parameter is not NULL.
-15604	`Value cannot be NULL.` Check that parameter is not NULL according to documentation.
-15605	`Node cannot be NULL.` Check that node parameter is not NULL.
-15606	`Text cannot be NULL.` Check that text parameter is not NULL.
-15607	`Target of a processing instruction cannot be NULL.` Check that target parameter is not NULL.
-15608	`Name of an entity reference cannot be NULL.` Check that entity name parameter is not NULL.
-15609	`XPath expression cannot be NULL.` Check that xpath parameter is not NULL.

Number	Description
-15610	`Filename cannot be NULL.` Check that filename parameter is not NULL.
-15611	`Document cannot be NULL.` Check that document parameter is not NULL.
-15612	`DTD string cannot be NULL.` Check that dtd parameter is not NULL.
-15613	`Stax cannot be NULL.` Check that stax parameter is not NULL.
-15614	`Malformed XML name.` Check that xml name is well-formed.
-15615	`Malformed XML string.` Check that xml string is well-formed.
-15616	`Malformed XML prefix.` Check that xml prefix is well-formed.
-15617	`Malformed XML namespace.` Check that xml namespace is well-formed.
-15618	`Bad validation type.` Check validation type parameter.
-15619	`No XML schema found.` Check that a valid XML schema is used for validation.
-15620	`No DTD schema found.` Check that a DTD schema is present in XML document.
-15621	`Feature or option cannot be NULL.` Check that parameters are not NULL.
-15622	`Feature or option is unsupported.` Check option or feature name according to documentation.
-15623	`Feature or option value is invalid.` Check option or feature validity according to documentation.
-15624	`Node is not part of the document.` Check that node belong to the same XML document.

Number	Description
-15625	`Node does not have the correct parent node.` Check that node to remove belongs to the right parent node.
-15626	`Node is already linked to another node.` Check that node is not already attached to another node.
-15627	`Cannot add a node to itself.` Check that node to add is not itself.
-15628	`Index is out of bounds.` Check index maximum value.
-15629	`StaxWriter runtime exception: reason` See SQLCA.SQLERRM for more details and check the reason for the error.
-15630	`StaxReader runtime exception: reason` See SQLCA.SQLERRM for more details and check the reason for the error.
-15631	`Serializer runtime exception: reason` See SQLCA.SQLERRM for more details and check the reason for the error.
-15632	`Document loading runtime exception, check xml.DomDocument.getErrorDescription() for more details.` Check detailed message of dom document.
-15633	`Document saving runtime exception, check xml.DomDocument.getErrorDescription() for more details.` Check detailed message of dom document.
-15634	`Invalid encoding.` Check encoding value.
-15635	`PublicID of a DTD cannot be set with a SystemID.` Check DTD node creation
-15636	`Undefined namespace prefix in the XPath expression.` Check an undeclared prefix used in XPath expression.
-15637	`XPath expression error.` Check XPath expression.
-15638	`A namespace in the XPath namespace list is missing.` Check for an undeclared namespace used in XPath expression
-15639	`XPath function has two mandatory parameters.`

Number	Description
	Check parameters according to documentation.
-15640	`Internal XPath error.` Contact your support center.
-15641	`Invalid XPath namespace.` Check namespace value passed to XPath method.
-15642	`Unable to load schema.` Check XML schema parameters in DomDocument.setFeature().
-15643	`Schemas are malformed or inconsistent.` Check XML schema validity in DomDocument.setFeature().
-15644	`URI is malformed.` Check that URI is well-formed according to documentation.
-15645	`Protocol layer needs a new try to complete operation.` Sax writer close operation requires a new request to complete previous one.
-15646	`Charset conversion error.` Check fglrun LANG and system locale.
-15647	`Unable to load xml security library.` Contact your support center.
-15648	`Xml security operation failed. See SQLCA.SQLERRM for more detail.` Check detailed message.
-15649	`URL cannot be null.` Check if XML-Security URL is NULL.
-15650	`CryptoX509 cannot be null.` Verify that CryptoX509 object has been correctly instantiated.
-15651	`CryptoKey cannot be null.` Verify that CryptoKey object has been correctly instantiated.
-15652	`Bad signature transformation.` Check transformation URL validity passed to appendReferenceTransformation()
-15653	`Bad signature digest.` Check digest URL validity passed to createReference().
-15654	`Bad signature node.`

Number	Description
	Check XML-Signature node passed to CreateFromNode().
-15655	`Bad key type.` Check key identifier URL.
-15656	`Bad key usage.` Verify usage of CryptoKey object passed to setKeyEncryptionKey() or setKey().
-15657	`Bad XPathFilter2 type, only intersect, subtract or union allowed.` Verify type used in a XPathFilter2 transformation.
-15658	`Bad derived key URL.` Check derived key identifier URL.
-15699	`Internal error, should not happen.` Contact your support center.
-15700	`Called operation failed, see SQLCA.SQLERRM for more details.` See SQLCA.SQLERRM for details on why the operation failed.
-15701	`Invalid parameter.` Check that your security library function has the correct parameters.
-15702	`File access denied.` Check that your security library function has the permissions to access to the file.
-15703	`File does not exist.` Check that the file exist on your system for the security library function to access.
-15704	`Algorithm not supported.` Check that the algorithm is in the supported list for security library function. See security.Digest.CreateDigest on page 2294.
-15705	`Invalid current object.` Check that the context for security library function is correctly initialized. See security.Digest.CreateDigest on page 2294.
-15799	`Internal security error.` Contact your support center.

Web services

Create a Web service client or server with Genero BDL.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2009 and The xml package on page 2103.

•

General

These topics provide you with an introduction to Genero Web Services and the information needed to get working with the latest version of the software.

- Introduction to Web Services on page 2400
- SOAP Web Services basics on page 2404
- RESTful Web Services basics on page 2416
- Getting started and examples on page 2416
- Debugging on page 2416
- Platform-specific notes on page 2416
- Known issues on page 2419
- Legal Notices on page 2419

Introduction to Web Services

This topic provides an introduction to Web Services with the Genero Web Services Package (GWS). It is intended to help those using GWS for the first time to understand basic Web Services concepts, and to quickly start their development with the Genero tools.

Concepts

Web services are a standard way of communicating between applications over an intranet or Internet. They define how to communicate between two entities:

- A server that exposes services
- A client that consumes services

Server usage example

A server exposes a"StockQuotation" service that responds to an operation "getQuote". For the "getQuote" operation, the input message is a stock symbol as a string, and the output message is a stock value as a decimal number.

The "getQuote" operation is a function written in Genero BDL, and it is published on the server. This function retrieves the stock value for the stock symbol passed in, and returns it.

Client usage example

The Web service client application calls the function as if it were a local function. It passes the stock symbol in to the function, and stores the returned value in a variable. If the Web Service operation is named **WebService_StockQuotation_getQuote** and the local variable is **svalue**, the Web Service is called as follows:

```
LET svalue = WebService_StockQuotation_getQuote( "MyStockSymbol" )
```

Service Oriented Architecture (SOA) and web services

Service Oriented Architecture (SOA) is a philosophy of how to connect systems and exchange data to solve business problems. Rather than concentrating on a specific task or transaction, SOA addresses how to use data from various sources, reduce human work, and mitigate the effects of change in a business process and its supporting systems.

The SOA defines the services to be provided; Web Services are the means of implementing those services. Web Services provide a ***platform-neutral technology*** to connect multiple systems in a flexible manner, where the platform-neutrality helps insulate the SOA from changes to the underlying systems.

Web Services work by answering requests for information and returning well defined, structured XML documents. Because XML is simple text and Web Services can be invoked via the hypertext transfer protocol (HTTP), it does not matter what platform runs the Web Service, or what platform receives the XML document.

An SOA's resilience to change is accomplished by adhering to good Web Services design practices:

- Build a Web Service that performs a specific task
- Have a rigid structure for the data

Web Services tell exactly how to ask for the information in an XML document written using the Web Services Descriptive Language (WSDL). This self-describing document describes the service the Web Service will perform and how to form the request for its data. Each Web Service must have an associated WSDL document, so that developers and applications know what to expect from the Web Service, and how to invoke it.

Migrating to SOA and web services

Developing an SOA and moving to Web Services is an iterative and evolutionary process. It requires work and diligent design. When switching to Web Services from another integration method, it is recommended to initially focus on shorter term business benefits, targeting an SOA and Web Services project that has tangible goals with measurable benefits.

Once an SOA contains some useful services, these services can be arranged together in a workflow that automates a business process. Web Services can be reused to answer new questions, and implemented as new business services in an SOA. A well-defined Web Service does not contain business logic or business process information. Because each Web Service in an SOA can be called individually to perform a specific task, they can be arranged (orchestrated) together to perform many different business functions. As a result, companies with a mature SOA in place can change business processes through configuring of the orchestration software as opposed to programming individual links between systems.

Planning a web service

When creating a Web Service, you not only have to think of the task at hand, but you should also consider growth. You likely want the Web Service to be flexible; to be able to handle different types of input. Prepare the Web Service for what is *probable*. Developers should think bigger than the needs of a single application. You should think of reusing existing services, and think how your services can be reused by others.

Security will likely play a larger role than it did previously with existing in-house application infrastructures using programmed links between systems; you will need to become versed in security issues.

Keep the goals of SOA in mind when designing and coding Web Services: **Flexibility**. **Reusability**. **Interoperability**.

Genero web services extension

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.

The Genero Application Server is required to manage your Web Services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

> **Important:** When programming a Web service, your applications must include `IMPORT com` at the top of each module. This imports the Genero Web Services Extension library named `com`:

```
IMPORT com
```

Web services standards

Web services are platform-independent and programming language-independent. The World Wide Web consortium defines the Web services standards. For more information about these standards, refer to the "Web services" section of their web site at http://www.w3.org. The Genero Web Services package supports the WSDL 1.1 specification of March 15, 2002 as well as some previous specifications.

The standards involved in what is commonly called "Web services" include XML, XML Schema, SOAP, WSDL, and HTTP.

XML

XML (eXtensible Markup Language) defines a machine-independent way of exchanging data. For example, an XML representation of the following BDL data structure:

```
DEFINE Person
RECORD Attribute (XMLName="Person")
   FirstName  VARCHAR(32) Attribute (XMLName="FirstName"),
   LastName   VARCHAR(32) Attribute (XMLName="LastName"),
   Age        INTEGER Attribute (XMLName="Age")
END RECORD
```

Could be:

```
<Person>
 <FirstName>John</FirstName>
 <LastName>Smith</LastName>
 <Age>35</Age>
</Person>
```

The record definition allows you to specify XML attributes for data types. This feature was added with Genero 2.00.

XML schema

XML Schema defines the elements, entities, and content model of an XML document. For example, for the example document shown in the topic XML on page 2402, the schema could say that the XML document contains an element "Person", and that each "Person" contains one and only one element "FirstName", "LastName", and "Age". The XML Schema has additional capabilities, such as data type control and content restrictions.

An XML Schema allows an XML document to be validated for correctness.

SOAP

SOAP (Simple Object Access Protocol) is a high-level communication protocol between a server and the client. It defines the XML data flow between the server and the client. The "StockQuote" service mentioned in the Concepts section exchanges messages using the following syntax:

Request

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
   <soap:Body>
      <getQuote>
         <stockSymbol>MyCompany</stockSymbol>
```

```
      </getQuote>
   </soap:Body>
</soap:Envelope>
```

Response

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
   <soap:Body>
      <getQuoteResponse>
         <stockValue>999.99</stockValue>
      </getQuoteResponse>
   </soap:Body>
</soap:Envelope>
```

SOAP relies on a lower-level protocol for the transport layer.

Genero Web Services use SOAP over HTTP, and can also perform low-level XML and TEXT over HTTP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP, as well as SOAP over HTTP.

WSDL

The WSDL (Web Services Description Language) file describes the services offered by a server. It contains:

- The description of the operations offered by the server, and each operation's input and output messages.
- The location of the SOAP server.
- Internal connection and protocol details (transport layer, encoding, namespaces, and so on).

A WSDL description is sufficient to provide all the information required to communicate with the SOAP server.

Genero Web Services package provides a tool, fglwsdl, that enables Genero client applications to obtain the WSDL description of a Web Service.

HTTP

HTTP (Hypertext Transfer Protocol) is the set of rules for exchanging files (text, graphic images, sound, video, and other multimedia files) on the World Wide Web.

Web services style options

The Web Services Style options available for created Genero Web services are WS-I (Web Services Interoperability organization) compliant:

- **RPC Style Service (RPC/Literal)** is generally used to execute a function, such as a service that returns a stock option.
- **Document Style Service** (**Doc/Literal**) is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document.
- **RPC Style Service (RPC/Encoded)** is the legacy style, now provided for backwards compatibility. You most likely will not be using the RPC/Encoded style to create new Web Services.

SOAP Web Services basics

Topics in this section are only relevant for Web Services based on the SOAP protocol.

Migration notes
Migrating GWS server applications
What you need to know when migrating GWS server applications.

- Migrating GWS server runners only on page 2404
- Migrating GWS server runners and using new APIs on page 2404
- Operation publication restrictions on page 2405

Migrating GWS server runners only

There is no need to create a special runner for Genero Web Services 2.x. Instead, the GWS 2.x library is imported into your applications. If you want to migrate your existing 1.x GWS Server application to 2.x to avoid the need for a special runner, as well as to take advantage of any bug fixes, take the following steps:

1. Add the following statement at the top of any .4gl module where you have used GWS 1.3x functions:

```
import com
```

2. Compile and re-link your GWS Server application (.42r).

This imports the new GWS **com** library, and ensures that any GWS 1.3x functions that you have used will be compatible. Your existing Genero 1.3x Client applications, as well as third-party Client applications, will continue to work.

Migrating GWS server runners and using new APIs

If you want to take advantage of the new features and simplify future migrations, you can migrate your Genero Web Services (GWS) Server runner and also use the new GWS 2.x APIs. All the 1.3x publishing functions for all the operations in your application must be replaced with 2.x publishing functions. Since this does not change the interface, all existing Genero 1.3x Client applications, as well as third-party Client applications, will continue to work.

Since 1.3x only supports RPC-Encoded style services, you must use the RPC style functions of the new 2.x APIs as the replacement functions, with **setInputEncoded** and **setOutputEncoded** set to true. And, you cannot add XML attributes to the records used as Web Service function parameters.

To replace the fgl_ws_server_publishfunction() statement in an existing GWS Server application; for example:

```
CALL fgl_ws_server_publishfunction(
  "EchoInteger",
  "http://tempuri.org/webservices/types/in", "echoInteger_in",
 "http://tempuri.org/webservices/types/out", "echoInteger_out",
 "echoInteger")
```

1. Add this statement at the top of each module:

```
import com
```

2. Define variables for the WebService and WebOperation objects:

```
DEFINE serv  com.WebService
DEFINE op    com.WebOperation  -- Operation of a WebService
```

3. Create the GWS Server object:

```
LET serv = com.WebService.CreateWebService(
  "EchoInteger",
  "http://tempuri.org/webservices")
```

4. Use the 2.x publishing functions for each operation:

```
LET op = com.WebOperation.CreateRPCStyle(
  "echoInteger",
  "EchoInteger",
  echoInteger_in,
  echoInteger_out)
CALL op.setInputEncoded(true)
CALL op.setOutputEncoded(true)
CALL serv.publishOperation(op,NULL)
```

5. Compile and re-link your GWS Server application (.42r)

GWS 2.x also allows your Server application (.42r) to contain multiple services. If you would like 2.x and 1.3x GWS to coexist in the same .42r executable, replace the existing publishing 1.3x functions.

Operation publication restrictions

If you use a variable as the name of the function to publish, you will have an error message at compile time.

For example:

```
com.WebOperation.CreateRPCStyle(test,"Add",add_in,add_out)
```

Where **test** is a string variable, add_in and add_out are input and output records.

At compile time, you get the error message:

```
error:(-9054) Web service function must be a string
```

The function name in parameter can only be a string literal not a string variable.

Since version 2.21, FGL has introduced the concept of PUBLIC/PRIVATE function, there is a risk for a user to publish private functions. Private functions are not always available at runtime.

As a workaround you can add a switch depending on the function name value in order to call the appropriate publication API with the name in a string literal such as following sample:

```
CASE function_name
  WHEN "Operation1"
    LET op = com.WebOperation.CreateDocStyle(
               "Operation1","Operation1",op1_in,op1_out)
  WHEN "Operation2"
    LET op = com.WebOperation.CreateDocStyle(
               "Operation2","Operation2",op2_in,op2_out)
  OTHERWISE
    DISPLAY "ERROR"
END CASE
```

In Java™ or in .NET you cannot publish different numbers of operations for a same service, everything is done at compile time. For instance, when you publish a web service in Java™, only the public methods will be published as operation of the service. There is no way to add or remove some methods at runtime. The only way you have is to create another Java™ class.

Be aware that if you dynamically change the service operations names you are creating a different service, which might be confusing for the web service client.

Enhance the GWS server application to be WS-I compliant (recommended)

> **Important:** You must be able to change all the Client applications that access your migrated Genero Web Services (GWS) Server.

If you use the Literal styles now available in GWS 2.x for your Web Service, your application will be WS-I compliant. However, the migration techniques still use the RPC/Encoded style (Only RPC/Encoded was supported in GWS 1.3x.). If you can change all the client applications that access your migrated GWS Server, we recommend that you enhance the GWS Server application to be WS-I compliant.

1. Replace the publishing functions in the GWS Server application, but omit the **setInputEncoded** and **setOutputEncoded** lines. The resulting style will be Literal.
2. The enhanced GWS Server will have a new RPC/Literal WSDL that must be used to regenerate the client stub with the fglwsdl tool:

```
fglwsdl -o NewClientstub http://localhost:8090/MyCalculator?WSDL
```

3. Compile that new client stub, and re-link it with the GWS Client application. This operation must be repeated for each Client application accessing that service.
4. Third party Client applications must also be changed to use the new WSDL.

Migrating GWS client applications
Migration from version 1.3x to 2.2x

If you use a Genero 2.2x runner for the GWS Client application, you must:

1. Regenerate the GWS Client stubs using the **-compability** option of the fglwsdl tool, so the function prototypes will be compatible:

```
fglwsdl -compatibility -o NewClientstub http://localhost:8090/
MyCalculator?WSDL
```

2. Compile the GWS Client stubs and re-link the Client application (.42r).

Migration from version 2.0x to 2.2x

You must regenerate all client stubs into your application using the fglwsdl tool.

This is mandatory because the generated code is based on the low-level COM and XML APIs and is completely different from versions prior to 2.1x; otherwise, you won't be able to execute the code.

Migration from version 2.1x to 2.2x

It is recommended to regenerate all client stubs into your application using the fglwsdl tool.

Migration from version 2.xx to 2.4x

It is recommended to regenerate all client stubs into your application using the fglwsdl tool.

If you have modified the server location at runtime via the generated global variable in your client application, you MUST apply following modification:

- Prior to version 2.40, you had something like following:

```
LET Calculator_CalculatorPortTypeLocation = "http://host:port/Calculator"
```

- Starting with version 2.40, you must have something like following:

```
LET Calculator_CalculatorPortTypeEndPoint.Address.Uri =
 "http://host:port/Calculator"
```

See Change client behavior at runtime.

Migration from version 2.xx to 3.xx

It is recommended to regenerate all client stubs into your application using the fglwsdl tool.

> **Important:** It is mandatory to regenerate the client stubs, to support fault response with HTTP error code of 200.

See Change client behavior at runtime.

WebService engine options

In the class **com.WebServiceEngine**, two options have been renamed and two options moved to a new class.

Renamed options

The **http_invoketimeout** and **tcp_connectiontimeout** options have been respectively renamed into **readwritetimeout** and **connectiontimeout**, as they are now available for either HTTP or TCP protocol. While the old option names remain for backward compatibility, using the new option names is **strongly** recommended.

Moved options

xml_ignoretimezone and **xml_usetypedefinition** options were part of the **com**.**WebServiceEngine** class. They have been moved to the class **xml.Serializer**, which groups functions on serialization.

I4GL migration guide

Migrate an I4GL web service provider to Genero

This section explains how to migrate a I4GL web service provider to a Genero application providing the same web service in order to let all clients, already accessing that service, unmodified (excepted for the hostname of course).

> **Note:** The migration will be based on the SOA zipcode demo in the I4GL package.

Step 1: Use the I4GL function and the I4GL .4cf configuration file

Use the I4GL .4cf configuration file to get all information about the I4GL web service

For example, the I4GL zipcode demo has following .4cf configuration file :

```
[SERVICE]
 TYPE               = publisher
 INFORMIXDIR        = /dbs/32bits/ifx/11.70.uc2
 DATABASE           = i4glsoa
 CLIENT_LOCALE      = en_US.8859-1
 DB_LOCALE          = en_US.8859-1
 INFORMIXSERVER     = ol_moscou1170uc2
 HOSTNAME           = moscou.strasbourg.4js.com
 PORTNO             = 9876
 I4GLVERSION        = 7.50.xC4
 WSHOME             = /dbs/32bits/ifx/11.70.uc2/AXIS2C
 WSVERSION          = AXIS1.5
 TMPDIR             = /tmp/zipcodedemo
 SERVICENAME        = ws_zipcode
 [FUNCTION]
  NAME           = zipcode_details
  [INPUT]
   [VARIABLE]NAME = pin TYPE = CHAR(10)[END-VARIABLE]
  [END-INPUT]
  [OUTPUT]
   [VARIABLE]NAME = city TYPE = CHAR(100)[END-VARIABLE]
   [VARIABLE]NAME = state TYPE = CHAR(100)[END-VARIABLE]
  [END-OUTPUT]
 [END-FUNCTION]
 [DIRECTORY]
  NAME           = /home/f4gl/fg/i4gl
  FILE           = soademo.4gl,
 [END-DIRECTORY]
[END-SERVICE]
```

Then simply copy your I4GL function without any modification into a new Genero file and add the Genero **IMPORT com** instruction at the beginning of the file.

For example, the I4GL soa demo contains the zipcode_details service (soademo.4gl)

```
IMPORT com

FUNCTION zipcode_details(pin)
  DEFINE state_rec RECORD
         pin CHAR(10),
         city CHAR(100),
         state CHAR(100)
       END RECORD,
       pin CHAR(10),
       sel_stmt CHAR(512);

  LET sel_stmt= "SELECT * FROM statedetails WHERE pin = ?";
  PREPARE st_id FROM sel_stmt;
  DECLARE cur_id CURSOR FOR st_id;
  OPEN cur_id USING pin;
  FETCH cur_id INTO state_rec.*;
  CLOSE cur_id;
  FREE cur_id;
  FREE st_id;
  RETURN state_rec.city, state_rec.state

END FUNCTION
```

Note: you may need some minor code modification for compatibility.

Step 2: Create a BDL RECORD for the input parameters

Add a new modular BDL record where all members map to one of your I4GL web service input parameter, and keep the parameter order as defined in I4gl .4cf file.

You must then specify the web service input message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .4cf file.

For example, in the I4GL zipcode demo there is only one parameter: **pin** . So add the following record at the beginning of the Genero file :

```
DEFINE zipcode_details_in RECORD ATTRIBUTES(XMLName="zipcode_details")
  pin CHAR(10)
  END RECORD
```

Note: Genero Web Services supports complex data type as input parameters.

Step 3: Create a BDL RECORD for the output parameters

Add another modular BDL record where all members map to one of your I4GL web service output parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the web service output message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .xcf file concatenated to response.

For example, in the I4GL zipcode demo there are two parameters: **city** and **state**. So add following record at the beginning of the Genero file:

```
DEFINE zipcode_details_out RECORD
 ATTRIBUTES(XMLName="zipcode_detailsresponse)
  city CHAR(100),
  state CHAR(100)
```

```
  END RECORD
```

Note: Genero Web Services supports complex data type as output parameters.

Step 4: Create a BDL wrapper function

Create a Genero BDL wrapper function without any parameters that will then use the input and output record created at Step 2 and 3 to call the I4GL function passing it the parameters retrieved from the records.

For example, in the I4GL zipcode demo there are 1 input and 2 output parameters. So the BDL wrapper function must use these records to call the I4GL function as following :

```
FUNCTION zipcode_details_g()
 CALL zipcode_details(zipcode_details_in.pin)
    RETURNING zipcode_details_out.city,zipcode_details_out.state
END FUNCTION
```

Step 5: Publish the wrapper function as a Genero web service

Use the COM APIs to publish the I4GL function as a web service based on I4GL .4cf configuration file to get a compatible Genero Web service.

To create a new BDL function in charge of the service publication, you will need the following elements of the I4GL .4cf configuration file:

- The name of the service that is defined in the SERVICENAME entry
- The namespace of the service that is defined as http://www.ibm.com/ concatenated to the FUNCTION NAME
- The name of the function to be published that is defined in the FUNCTION NAME entry

For example, the I4GL zipcode demo has one function published as a Doc/Literal service.

```
FUNCTION create_zipcode_details_web_service()
  DEFINE serv com.WebService
  DEFINE op   com.WebOperation

  #
  # Create the web service based on the entries of the .4cf file
  #   SERVICENAME: The name of service is 'ws_zipcode'
  #   FUNCTION NAME: The namespace of the service is built from
  #                  the base url 'http://www.ibm.com/' concatenated to
  #                  the NAME of the I4GL function 'zipcode_details'
  #
  LET serv = com.WebService.CreateWebService("ws_zipcode",
              "http://www.ibm.com/zipcode_details")

  #
  # Create and publish the Doc/Literal web function based on
  #  step 2, step 3 and step 4
  #  and from the FUNCTION NAME defined in the .4cf file
  #
  LET op = com.WebOperation.CreateDOCStyle("zipcode_details_g",
            "zipcode_details",
            zipcode_details_in,
            zipcode_details_out)
  CALL serv.publishOperation(op,NULL)

  #
  # Register the service into the SOAP engine
  #
  CALL com.WebServiceEngine.RegisterService(serv)
```

```
END FUNCTION
```

Note: I4GL supports only Doc/Literal services.

Note: Genero Web Services can contain several BDL functions in the same service. In other words, you can group several I4GL services into the same Genero service.

Step 6: Create the server

I4GL uses Axis as server for its services, but Genero has its own server programmable via the COM library. Create a new file and add the `IMPORT com` instruction at beginning of the server file, then simply create the main loop in BDL that will process any incoming HTTP request.

The port of the service defined in the I4GL .4cf configuration file (via the PORTNO entry) can be reused by setting the FGLAPPSERVER environment variable to the same value before to run the server. However, only on development or for tests, on production Genero Web services requires an application server called GAS in charge of load balancing. See the GAS documentation for more details about port configuration for deployment purpose.

For example, to migrate the I4GL zipcode demo, the service must be created in the server before run the main loop as following :

```
MAIN
  DEFINE ret INTEGER
  DEFER INTERRUPT

  # Create zipcode_details service
  CALL create_zipcode_details_web_service()

  # Start the server on port set in FGLAPPSERVER
  #    (to be set to same value as PORTNO defined in the .4cf file)
  CALL com.WebServiceEngine.Start()

  # Handle any incoming request in a WHILE loop...
  # See <?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE concept PUBLIC "-//IBM//DTD DITA IBM Concept//EN" "ibm-

 manage your application.
For deployment, the GWS Server application must be added to the GAS
 configuration. See <cite>Adding
Applications</cite> in the <cite>Genero Application Server User Guide</
cite>. </note></section>
</conbody>

</concept>

END MAIN
```

> **Note:** With Genero Web Services, one server can contain several services. In other words, you can put all your I4GL services into one server.

Step 7: Configure the database

Based on the DATABASE entry in the I4GL .4cf configuration file, use the Genero instruction to connect to the informix database at server startup.

For example, in the I4GL zipcode demo the service access the database called: **i4glsoa** . So add following instruction at the beginning of the server file created in step 6:

```
DATABASE i4glsoa
MAIN
...
END MAIN
```

Step 8: Compile and run the Genero service

Compile and link the 2 Genero files created above and run your Genero service. It will be directly available for any client, and provide the WSDL when requested via a HTTP GET with WSDL as query string.

Example

The Genero web service is accessible on URL: **http://hostname:9876/ws_zipcode** and can return the WSDL on URL: **http://hostname:9876/ws_zipcode?WSDL**.

```
$ fglcomp -M genero_service.4gl
$ fglcomp -M genero_server.4gl
$ fgllink -o genero_zipcode genero_service.42m genero_server.42m
$ export FGLAPPSEVER=9876
$ fglrun genero_zipcode.42r
```

Note: The hostname depends on the machine your Genero application is started.

Note: For deploying the service on production you will need the Genero application server (GAS) to load-balance the service. See the GAS documentation about Web Services when deployment is required.

Step 9: Disable Axis support of MTOM/XOP and WS-Addressing

I4GL is based on Axis web service for the SOAP layer and sends by default requests in MTOM/XOPand with support of WS-Addressing. However, Genero Web services doesn't support MTOM/XOP and WS-Addressing, therefore you have to unset both features on your Axis installation if you still want your I4GL client applications to communicate with the Genero web service after migration.

For example, the Axis installation contains a file called axis.xml where following two lines have to be removed:

```
<parameter name="enableMTOM" locked="false">true</parameter>
<module ref="addressing"/>
```

Migrate an I4GL web service consumer to Genero

This section explains how to migrate a I4GL web service consumer to a Genero application accessing the same web service. **Notice** that the migration will be based on the soa demo in the I4GL package.

Step 1: Generate the Genero web service stub from an I4GL WSDL

Use the I4GL WSDL located on the Axis server to generate the Genero web service client stub via the tool called **fglwsdl**.

For exampl, the WSDL file of the I4GL zipcode demo is located on $INFORMIXDIR/AXIS2C/services/ws_zipcode/zipcode_details.wsdl. So do following command:

```
$ fglwsdl -noFacets zipcode_details.wsdl
```

It will generate these two Genero files:

- ws_zipcode_zipcode_detailsservice.4gl

  - It contains the Genero functions to connect to the server in SOAP over HTTP.
  - Take a look into that file if you are interested into Genero HTTP and XML low-level APIs.
- ws_zipcode_zipcode_detailsservice.inc
  - It contains the Genero data types and variables used for XML serialization.
  - Take a look into that file if you are interested into Genero XML to BDL variable mapping.

    Note: Option -noFacets is required for this demo because the I4GL CHAR data type will be generated as string in Genero what can lead to XML serialization error if not present.

Step 2: Modify the Genero .inc stubs to fix wrong I4GL WSDL

The I4GL WSDL contains namespace declaration for all I4GL web service data types, but in practice the I4GL axis server doesn't care about namespaces, but Genero does. So you have to open the generated Genero .inc file and remove all attributes called **XMLNamespace** and **XSTypeNamespace** .

For example, the generated .inc file from the I4GL WSDL must be modified as following:

```
#----------------------------------------------------------------------------
# File: ws_zipcode_zipcode_detailsservice.inc
# GENERATED BY fglwsdl 101601
#----------------------------------------------------------------------------
# THIS FILE WAS GENERATED. DO NOT MODIFY.
#----------------------------------------------------------------------------

GLOBALS
...
#
# TYPE : tzipcode_details
#
TYPE tzipcode_details RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_details")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
   pin STRING ATTRIBUTES(XMLName="pin")
END RECORD
#----------------------------------------------------------------------------
#
# TYPE : tzipcode_detailsresponse
#
TYPE tzipcode_detailsresponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_detailsresponse")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
   city STRING ATTRIBUTES(XMLName="city"),
   state STRING ATTRIBUTES(XMLName="state")
END RECORD
...
#----------------------------------------------------------------------------
#
# Operation: zipcode_details
#
# FUNCTION: zipcode_details_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# FUNCTION: zipcode_details(p_pin)
#   RETURNING: soapStatus ,p_city ,p_state
#
# FUNCTION: zipcode_detailsRequest_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#
```

```
# FUNCTION: zipcode_detailsResponse_g()
#   RETURNING: soapStatus
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
#--------------------------------------------------------------------------------
# VARIABLE : zipcode_details
DEFINE zipcode_details tzipcode_details
  ATTRIBUTES(XMLName="zipcode_details")
  #,XMLNamespace="http://www.ibm.com/zipcode_details")
#--------------------------------------------------------------------------------
# VARIABLE : zipcode_detailsresponse
DEFINE zipcode_detailsresponse tzipcode_detailsresponse
  ATTRIBUTES(XMLName="zipcode_detailsresponse")
  #,XMLNamespace="http://www.ibm.com/zipcode_details")
END GLOBALS
```

> **Note:** Genero Web Services provides a lots of XML mapping attributes.

Step 3: Include the generated stub into your I4GL application

Add in all I4GL files calling a web service the generated .inc stub with a GLOBALS instruction.

For example, in the I4GL zipcode demo, only the **clsoademo.4gl** file uses web services. So add following line at beginning of the file :

```
GLOBALS "ws_zipcode_zipcode_detailsservice.inc"
MAIN
...
END MAIN
```

> **Note:** This allows access to the Genero global variables and data types used in the web service call, so as the Genero global **wsError** record to retrieve error codes if any.

Step 4: Modify the I4GL web service function call

The Genero Web service function name is defined in the generated .4gl file and must be used instead of the I4GL function name.

For example, in the I4GL zipcode demo, the web service function name is **cons_ws_zipcode** and must be renamed to **zipcode_details** as following:

```
FUNCTION func_cons_ws_zipcode()
   DEFINE state_rec RECORD
            pin CHAR(10),
            city CHAR(100),
            state CHAR(100)
         END RECORD;
   #
   # Genero web service status returning
   # whether web function call was successful or not
   #
   DEFINE soapstatus INTEGER

   #
   # I4GL web service function name is 'cons_ws_zipcode'
   # CALL cons_ws_zipcode("97006")
   #   RETURNING state_rec.city, state_rec.state
   # Genero web service function name is 'zipcode_details'
   CALL zipcode_details("97006")
     RETURNING soapstatus, state_rec.city, state_rec.state
   ...
END FUNCTION
```

Note: In Genero Web Services there is an additional returned parameter, **soapstatus**. If it contains 0 the operation was a success, otherwise an error occurred.

Step 5: Handle Genero web services errors

I4GL web service errors are returned on a non conventional SOAP fault what cannot be handled in Genero. However the errors are handled through the additional returned parameter **soapstatus** that must be checked after each web service call. If its value is not zero, an error has occurred and can be retrieved via the global Genero **wsError** record defined in the above generated .inc file.

Example

In the Genero Web Service you must check the soap status after each web service call:

```
FUNCTION func_cons_ws_zipcode()
   DEFINE state_rec RECORD
             pin CHAR(10),
             city CHAR(100),
             state CHAR(100)
          END RECORD;
   #
   # Genero web service status returning
   #  whether web function call was successful or not
   #
   DEFINE soapstatus INTEGER

   # Genero web service function call
   CALL zipcode_details("97006")
     RETURNING soapstatus, state_rec.city, state_rec.state
   # Check soap status for errors after zipcode_details call
   IF soapstatus<>0 THEN
      # Display error information from the server
      DISPLAY "Error:"
      DISPLAY "  code :",wsError.code
      DISPLAY "  ns   :",wsError.codeNS
      DISPLAY "  desc :",wsError.description
      DISPLAY "  actor:",wsError.action
   ELSE
      # Display results
      DISPLAY "\n ------------------------ \n"
      DISPLAY "SUPPLIED ZIP CODE: 97006 \n"
      DISPLAY " ------------------------ \n"
      DISPLAY "RESPONSE FROM WEB SERVICE \n"
      DISPLAY " ------------------------ \n"
      DISPLAY " CITY:",state_rec.city
      DISPLAY "\n STATE:",state_rec.state
      DISPLAY "\n ======================== \n"
   END IF
   ...
END FUNCTION
```

Step 6: Compile and run the Genero client

Then simply compile your modified I4GL application for Genero and execute it. Your application will then connect to the web service passing and returning the parameters as it were only simple BDL function calls.

For example, to compile your I4GL web service application for Genero, you must do the following commands:

```
$ fglcomp -M ws_zipcode_zipcode_detailsservice.4gl
$ fglcomp -M clsoademo.4gl
$ fgllink -o clsoademo.42r clsoademo.42m
 ws_zipcode_zipcode_detailsservice.42m
```

```
$ fglrun clsoademo.42r
```

Step 7: Disable Axis support of MTOM/XOP and WS-Addressing

I4GL is based on Axis web service for the SOAP layer and sends by default requests in MTOM/XOP and with support of WS-Addressing. However, Genero Web services doesn't support MTOM/XOP and WS-Addressing, therefore you have to unset both features on your Axis installation if you want your Genero client application to communicate with an I4GL web service provider.

For example, the Axis installation contains a file called axis.xml where following two lines have to be removed:

```
<parameter name="enableMTOM" locked="false">true</parameter>
<module ref="addressing"/>
```

Remark: Standalone Axis server is buggy

The I4GL standalone axis server adds an extra CR LF after the body of the SOAP HTTP post response what leads the Genero client to return the error message : `Body content bigger than expected`. This is not allowed as defined in HTTP [RFC2616].

> **Important:** Notice however that Axis works as expected if loaded from Apache server.

RESTful Web Services basics

Topics in this section are only relevant for Web Services based on the SOAP protocol.

Getting started and examples

Genero Web Services code examples are located in **FGLDIR/demo/WebServices**, where **FGLDIR** is the Genero BDL installation directory.

Debugging

The Genero Web Services library gives you the ability to log the data your Web Service application is receiving from or sending to another application by turning on the debug mode.

Debug information is written to the standard error stream of the console; if needed, it can be redirected to a file.

To turn on the debugging feature, set the FGLWSDEBUG environment variable before starting the application.

The level of debugging depends on the value set for the FGLWSDEBUG variable.

Possible values are described in the FGLWSDEBUG environment variable definition.

> **Note:** To debug a Web Service application managed by the Application Server, you have to modify the value of the FGLWSDEBUG environment variable in the Application Server configuration file. For more information, refer to the *Genero Application Server Manual* documentation.

Platform-specific notes

IBM® AIX®

- The "IBM® C++ Runtime Environment Components for AIX®" must be installed in order to use Genero Web Services Extension 2.0. See the IBM® support center for more information about downloading the component.

  > **Note:** If not installed, you will get the following error message:
  >
  > ```
  > Could not load C extension library 'com'. Reason: A file or directory
  > in the path name does not exist.
  > ```

- Due to an IBM® issue on 64-bit platforms, the openssl library is unable to open the system /dev/urandom device to generate a PRNG number.

  You must install the **Entropy Gathering Daemon (a.k.a EGD)** if you need security in your GWS application, and especially if you access a server in HTTPS.

GMI / iOS Web Services limitations
Some Web Services classes are not supported on iOS devices (GMI).

Web Services COM package

The following com classes are not supported in GMI:

- `com.Util`
- `com.TCPRequest`
- `com.TCPResponse`
- `com.WebService`
- `com.WebOperation`
- `com.WebServiceEngine` (except for `SetOption()`/`GetOption()` methods, for option `SoapModuleURI` only)
- `com.HTTPServiceRequest`

The following methods have a different behavior:

- `com.HTTPRequest.setVersion()` has no effect, the iOS HTTP stack supports HTTP 1.1 only.
- `com.HTTPRequest.getAsyncResponse()` is not working asynchronously, it works like `com.HTTPRequest.getResponse()`.
- `com.HTTPRequest.setAutoReply()` has no effect, the iOS HTTP stack does not provide an auto reply option.
- `com.HTTPRequest.setMaximumResponseLength()` has no effect, the iOS HTTP stack does not provide a maximum response length option.
- `com.HTTPRequest.setConnectionTimeout()` and `com.HTTPRequest.setTimeout()`: the max of both settings is used as timeout by the iOS HTTP stack.

Web Services XML package

The following xml classes are not supported in GMI:

> **Note:** These classes are currently not supported on iOS, as OpenSSL cannot be used to implement these classes on iOS. OpenSSL is used to implement these classes for other platforms.

- `xml.CryptoKey`
- `xml.CryptoX509`
- `xml.Signature`
- `xml.Encryption`
- `xml.KeyStore`

For all other classes of the xml package, methods using an URL parameter accept only a file URI:

- `xml.DomDocument.Load()`
- `xml.DomDocument.save()`
- `xml.StaxWriter.writeTo()`
- `xml.StaxReader.readFrom()`

If the parameter is not a file URI, these methods can raise runtime exceptions such as -15629, -15630, -15632, -15633.

SOAP protocol

GMI is not able to handle SOAP errors or faults, as the iOS API does not allow a retrieval of an HTTP response body if the server uses an HTTP code of 500. As a result, GMI will not get notified about what went wrong during a remote procedure call.

If the server returns a SOAP error or fault, GMI will raise exception -15559. Modify your call of a remote web service as follows:

```
DEFINE wsstatus INTEGER
...
   LET wsstatus = Webservice_Function_g()
   IF wsstatus==-15559 THEN
      MESSAGE "Handle generic SOAP error or fault"
   END IF
```

Web Services configuration options

GWS configuration entries of FGLPROFILE are not supported on iOS.

FGLPROFILE entries are described here: FGLPROFILE entries on page 2510.

Long running HTTP request popup

If the `com.HTTPRequest.getResponse()`/`getAsyncResponse()` methods take more than 5 seconds to complete, the GMI will show a typical iOS popup message to ask the user if the request must be canceled. If the user cancels the request, the runtime system raises an exception. A progress bar is displayed if the Content-Length for a request is available (i.e. self made uploads and most downloads)

HTTP request compression for POST/PUT

HTTP request compression for POST/PUT is not supported on iOS devices.

Multipart HTTP request

On iOS, multipart HTTP requests are not supported. See com.HTTPRequest.setMultipartType on page 2066.

Changing the SOAP client behavior at runtime

The following features have a limited usage on iOS devices:

- HTTP version protocol definition is ignored.
- Connection timeout and read/write timeout are identical.

FGLPROFILE settings for Web Services client

FGLPROFILE settings for Web Services are not supported on iOS:

- Settings for logical names is not supported.
- Settings for HTTP proxy configuration is ignored: Uses device settings.
- Settings for client authentication to server is not supported: Use HTTPRequest API instead.
- Settings for client authentication to proxy is not supported: Uses device settings.
- Settings for server certificate authority is not supported: Uses device KeyChain.

GMA / Android™ Web Services requirements

Requirements to use Web Services on Android platforms.

V3 SSL Certicates

The SSL certificates for secured servers must be of type V3: Android does not support other types of SSL certificates. When creating your own self-signed certificates (to be installed in the "Install from storage" Keystore of Android), make sure that type V3 is used.

Known issues

Forcing RPC style convention when no input message

In RPC style, the convention defines names for input messages and output messages, but if there is no input message, its name cannot be redefined.

To workaround this issue, respect RPC style convention in wsdl, or force RPC convention (on client and server side) by using the `-fRPC` option of the `fglwsdl` tool.

Variable names conflicts with library names

The `fglwsdl` tool can generate variable names conflicting with `IMPORT` library names.

For example:

```
DEFINE xml xml.DomDocument
```

will conflict with the `xml` library, if the code defines also the instruction:

```
IMPORT xml
```

Concepts

These topics cover various Genero Web Services concepts.

- High-level and low-level web services APIs on page 2420
- SOAP features on page 2420
- Stateful web services on page 2422
- Encryption, base64 and password agent with fglpass tool on page 2429
- HTTP compression on page 2432
- SOAP multipart style requests in GWS on page 2434

High-level and low-level web services APIs

With Genero, we distinguish two type of APIs to implement web services.

- High-level web services are SOAP web services managed on server side with the high-level APIs `WebService` and `WebOperation`, or if you have generated code via the fglwsdl tool (client and server side).
- Low-level web services are implemented with `HTTPRequest`, `HTTPResponse` and `HTTPServiceRequest` classes, where you have to write all the HTTP code of your services by hand.

SOAP features

SOAP 1.1 and 1.2

Since 2.40, Genero Web Services (GWS) supports SOAP 1.2. GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

Server side

A Genero Web Services server can deliver a service in SOAP 1.1 or SOAP 1.2 using the com.WebService.setFeature function.

For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server offers the service in SOAP 1.1 and SOAP 1.2.

```
LET serv = com.WebService.CreateWebService("Calculator",serviceNS)
CALL serv.setFeature("Soap1.1",TRUE)
CALL serv.setFeature("Soap1.2",TRUE)
```

Client side

A GWS client can consume a service in SOAP 1.1 or SOAP 1.2.

For example:

- To create a client that consumes the Calculator service in SOAP 1.1 use command:

```
fglwsdl -soap11 -o ws_calculator http://localhost:8090/Calculator?WSDL
```

- To create a client that consumes the Calculator service in SOAP 1.2 use command:

```
fglwsdl -soap12 -o ws_calculatorSoap12 http://localhost:8090/Calculator?
WSDL
```

Be aware to generate different clients for each SOAP versions. Even if the same operations are provided, the services are using different protocols so the underlying generated stubs are also different.

SOAP Fault

Since 2.40, Genero Web Services supports SOAP fault.

For backward compatibility, fglwsdl tool provides option **-ignoreFaults** to disable SOAP fault management.

Server side

A Genero Web Services server can throw a SOAP fault if any processing error is encountered.

To generate a SOAP fault you need to:

- create the fault variable with com.WebService.createFault()
- add it to your operation with com.WebOperation.addFault
- use it with com.WebServiceEngine.SetFaultDetail

For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server has a **divide_by_zero** SOAP fault. The SOAP fault is raised when you try to divide a number by zero. To generate a SOAP fault proceed as follow:

Create a SOAP fault

You define the variable to send as a SOAP fault. It can be a simple string like in this example or a complex type. Remember to assign a XMLName to the variable.

```
DEFINE divide_by_zero STRING ATTRIBUTES (XMLName="DividedByZero")
```

Then you inform the service that it can use this fault variable using function com.WebService.createFault().

```
LET serv = com.WebService.CreateWebService("Calculator",serviceNS)
CALL serv.createFault(divide_by_zero,FALSE)
```

Add the SOAP fault to an operation

A SOAP fault can be used by an operation to inform the client that an error has occurred. An operation can use different SOAP faults but **only one at a time**.

```
LET op =
 com.WebOperation.CreateRPCStyle("divide","Divide",divide_in,divide_out)
CALL op.addFault(divide_by_zero,NULL)
```

Here, the SOAP fault is added to the "divide" operation.

Send the SOAP fault

Set the values to the fault variable. The fault message is be sent to the client at the end of the operation processing.

```
LET divide_by_zero = "Cannot divide "||divide_in.a||" by zero"
CALL com.WebServiceEngine.SetFaultDetail(divide_by_zero)
```

Client side

If a SOAP fault occured the operation returns the SOAP fault number in the operation status. The SOAP fault number is defined in the generated stubs as a BDL constant prefixed with the string **FaultID**_.

> **Note:** A SOAP fault can occur in case of HTTP error 200 and 500.

For example in $FGLDIR/demo/WebServices/calculator/client/ws_calculator.inc, **Divide** operation has a SOAP fault that informs the client when a number is divided by zero.

```
# List of Soap fault constants
CONSTANT FaultID_DividedByZero = 1
...
# VARIABLE : DividedByZero
DEFINE DividedByZero STRING ATTRIBUTES(XMLName="DividedByZero",
  XMLNamespace="http://tempuri.org/")
...
# Operation: Divide
# FAULT #1: GLOBALS DividedByZero
```

You can test the operation status code accordingly and display the SOAP fault message.

For example in $FGLDIR/demo/WebServices/calculator/client/calculatorClient.4gl, when the divide operation status is 1, DividedByZero message is displayed.

```
ON ACTION divide
   CALL Divide(op1, op2) RETURNING wsstatus, result, remaind
   CASE wsstatus
      WHEN 0
         DISPLAY BY NAME result,remaind
         DISPLAY "OK" TO msg
      WHEN FaultID_DividedByZero
         DISPLAY DividedByZero TO msg
      OTHERWISE
         DISPLAY wsError.description TO msg
   END CASE
```

Stateful web services

Concept

A stateful service is a service that maintains a context between a web services client and server. It enables the service to keep trace of previous requests from that context, in order to manage different states in the web service server.

Genero Web Services supports two kinds of stateful services:

- Based on the WS-Addressing 1.0 specification to define the XML format used to convey the context from client to the server
- Based on an HTTP session cookie to convey the context from client to the server

The Genero Web Service engine uses a BDL variable defined at stateful service creation via createStatefulWebService() as service context. Use that variable to hold a service state in a database.

It is up to the BDL programmer to create, store and remove the service state in the database.

The SOAP engine is responsible for:

- Deserializing the state variable when getting an new incoming request. *The programmer can then read the state variable for any published BDL web service operation and restore the service state corresponding to that variable.*
- Serializing a new instance of the state variable in a web service response for all BDL web service operations set as session initiator via initiateSession(). *The programmer must instantiate a new state by filling the state variable and storing it into a database for further use.*

WS-Addressing 1.0 stateful services

A stateful service based on WS-Addressing uses the WS-Addressing EndpointReference type as state variable and is independent from the transport layer used. (See WS-Addressing 1.0 EndpointReferenceType). The session state is conveyed from the client to the server as WS-Addressing 1.0 reference parameters.

Server side
Perform these steps to create a WS-Addressing stateful service.
Step 1: Declare a W3CEndpointReference record to be used as state variable

This record **MUST** have:

- A mandatory member of type STRING, where you can define a different service end point URL, otherwise the current server URL will be used.
- A sub record to contain one or more BDL variables used as state variables and defined as reference parameter in the WS-Addressing 1.0 specification.

For example:

```
DEFINE EndpointReferenceState RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, # Mandatory
  ref RECORD # Sub-record Reference parameters containing one
             # or more state variables
    OpaqueID STRING ATTRIBUTES(XMLName="OpaqueID"), # Unique ID to
               #identify the service state in the database
    Expiration DATE ATTRIBUTES(XMLName="Expiration",
      XMLNamespace="http://tempuri.org") # Session state expiration date
  END RECORD
END RECORD
```

You can use a unique ID of a database table to manage the web services sessions in place of OpaqueID.

Step 2: Create a stateful WS-Addressing enabled web service with W3CEndpointReference record as a parameter

The Genero Web Service extension provides a new Web service constructor called createStatefulWebService() to perform stateful services. This function works as the stateless constructor, but expects a W3CEndpointReference record as parameter.

For example:

```
DEFINE serv com.WebService
LET serv = com.WebService.CreateStatefulWebService(
  "StatefulWSAddressingService","http://4js.com/services",
  EndpointReferenceState) # Create a stateful service
  # with a W3CEndpointReference state variable
CALL serv.setFeature("WS-Addressing1.0","REQUIRED") # enable
  # support of WS-Addressing 1.0
```

Step 3: Publish a web service operation returning the W3CEndpointReference state variable and set it as session initiator

You must define which web service operation will initiate the session on your service and return the W3CEndpointReference state variable.

All other web service operations (not defined as session initiator) will return an error if they don't get reference parameters defined in the W3CEndpointReference state variable as WS-Addressing 1.0 headers.

For example:

```
DEFINE op com.WebOperation
LET op = com.WebOperation.CreateDocStyle("GetInstance",
  "GetInstance",NULL,EndpointReferenceState)
CALL op.initiateSession(TRUE)
CALL serv.publishOperation(op,NULL)
```

There is no restriction regarding the input parameter of the web service initiator function, but the output parameter must be the same W3CEndpointReference record passed to the service creation constructor.

It is not required to have a web operation which initiate the session in the same service, but then you have to return the same W3CEndpointReference record in another web service to instantiate the session, such as a Factory service that instantiates all sessions for other stateful services.

Step 4: Create the BDL session initiator function and instantiate a new session

In your BDL function declared as session initiator, you have to:

- Handle the creation of the session
- Fill the state variable before to return from the function

- Store the new session in a database based on the state variable (in order to keep the session across consecutive requests from the same client).

For example:

```
FUNCTION GetInstance()
  LET EndpointReferenceState.address = NULL
  # Use default end point location
  LET EndpointReferenceState.ref.OpaqueID = com.Util.CreateUUIDString()
  # Generate an unique string (can come from a database table id)
  LET EndpointReferenceState.ref.Expiration = CURRENT  + INTERVAL HOUR TO
 HOUR (1)
  # Create expiration date in one hour to discard request after that date
  ... Store OpaqueID into database or use directly a database table entry
  ... to hold the session
END FUNCTION
```

Step 5: Restore the session in any BDL web operation from the W3CEndpointReference record

In any publish BDL web function, the SOAP engine deserializes the WS-Addressing 1.0 reference parameter headers into the W3CEndpointReference sub-record so that you can retrieve the session from the state variable.

For example:

```
FUNCTION MyFunction()
  IF EndpointReferenceState.ref.OpaqueID IS NULL THEN
    CALL com.WebServiceEngine.SetFaultString("Invalid session id")
    RETURN
  ELSE
    ... Restore the service session based on the OpaqueID state
    ... variable from the database
  END IF
  ... Process the operation
END FUNCTION
```

Client side
Perform these steps to communicate with a stateful web service based on WS-Addressing 1.0.
Step 1: Generate the client stub from your WS-Addressing stateful service

Use the fglwsdl tool as usual. It will detect that the service returns a W3CEndpointReference and generate the appropriate code.

The WSDL imports the WS-Addressing 1.0 schema, so the fglwsdl tool requires an access to the W3C server. Use the option -proxy if you need to connect via a proxy server.

For example:

```
$ fglwsdl -o ws_stub http://localhost:8090/StatefulWSAddressingService?WSDL
```

The generated .inc file contains a variable of type tWSAGlobalEndpointType to be used to transmit the WS-Addressing 1.0 reference parameters.

Example of a global variable name

```
DEFINE
 StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint
   tGlobalWSAEndpointType
```

Step 2: Create the MAIN application

In your main application:

1. Import the XML library. This is due to the support of WS-Addressing 1.0 with **IMPORT XML**.
2. Import the generated .inc file with **GLOBALS "ws_stub.inc"**
3. Manage the WS-Addressing 1.0 reference parameters representing the session state (if your client has to handle several instances of a same service).

For example:

```
IMPORT XML # Import the XML library required for WS-Addressing 1.0

GLOBALS "ws_stub.inc" # Import service global definition

TYPE InstanceType DYNAMIC ARRAY OF xml.DomDocument
  # End point WSA reference parameters

DEFINE instance1,instance2,instance3 InstanceType
   # Store the different sessions the client will have to manage

MAIN
  ...
END MAIN
```

Step 3: Instantiate a new session by calling the web service operation set as session initiator

Call the BDL function generated from the WSDL that is defined as session initiator on the server. This function returns a **W3CEndpointReference** parameter that contains the WS-Addressing 1.0 reference parameters representing the new instance created on server side.

If your application handles several instances, you will have to copy and store those parameters in your application to identify a service instance for further requests.

As the WS-Addressing 1.0 reference parameters are defined as any XML document, they are represented as a dynamic list of xml.DomDocument in BDL.

For example:

```
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session initiator
                               # web function
IF wsstatus == 0 THEN
   FOR ind=1 TO
     ns1GetInstanceResponse.return.ReferenceParameters._LIST_0.getLength()
      LET instance1[ind]=

 ns1GetInstanceResponse.return.ReferenceParameters._LIST_0[ind].clone()
        # copy the service returned WS-Addressing 1.0 reference parameters
   END FOR
ELSE
     ... handle soap errors
END IF
```

When creating a new instance, ensure that the **Parameters** member of the generated global variable of type tWSAGlobalEndpointType has been set to NULL, otherwise the server will complain.

Step 4: Call any web service operation with previously returned WS-Addressing 1.0 reference parameters

Before calling any web service operation, you must set the WS-Addressing 1.0 reference parameters returned by a session initiator function to identify the session to the server.

For example:

```
LET StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint.
Address.Parameters.* = instance1.*
# assign WS-Addressing 1.0 reference parameters dynamic array by reference
CALL MyFunction("Hello") RETURNING wsstatus,ret
# Call web operation MyFunction of instance 1
```

Stateful services based on HTTP cookies

A stateful service based on HTTP cookies uses the HTTP transport protocol and its ability to convey cookies, used as session context. **Notice** that it works only if the communication path between the client and the server is performed in HTTP, otherwise it is recommended to use WS-Addressing stateful services.

Server side
Perform these steps to create an HTTP cookie based stateful service.
Step 1: Declare any BDL simple variable to be used as state variable

For example:

```
DEFINE ServiceState STRING # Unique ID to identify the service state in the
 database
```

For instance, you can use a unique ID of a database table to manage the web services sessions.

Step 2: Create a stateful web service with state variable as parameter

The Genero Web Service extension provides a new Web service constructor called createStatefulWebService() to perform stateful services. This function works as the stateless constructor, but expects a simple state variable as parameter.

Example

```
DEFINE serv com.WebService
LET serv =
 com.WebService.CreateStatefulWebService("StatefulCookieService",
           "http://4js.com/services",ServiceState)
# Create a stateful service with a simple BDL variable as state
 variable
```

Step 3: Publish a web service operation defined as session initiator

Define which web service operation will initiate the session on your service and instantiate a new session. All other web service operations (not defined as session initiator) will return an error if they don't get an HTTP cookie called **GSESSIONID**.

For example:

```
DEFINE op com.WebOperation
LET op =
 com.WebOperation.CreateDocStyle("GetInstance","GetInstance",NULL,NULL)
CALL op.initiateSession(true)
CALL serv.publishOperation(op,NULL)
```

There is no restriction on the web service session initiator function regarding to the input and output parameters.

Step 4: Create the BDL session initiator function and instantiate a new session

In your BDL function declared as session initiator, you must:

- Handle the creation of the session.
- Fill the state variable before to return from the function.
- Store the state variable in a database based on the state variable (in order to keep the session across consecutive requests from a same client).

For example:

```
FUNCTION GetInstance()
  # Generate an unique string (can come from a database table id)
  LET ServiceState = com.Util.CreateUUIDString()
      ... Store ServiceState value into database or use directly a
          database table entry to hold the session
END FUNCTION
```

Step 5: Restore the session in any BDL web operation from the state variable

In any publish BDL web function, the SOAP engine deserializes the HTTP Cookie called **GSESSIONID** from the HTTP layer into the state variable. You can then retrieve the session in BDL via that state variable.

For example:

```
FUNCTION MyFunction()
  IF ServiceState IS NULL THEN
    CALL com.WebServiceEngine.SetFaultString("Invalid session id")
    RETURN
  ELSE
    ... Restore the service session based on the ServiceState
        variable from the database
  END IF
  ... Process the operation
END FUNCTION
```

Step 6: Deployment recommendation

When deploying stateful web services based on HTTP cookies, the complete server path will be added into the cookie when first instantiated, so you must pay attention to that URL. In other words, you MUST always call the service via the complete URL containing the service name inside. For instance if your service is named **MyService** and if you GAS configuration file is called **Server.xcf**, the stateful service is accessible at URL: **http://localhost:6394/ws/r/group/Server/MyService**.

Client side
Perform the following steps to communicate with a stateful web service based on HTTP cookies.
Step 1: Generate the client stub from your stateful service

Use the fglwsdl tool as usual.

For example:

```
$ fglwsdl -o ws_stub http://localhost:8090/StatefulCookieService?WSDL
```

The generated .inc file contains a variable of type tGlobalEndpointType to be used to transmit the HTTP Cookie.

Example of a global variable name

```
DEFINE StatefulCookieService_StatefulCookieServicePortTypeEndpoint
 tGlobalEndpointType
```

Step 2: Create the MAIN application

In your main application:

- Import the generated .inc file with **GLOBALS "ws_stub.inc"**.
- Manage the HTTP cookies representing the session state (if your client has to handle several instances of a same service).

For example:

```
GLOBALS "ws_stub.inc" # Import service global definition

# Store the different sessions the client will have to manage
# in a string
DEFINE instance1,instance2,instance3 String

MAIN
  ...
END MAIN
```

Step 3: Instantiate a new session by calling the web service operation set as session initiator

Call the BDL function generated from the WSDL that was defined as session initiator on the server. This function returns a new HTTP Cookie saved into the **Binding.Cookie** member of the global service variable of type tGlobalEndpointType. If your application handles several instances, you will have to copy and store that cookie in your application to identify a service instance for further requests.

For example:

```
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session
                               # initiator web function
IF wsstatus == 0 THEN
  # copy the service returned HTTP cookie
  LET instance1 =

 StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie
ELSE
  ... handle soap errors
END IF
```

When creating a new instance, ensure that the **Binding.Cookie** member of the generated global variable of type tGlobalEndpointType has been set to NULL, otherwise the server will complain.

Step 4: Call any web service operation with previously returned HTTP cookie

Before calling any web service operation, set the HTTP cookie returned by a session initiator function to identify the session to the server.

For example:

```
# use instance1
LET
 StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie
 =
 instance1
# Call web operation MyFunction of instance 1
CALL MyFunction("Hello") RETURNING wsstatus,ret
```

Step 5: Troubleshooting

If your Genero application doesn't set the HTTP cookie when accessing a stateful service via the GAS, it is possible that you didn't use the complete URL when accessing the service.

For instance if your service is named **MyService** and if you GAS configuration file is called **Server.xcf**, the stateful service is accessible at URL: **http://localhost:6394/ws/r/group/Server/MyService**.

Encryption, base64 and password agent with fglpass tool

For security reasons, it is recommended that you avoid storing clear passwords in a file. The Genero Web Services enables the password encryption of a HTTP Authenticate entry in the FGLPROFILE file. The encrypted password is decrypted by the Genero Web Services engine when required.

The fglpass tool

The Genero Web Services package provides a command line tool called **fglpass**. The **fglpass** tool can encrypt a password from a X.509 certificate or a RSA private key. The encrypted password is displayed on the console in a Base64 form, composed only of alphanumeric characters, and therefore easily usable in any text file.

See fglpass for more details.

Encrypt a HTTP authenticate password

1. Find the HTTP Authenticate entry with the password you want to encrypt:

```
authenticate.myentry.login    = "mylogin"
authenticate.myentry.password = "mypassword"
```

2. Add the certificate and its private key in the FGLPROFILE file as follows:

```
security.mykey.certificate = "MyCertificate.crt"
security.mykey.privatekey  = "MyPrivateKey.pem"
```

3. Encrypt the password with **fglpass**:

```
$ fglpass -c MyCertificate.crt
Enter password :mypassword
```

The **fglpass** output looks like the following:

```
BASE64 BEGIN
dBy3E5JCVxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
/onWviG0M5mqubBeS7QUlt/ZK0D1aO9/R5RVa5wylQu//6vxfyd8NG/
SFJmlVH63kuyXfiVfq6bHo5+nlQZpVjSHfF2msET3S9HTpZUt4NblP4=BASE64 END
```

> **Note:** The encrypted password corresponds to the big suite of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (*mykey* in our case):

```
authenticate.myentry.login = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCVxuoxsR+
aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
/onWviG0M5mqubBeS7QUlt/ZK0D1aO9/R5RVa5wylQu//6vxfyd8NG/
SFJmlVH63kuyXfiVfq6bHo5+nlQZpVjSHfF2msET3S9HTpZUt4NblP4="
```

> **Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

Encrypt a HTTP authenticate password using a certificate in the Windows™ key store

1. Find the HTTP Authenticate entry with the password you want to encrypt:

```
authenticate.myentry.login    = "mylogin"
authenticate.myentry.password = "mypassword"
```

2. Add the subject of the certificate registered in the Windows™ key store:

```
security.mykey.subject = "Georges"
```

3. Encrypt the password with **fglpass**:

```
$ fglpass -s Georges
Enter password :mypassword
```

The **fglpass** output looks like this:

```
BASE64 BEGIN
dBy3E5JCVxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
/onWviG0M5mqubBeS7QUlt/ZK0D1aO9/R5RVa5wylQu//6vxfyd8NG/
SFJmlVH63kuyXfiVfq6bHo5+nlQZpVjSHfF2msET3S9HTpZUt4NblP4=
BASE64 END
```

> **Note:** The encrypted password corresponds to the big suite of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (*mykey* in our case):

```
authenticate.myentry.login          = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCVxuoxsR+
aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
/onWviG0M5mqubBeS7QUlt/ZK0D1aO9/R5RVa5wylQu//6vxfyd8NG/
SFJmlVH63kuyXfiVfq6bHo5+nlQZpVjSHfF2msET3S9HTpZUt4NblP4="
```

> **Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

Use the password agent

The **fglpass** tool can be started as an agent, to help any BDL application who requires a password to grant access to a private key, by getting it without having to type it. You simply need to enter the password once for each private key at the agent startup, and then **any BDL application started on the same machine and with the same user name as the agent itself can get rid of entering the different passwords**.

Of course, authentication and data encryption are performed between the BDL application and the agent to guarantee passwords confidentiality, and the passwords are also stored encrypted in the agent memory.

1. To start the password agent at port number **4242** and to serve the BDL applications with the passwords of the private key **RSAKey1.pem** and **DSAKey2.der**, specify the option `-agent`, followed by a colon, followed by the port number where it will be reachable, followed by the list of private keys the agent will handle for all BDL applications.

```
fglpass -agent:4242 RSAKey1.pem DSAKey2.der
```

2. The agent will ask you to silently enter the password of the different keys*(the passwords are not displayed to the console when being typed)*. In this example, you have:

```
Enter pass phrase for RSAKey1.pem:
```

Followed by:

```
Enter pass phrase for DSAKey2.der:
```

3. Once all keys have been treated, it displays following message to notify that the agent is ready to serve.

```
Agent started
```

4. To enable one BDL application to use the password agent capability, set the entry called security.global.agent in the FGLPROFILE file with the port number of the agent.

   In our example, with value 4242:

```
security.global.agent = "4242"
```

Encrypt a password

The **fglpass** tool can encrypt a password using an RSA key or certificate, and then encode it in BASE64 form. This allows you to easily add a protected password in the FGLPROFILE file for future use by any BDL application.

1. To encrypt a password from an RSA key and encoded in BASE64, enter:

```
fglpass -e -k RSAPub.pem
```

2. You are prompted to enter the password you want to encrypt.

```
Enter password :hello
```

   The **fglpass** tool outputs the BASE64 form of the encrypted password on the console.

```
BASE64 BEGIN
Pzk/fNRhetdJDZz5kjNg7P0XET4XsW6bys/fi0DvugxRPh9d/s41oAws65
JY0EPb2zytQjxZ/dwaaRzJPYoQmA==
BASE64 END
```

   Note: The BASE64 encrypted password is the string between the BASE64 BEGIN and BASE64 END.

Decrypt a password

The **fglpass** tool can decrypt a BASE64 encoded and encrypted password using the RSA private key that was used to encrypt it or that is associated to a certificate containing the public part of that private key.

1. To decrypt a BASE64 encoded and encrypted password from a RSA private key, enter:

```
fglpass -d -k RSAPriv.pem
```

2. If the RSA key is protected with a password, you are asked to silently enter that password *(the password is not displayed to the console when being typed)*.

```
Enter pass phrase for RSAPriv.pem:
```

3. You are prompted to enter the BASE64 encoded and encrypted password you want to decrypt.

```
Enter password :Pzk/fNRhetdJDZz5kjNg7P0XET4XsW6bys/fi0
DvugxRPh9d/s41oAws65JY0EPb2zytQjxZ/dwaaRzJPYoQmA==
```

   The fglpass tool outputs the password in clear text on the console.

```
hello
```

Encode a file in BASE64 form

The **fglpass** tool can encode a file in BASE64 form.

1. To encode the file **MyFile** in BASE64, enter:

```
fglpass -enc64 MyFile
```

The **fglpass** tool outputs the BASE64 form of the file to the console.

```
BASE64 BEGIN
c2VjdXJpdHkuZ2xvYmFsLmFnZW50ICAgICAgPSAiNDI0MiINCmNyeXB0by
5pZDEua2V5ICAgICAgICAgICAgID0gIlJTQTEwMjRLZXkucGVtIg0KY3J5
cHRvLmlkMi5rZXkgICAgICAgICAgPSAiUlNBMjA0OEtleS5wZW0iDQ
pjcnlwdG8uaWQzLmtleSAgICAgICAgICA9ICJEU0ExMDI0S2V5LnBl
bSINCmNyeXB0by5pZDQua2V5ICAgICAgICAgID0gIlJTQTUxMlByb3
RlY3RlZC5wZW0iDQpjcnlwdG8uaWQ1LmtleSAgICAgICAgICA9ICJE
U0E1MTJSZWFsbHlQcm90ZWN0ZWQucGVtIg0K
BASE64 END
```

Note:

- The BASE64 encoded file is the string between BASE64 BEGIN and BASE64 END.
- You can redirect the output of **fglpass** tool to a file. For example:

```
fglpass -enc64 MyFile > Base64filename
```

Decode a BASE64 form encoded file

The **fglpass** tool can decode a BASE64 encoded file.

1. To decode a file encoded in BASE64 form, enter:

```
fglpass -dec64 Base64filename
```

The **fglpass** tool outputs the file in clear form on the console.

```
security.global.agent      = "4242"
crypto.id1.key             = "RSA1024Key.pem"
crypto.id2.key             = "RSA2048Key.pem"
crypto.id3.key             = "DSA1024Key.pem"
crypto.id4.key             = "RSA512Protected.pem"
crypto.id5.key             = "DSA512ReallyProtected.pem"
```

Note:

- You don't have to remove the BASE64 BEGIN and BASE64 END tags, if they are present in the file, because the **fglpass** tool detects and removes them automatically.
- You can redirect the output of the **fglpass** tool to a file. For example:

```
fglpass -dec64 Base64MyFile > MyFile2
```

HTTP compression

HTTP compression is a capability that can be built into web servers and web clients to make better use of available bandwidth, and provide greater transmission speeds between both.

There are a variety of places where you can set up HTTP compression.

- You can set up the Web services client to send and receive compressed requests. See Compression and a Web services client on page 2433.
- You can enable compression for the Web server. Refer to your Web server documentation for details.
- You can enable compression in the Genero Application Server. Compression is enabled by default in `$FGLASDIR/etc/imt.cfg`. Refer to the *Genero Application Server User Guide* for more information.

- You can set up the Web services server to send and receive compressed requests. See Compression and a Web services server on page 2434.

Compression and a Web services client
Send and receive compressed requests from a Web services client.

When you create a low-level Web service and do not have any stubs created by `fglwsdl`, you need to manage it by setting the HTTP headers.

Important: HTTP request compression for POST/PUT is not supported on GMI mobile devices.

Send a compressed request

The method used to set up the client for sending a compressed request depends on whether the Genero Web Services client is a high-level or low-level Web services client. A *high-level client* is a Genero Web Services client that includes the stub files created by the fglwsdl tool. A *low-level client* is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Regardless of the type of client, the server must be set up to handle such compression, otherwise the request will be rejected.

Send a compressed request from a high-level client

A *high-level client* is a Genero Web Services client that includes the stub files created by the fglwsdl tool.

Set the variable Binding.CompressRequest to either "gzip" or "deflate".

```
LET EchoDocStyle_EchoDocStylePortTypeEndpoint.Binding.CompressRequest =
 "gzip"
```

The `Binding.CompressRequest` variable is defined in the stub file, specifically the client's global (`inc`) file.

```
#
# Global Endpoint user-defined type definition
#
TYPE tGlobalEndpointType RECORD   # End point
        Address RECORD # Address
           Uri STRING                # URI
        END RECORD,
        Binding RECORD # Binding
          Version STRING,             # HTTP Version (1.0 or 1.1)
          Cookie STRING,              # Cookie to be set
          ConnectionTimeout INTEGER,  # Connection timeout
          ReadWriteTimeout INTEGER,   # Read write timeout
          CompressRequest STRING      # HTTP request compression mode (gzip
 or deflate)
       END RECORD
     END RECORD

#
# Location of the SOAP endpoint.
# You can reassign this value at run-time.
#

DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

Send a compressed request from a low-level client

A *low-level client* is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Set the `Content-Encoding` field in the request header to either "gzip" or "deflate".

This example sets the `Content-Encoding` field to "gzip", where the request is a `com.HTTPRequest` object.

```
CALL request.setHeader("Content-Encoding","gzip")
```

Accept a compressed response

A Genero Web Services client can accept a compressed request if it sets the `Accept-Encoding` field in the header to "gzip, deflate". These values represent supported compression schema names (called content-coding tokens) separated by commas.

This example sets the `Accept-Encoding` field with the `setHeader` method, where the request is a `com.HTTPRequest` object.

```
CALL request.setHeader("Accept-Encoding","gzip, deflate")
```

Compression and a Web services server

Send and receive compressed requests from a Web services server.

If the Genero Web Services client accepts compression, the Genero Web Services server will reply with a compressed response.

To disable compression, you must disable compression in the Genero Application Server `$FGLASDIR/etc/imt.cfg` file. See the `Genero Application Server User Guide` for more information.

SOAP multipart style requests in GWS

This topic describes multipart support with Genero Web Services

What is multipart style in SOAP?

Multipart style SOAP is the ability to send and receive a SOAP request in multiple pieces. The sending of attached files in separate parts of the SOAP request is one example of a multipart style SOAP request.

Multipart SOAP on the client

When using a WSDL with multipart style, `fglwsdl` generates a client-side stub handling multipart requests. For more details, see Multipart in the client stub on page 2460.

Multipart SOAP on the server

Multipart style is not yet supported with the high-level WS API of Genero.

- It is not possible to write a GWS server handling multipart style SOAP requests with the high-level API.
- When generating code from a WSDL using multipart style, the `fglwsdl` will produce a warning message: `WARNING : Unable to manage MIME Mutlipart binding on message '`*`name`*`'`, where *name* is the name of the message in XML.

Implementing multipart using the low-level APIs

If required, you can implement a WS server handling multipart with the low-level APIs of Genero Web Services. For more details, see com.HTTPServiceRequest.getRequestMultipartType on page 2044.

Security

These topics covers security and Genero Web Services.

- Encryption and authentication on page 2435
- Accessing secured services on page 2438
- HTTPS configuration on page 2440
- Certificates in practice on page 2441
- Examining certificates on page 2443
- Troubleshoot common issues on page 2446
- The Diffie-Hellman key agreement algorithm on page 2447

Encryption and authentication

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

- Secured communications on page 2435
- Certificates on page 2436
- Certificate authorities on page 2437
- Certificates and private keys storage on page 2438

Secured communications

Secured communications are important. If an application wants to send or receive messages from a financial, business, or personnel application on the web, it must be able to authenticate the origin of the message, ensure that no malicious application has altered the original message, and ensure that no third party application can intercept the message.

Suppose that a person named Georges wants to send a message to his bank to transfer some money on the Internet. In this scenario, he faces the following concerns:

1. The **privacy** of the message, since it includes his account number and the transfer amount.
2. The **integrity** of the message, since someone might try to modify the original message or substitute a different message in order to transfer the money to another account.
3. The **authentication** of the message, since the bank must ensure that the message was sent from the right person.

Message privacy

To keep a message private, use a cryptographic algorithm - a technique that transforms a message into an encrypted form unreadable except by those it is intended for. Once it is in this form, the message may only be interpreted through the use of a secret key. There are two kinds of cryptography algorithms: symmetric and asymmetric.

Symmetric means the sender and the receiver of a message have to share the same key used to encrypt a clear message into an encrypted form, and then to decrypt it back into the original message. If that key is kept secret, nobody other than the sender and the receiver can read the message. However, the task of choosing a private key before communicating can be problematic.

Asymmetric means that there are two different keys working as a key-pair. One key is used to encrypt a message, and the second one is used to decrypt the encrypted message back into its original form. This solves the problem of key sharing in the symmetric cryptography algorithm, and makes it possible to receive secure messages, simply by publishing the key used to encrypt messages (the *public key*), and keeping secret the key used to decrypt messages (the *private key*). Anyone can encrypt a message using the public key, but only the owner of the private key can read it.

> **Important:** The use of an asymmetric key-pair (public and private key), allows Georges to send private messages to his bank, simply by using the bank's public key to encrypt a message. Only the owner of the corresponding private key (the bank in this scenario) is able to read it.

Message integrity

To guarantee the integrity of a message, send a concise summary of the original message. The receiver of the message can create its own summary and compare it to the sender's summary. If they are similar, the message is considered intact, meaning that no third party has modified the original message.

Such a summary is called a *message digest* and is based on hash algorithms that produce a fixed-length representation of variable-length messages. Message digests are designed to make it very difficult (if not impossible) to determine the original message from a summary.

The message digest must be sent to the receiver in a secure way to assure the message integrity. This is achieved with a digital signature authenticating the sender and containing the sender's message digest.

> **Important:** The use of message digests allows Georges' bank to verify that no one has modified the original message he sent.

Message authentication

To authenticate a message, add a digital signature to that message.

A *digital signature* is another message, created by encrypting the message digest, along with some other information, with the sender's private key. Anyone with the corresponding public key can decrypt the digital signature. If an application is able to decrypt it, it means the owner of the private key was able to encrypt it, proving that the message comes from this sender and not from someone else.

Once the sender has been authenticated, the receiver can compare the message digest integrated into the digital signature to the one it created from the message it receives, in order to check the message integrity.

> **Important:** The use of digital signatures allows Georges' bank to verify that the message really comes from him.

Certificates

An SSL certificate is a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity.

Now that Georges is able to send a secured message to his bank, there is still a problem. How can Georges be sure that the server he is connected to is really the bank's server and not a malicious server?

Georges must be sure that the public key he is using to encrypt his message corresponds to the bank's private key. Similarly, the bank needs to verify that the message signature it receives corresponds to Georges' signature.

To identify a remote peer, use a *certificate* - a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity (known as the *subject*). It also includes the identification and signature of the Certificate Authority that issued the certificate, and the period of time during which the certificate is valid. It may have additional information (or extensions) as well as administrative information for the Certificate Authority's use, such as a serial number.

A standard X.509 certificate contains the following standard fields:

- Certificate version
- Serial number of the certificate
- The distinguished name of the certificate issuer
- The distinguished name of the certificate owner
- The validity period of the certificate
- The public key
- The digital signature of the issuer

- Signature algorithm used
- Zero or more certificate extensions

Note:

1. An example of a distinguished name is: **CN=Georges,E=georges@mycompany.com,OU=Sales,O=My Company Name,C=FR,S=France**
2. The CN (Common Name) of the distinguished name of the certificate owner corresponds to the certificate subject, and identifies the owner of that certificate.

Certificate authorities

When a certificate authority signs a certificate, it is validating that the certificate is valid.

Each time Georges sends a message to his bank, he will present his own certificate to the bank, and will get the bank's certificate back. But as every one can create a certificate in the name of Georges, a higher authority that confirms the validity of a certificate is necessary. The bank must be sure it is Georges' certificate, and that no one else has taken his identity. Similarly, Georges needs an authority that confirms that the certificate coming from the server is really the bank's certificate.

The solution to validating a certificate is to sign it with a trusted certificate called **certificate authority**. This is a certificate in which an application creates total confidence concerning the validity of the certificates it has signed. Before signing a certificate, a certificate authority must proceed with a strict identification of the owner of that certificate.

Note: The private key associated to a Certificate Authority must be managed with care, as it is the entity in charge of the validity of all other certificates it has signed.

There are several companies (such as *VeriSign*, *GlobalSign* or *RSA Security*) that have established themselves as certificate authorities and provide the following services over the Internet:

- Verifying certificate requests
- Processing certificate requests
- Issuing and managing certificates

Note: It is also possible to create your own Certificate Authority, but it is up to you to manage it securely.

Root Certificate Authority

A Certificate Authority signed by itself is called a Root Certificate Authority, meaning that the certificate issuer is the same as the certificate subject. Most of the time, such a certificate belongs to a company established as a Certificate Authority, and is used to sign certificate requests coming from different companies that want their own Certificate Authority. If a client certificate is signed by a Certificate Authority previously signed by a Root Certificate Authority, the client certificate can be validated by the Root Certificate Authority even if the Certificate Authority is not present.

For example, if a company wants to buy a Certificate Authority from VeriSign, VeriSign signs that Certificate Authority with its own Root Certificate Authority. The company can then create certificates with the Certificate Authority provided by VeriSign and connect to secure servers without providing them their own Certificate Authority. The secure server, of course, has to know the VeriSign Root Certificate Authority.

Certificate chains

A certificate authority may issue a certificate for another certificate authority. This means that when an application wants to examine the certificate of the issuer, it must check all parent certificates of that issuer until it reaches one it which it has confidence.

The certificate chain corresponds to the number of parent certificate authorities allowed to validate a certificate.

Certificate Authority List

A Certificate Authority List is a list of all certificate authorities considered as trusted by one application, classified by order of importance. Each of these certificates allows the authentication of a certificate presented to that application from a remote peer.

> **Note:** With most applications, the Certificate Authority List is a concatenated file of all certificate authorities.

Certificates and private keys storage

The entire concept of security is based on the publication of the public key, and the privacy of the associated private key. For maximum security, it is critical to restrict the access of the private key to the owner of the certificate and associated private key.

> **Note:** Some companies provide systems to manage certificates and private keys in complete security.

UNIX™ systems

As the UNIX™ system is already able to restrict the access of a file to only one person, simply restrict access to the private key to the owner of that key to achieve a good level of security. This provides enough security to allow a Genero Web Services client to perform secured communications in the name of the certificate and private key owner, because access to the private key file is granted only if the correct user has logged in.

Windows™ systems

The Windows™ system doesn't provide a reliable and sufficiently strong file access rights policy to secure a file. However, Windows™ has an integrated **key store** system to manage certificates and private keys. It allows the registration and the storage of X.509 certificate authorities, as well as personal X.509 certificates and their associated private keys accessible only if the correct user has logged in. It is recommended that you store the certificate and associated private key in the Windows™ key store instead of in files on the disk.

Accessing secured services

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

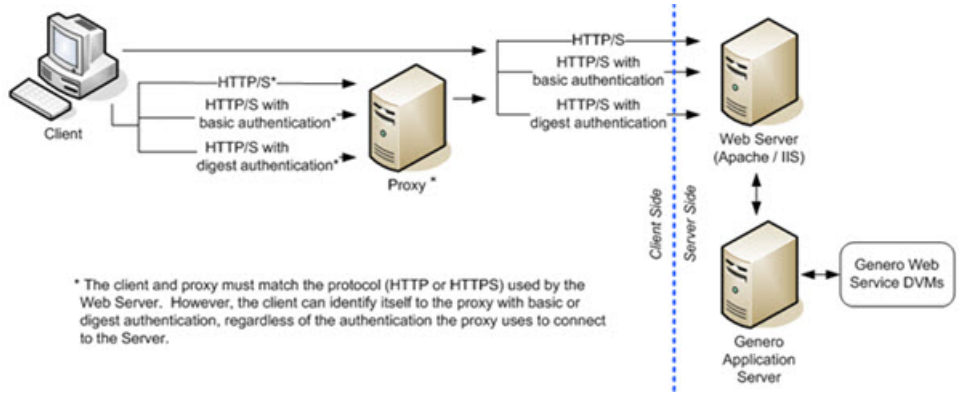

Figure 104: Communications options for a client to connect to a Web Service

HTTP	Client connects to a Web Server (or a Web Service) using HTTP as the communication protocol. (**No security** , **No authentication**).
HTTP with Basic Authentication	Client connects to a Web Server using HTTP as the communication protocol, but a valid login and

	password are required from the Web Server to grant access to the Web Service. (**No security** , **Weak Authentication)**. The login and password are sent in clear text on the communication layer.
HTTP with Digest Authentication	Client connects to the Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**No security** , **Authentication**). The login and password are encoded using a digest algorithm, requiring additional information from the Web Server. This means that the first connection will always fail, but it is necessary in order to return Web Server additional information back to the client.
HTTPS	Client connects to a Web Server using HTTPS as the communication protocol. (**Security** , **No authentication**). The communication channel is encrypted by SSL.
HTTPS with Basic Authentication	Client connects to a Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**Security** , **Weak Authentication**). The login and password are sent in clear text on the communication layer, but the communication channel is encrypted by SSL.
HTTPS with Digest Authentication	Client connects to the Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**Security** , **Authentication**). The login and password are encoded using a digest algorithm, requiring additional information from the Web Server. This means that the first connection will always fail, but it is necessary in order to return Web Server additional information back to the client. The communication channel is encrypted by SSL.

To improve communication speed with the cache mechanism, or to restrict internet access to specific clients, Genero Web Services allows a client to connect via proxies. The proxy is in charge of dispatching the client request to the server, and uses the same protocol as that used by the server. So, when a client connects via a proxy to access a HTTP server, the configuration of the HTTP proxy is used, and when the client communicates in HTTPS, the HTTPS proxy configuration is used.

HTTP proxy	Client connects via a proxy using HTTP as the communication protocol.
HTTP proxy with Basic Authentication	Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy.
HTTP proxy with Digest Authentication	Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch

	the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client.
HTTPS proxy	Client connects via a proxy using HTTPS as the communication protocol. The communication channel is encrypted by SSL.
HTTPS proxy with Basic Authentication	Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy, but the communication channel is encrypted by SSL.
HTTPS proxy with Digest Authentication	Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client. The communication channel between client and proxy is encrypted by SSL.

HTTPS configuration

If no HTTPS is provided, Genero Web Services (GWS) does the HTTPS request transparently.

For GWS, use an implicit certificate when no HTTP configuration is provided. For stronger security, you can provide HTTPS configuration with your own certificates and CA list.

The implicit client certificate

For the implicit certificate, no configuration is required. GWS creates a temporary certificate for the HTTPS request. The temporary certificate is valid for the application session.

The explicit client certificate

For the explicit certificate, configure your certificate with `fglprofile` entries.

For access to a specific site, specify `security.ident.certificate` and `security.ident.privatekey`.

If you use the same certificate across all sites, specify `security.global.certificate` and `security.global.privatekey`.

Certificate authorities

Certificate authorities are provided by the system (the operating system keystore). If they are not provided by the system, they are looked for in *`FGLDIR`*`/web_utilities/certs`. Genero Web Services will laod the CA from the directories listed in the `fglprofile` entry "`security.global.ca.lookuppath`". This entry is a list of directories, separated by a semicolon.

You can configure your CA list with the `fglprofile` entry `security.global.ca`.

Mobile platforms

On mobile platforms, no HTTPS configuration is required, because the Web Service library uses the SSL certificates installed in the key database of the device (Keystore for Android™ and Keychain for iOS).

See also GMA / Android Web Services requirements on page 2419.

Certificates in practice

Procedures and tools for creating, importing, and viewing certificates and keys.

- The OpenSSL (openssl) tool on page 2441
- Create a root certificate authority on page 2441
- Create a certificate authority on page 2442
- Create a certificate on page 2442
- Create a certificate authority list on page 2442
- Import a certificate and its private key into the Windows key store on page 2443
- Import a certificate authority into the Windows key store on page 2443
- View a certificate on page 2443
- HTTPS configuration on page 2440

The OpenSSL (openssl) tool

The `openssl` command line tool creates certificates for the configuration of secured communications.

It requires a configuration file with the default parameters such as the key size or the private key name. **OpenSSL** is provided with a default configuration file `openssl.cnf`.

The `openssl` tool looks for the `openssl.cnf` file in the directory where it is executed; it stops if the file is not present. To use the `openssl` tool from any directory, set the `OPENSSL_CONF` environment variable to specify the location of the configuration file.

For information on how the `openssl` tool works, refer to the `openssl` documentation at http://www.openssl.org/docs/apps/openssl.html.

Create a root certificate authority

This procedure allows you to create a root certificate authority.

1. Create the root certificate authority serial file:

```
$ echo 01 > MyRootCA.srl
```

2. Create a CSR (Certificate Signing Request):

```
$ openssl req -new -out MyRootCA.csr
```

   This creates a **privkey.pem** file containing the RSA private key of that certificate and protected by a password.

3. Remove the password of the private key (Optional):

```
$ openssl rsa -in privkey.pem -out MyRootCA.pem
```

   Note: Removing the password of a certificate authority's private key is not recommended.

4. Create a self-signed certificate from the Certificate Signing Request for a validity period of 365 days:

```
$ openssl x509 -trustout -in MyRootCA.csr -out MyRootCA.crt
 -req -signkey MyRootCA.pem -days 365
```

Note: If you want an official Root Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with **openssl**).

Create a certificate authority
This procedure allows you to create a certificate authority.

1. Create a CSR (certificate signing request):

```
$ openssl req -new -out MyCA.csr
```

   This creates a **privkey.pem** file containing to the RSA private key of that certificate and protected by a password.
2. Remove the private key password (Optional):

```
$ openssl rsa -in privkey.pem -out MyCA.pem
```

   Note: Removing the password of a certificate authority's private key is not recommended.
3. Create a certificate from the Certificate Signing Request and trusted by the Root Certificate Authority:

```
$ openssl x509 -in MyCA.csr -out MyCA.crt -req -signkey MyCA.pem
 -CA MyRootCA.crt -CAkey MyRootCA.pem -days 365
```

   Note: If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with **openssl**).

Create a certificate
This procedure allows you to create a certificate.

1. Create the certificate serial file:

```
$ echo 01 > MyCA.srl
```

2. Create a CSR (Certificate Signing Request):

```
$ openssl req -new -out MyCert.csr
```

   This command creates a **privkey.pem** file containing the RSA private key of that certificate and protected by a password.
3. Remove the private key password (Optional):

```
$ openssl rsa -in privkey.pem -out MyCert.pem
```

4. Create a certificate from the Certificate Signing Request and trusted by the Certificate Authority:

```
$ openssl x509 -in MyCert.csr -out MyCert.crt -req -signkey MyCert.pem
 -CA MyCA.crt -CAkey MyCA.pem -days 365
```

   Note: If you want an official Certificate, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with **openssl**).

Create a certificate authority list
This procedure allows you to create a certificate authority list using the `openssl` command.

Concatenate all certificate authorities by order of importance, listing the most important first:

```
$ openssl x509 -in MyCA1.crt -text >> CAList.pem
$ openssl x509 -in MyCA2.crt -text >> CAList.pem
```

```
$ openssl x509 -in MyCA3.crt -text >> CAList.pem
```

Import a certificate and its private key into the Windows™ key store
This procedure allows you to import a certificate and its private key.

1. Create a certificate.

   See Create a certificate.
2. Create a specific PKCS12 file containing the certificate and its private key in one file:

   ```
   $ openssl pkcs12 -export -inkey MyCert.pem -in MyCert.crt -out MyCert.p12
   ```

   Note: The .p12 generated file is protected by a password and can then be transported without any risk.
3. On a Windows™ system, open this .p12 file and follow the instructions provided.

   Note: If you select strong verification during the importation process, a popup displays each time an application accesses the private key asking the user whether the application is allowed to use it.

Import a certificate authority into the Windows™ key store
This procedure allows you to import a certificate authority.

1. Create a certificate authority.

   See Create a certificate Authority.
2. Open the .crt certificate file
3. Click **Install Certificate** and follow the instructions provided.

   Windows™ automatically places the certificate in the certificate authority list of the key store.

View a certificate
This procedure allows you to view a certificate using the `openssl` command.

To view a certificate, enter the x509 command:

```
openssl x509 -in MyCompanyCA.crt -noout -text
```

Examining certificates

When you receive a URL in https, you are asked to either accept a certificate or the certificate has already been accepted. In the second case, you can still check the server certificate.

- Check the server certificate using FireFox on page 2443
- Check the server certificate using Internet Explorer on page 2444
- Selecting the certificate to add on page 2444
- Missing certificates on page 2445

Check the server certificate using FireFox
This procedure allows you to check the server certificate using FireFox.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.

   The Page Info for the certificate displays.
3. In the Security tab, click on the View button.

   The Certificate Viewer opens.
4. In the Details tab, view the Certificate Hierarchy.

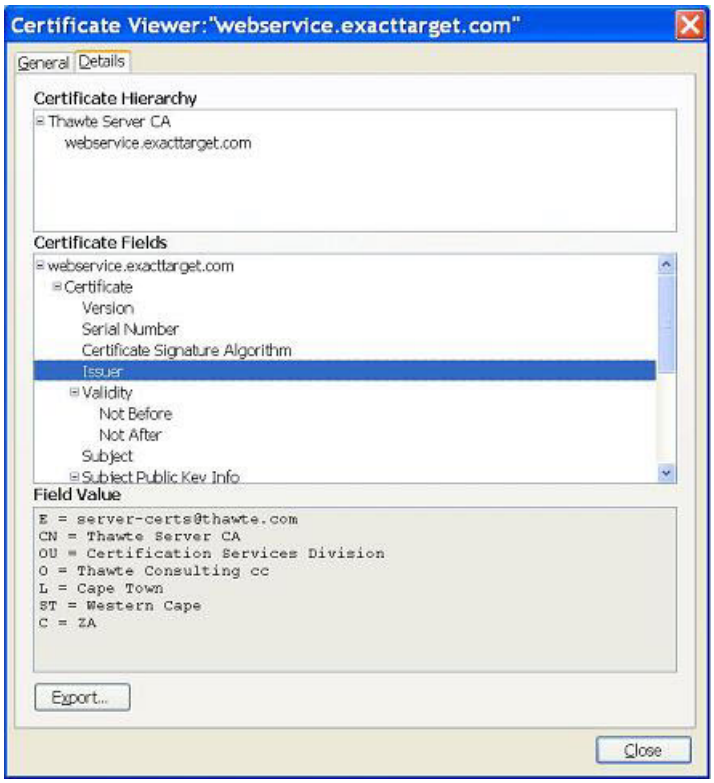

Figure 105: Certificate Viewer; Details tab.

Check the server certificate using Internet Explorer

This procedure allows you to check the server certificate using Internet Explorer.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.

   The Certificate window displays.
3. On the Certification Path, view the certificate hierarchy.

Selecting the certificate to add

The certificate authority (CA) is the authority that validates the server. The certificate to add to the CA list is the authority certificate, not the server certificate.

There are default certificates known by browsers like:

- VeriSign: http://www.verisign.com/support/roots.html
- Thawte: http://www.thawte.com/roots/index.html

Get the server issuer certificate (and all the parents, grandparents, and so on).

For example, if your server is validated by Thawte, add the Thawte certificate to the list.

To check whether your certificate is the CA certificate, search for the CNs (Common Names) in the .cer files. The CA Subject entry should be the Issuer CN in the server certificate.

```
openssl x509 -in server.pem -noout -subject
```

gives:

subject= /C=ZA/ST=Western Cape/L=Cape Town/O=Thawte Consulting cc/OU=CertificationServices Division/ **CN=Thawte Server CA** /emailAddress=server-certs@thawte.com

To convert a .cer certificate to the .pem format used by Genero Web Services:

```
openssl x509 -inform DER -in server.cer -outform PEM -out server.crt
```

Missing certificates

Sometimes the CA hierarchy described in the server certificate is incomplete or needs another certificate (default ones use by browsers or private ones).

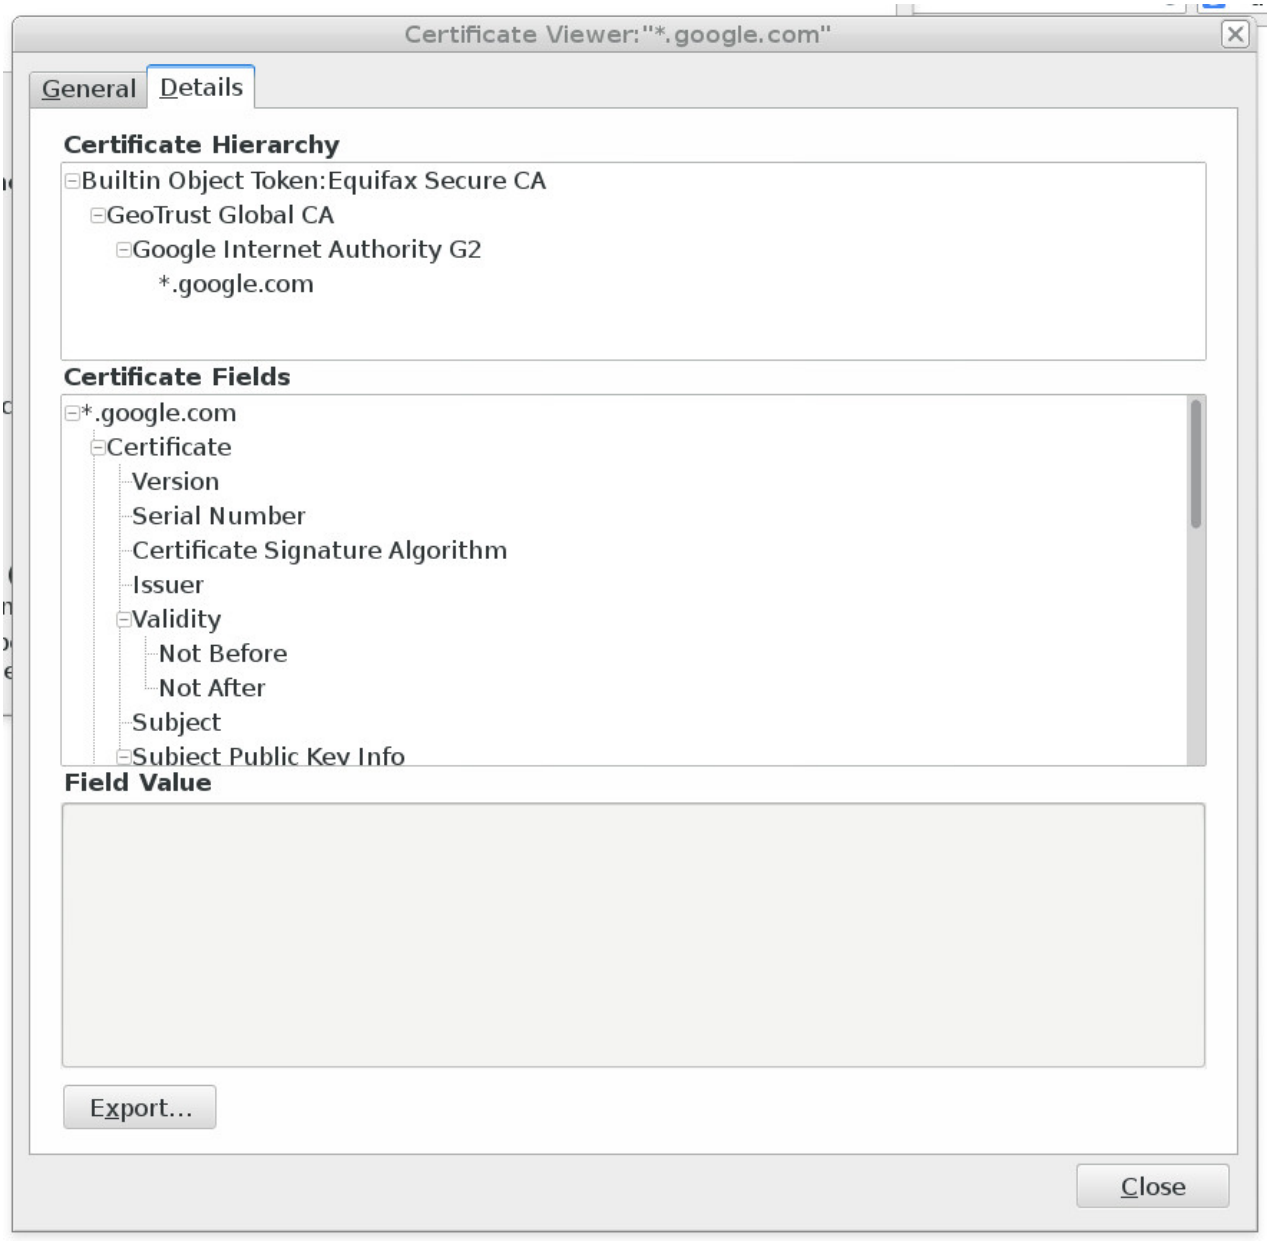

Figure 106: Certificate Viewer in Firefox Web Browser; Details Tab

When this occurs, you will have this kind of error message when you set FGLWSDEBUG:

```
WS-DEBUG (Security error)
Error with certificate at depth: 3
 issuer = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification
 Authority
```

```
 subject = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification
 Authority
 err 19:self signed certificate in certificate chain
WS-DEBUG END
```

This means openssl is looking for a third ancestor that is not listed in the hierarchy above. In this example, gatewaybeta.fedex.com only has two ancestors, and none are named "Class 3 Public Primary Certification Authority". You need to download the root certificates from VeriSign and add "Class 3 Public Primary Certification Authority" in your CA list.

Troubleshoot common issues

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

HTTP 401 error message

An HTTP 401 error message means the server is asking for, but not receiving, authentication (login and password).

This means **authenticate.xxx.login** and **authenticate.xxx.password** are not correctly configured. The login and password should be provided in the FGLPROFILE.

Solution:

1. Open the FGLPROFILE used by the application.
2. Add entries for **authenticate.xxx.login** and **authenticate.xxx.password** .
3. Save your changes.

Error: Peer certificate is issued by a company not in our CA list

When a client needs to connect to a server with https, the client needs to trust the server it is talking to. So the client needs to included the server CAs (certificate authorities list) to its trusted CAs.

This error means the client CA list is missing a certificate authority in its CA list.

To display the client CA list, use the following command:

```
openssl x509 -in ClientCAList.pem -noout -text
```

Solution:

1. Add the missing CA list to the client CA list.

   ```
   openssl x509 -in MyCompanyCA.crt -text >> ClientCAList.pem
   ```

Theory:

Usually certificates work in pairs: a public key and a private key.

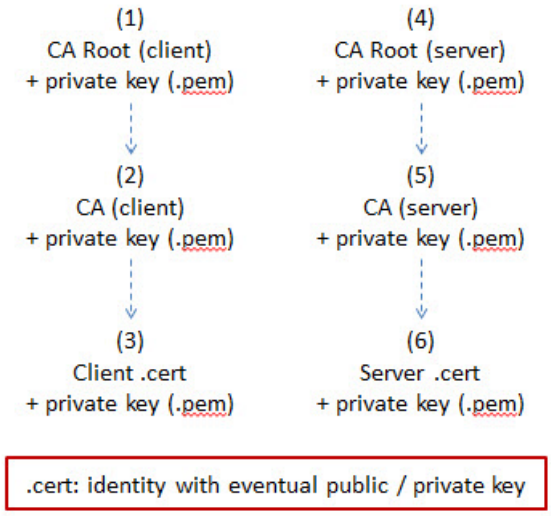

Figure 107: Certificates working in pairs: a public key and a private key

This means that the client has a certificate that can be signed by an authority signed itself by a root authority. Likewise, the server has a certificate that can be signed by an authority signed itself by a root authority. In some instances, a certificate can be signed by itself.

Things to remember:

- The server certificate should have its hostname as CN (Common Name). For example: if you want to access the server https://www.mycompany.com the CN should be www.mycompany.com.
- In client CA list you should have all the CA of the server. In this example you need the server CA (5) and the server CA Root (4). If the server is self-signed then add the server certificate (6) to the client CA list.
- Sometimes, the needed CAs are not listed in the certificates hierarchy. Setting environment variable FGLWSDEBUG=3, will give you information about the missing CA.

The Diffie-Hellman key agreement algorithm

Diffie-Hellman is a key-agreement algorithm. It allows two peers to agree on the same symmetric key, the shared secret, without exchanging confidential data.

The Diffie-Hellman key agreement algorithm is a method that allows two devices to communicate over a network by establishing a shared secret without exchanging any secret data. Knowing the used key-agreement algorithm, the two devices only need to exchange their public key. Then, using the other peer's public key and its own private key, each device performs the algorithm specific key generation operation to obtain the shared secret. The shared secret is a ready-to-use symmetric key for further signed or encrypted exchanges between the two peers.

Genero Web Services provides several shared secret type for signature, encryption, or key encryption purposes. Using the Diffie-Hellman key agreement algorithm, one of the following types of shared secrets can be computed:

- Symmetric AES128 encryption key
- Symmetric AES192 encryption key
- Symmetric AES256 encryption key
- Symmetric TripleDES encryption key
- Symmetric key wrap AES128 key encryption key
- Symmetric key wrap AES192 key encryption key
- Symmetric key wrap AES256 key encryption key
- Symmetric key wrap TripleDES key encryption key
- Symmetric HMAC-SHA1 signature key

In the Diffie-Hellman key agreement algorithm, two shared constants (called parameters) are used in addition to the private and public key. These two parameters are:

- The modulus (called P): A very big prime number chosen at random.
- The generator (called g): A prime number between two and five. Genero Web Services only uses two (2) for the generator.

If the private key (Priv) is a big number (not necessarily prime) chosen randomly, the public key (Pub) is calculated using P, g, and Priv as follows:

$Pub = g^{Priv} \bmod P$

Both devices need to use the same parameters for P and g. There are two ways to ensure this happens: Either P and g are chosen by a third party (such as a security authority) or one of the devices chooses them and sends them to the other peer with its public key.

Genero Web Services allows the Web service to generate the parameters itself, to load them from a string or from a PEM or DER file. The public key and the parameters can also be exchanged using an XML file.

This diagram shows the Diffie-Hellman algorithm steps between two devices, A and B, that need to communicate. Device A is in charge of generating the parameters. The shared secret is labeled K.

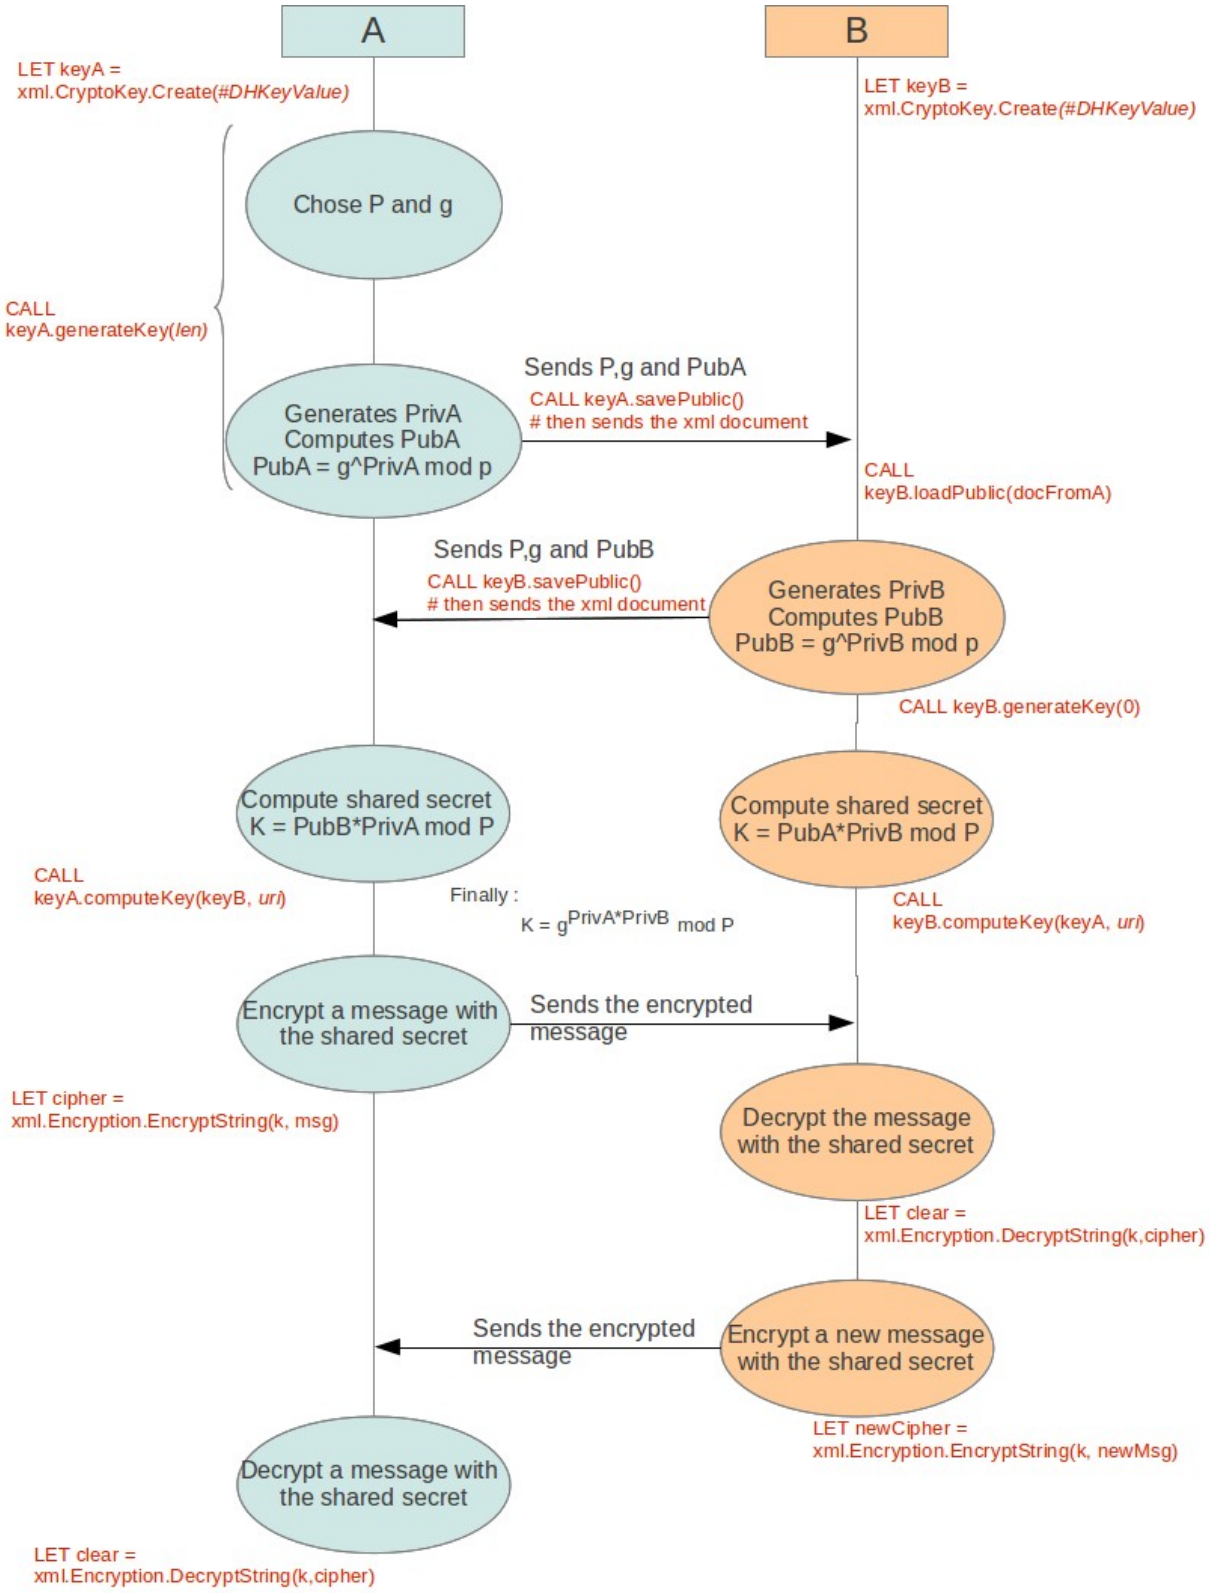

Figure 108: The Diffie-Hellman algorithm

For complete details about the mathematical basics underlying the Diffie-Hellman algorithm, see [RFC2631].

It is nearly impossible to get the private key from the public key, even knowing the values of parameters P and g. Therefore, a middle man will not be able to obtain the shared secret K. While devices A and B exchange their public key, and maybe the parameters as well, these values pass through different intermediate points. It is critical that A receives the correct public key from B, and that B receives the correct public key from A, in order to establish a common shared secret. A middle man could corrupt or replace one public key with his own. If that happens, A and B would be able to communicate because they won't compute the same shared secret. No secret data will be exchanged and readable to the middle man. To avoid this situation, one can use Digital Certificate that helps to deliver the public key and the parameters in an authenticated method.

Once the shared secret is established, the Diffie-Hellman public key, private key and parameters are no longer useful. The Diffie-Hellman key agreement algorithm is achieved.

With the library provided as part of Genero Web Services, the shared secret has been computed to fit given specifications such as HMAC, 3DES, AES128, AES192, AES256, KW-3DES, KW-AES128, KW-AES192, or KW-AES256. The shared secret is actually a symmetric key ready to be used in a signature (HMAC) or cipher algorithm. It allows devices A and B to finally communicate via an authenticated (HMAC) or encrypted method.

SOAP Web Services

Write a Web Services client or server using the SOAP protocol.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2009 and The xml package on page 2103.

Writing a Web Services client application

Create, configure and deploy a Genero Web Services client using the SOAP protocol.

- Steps to write a WS client on page 2450
- Change WS client behavior at runtime on page 2453
- WS client stubs and handlers on page 2456
- Using logical names for service locations on page 2462
- Configure a WS client to connect via an HTTP Proxy on page 2463
- Authenticate the WS client to a server on page 2464
- Authenticate the WS client to a proxy on page 2465
- Configure a WS client to access an HTTPS server on page 2466

Steps to write a WS client

The Genero Web Services package (GWS) allows a BDL program to access Web services found on the Internet. GWS supports the WSDL1.1 specification of March 15, 2002. This example illustrates a client application that accesses the Add operation in the GWS Web Service **MyCalculator**.

See Writing a Web server application on page 2473 for information about the Service.

- Obtaining the WSDL information on page 2450
- Calling a web service on page 2452
- Setting a time period for the response on page 2453
- Handling GWS server errors on page 2453
- Compiling the client application on page 2453

Obtaining the WSDL information

To access a remote Web service, you must get the WSDL information from the service provider. Sample services can be found through UDDI registries or on other sites such as XMethods (http://www.xmethods.net).

You can use the **fglwsdl** tool provided by the Genero Web Services package to obtain the necessary WSDL information. The following example obtains the WSDL information for the GWS Service MyCalculator created by the Writing a Web server application on page 2473:

```
fglwsdl -o Example2Client http://localhost:8090/MyCalculator?WSDL
```

This generates two files:

- `Example2Client.inc` - the globals file containing the definitions of the input and output records, and the prototypes of the operations.
- `Example2Client.4gl` - a module containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request.

  Note: The MyCalculator GWS Service must be running on the specified port in order to provide the WSDL information.

The following definitions were generated in the globals file, **Example2Client.inc**:

Input and Output records

```
DEFINE Add RECORD
  ATTRIBUTES( XMLName="Add",
              XMLNamespace="http://tempuri.org/webservices" )
  a INTEGER ATTRIBUTES( XMLName="a", XMLNamespace="" ),
  b INTEGER ATTRIBUTES( XMLName="b", XMLNamespace="" )
END RECORD

DEFINE AddResponse RECORD
  ATTRIBUTES( XMLName="AddResponse",
              XMLNamespace="http://tempuri.org/webservices" )
  r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="" )
END RECORD
```

Since BDL functions cannot have complex structures as parameters, the data types are defined as global or modular variables.

Function prototypes for the Operations

This globals file contains the prototype of two functions for the Add operation.

The **Add** function uses input and output parameters, and returns the status and result. This function can only be used if the input and output parameters are not complex structures such as arrays or records. Using this function, developers do not access the global records directly.

The **Add_g** function can be used with the global input and output records. Before calling this function, you must set the values in the variables of the global input record.

```
Operation: Add
#
# FUNCTION: Add_g()
# RETURNING: soapStatus
# INPUT: GLOBAL Add
# OUTPUT: GLOBAL AddResponse
#
# FUNCTION: Add(p_a, p_b)
# RETURNING: soapStatus ,p_r
```

See fglwsdl on page 1503 and WS client stubs and handlers on page 2456 for more details regarding the **fglwsdl** tool, its output and the generated functions.

Calling a web service

Step 1: Import the COM library of the GWS package

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). If you use any of these methods in your client application, you must import the library. Since this example application sets the timeout period that the client will wait for the Service to respond, include the following line at the top of the module:

```
IMPORT com
```

If your generated .inc file uses xml class data types, you need to add `IMPORT xml`.

Step 2: Specify the globals file

Use a GLOBALS statement to specify the generated globals file.

```
GLOBALS "Example2Client.inc"
```

Step 3: Write the MAIN program block

Provide values for the input and output messages of the operation, and call one of the generated functions. Since the input and output messages are simple integers, we can call the **Add** function.

```
MAIN
  DEFINE op1        INTEGER
  DEFINE op2        INTEGER
  DEFINE result     INTEGER
  DEFINE wsstatus   INTEGER

  LET op1 = 1
  LET op2 = 2
  CALL Add(op1, op2) RETURNING wsstatus, result
  IF wsstatus = 0 THEN
    DISPLAY "Result: ", result
  ELSE
    -- Use the global wsError record
    DISPLAY "Error: ", wsError.description
  END IF
END MAIN
```

Alternatively, we can use the global input and output records directly, calling the **Add_g** function:

```
MAIN
  DEFINE wsstatus INTEGER

  LET Add.a = 1
  LET Add.b = 2
  LET wsstatus = Add_g()
  IF wsstatus != 0 THEN
    -- Use the glocal wsError record
    DISPLAY "Error :", wsError.Description
  ELSE
    DISPLAY "Result: ", AddResponse.r
  END IF
END MAIN
```

These examples are very basic versions of the code. For complete examples, see the code samples provided with the package in **demo/WebServices**.

Setting a time period for the response

To protect against remote server failure or unavailability, set a timeout value that indicates how long you are willing to wait for the server to respond to your request.

Use the `SetOption()` method of the `WebServiceEngine` class to set the **readwritetimeout** option.

For example, to wait no more than 10 seconds:

```
CALL com.WebServiceEngine.SetOption( "readwritetimeout", 10 )
```

A timeout value of **-1** means "wait forever". This is the default value.

Handling GWS server errors

When a Genero Web Services Service operation returns a status that is non-zero, you can get a more detailed error description from the global record **wsError**.

This record is defined defined in the globals `.inc` file.

```
DEFINE wsError RECORD
  code STRING,          -- Short description of the error
  codeNS STRING,        -- The namespace of the error code
  description STRING,   -- Long description of the error
  action STRING         -- internal "SOAP action"
END RECORD
```

Compiling the client application

The library file `WSHelper.42m`, included in the `$FGLDIR/lib` directory of the Genero Web Services package, should be linked into every client or server program. Assuming the example client code shown above is in a module named `clientmain.4gl`, you can compile and link the client program:

```
fglcomp clientmain.4gl Example2Client.4gl
fgllink -o myclient.42r clientmain.42m Example2Client.42m WSHelper.42m
```

Change WS client behavior at runtime

Genero Web Services generates a global record called tGlobalEndpointType to change the client behavior at runtime without the need to modify any generated client stub. If WS-Addressing 1.0 is enabled, the global generated record is called tWSAGlobalEndpointType, and if needed you can also access the HTTP layer via the Request and Response record of the binding section.

- Global Endpoint type definition on page 2453
- WS-Addressing 1.0 Global Endpoint type definition on page 2454
- Change server location on page 2454
- Change the HTTP protocol version on page 2455
- Set an HTTP cookie on page 2455
- Set the connection timeout for a service on page 2455
- Set the read and write timeout for a service on page 2455
- Access HTTP request and response headers for a service on page 2455

Global Endpoint type definition

The following global type is used by any generated client stub to allow the programmer to change the client behavior at runtime.

```
TYPE tGlobalEndpointType RECORD # End point
      Address RECORD # Address
         Uri STRING # URI
      END RECORD,
      Binding RECORD # Binding
         Version STRING, # HTTP Version (1.0 or 1.1)
```

```
          Cookie STRING, # Cookie to be set
          ConnectionTimeout INTEGER,# Connection timeout
          ReadWriteTimeout INTEGER # Read write timeout
      END RECORD
END RECORD
```

Description of variables:

- `Address.Uri`: Represents the location of the server.

  Important: It replaces the global variable of type STRING generated prior to version 2.40, therefore it is mandatory to regenerate the client stub and to modify the location assignation in your application.
- `Binding.Version`: Represents the HTTP version to use for communication (only 1.0 or 1.1 allowed, default is 1.1).
- `Binding.Cookie`: Represents the HTTP cookie to use for communication (or NULL if there is no cookie to send).
- `Binding.ConnectionTimeout` : Represents the maximum time in seconds to wait for the establishment of the connection to the server.
- `Binding.ReadWriteTimeout`: Represents the maximum time in seconds to wait for a connection read or write operation before breaking the connection.

WS-Addressing 1.0 Global Endpoint type definition

The following global type is used by any generated client stub where support of WS-Addressing 1.0 is enabled. It allows the programmer to change the client behavior at runtime, and to send additional WS-Addressing 1.0 reference parameters to a server.

If this global type is used in your main application, you must add the `IMPORT xml` instruction.

```
TYPE tWSAGlobalEndpointType RECORD # End point
  Address RECORD # Address
    Uri STRING, # URI
    Parameters DYNAMIC ARRAY OF xml.DomDocument
      ATTRIBUTES(XMLNamespace="##any",XMLAny) # End point WSA reference
 parameters
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    ConnectionTimeout INTEGER,# Connection timeout
    ReadWriteTimeout INTEGER # Read write timeout
  END RECORD
END RECORD
```

Description of variables:

- `Address.Parameters`: Represents the WS-Addressing 1.0 reference parameter to send to a WS-Addressing 1.0 compliant server.

Change server location

To change the server location at runtime, set the record `Uri` member with a valid URL of another service. All services must respect the same WSDL contract. If you let the variable unset, the client will connect to the server URL defined in the WSDL at code generation time.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri =
  http://zeus:1111/mydomain/Calculator
```

You can assign this variable with a URL set in the FGLPROFILE (see Logical Service location).

If you are migrating from a version prior to 2.40, see the migration note.

Change the HTTP protocol version

To communicate with a service that speaks only a given version of HTTP, set the record `Version` member with the desired value. If you let the variable unset, the client will communicate in HTTP 1.1.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.Version = "1.0"
```

If you do not want the request to be split into chunks, set the HTTP protocol version to 1.0.

> **Important:** On GMI mobile devices, the HTTP protocol version definition is ignored, it will always be version 1.1.

Set an HTTP cookie

To send an HTTP cookie to the service, set the record `Cookie` member with the cookie value. If you let the variable unset, the client won't send any cookie.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.Cookie = "MyCookie=AValue"
```

Unset that variable if you don't need the cookie to be sent anymore.

Set the connection timeout for a service

To change the default timeout value for the establishment of the connection to the service, set the record `ConnectionTimeout` member with the timeout value in seconds.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.ConnectionTimeout = 15
```

> **Important:** On GMI mobile devices, the max of `ConnectionTimeout` and `ReadWriteTimeout` will be used.

Set the read and write timeout for a service

To change the default time of reading and writing to or from a service, set the record `ReadWriteTimeout` member with the time out value in seconds.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.ReadWriteTimeout = 5
```

> **Important:** On GMI mobile devices, the max of `ConnectionTimeout` and `ReadWriteTimeout` will be used.

Access HTTP request and response headers for a service

To access HTTP headers exchanged between the Genero client and a web service, you must use following records in the binding section :

- one record called `Request` in order to customize HTTP headers to be sent to a web service
- one record called `Response` in order to retrieve all HTTP headers returned by a web service

```
TYPE tGlobalEndpointWithHttpLayerType RECORD # End point
  Address RECORD # Address
    Uri STRING # URI
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
```

```
    Cookie STRING, # Cookie to be set
    Request RECORD
      Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
        Name   STRING,
        Value  STRING
    END RECORD,
    Response RECORD
      Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
        Name   STRING,
        Value  STRING
    END RECORD,
    ConnectionTimeout INTEGER,# Connection timeout
    ReadWriteTimeout INTEGER # Read write timeout
    CompressRequest  STRING # HTTP compression mode (gzip or deflate)
  END RECORD
END RECORD
```

Description of additional Request and Response variables:

- `Binding.Request.Headers`: Represents the additional HTTP headers to be sent to the web service. (Notice that client stub headers will replace user ones if the same name).
- `Binding.Response.Headers`: Represents the HTTP headers returned by a web service.

WS client stubs and handlers

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

- Generating stub files for a GWS Client on page 2456
- Handling GWS server errors on page 2453
- Global Endpoint user-defined type definition on page 2457
- The generated functions on page 2457
- The generated callback handlers on page 2458
- Example output on page 2459
- Using the generated functions on page 2461

Generating stub files for a GWS Client

Use the `fglwsdl` tool to generate the BDL stub from a WSDL URL or file.

The next example requests the Calculator Web Service information from the specified URL, and the output files will have the base name ws_calculator:

```
fglwsdl -o ws_calculator http://localhost:8090/Calculator?WSDL
```

For a client application, `fglwsdl` generates two output files, which should not be modified:

- *filename*.inc - the globals file, containing declarations of global variables that can be used as input or output for functions accessing Web Service operations, and the global wsError record. In our example, the file is `ws_calculator.inc`.

  This file must be listed in a GLOBALS statement at the top of any .4gl modules that you write for your GWS Client application.
- *filename*.4gl - containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request. In our example, the file is `ws_calculator.4gl`.

  This file must be compiled and linked into your GWS Client application.

Handling GWS server errors

When a Genero Web Services Service operation returns a status that is non-zero, you can get a more detailed error description from the global record **wsError**.

This record is defined defined in the globals `.inc` file.

```
DEFINE wsError RECORD
  code STRING,          -- Short description of the error
  codeNS STRING,        -- The namespace of the error code
  description STRING,   -- Long description of the error
  action STRING         -- internal "SOAP action"
END RECORD
```

Global Endpoint user-defined type definition

The fglwsdl tool generates the globals (inc) file to use for a Web services client. Part of this globals file is a global endpoint user-defined type definition.

```
#
# Global Endpoint user-defined type definition
#
TYPE tGlobalEndpointType RECORD   # End point
        Address RECORD # Address
           Uri STRING                # URI
        END RECORD,
        Binding RECORD # Binding
          Version STRING,             # HTTP Version (1.0 or 1.1)
          Cookie STRING,              # Cookie to be set
          ConnectionTimeout INTEGER,  # Connection timeout
          ReadWriteTimeout INTEGER,   # Read write timeout
          CompressRequest STRING      # HTTP request compression mode (gzip
 or deflate)
       END RECORD
     END RECORD

#
# Location of the SOAP endpoint.
# You can reassign this value at run-time.
#

DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

The `CompressRequest` entry is of type string. It is NULL by default, meaning that no request is compressed. To compress a request, set this variable to **gzip** or **deflate**. The server must support compression, otherwise the request will be rejected.

The generated functions

Genero Web Services (GWS) client functions have the following requirements:

- The function cannot have input parameters.
- The function cannot have return values.
- The function's input message must be defined as a global or module RECORD.
- The function's output message must be defined as a global or module RECORD.

As a result, two types of GWS functions are generated for the Web Service operation that you requested:

- One function type uses global records for the input and output. The names of these functions end in "_g". Before calling the function in your GWS Client application, you must set the values in the global input record. After the function call, the status of the request is returned from the server, and the output message is stored in the global output record. In addition to performing the desired operation, this function handles the communication for the SOAP request and response, and sets the values in the wsError record as needed.

- The other function type serves as a "wrapper" for the "_g" function. It passes the values of input parameters to the "_g" function, and returns the output values and status received from the "_g" function. Your client application does not need to directly access the global records. This function can only be used if the parameters are simple variables (no records or arrays).

The generated **.inc** globals file contains comments that list the prototypes of the functions for the GWS operation, and the definitions of the global INPUT and OUTPUT records.

The generated callback handlers

More and more Web Services provide support of the different **WS-*** specifications. To enable a better interoperability with such services, the fglwsdl tool allows the programmer to modify the SOAP request before it is sent, and to perform additional verifications of the SOAP response before it is returned from the BDL function.

When option **-domHandler** is used, the fglwsdl tool performs the following two operations at once:

- It generates the client stub based entirely on the DOM API to ease the manipulation of the XML requests and responses.
- It generates additional calls for each operation of a service to execute one of the three callback handlers the programmer has to implement.

Handler definition

There are three kind of callbacks you **must** implement for each service generated with the -domHandler option.

- The request handler that allows the modification of the entire SOAP request before it is send over the net.

  It must be named ***ServiceName*_HandleRequest**, where *ServiceName* is the name of the service according to the different prefix options used during generation.

  It must return **TRUE** if you want the caller function to continue normally or **FALSE** to return from the caller function with a SOAP error you can define via the **wsError** record.

```
FUNCTION ServiceName_HandleRequest(operation,doc,header,body)
  DEFINE operation STRING          -- Operation name of the
                                   -- request to be modified.
  DEFINE doc       xml.DomDocument -- Entire XML document of the request
  DEFINE header    xml.DomNode     -- XML node of the SOAP header
                                   -- of the request
  DEFINE body      xml.DomNode     -- XML node of the SOAP body of the
                                   -- request
  CASE operation
    WHEN "Add"
      ... -- Use the DOM APIs to modify the request of the Add operation
    WHEN "Sub"
      ... -- Use the DOM APIs to modify the request of the Sub operation
    OTHERWISE
      DISPLAY "No modification for operation :",operation
  END CASE
  RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

- The response handler that allows the validation of the entire SOAP response before it is de-serialized into the corresponding record.

  It must be named ***ServiceName*_HandleResponse**, where *ServiceName* is the name of the service according to the different prefix options used during generation.

  It must return **TRUE** if you want the caller function to continue normally or **FALSE** to return from the caller function with a SOAP error you can define via the **wsError** record.

```
FUNCTION ServiceName_HandleResponse(operation,doc,header,body)
```

```
  DEFINE operation STRING         -- Operation name of the
                                  -- response to be checked.
  DEFINE doc      xml.DomDocument -- Entire XML document of the response
  DEFINE header   xml.DomNode     -- XML node of the SOAP header of
                                  -- the response
  DEFINE body     xml.DomNode     -- XML node of the SOAP body of the
                                  -- response
  CASE operation
    WHEN "Add"
      ... -- Use the DOM APIs to check the response of the Add operation
    WHEN "Sub"
      ... -- Use the DOM APIs to check the response of the Sub operation
    OTHERWISE
      DISPLAY "No verification for operation :",operation
  END CASE
  RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

- The fault response handler that allows the verification of the entire SOAP fault response before it is de-serialized into the wsError record.

  It must be named ***ServiceName*_HandleResponseFault**, where *ServiceName* is the name of the service according to the different prefix options used during generation. It must return **TRUE** if you want the caller function to continue normally or **FALSE** to return from the caller function with a SOAP error you can define via the **wsError** record.

```
FUNCTION ServiceName_HandleResponseFault(operation,doc,header,body)
  DEFINE operation STRING          -- Operation name of the fault
                                   -- response to be checked.
  DEFINE doc       xml.DomDocument -- Entire XML document of the fault
 response
  DEFINE header    xml.DomNode     -- XML node of the SOAP header of the
                                   -- fault response
  DEFINE body      xml.DomNode     -- XML node of the SOAP body of the
 fault
                                   -- response
  CASE operation
    WHEN "Add"
      ... -- Use the DOM APIs to verify the SOAP fault response
          -- of the Add operation
    WHEN "Sub"
      ... -- Use the DOM APIs to verify the SOAP fault response
          -- of the Sub operation
    OTHERWISE
      DISPLAY "No verification for operation :",operation
  END CASE
  RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

Example output

The example Web Service for which the WSDL information was requested, Calculator, has an Add operation that returns the sum of two integers.

The generated file **ws_calculator.inc** lists the prototype for the **Add** and **Add_g** functions, the asynchronous **AddRequest_g** and **AddResponse_g** functions, as well as the definitions of the global variables **Add** and **AddResponse**:

```
# Operation: Add## FUNCTION: Add_g()  -- Function that uses the global input
                                     -- and output records
#   RETURNING: soapStatus            -- An integer where 0 represents
 success
#   INPUT: GLOBAL Add
```

```
#   OUTPUT: GLOBAL AddResponse
#
# FUNCTION: Add(p_a, p_b)             -- Function with input parameters
 that
#  RETURNING: soapStatus ,p_r         -- correspond to the a and b
 variables
                                      -- of the global INPUT record
                                      -- Return values are the status
 integer
                                      --  and the value in the r variable
 of
                                      -- the global OUTPUT record
#
# FUNCTION: AddRequest_g()            -- Asynchronous function that uses
 the
                                      -- global input record
#  RETURNING: soapStatus               -- An integer where 0 represents
#   INPUT: GLOBAL Add                  -- success, -1 error and -2 means
 that
                                      -- a previous request was sent
                                      -- and that a response is in progress.
#
# FUNCTION: AddResponse_g()           -- Asynchronous function that uses
                                      -- the global output record
#  RETURNING: soapStatus               -- An integer where 0 represents
#   OUTPUT: GLOBAL AddResponse         -- success, -1 error and -2 means that
                                      -- the response was not
                                      -- yet received, and that a new call
                                      -- should be done later.

#VARIABLE : Add   -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
                             XMLNamespace="http://tempuri.org/")
       a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
       b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
    END RECORD

# VARIABLE : AddResponse   -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
                          XMLNamespace="http://tempuri.org/")
       r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
    END RECORD
```

Multipart in the client stub

You can generate a client stub for a Web service that has multiple parts.

If the WSDL for a Web service indicates that the Web service uses multiple parts, the client stub generated will support multiple parts.

For the request

There are as many `com.HTTPPart` input parameters as parts defined for the input request, plus one `AnyInputParts DYNAMIC ARRAY OF com.HTTPPart` parameter, to manage the optional parts a user can add to the request.

For example:

```
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n, AnyInputParts)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
```

```
  RETURN wsstatus
END FUNCTION
```

For the response

There are as many `com.HTTPPart` variables are described in the WSDL, plus one `AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart` to handle the optional parts that may be returned by a service.

For example:

```
FUNCTION xxx_g()
  DEFINE wsstatus INTEGER
  DEFINE OutputHttpPart_1 com.HTTPPart
  DEFINE AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus, OutputHttpPart_1, AnyOutputParts
END FUNCTION
```

Using the generated functions

The information obtained from the **ws_calculator.inc** file allows you to write code in your own .4gl module as part of the Client application, using the Web Service operation Add.

Using parameters and return values

Since the input variables for our example are simple integers, you can call the **Add** function in your Client application, defining variables for the parameters and return values.

```
FUNCTION myWScall()
  DEFINE op1 INTEGER
  DEFINE op2 INTEGER
  DEFINE result INTEGER
  DEFINE wsstatus  INTEGER
  ...
  LET op1 = 6
  LET op2 = 8
  CALL Add(op1, op2)
    RETURNING wsstatus, result ...
  DISPLAY result
```

Using global records

You could choose to call the **Add_g** function instead, using the global records **Add** and **AddResponse** directly. If the input variables are complex structures like records or arrays, you are required to use this function.

```
FUNCTION myWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = Add_g()
  ...
  DISPLAY AddResponse.r
```

In this case, the status is returned by the function, which has also put the result in the **AddResponse** global record.

See Tutorial: Writing a Client Application for more information. The **demo/WebServices** subdirectory of your Genero installation directory contains complete examples of Client Applications.

Using asynchronous calls

If you don't want your application to be blocked when waiting for the response to a request, you should first call **AddRequest_g**; this will send the request using the global **Add** record to the server. It returns a status of 0 (zero) if everything goes well, -1 in case of error, or -2 if you tried to resend a new request before the previous response was retrieved.

```
FUNCTION sendMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = AddRequest_g()
  IF wstatus <> 0 THEN
    DISPLAY "ERROR :", wsError.code
  END IF
  ...
```

You can then call **AddResponse_g** to retrieve the response in the **AddResponse** global record of the previous request. If returned status is 0 (zero) the response was successfully received, -1 means that there was an error, and -2 means that the response was not yet received and that the function should be called later.

```
FUNCTION retrieveMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET wsstatus = AddResponse_g()
  CASE wstatus
    WHEN -2
      DISPLAY "No response available, try later"
    WHEN 0
      DISPLAY "Response is :",AddResponse.r
    OTHERWISE
      DISPLAY "ERROR :", wsError.code
  END CASE
  ...
```

You can mix the asynchronous call with the synchronous one as they are using two different requests. In other words, you can perform an asynchronous request with **AddRequest_g**, then a synchronous call with **Add_g**, and then retrieve the response of the previous asynchronous request with **AddResponse_g**.

> **Important:** In development mode, a single BDL Web Service server can only handle one request at a time, and several asynchronous requests in a row without retrieving the corresponding response will lead to a deadlock. To support several asynchronous requests in a row, it is recommended that you are in deployment mode with a GAS as the front end.

Using logical names for service locations

Genero Web Services, starting with version 2.00, provides a repository for Web Service locations using FGLPROFILE. To achieve maximum flexibility, you can map a logical reference used by your Web Services Client application to an actual URL. This is subject to the network configuration and access rights management of the deployment site.

> **Important:** On GMI mobile devices, FGLPROFILE settings for logical names are not supported.

- FGLPROFILE entry on page 2463
- Logical reference in the client application on page 2463
- Logical reference in the URL on page 2463

FGLPROFILE entry

The following entry in the FGLPROFILE file maps the logical reference "myservice" to an actual URL:

```
ws.myservice.url = " http://www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/
MyWebService"
```

Logical reference in the client application

When you generate a Client stub from WSDL information using the tool **fglwsdl**, a global variable for the URL of the Web Service is contained in the **.inc** file.

For example:

```
# Location of the SOAP server.
# You can reassign this value at run-time.
#
DEFINE Calculator_CalculatorPortTypeEndpoint tGlobalEndpointType
```

You can assign a logical name to this global variable in your Web Services Client application:

```
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri = "alias://myservice"
```

When the Client application accesses the Service, the actual location will be supplied by the entry in FGLPROFILE on the Client machine. This allows you to provide the same compiled .42r application to different customers. The entries in FGLPROFILE on each customer's machine would customize the Web Service location for that customer.

If you are migrating from a version prior to 2.40, see migration note.

Logical reference in the URL

When you deploy a Genero Web Service with a GAS behind a Web Server, the service can be accessed by two different URLs. You can use a logical name in the URL, mapping the actual location of the Web Service in FGLPROFILE, depending on the location of the client machine.

For example:

- For internal Clients: **http://zeus:6394/ws/r/myservice**
- For Clients using the Web: **http://www.myServer.com/...**

These two URLS could be mapped in the FGLPROFILE file on the Client machine, each specifying the location of the Service.

Configure a WS client to connect via an HTTP Proxy

Configuration steps to connect via a HTTP proxy.

> **Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add the location of the proxy to `fglprofile` with the `proxy.http.location` entry.

   Add the entry `proxy.http.location` to your `fglprofile`. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your `fglprofile`:

   ```
   proxy.http.location = "10.0.0.170:8080"
   ```

   > **Note:** To configure the client to connect via an HTTPS proxy, replace *http* with *https*.

2. Define the list of host names the client will **not** have to connect to via a proxy with the `proxy.http.list` entry.

Add the entry `proxy.http.list` to your `fglprofile`. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your `fglprofile`:

```
proxy.http.list = "www.mycompany.com;www.google."
```

Configure a WS client to use IPv6
Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access to a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in `[]` square brackets, for example:

```
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 otherwise. To overcome the default behavior, you can specify explicitely the IP version.

Indeed, the platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the `ip.global.version` entry in `fglprofile`, by specifying "4" for IPv4 or "6" for IPv6.

   For example, to force IPv4 (when IPv6 is available):

   ```
   ip.global.version = "4"
   ```

2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitely specify what interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in `fglprofile`.

   In order to specify the IPv6 network interface by name, use:

   ```
   ip.global.v6.interface.name = "eth0"
   ```

   > **Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft™ Windows™ platforms.

   In order to specify the IPv6 network interface by id, use:

   ```
   ip.global.v6.interface.id = "2"
   ```

Authenticate the WS client to a server
Configuration steps to authenticate the client to a server (HTTP authentication).

> **Important:** On GMI mobile devices, FGLPROFILE settings are ignored: Use the com.HTTPRequest.setAuthentication on page 2063 API instead.

1. Add HTTP authenticate entries to `fglprofile`.

   To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (`httpauth` in this example) to define a HTTP Authentication with "`mylogin`" as login and "`mypassword`" as password:

   ```
   authenticate.httpauth.login = "mylogin"
   authenticate.httpauth.password = "mypassword"
   ```

   See [RFC2617] for more details.

2. Encrypt the password.

   Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool `fglpass`, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:

a) Encrypt the clear text password with `fglpass` using the client certificate.

```
$ fglpass -e -c MyClient.crt
Enter password :mypassword
```

Note: **fglpass** outputs the encrypted password on the console but can be redirected to a file.

b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it (id1 in our case)

```
authenticate.id2.password.id1="HWTFu8QE2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS
+C
loiliGCwZvZ9eWpfmIWSON9IwoiJheYxfnu20uaGGmmiUGiHxT6341ePXNSicu32NtlVp9t6RcS0
wN/p9a6D4XtiD9iHW7iQvXhqC9uamd3gI9Q3GhHwXOMMlY//c8Y="
```

Note: Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for authenticate.id2.password.id1 is a single string with no spaces.

Note: The size of the encrypted password depends on the size of the public key, and can change according to the certificate used to encrypt it.

3. Configure the client to authenticate to a server.

As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that correspond to each server. To authenticate the client known as "myclient" and with the password **passphrase** by the server **myserver**, add the following entry:

```
ws.myserver.authenticate = "httpauth"
```

Authenticate the WS client to a proxy

Configuration steps to authenticate the client to a proxy (proxy authentication).

Important: On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to `fglprofile`.

To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.

The following two entries must be defined with an unique identifier (**proxyauth** for our example) to define a HTTP Proxy Authentication with **myapplication** as login and **mypassword** as password:

```
authenticate.proxyauth.login = "myapplication"
authenticate.proxyauth.password = "mypassword"
```

See [RFC2617] for more details.

2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.

To authenticate a client known as **myapplication** and with **mypassword** as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:

```
proxy.http.authenticate = "proxyauth"
```

Note: To authenticate the client to a HTTPS proxy, replace *http* with *https*.

Configure a WS client to access an HTTPS server

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you will need to configure for the client certificate, configure for the certificate authority list, and the add additional entries for the server to the `fglprofile`.

> **Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device KeyChain must hold the server certificate authority.

1. Configure for the client certificate. See Configure for the client certificate on page 2466.
2. Configure for the certificate authority list. See Configure for the certificate authority list on page 2467.
3. Add configuration entries for the server to `fglprofile`.

   The Genero Web Services client needs a set of configuration entries that specify the security configuration and the HTTP authentication when accessing an HTTPS server. The following entries must be defined with an unique identifier (such as **myserver**) :

   ```
   ws.myserver.url =
   "https://www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/MyWebService"
   ws.myserver.security = "id1"
   ```

   (line breaks added for document readability)

   - The unique identifier **myserver** can be used in the BDL client code in place of the actual URL.
   - The security entry value (`id1` in this example) must match the unique identifier defined by the client security entry created in 3 on page 2467.

Configure for the client certificate

You generate a client certificate and configure your application to use the client certificate generated. For production systems, you add the configuration details to `fglprofile`.

During development, if you do not have the certificate information in your `fglprofile`, Genero creates a certificate for you. When you move into production, however, the server provides a certificate for you, and you need to add the certificate information to the `fglprofile`.

1. Create the root certificate authority.
   a) Create the root certificate authority serial file.
      ```
      $ echo 01 > MyCompanyCA.srl
      ```
   b) Create the Root Authority's Certificate Signing Request and private key.
      ```
      $ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
      ```
   c) Create the Root Certificate Authority for a period of validity of 2 years.

      (line breaks added for document readability)

      ```
      $ openssl x509 -trustout -in MyCompanyCA.csr
      -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem
      -days 730
      ```

      (line breaks added for document readability)

      > **Note:** The private key file (`MyCompanyCA.pem`) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.
2. Create the client's X.509 certificate and private key.
   a) Create the client serial file.
      ```
      $ echo 01 > MyClient.srl
      ```
   b) Create the client's Certificate Signing Request and private key.
      ```
      $ openssl req -new -out MyClient.csr
      ```

Note: By default, `openssl` outputs the private key in the `privkey.pem` file.

c) Remove the password from the RSA private key.

```
$ openssl rsa -in privkey.pem -out MyClient.pem
```

Note: The key is also renamed in `MyClient.pem`.

d) Create the client's Certificate trusted by the Root Certificate Authority (self-signed X.509 certificate valid for a period of 1 year).

(line breaks added for document readability)

```
$ openssl x509 -in MyClient.csr -out MyClient.crt -req
-signkey MyClient.pem -CA MyCompanyCA.crt
-CAkey MyCompanyCA.pem -days 365
```

Note: Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessary need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates.

Note: The purpose of the client's Certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.

Note: To import the certificate in a keystore you can create a pkcs12 certificate.

3. Add the client's security configuration to `fglprofile`.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during communication with an HTTPS communication. The security entry must be defined with an unique identifier (**id1**in this example).

```
security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"
```

Note: If the private key is protected with a password, you must remove it or create a script that returns the password on demand.

A client certificate is created and your application is configured to use it. The client certificate is not self-signed but issued by a company, created with a root certificate.

Configure for the certificate authority list

When a client accesses a server with a certificate, the server sends back its certificate. The client needs to check to see if that certificate is trusted. This is done using a certificate authority list.

1. Create the client's certificate authority list.

a) Save the certificate of the HTTPS server to disk.

Type the server's URL in your Internet browser. When prompted, save the certificate to disk.

b) Create the client's Certificate Authority List from the certificate that you saved to disk.

```
$ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem
```

Note: All trusted certificate authorities are listed. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client.

2. Set the global certificate authority list in `fglprofile`.

The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

```
security.global.ca = "ClientCAList.pem"
```

If `security.global.ca` is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise `security.global.ca.lookuppath` will be used.

The client application is configured to use the appropriate certificate authority list to validate a server's certificate.

Writing a Web Services server application

These topics cover creating a Genero Web Services server using the SOAP protocol.

- Writing a Web services server function on page 2468
- WS server stubs and handlers on page 2470
- Writing a Web server application on page 2473
- Get HTTP headers information at WS server side on page 2481
- Choosing a web services style on page 2483
- Web services server program deployment on page 2506
- Configuring the apache web server for HTTPS on page 2507

Writing a Web services server function

Writing a Web service with Genero is quite simple. You create a standard Genero function and publish it as a Web function (Web services operation) using methods from the classes in the COM library. There are restrictions on the function - input and output parameters are not allowed. By using global or module variables, however, to work around this exception.

See also Tutorial: Writing a GWS Server Application

The steps for writing a Web Services function:

1. Define the input parameters on page 2468
2. Define the output parameters on page 2469
3. Write the BDL function on page 2469
4. Create and publish the Web services operation on page 2469

Define the input parameters

As stated in the introduction, input parameters in Genero Web Service operations are not allowed. However, each Web Function can have one global variable or module variable that defines the input message of the function. This variable must be a record in which each field represents one of the input parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

Example

```
DEFINE add_in RECORD
  a INTEGER,
  b INTEGER
END RECORD
```

Note: Genero version 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

Define the output parameters

Output parameters in Genero Web Functions are not allowed, but each Web Function can have one global variable or module variable that defines the output message of the function. This message must be a record where each field represents one of the output parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

Example

```
DEFINE add_out RECORD
  r INTEGER
END RECORD
```

Note: GWS 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

Write the BDL function

A Web Function is a normal BDL function that uses the input and output records that you have defined.

Example

```
FUNCTION add()
   LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

Create and publish the Web services operation

Methods are available in the Genero Web Services library (**com**) to:

- Define the Web Service, by creating a WebService object
- Define the Web Services operation for your function, by creating a WebOperation object
- Publish the operation - associate it with the Web Service object that you defined.

The **com** library must be imported into each module of a Web Services Server application.

The following abbreviated example is from the Web Services Server tutorial:

```
IMPORT com
...
FUNCTION createservice()
    DEFINE serv  com.WebService    # A WebService
    DEFINE op    com.WebOperation  # Operation of a WebService

   --Create WebService object
   LET serv = com.WebService.CreateWebService("MyCalculator",
                       "http://tempuri.org/webservices")

   --Create WebOperation object
   LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)

   --Publish the operation, associating it with the WebService object
   CALL serv.publishOperation(op,NULL)
...
END FUNCTION
```

See the Web Services Server tutorial and Choosing a Web Service Style for complete examples and explanations.

WS server stubs and handlers

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

Generating files for a GWS server

You can write a Genero Web Services Server application for a Web Service that you have created; see Tutorial: Writing a Server Application.

If you want to make sure your Web Service is compatible with that of a third-party (an accounting application vendor, for example), you can use the **fglwsdl** tool to obtain the WSDL information that complies with that vendor's standards, and to generate corresponding files that can be used in your GWS Server application.

This example requests the Calculator Web Service information from the specified URL, and the output files will have the base name "ws_calculator".

```
fglwsdl -s -o ws_calculator http://localhost:8090/Calculator?WSDL
```

For a server application, fglwsdl generates two files, which should not be modified:

- *filename*`.inc` - the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations. In our example, the file is **ws_calculatorService.inc**.

  This file must be listed in a GLOBALS statement at the top of any .4gl modules that you write for your GWS Server application.
- *filename*`.4gl` - containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service. In our example, the file is **ws_calculatorService.4gl**.

  This file must be compiled and linked into your GWS Server application.

Server handlers

The COM library enables to intercept high-level web services operation on server side. You can now define three BDL functions via the following methods of the web service class. They will be executed at different steps of a web service request processing in order to modify the SOAP request, response or the generated WSDL document before or after the SOAP engine has processed it. This helps handle **WS-*** specifications not supported in the web service API.

- Method **registerWSDLHandler()**
- Method **registerInputRequestHandler()**
- Method **registerOutputRequestHandler()**

All three kinds of BDL callback functions must conform to this prototype:

```
FUNCTION CallbackHandler( doc xml.DomDocument )
   RETURNING xml.DomDocument
```

Example 1: Modify the generation of a WSDL

Register your handler with:

```
CALL serv.registerWsdlHandler("WSDLHandler")
```

where serv is of class *com.WebService* and *WSDLHandler* is the following function:

```
FUNCTION WSDLHandler(wsdl)
  DEFINE wsdl Xml.DomDocument
  DEFINE node Xml.DomNode
  DEFINE list Xml.DomNodeList
  DEFINE ind  INTEGER
  DEFINE name STRING
  # Add a comment
  LET node = wsdl.createComment(
             "First modified WSDL via a BDL callback function")
  CALL wsdl.prependDocumentNode(node)
  # Rename input and output parameter in UPPERCASE
  LET list = wsdl.selectByXPath(
             "//wsdl:definitions/wsdl:types/xsd:schema/
xsd:complexType/xsd:sequence/xsd:element/xsd:complexType/
xsd:sequence/xsd:element",NULL)
-- first input parameter for selectByXPath above
-- one string, no spaces!
  FOR ind=1 TO list.getCount()
    LET node = list.getItem(ind)
    LET name = node.getAttribute("name")
    LET name = name.toUpperCase()
    CALL node.setAttribute("name",name)
  END FOR
  RETURN wsdl
END FUNCTION
```

If NULL is returned from the callback function, an HTTP error will be sent and the ProcessServices() returns error code -20.

Example 2: Change the SOAP incoming request

Register your handler with:

```
CALL serv.registerInputRequestHandler("InputRequestHandler")
```

where serv is of class *com.WebService* and *InputRequestHandler* is this function:

```
FUNCTION InputRequestHandler(in)
  DEFINE in Xml.DomDocument
  DEFINE ind  INTEGER
  DEFINE node Xml.DomNode
  DEFINE copy Xml.DomNode
  DEFINE tmp  Xml.DomNode
  DEFINE parent Xml.DomNode
  DEFINE name STRING
  DEFINE list Xml.DomNodeList
  # Change input parameter below myrecord in lower case
  # to follow high-level web service
  LET list = in.SelectByXPath(
    "//SOAP:Envelope/SOAP:Body/fjs:EchoDOCRecordRequest/fjs:myrecord/*",
    "SOAP","http://schemas.xmlsoap.org/soap/envelope/",
    "fjs","http://www.mycompany.com/webservices")
  FOR ind = 1 TO list.getCount()
    LET node = list.getItem(ind)
    LET parent = node.getParentNode()
    LET name = node.getLocalName()
    LET copy = in.createElementNS(node.getPrefix(),
      name.toLowerCase(),node.getNamespaceURI())
    LET tmp = node.getFirstChild()
    LET tmp = tmp.clone(true)
```

```
    CALL copy.appendChild(tmp)
    CALL parent.replaceChild(copy,node)
  END FOR
  RETURN in
END FUNCTION
```

If NULL is return from the callback function, a SOAP fault will be sent (but can be changed from the output handler) and the ProcessServices() returns error code -18.

Example 3: Modify the SOAP outgoing request

Register your handler with:

```
CALL serv.registerOutputRequestHandler("OutputRequestHandler")
```

where serv is of class *com.WebService* and *OutputRequestHandler* is this function:

```
FUNCTION OutputRequestHandler(out)
  DEFINE out Xml.DomDocument
  DEFINE ind  INTEGER
  DEFINE node Xml.DomNode
  DEFINE copy Xml.DomNode
  DEFINE tmp  Xml.DomNode
  DEFINE parent Xml.DomNode
  DEFINE name STRING
  DEFINE list Xml.DomNodeList
  # Change output parameter below myrecord in uppercase
  # before sending back to the client
  LET list = out.SelectByXPath(
    "//SOAP:Envelope/SOAP:Body/fjs:EchoDOCRecordResponse/fjs:myrecord/*",
    "SOAP","http://schemas.xmlsoap.org/soap/envelope/",
    "fjs","http://www.mycompany.com/webservices")
  FOR ind = 1 TO list.getCount()
    LET node = list.getItem(ind)
    LET parent = node.getParentNode()
    LET name = node.getLocalName()
    LET copy = out.createElementNS(node.getPrefix(),name.toUpperCase(),
      node.getNamespaceURI())
    LET tmp = node.getFirstChild()
    LET tmp = tmp.clone(true)
    CALL copy.appendChild(tmp)
    CALL parent.replaceChild(copy,node)
  END FOR
  RETURN out
END FUNCTION
```

If NULL is return from the callback function, a SOAP fault will be sent and the ProcessServices() returns error code -19.

Example output

In the generated file **ws_calculatorService.inc**, the definitions of the variables for the input and output record are the same as those generated for the Web Service Client application:

```
#VARIABLE : Add -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
                             XMLNamespace="http://tempuri.org/")
  a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
  b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse -- defines the global OUTPUT record
```

```
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
                                     XMLNamespace="http://tempuri.org/")
  r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
END RECORD
```

The generated file **ws_calculatorService.4gl** contains a single function that creates the Calculator service, creates and publishes the service operations, and registers the Calculator service:

```
FUNCTION Createws_calculatorService()
  DEFINE service com.WebService
  DEFINE operation com.WebOperation
  ...  # Create Web Service
  LET service = com.WebService.CreateWebService("Calculator",
    "http://tempuri.org/")
  # Publish Operation : Add
  LET operation = com.WebOperation.CreateRPCStyle("Add","Add",
    Add,AddResponse)
  CALL service.publishOperation(operation,"")  ...
  # Register Service
  CALL com.WebServiceEngine.RegisterService(service)
  RETURN 0
  ...
END FUNCTION
```

Writing your functions

The ws_calculator.inc file provides you with the global input and output records and function names that allow you to write your own code implementing the Add operation. Your new code should not be written in the generated modules. For example, do not add your own version of the Add function to the generated ws_calculator.4gl module; it can be included in your module containing the MAIN program block, or in a separate module to be included as part of the Web server application. The function must use the generated definitions for the global input and output records.

In your version of the operation, this function adds 100 to the sum of the variables in the input record:

```
FUNCTION Add()
  LET AddResponse.r = (Add.a + Add.b) + 100
END FUNCTION
```

See Tutorial: Writing a Server application for more information. The **demo/WebServices** subdirectory of your Genero installation directory contains complete examples of Server Applications.

Writing a Web server application

This tutorial guides you through the steps to create a Server application for a Genero Web Service that can be accessed over the web by Client applications. A complete example is provided at `$FGLDIR/demo/WebServices`.

You can write your Server application based on input/output records that you have defined. Or, you can use the **fglwsdl** tool to include third-party WSDL information in your Server application.

Including the web services library

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). Include this line at the top of each module of your GWS Server application to import the library:

```
IMPORT com
```

Example 1: Writing the entire server application

You can define a Web Service in your application and write definitions for the input and output records that will be used by the Service. This example illustrates a Service that has one operation, **Add**, to provide the sum of two numbers.

- Step 1: Define input and output records on page 2474
- Step 2: Write a BDL function for each service operation on page 2474
- Step 3: Create the service and operations on page 2474
- Step 4: Register the service on page 2476
- Step 5: Start the GWS server and process requests on page 2476

Step 1: Define input and output records

Based on the desired functionality of the operations that you plan for the Service, define the input and output records for each operation. BDL functions that are written to implement a Web Service operation cannot have input parameters or return values. Instead, each function's input and output message must be defined as a global or module RECORD.

The Input message

The fields of the global or module record represent each of the input parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

The Output message

The fields of the global or module record represent each of the output parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

Your Genero Web Services service has one planned operation that adds two integers and returns the result. The input and output records are defined as follows:

```
GLOBALS
  DEFINE
    add_in RECORD   # input record
      a INTEGER,
      b INTEGER
    END RECORD,
    add_out RECORD  # output record
      r INTEGER
    END RECORD
END GLOBALS
```

Step 2: Write a BDL function for each service operation

You will need to write a function to implement each operation, using the input and output global records.

To implement your **Add** operation:

```
#User Public Functions
FUNCTION add()
  LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

Step 3: Create the service and operations

The Genero Web Services library (**com**) provides classes and methods that allow you to use Genero BDL to configure a Web Service and its operations.

- **WebService** - this is a container for web operations.
- **WebOperation** - describes the operation.

Define variables for the WebService and WebOperation objects

```
FUNCTION createservice()
  DEFINE serv  com.WebService    # A WebService
  DEFINE op    com.WebOperation  # Operation of a WebService
```

Choose a Namespace

XML uses namespaces to group the element and attribute definitions, and to avoid conflicting names. In practice, a namespace must be a unique identifier (URI: Uniform Resource Identifier). If you do not know the unique identifier to use, your company's Web site domain name is guaranteed to be unique (such as "www.mycompany.com"); then, append any string.

Examples of valid namespaces for the fictional My Company company:

- **"http://www.mycompany.com/MyServices"**
- **"http://www.mycompany.com/any_string"**

Another option (for testing only) is to use the temporary namespace "http://tempuri.org/".

Create the WebService object

Call the constructor method of the WebService class. The parameters are:

1. Service name
2. Valid namespace

This example uses the temporary namespace and creates a Service named "MyCalculator".

```
LET serv =
  com.WebService.CreateWebService("MyCalculator", "http://tempuri.org/
webservices")
```

Create the WebOperation object

A WebService object can have multiple operations. The operations can be created in RPC style or Document style by calling the corresponding constructor method of the WebOperation class. The parameters are:

1. the name of the BDL function that is executed to process the XML operation
2. the name you wish to assign to the XML operation
3. the input record defining the input parameters of the operation (or NULL if there is none)
4. the output record defining the output parameters of the operation (or NULL if there is none)

To create the operation for the previously defined **add** function in RPC style:

```
LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)
```

To create the operation for the previously defined **add** function in Document style:

```
LET op = com.WebOperation.CreateDOCStyle("add", "Add", add_in, add_out)
```

Mixing RPC style and Document style operations in the same service is not recommended, as it is not WS-I compliant. See Web Services Styles for additional information about styles.

The rest of the code in your application is the same, regardless of the Web Services style that you have chosen.

Publish the operation

Once an operation is defined, it must be associated with its corresponding WebService (the operation must be published). The publishOperation method of the WebService object has the following parameters:

- the WebOperation to be published
- a string to identify the operation if several operations have the same name; if this is NULL, the default value is an empty string

For example, to publish the **Add** operation of the **Calculator** service, which was defined as **op**:

```
CALL serv.publishOperation(op,NULL)
```

Step 4: Register the service

Once the Service and operations are defined and the operations are published, the WebService and WebOperation objects have completed their work. Registering a service puts the Genero DVM in charge of the execution of all the operations of that service - dispatching the incoming message to the right service, returning the correct output, and so on. The same service may be registered at different locations on the Web.

The WebServiceEngine is a global built-in object that manages the Server part of the Genero DVM. Use the **RegisterService** class method of the WebServiceEngine class. The parameter is:

1. The name of the WebService object

To register the Calculator service example created in Step 3: Create the service and operations on page 2474:

```
CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION
```

> **Note:** If you wanted to create a single GWS Server DVM containing multiple Web Services, you could define additional input and output records and repeat steps 2 through 6 for each Web Service. In Step 5: Start the GWS server and process requests on page 2476, a GWS Server DVM is started, containing as many Web Services as you have defined. See Web services server program deployment on page 2506 for additional discussion of GWS Services and GWS Servers.

Step 5: Start the GWS server and process requests
Once you have registered the Web Service(s), you are ready to start the Genero Web Services (GWS) Server and process the incoming SOAP requests.

The GWS Server is located on the same physical machine where the application is being executed (In other words, where `fglrun` executes).

This is the `MAIN` program block of your application.

Define a variable for status

Define a variable to hold the returned status of the request:

```
MAIN
  DEFINE ret INTEGER
```

Call the function that you created, which defined and registered the service and its operations:

```
  CALL createservice()
```

Start the GWS Server

Use the `Start` class method of the `WebServiceEngine` class to start the server.

```
  CALL com.WebServiceEngine.Start()
```

Process the requests

This example uses the `ProcessServices` method of the `WebServiceEngine` class to process each incoming request. It returns an integer representing the status. The parameter specifies the timeout period (in seconds) for which the method should wait to process a service. The value -1 specifies an infinite waiting time.

```
  WHILE TRUE
    # Process each incoming requests (infinite loop)
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
      WHEN 0
        DISPLAY "Request processed."
      WHEN -1
        DISPLAY "Timeout reached."
      WHEN -2
        DISPLAY "Disconnected from application server."
        EXIT PROGRAM
      WHEN -3
        DISPLAY "Client Connection lost."
      WHEN -4
        DISPLAY "Server interrupted with Ctrl-C."
      WHEN -10
        DISPLAY "Internal server error."
        EXIT PROGRAM
      WHEN -15
        DISPLAY "Server was not started."
        EXIT PROGRAM
      OTHERWISE
        DISPLAY "ERROR: ", STATUS, SQLCA.SQLERRM
    END CASE
    IF int_flag<>0 THEN
      LET int_flag=0
      EXIT WHILE
    END IF
  END WHILE

  DISPLAY "Server stopped"

END MAIN
```

> **Note:** For testing purposes only, the GWS Server can be started in standalone mode. In a production environment, the Genero Application Server (GAS) is required to manage your application. For deployment, the GWS Server application must be added to the GAS configuration. See *Adding Applications* in the *Genero Application Server User Guide*.

Example 2: Writing a server using third-party WSDL (the fglwsdl tool)

To write a Web Service that is compatible with the specification of the input and output records defined by a third-party (for example, a vendor of manufacturing software, or a WSDL specialist in your company) you can use the `fglwsdl` tool to obtain the WSDL information and generate a part of the Server application. See fglwsdl on page 1503 for a complete description of the tool and its use.

- Step 1: Get the WSDL description and generate files on page 2478
- Step 2: Write a BDL function for your service operation on page 2479
- Step 3: Create service, start server and process requests on page 2479

Step 1: Get the WSDL description and generate files

This tutorial uses fglwsdl and the Calculator Service defined in Example 1: Writing the entire server application on page 2474 to obtain the WSDL information and generate two corresponding BDL files:

- the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations.
- a .4gl file containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service.

```
fglwsdl -s -o example1 http://localhost:8090/MyCalculator?WSDL
```

> **Note:** the MyCalculator Genero Web Services Service created in Example 1: Writing the entire server application on page 2474 must be running in order to obtain the WSDL information.

The generated globals file

The globals file **example1Service.inc** provides the definition of the global input and output records as described in the Step 1: Define input and output records on page 2474 of the Example 1: Writing the entire server application on page 2474 GWS Server program. The names of the input and output records have been assigned by **fglwsdl**, in accordance with the Style of the Web Service MyCalculator (created as RPCStyle in the Example1 program). Do not modify this file.

Input and output records:

```
# VARIABLE : Add
DEFINE Add RECORD
           ATTRIBUTES( XMLName="Add",
                       XMLNamespace="http://tempuri.org/webservices" )
  a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
  b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse
DEFINE AddResponse RECORD
                   ATTRIBUTES(XMLName="AddResponse",
                              XMLNamespace="http://tempuri.org/webservices" )
  r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
END RECORD
```

The generated .4gl file

The **example1Service.4gl**file contains a single function that creates the service, publishes the operation, and registers the Service. The Web Service Style that is created is determined by the style specified in the WSDL information. The functions in this file accomplish the same tasks as Step 3: Create the service and operations on page 2474 and Step 4: Register the service on page 2476 of Example 1. Do not modify this file.

```
# example1Service.4gl
# Generated file containing the function Createexample1Service

IMPORT com
GLOBALS "example1Service.inc"

# FUNCTION Createexample1Service
#   RETURNING soapstatus
FUNCTION Createexample1Service()
DEFINE service      com.WebService
DEFINE operation    com.WebOperation
  # Set ERROR handler
WHENEVER ANY ERROR GOTO error
```

```
  # Create Web Service
LET service = com.WebService.CreateWebService(
                             "MyCalculator",
                             "http://tempuri.org/webservices")
  # Operation: Add
  # Publish Operation : Add
LET operation = com.WebOperation.CreateRPCStyle(
                                "Add",
                                "Add",
                                Add,
                                AddResponse)
CALL service.publishOperation(operation,"")
  # Register Service
CALL com.WebServiceEngine.RegisterService(service)
RETURN 0
  # ERROR handler
LABEL error:
RETURN STATUS
  # Unset ERROR handler
WHENEVER ANY ERROR STOP
END FUNCTION
```

Step 2: Write a BDL function for your service operation

Using the information from these generated files, the Add operation from Example 1: Writing the entire server application on page 2474 is rewritten to have different functionality but to still be compatible with the WSDL description of the operation. This step accomplishes the same thing as Step 2: Write a BDL function for each service operation on page 2474 in Example 1. In this version of the add operation, the sum of the two numbers in the input record is increased by 100.

```
# my_function.4gl                           -- file containing the function
                                            -- definition
IMPORT com                                  -- import the Web Services library

GLOBALS "example1Service.inc"               -- use the generated globals file
#User Public Functions
FUNCTION add()                              -- new version of the add function
LET AddResponse.r = (Add.a + Add.b)+ 100    -- the global input and output
                                            -- records are used
END FUNCTION
```

Step 3: Create service, start server and process requests

Create your own Main module that calls the function from the generated .4gl file to create the service, and then starts the Genero Web Services Server and manages requests as in Step 5: Start the GWS server and process requests on page 2476 of Example 1: Writing the entire server application on page 2474.

```
# example2main.4gl file -- contains the MAIN program block

IMPORT com

GLOBALS "example1Service.inc"

MAIN
   DEFINE create_status INTEGER

   DEFER INTERRUPT

   CALL Createexample1Service()  -- call the function generated
                                 -- in example1Service.4gl
      RETURNING create_status
   IF create_status <> 0 THEN
      DISPLAY "error"
```

```
   ELSE
      # Start the server and manage requests
      CALL ManageService()
   END IF

END MAIN

FUNCTION ManageService()
   DEFINE ret INTEGER
   CALL com.WebServiceEngine.start()
   WHILE TRUE
   # continue as in Step 5 of Example 1
   ...
END FUNCTION
```

Compiling GWS server applications

The library file `WSHelper.42m`, included in the $FGLDIR/lib directory of the Genero Web Services package, should be linked into every GWS Server application.

If your application uses the `fglwsdl` tool to generate information, link the .4gl generated file into the application.

Examples

Compiling the Example 1: Writing the entire server application on page 2474 program:

```
fglcomp example1.4gl
fgllink -o example1.42r example1.42m WSHelper.42m
```

Compiling the Example 2: Writing a server using third-party WSDL (the fglwsdl tool) on page 2477 program:

```
fglcomp example2main.4gl my_function.4gl example1Service.4gl
fgllink - o example2.42r example2main.42m my function.42m
   example1Service.42m WSHelper.42m
```

Testing the GWS service in stand-alone mode

For testing and development purposes only, the Genero Web Services Server application can be executed directly, without using the Genero Application Server (GAS).

1. Use the Genero `fglrun` command to execute the GWS Server application, which must reside on the same machine:

   ```
   fglrun <gws application>
   ```

   This will start the GWS Server on the port specified by the FGLAPPSERVER environment variable. If this environment variable is not set for the user, port number 80 is used. For example, if FGLAPPSERVER is set to 8090, the server will be started on that port.

   > **Note:** The user must not set the FGLAPPSERVER variable in production environments, since the port number is selected by the Genero Application Server.

2. Obtain the WSDL information for your Service and write a test Client application. If the GWS Server in step 1 was started on your local machine, for example, the command to get the WSDL information would be:

   ```
   fglwsdl -o <test-client> http://localhost:8090/<service-name>?WSDL
   ```

Configuring the Genero application server for the GWS Application

The final step is to configure the Genero Application Server (GAS) to handle the GWS application. In a production environment, Genero Web Services becomes a part of a global application architecture handled by the application server of the **GAS** package. See Web services server program deployment on page 2506, as well as *Adding Applications* in the GAS manual.

Making the GWS service available

Once you compile and deploy your Genero Web Services Server application (see Web services server program deployment on page 2506), it can be used by others to obtain the WSDL information and write a client application that accesses your Genero Web Service. See Steps to write a WS client on page 2450.

Your company can provide the location of the GWS Server to potential users of your Web Service in various ways. For example:

- Provide the location on a company web site
- Register the Web Service with UDDI (Universal Description, Discovery, and Integration) - the XML-based registry providing Internet listings for companies worldwide
- Communicate directly with your potential users

Get HTTP headers information at WS server side

In high level web services, we now give access to the HTTP headers request and response.

The web service can get information from the request headers and reply with custom headers and status.

1. Declare variables to receive or send HTTP headers.
2. Register these variables to the web service server.

Declare variables to receive or send HTTP headers

The variable for the request headers:

```
DEFINE http_in RECORD
           verb STRING,
           url STRING,
           headers DYNAMIC ARRAY OF RECORD
                     name STRING,
                     value STRING
                   END RECORD
           END RECORD
```

After the web service operation has been processed, the variable is set to NULL.

The variable for the response headers:

```
DEFINE http_out RECORD
           code INTEGER,
           desc STRING,
           headers DYNAMIC ARRAY OF RECORD
                     name STRING,
                     value STRING
                   END RECORD
         END RECORD
```

After the web service operation has been processed, the variable is set to NULL.

> **Note:** While the variables must follow the structure shown, the variable name can be any name you choose.

The web service engine headers have precedence. For example, if you set the "Content-Length" value, the one that is taken into account is the one defined by the Genero Web Services engine.

Register the variables to the server

This code example uses two methods, which use the defined variables:

- `com.WebService.registerInputHttpVariable(`*`http_in`*`)` where *http_in* is the RECORD variable for the request headers.
- `com.WebService.registerOutputHttpVariable(`*`http_out`*`)` where *http_out* is the RECORD variable for the response headers

Example

```
FUNCTION CreateService()

  LET http_out.headers[1].value = "MyPersonalValue"

END FUNCTION
```

Choosing a web services style

Genero Web Services 2.0 allows you to create Web Services operations in the following styles:

Table 555: Web Services Styles

Web Services Style	Description
RPC Style Service (RPC/Literal)	Generally used to execute a function, such as a service that returns a stock option.
Document Style Service (Doc/Literal)	Generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (Web Services Interoperability organization).
RPC Style Service (RPC/Encoded)	Provided only for backwards compatibility with older versions of web services already published. **Important:** This style is deprecated by the WS-I organization, and is not recommended, as most Web Service

Web Services Style	Description
	implementations won't support it in the future.

The style of service to be created is specified in the Genero application for the Web Service, using the following methods of the WebOperation class from from the Web Services COM Library (**com**). The parameters are the same for both methods:

1. The name of the BDL function that is executed to process the Web Service operation
2. The name you wish to assign to the Web Service operation
3. The input record defining the input parameters of the operation (or NULL if there is none)
4. The output record defining the output parameters of the operation (or NULL if there is none)

```
LET op = com.WebOperation.CreateRPCStyle("add","Add",
           add_in,add_out)
LET op = com.WebOperation.CreateDOCStyle("checkInvoice",
           "CheckInvoice",invoice_in,invoice_out)
```

Calling the appropriate function for the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

> **Important:** Do not use the setInputEncoded() and setOutputEncoded() methods of the WebService class from the Web Services COM Library (**com**), as they apply only to RPC/Encoded Style, which is not recommended.
>
> **Note:** If you add headers to your RPC Style service, choose the Literal serialization mechanism by setting the **encoded** parameter of the createHeader() method to FALSE:
>
> ```
> CALL serv.createHeader(var,FALSE)
> ```
>
> **Note:** GWS release 2.0 allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

How To's

These topics provide you with the information needed to perform specific tasks related to Genero Web Services using the SOAP protocol.

How to call Java™ APIs from Genero in a SOA environment

Overview

This tutorial explains how to call a Java™ library from Genero in a SOA environment, using Genero and Java™ Web services. This can easily be done using the Java™ JAX-WS framework on a server, and a Genero application for the client part. Notice that there is no strong linkage between Genero and a java JVM.

For this tutorial we will use a Java™ barcode creation library to build a picture from a code.

> **Note:** Accessing a .NET library could be done in the same manner.

Recommendation

The usage of Genero Web Services to call a Java™ service is recommended in a **SOA** environment. It enables several Genero applications to connect to a centralized Java™ service without the need to start a new JVM for each running Genero application. It also provides more flexibility because there is no strong linkage between Genero and the Java™ virtual machine. You can for instance upgrade the Java™ service without changing anything in your Genero code.

However, due to the XML serialization process and the HTTP transport protocol in Web Services, there can be some performance issues. So if your main concern is performance, it is recommended to use the Genero Java™ bridge.

Prerequisites

- A JRE 1.5 or above
- The Java™ barcode library (available here)
  - You must add these JARs to the Java™ CLASSPATH: **barcode.jar** and **BarcodeReader.jar**
  - The trial version has some functions partially implemented.
- Download the JAX-WS framework from the Sun metro project here; add this JAR to the java CLASSPATH: **webservices-tools.jar**

Using the barcode library

The **barcode library** is composed of two libraries:

- A library for building a barcode image from a numeric code
- A library for reading a barcode image to return the numeric code

This section depends on the library you want to use in Genero.

In our tutorial, we create two functions called **buildImage** and **readImage**.

This is the Java™ implementation:

```
buildImage( type : String, code : String) : byte[ ]
```

```
try {
  Barcode builder=new Barcode();
  builder.setType(GetBarcodeBuilderType(type));
  builder.setData(data);
  builder.setAddCheckSum(true);
  ByteArrayOutputStream out=new ByteArrayOutputStream();
  if (builder.createBarcodeImage(out)) {
   byte[] ret = out.toByteArray();
   return ret;
 } else {
   return null;
 }
} catch (Exception e) {
  return null;
}
```

```
readImage( type : String, img : byte[ ]) : String
```

```
try {
  File f=new File("tmp.jpg");
  FileOutputStream stream=new FileOutputStream(f);
  stream.write(img);
  stream.close();  String[] datas =
    BarcodeReader.read(f, GetBarcodeReaderType(type));
  if (datas==null) {
    return null;
  } else {
```

```
    String ret = datas[0];
    return ret;
  }
} catch (Exception e) {
  return null;
}
```

The following two functions convert the type of a code bar to the type expected by the library:

```
private int GetBarcodeBuilderType(String str) {
  if (str.equals("CODABAR")) {
    return Barcode.CODABAR;
  } else if (str.equals("CODE11")) {
    return Barcode.CODE11;
  } else if (str.equals("CODE128")) {
    return Barcode.CODE128;
  } else if (str.equals("CODE128A")) {
    return Barcode.CODE128A;
  } else if (str.equals("CODE128B")) {
    return Barcode.CODE128B;
  } else if (str.equals("CODE128C")) {
    return Barcode.CODE128C;
  } else if (str.equals("CODE2OF5")) {
    return Barcode.CODE2OF5;
  } else if (str.equals("CODE39")) {
    return Barcode.CODE39;
  } else if (str.equals("CODE39EX")) {
    return Barcode.CODE39EX;
  } else if (str.equals("CODE93")) {
    return Barcode.CODE93;
  } else if (str.equals("CODE93EX")) {
    return Barcode.CODE93EX;
  } else if (str.equals("EAN13")) {
    return Barcode.EAN13;
  } else if (str.equals("EAN13_2")) {
    return Barcode.EAN13_2;
  } else if (str.equals("EAN13_5")) {
    return Barcode.EAN13_5;
  } else if (str.equals("EAN8")) {
    return Barcode.EAN8;
  } else if (str.equals("EAN8_2")) {
    return Barcode.EAN8_2;
  } else if (str.equals("EAN8_5")) {
    return Barcode.EAN8_5;
  } else if (str.equals("INTERLEAVED25")) {
    return Barcode.INTERLEAVED25;
  } else if (str.equals("ITF14")) {
    return Barcode.ITF14;
  } else if (str.equals("ONECODE")) {
    return Barcode.ONECODE;
  } else if (str.equals("PLANET")) {
    return Barcode.PLANET;
  } else if (str.equals("POSTNET")) {
    return Barcode.POSTNET;
  } else if (str.equals("RM4SCC")) {
    return Barcode.RM4SCC;
  } else if (str.equals("UPCA")) {
    return Barcode.UPCA;
  } else if (str.equals("UPCE")) {
    return Barcode.UPCE;
  } else {
    return -1;
  }
```

```
}

private int GetBarcodeReaderType(String str) {
  if (str.equals("CODABAR")) {
    return BarcodeReader.CODABAR;
  } else if (str.equals("CODE11")) {
    return BarcodeReader.CODE11;
  } else if (str.equals("CODE128")) {
    return BarcodeReader.CODE128;
  } else if (str.equals("CODE39")) {
    return BarcodeReader.CODE39;
  } else if (str.equals("CODE39EX")) {
    return BarcodeReader.CODE39EX;
  } else if (str.equals("CODE93")) {
    return BarcodeReader.CODE93;
  } else if (str.equals("DATAMATRIX")) {
    return BarcodeReader.DATAMATRIX;
  } else if (str.equals("EAN13")) {
    return BarcodeReader.EAN13;
  } else if (str.equals("EAN8")) {
    return BarcodeReader.EAN8;
  } else if (str.equals("INTERLEAVED25")) {
    return BarcodeReader.INTERLEAVED25;
  } else if (str.equals("ITF14")) {
    return BarcodeReader.ITF14;
  } else if (str.equals("ONECODE")) {
    return BarcodeReader.ONECODE;
  } else if (str.equals("PLANET")) {
    return BarcodeReader.PLANET;
  } else if (str.equals("POSTNET")) {
    return BarcodeReader.POSTNET;
  } else if (str.equals("QRCODE")) {
    return BarcodeReader.QRCODE;
  } else if (str.equals("RM4SCC")) {
    return BarcodeReader.RM4SCC;
  } else if (str.equals("RSS14")) {
    return BarcodeReader.RSS14;
  } else if (str.equals("RSSLIMITED")) {
    return BarcodeReader.RSSLIMITED;
  } else if (str.equals("UPCA")) {
    return BarcodeReader.UPCA;
  } else if (str.equals("UPCE")) {
    return BarcodeReader.UPCE;
  } else {
    return -1;
  }
}
```

Calling Java™ from Genero

The integration of one or several Java™ libraries with multiple methods in a Genero application can be performed, as described in the following topics.

Step 1: Write a new java class

Instead of writing the functions in 4GL, you simply need to write them in a Java™ class with the methods you want to use in 4GL. In our example, the two functions are **buildImage** and **readImage**. And of course, don't forget to import the necessary Java™ import instructions.

```
import com.barcodelib.barcodereader.BarcodeReader;
import com.barcodelib.barcode.Barcode;
import java.io.*;
```

```
import javax.jws.*;
import javax.jws.soap.SOAPBinding;
import javax.xml.ws.Endpoint;

public class BarcodeService {
  public byte [] buildImage(String type, String data)
  {
  /*BUILDIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*/
  }
  public String readImage(String type,byte[] img)
  { { { {
  /*READIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*/
  } }
}
```

Notice that if you want the service to run standalone, you must also add following the main method to tell the system the port number on which the service will run:

```
public static void main(String[] args)
{
  String endpointUri = "http://localhost:9090/";
  Endpoint.publish(endpointUri, new BarcodeService ());
  System.out.println("BarcodeService started at " + endpointUri);
}
```

Step 2: Transform the Java™ class in a web service

To transform the previous java class in a Web Service, simply add a WebService annotation:

```
@WebService(targetNamespace = http://www.mycompany.com/barcode ",
  name="Barcode",
  serviceName="BarcodeService")
public class BarcodeService{
...
}
```

This defines all public and non static methods of the class as operations of the **BarcodeService** Web Service.

Step 3: Start the service

Compile the previously created java class, and run it.

Commands to compile and execute the service in standalone mode:

```
$ javac BarcodeService.java
$ java BarcodeService
```

Once the service is started, it is ready to accept requests and you can also retrieve its WSDL at following URL:

http://localhost/9090/BarcodeService?WSDL

> **Note:** If you want the service to be started on a web server, you must deploy it first using Eclipse or the Web Server deployment tools.

Step 4: Generate BDL stub to access the Java™ library

Use the **fglwsdl** tool to generate the client stub to access the BarcodeService:

```
$ fglwsdl http://localhost:9090/BarcodeService?WSDL
```

This will create two .4gl files that must be compiled and linked into your BDL application in order to call the Java™ barcode library functions. These files contain the BDL interface to access the Java™ library where you will find the two functions, **readImage** and **buildImage**, defined in BDL.

Step 5: Modify your BDL application

The last step is to modify the existing application where you want to use the Java™ library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your Java™ library.

Example program

This program calls the **buildImage** function of the Barcode Java™ library.

```
GLOBALS "BarcodeService_BarcodePort.inc"

MAIN

DEFINE wsstatus INTEGER

IF num_args() != 3 THEN
   CALL ExitHelp()
END IF

LET ns1buildImage.arg0 = arg_val(1)
LET ns1buildImage.arg1 = arg_val(2)
LOCATE ns1buildImageResponse.return IN MEMORY

LET wsstatus = buildImage_g()
IF wsstatus <> 0 THEN
  DISPLAY "Error ("||wsError.code||") : ",wsError.description
ELSE IF
  IF ns1buildImageResponse.return IS NULL THEN
    DISPLAY "Encoding failed"
  ELSE
    CALL ns1buildImageResponse.return.writeFile(arg_val(3))
  END IF
END IF

FREE ns1buildImageResponse.return

END MAIN

FUNCTION ExitHelp()
  DISPLAY arg_val(0)||" <type> <data> <filename>"
  DISPLAY "type : barcode type such as EAN8 or CODE128"
  DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
  DISPLAY "filename : resulting image filename"
  DISPLAY "example : createImage EAN8 12358723A mybarcode.jpg"
 EXIT PROGRAM (-1)
END FUNCTION
```

Conclusion

In a SOA environment, you can call any Java™ library from Genero using Web Services, and without a strong dependency to a JVM. This follows SOA principles - it allows you to reuse the Java™ library in another BDL application without any new development, you can update the Java™ part without recompiling any .4gl source, and integrate any function available from a SOA platform.

How to call .NET APIs from Genero in a SOA environment

Overview

This document explains how to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual Studio .NET.

Notice that there is no strong linkage between Genero and .NET, and you can even call a .NET library from a non-Windows Genero platform.

For the tutorial, we will use a .NET barcode creation library to build a picture from a numeric code, and C# as the development language. This will also work with any other .NET language.

> **Note:** Accessing a Java™ library could be done in the same manner.

Prerequisites

- IIS (Internet Information Services) Web server
- Visual Studio Professional Edition C#
  - Visual Studio in only needed for development. Once the service is built, you can deploy on any IIS Web Server.
- The .NET barcode library (available here)
  - The trial version has some functions partially implemented.
  - The .NET library is called BarcodeLib.Barcode.dll, and must be added to the Visual Studio Project.

Using the barcode library

This section depends on the library you want to use in Genero. In our tutorial, we create one function called **buildImage**. This is the C# implementation:

```
buildImage( type : String, code : String) : byte[]
```

```
Linear barcode = new Linear();
barcode.Data = code;
barcode.Type = GetBarcodeBuilderType(type);
barcode.AddCheckSum = true;
// save barcode image into your system
barcode.ShowText = true;
byte[] ret = barcode.drawBarcodeAsBytes();
if (ret != null) return ret;
else return null;
```

You will also need to convert the type of a code bar to the right type as expected by the library. Therefore, you will need this function.

```
private BarcodeType GetBarcodeBuilderType(String str)
{
if (str.Equals("CODABAR")) {
      return BarcodeType.CODABAR;
   } else if (str.Equals("CODE11")) {
      return BarcodeType.CODE11;
   } else if (str.Equals("CODE128")) {
      return BarcodeType.CODE128;
   } else if (str.Equals("CODE128A")) {
      return BarcodeType.CODE128A;
   } else if (str.Equals("CODE128B")) {
      return BarcodeType.CODE128B;
   } else if (str.Equals("CODE128C")) {
      return BarcodeType.CODE128C;
   } else if (str.Equals("CODE2OF5")) {
      return BarcodeType.CODE2OF5;
   } else if (str.Equals("CODE39")) {
      return BarcodeType.CODE39;
```

```
    } else if (str.Equals("CODE39EX")) {
       return BarcodeType.CODE39EX;
    } else if (str.Equals("CODE93")) {
       return BarcodeType.CODE93;
    } else if (str.Equals("EAN13")) {
       return BarcodeType.EAN13;
    } else if (str.Equals("EAN13_2")) {
       return BarcodeType.EAN13_2;
    } else if (str.Equals("EAN13_5")) {
       return BarcodeType.EAN13_5;
    } else if (str.Equals("EAN8")) {
       return BarcodeType.EAN8;
    } else if (str.Equals("EAN8_2")) {
       return BarcodeType.EAN8_2;
    } else if (str.Equals("EAN8_5")) {
       return BarcodeType.EAN8_5;
    } else if (str.Equals("INTERLEAVED25")) {
       return BarcodeType.INTERLEAVED25;
    } else if (str.Equals("ITF14")) {
       return BarcodeType.ITF14;
    } else if (str.Equals("ONECODE")) {
       return BarcodeType.ONECODE;
    } else if (str.Equals("PLANET")) {
       return BarcodeType.PLANET;
    } else if (str.Equals("POSTNET")) {
       return BarcodeType.POSTNET;
    } else if (str.Equals("RM4SCC")) {
       return BarcodeType.RM4SCC;
    } else if (str.Equals("UPCA")) {
       return BarcodeType.UPCA;
    } else if (str.Equals("UPCE")) {
       return BarcodeType.UPCE;
    } else {
       throw new Exception();
    }
}
```

Calling .NET from Genero

Step 1: Create an ASP.NET Web Service Application

Start Visual Studio, and create a new web project with the name BarCodeService.

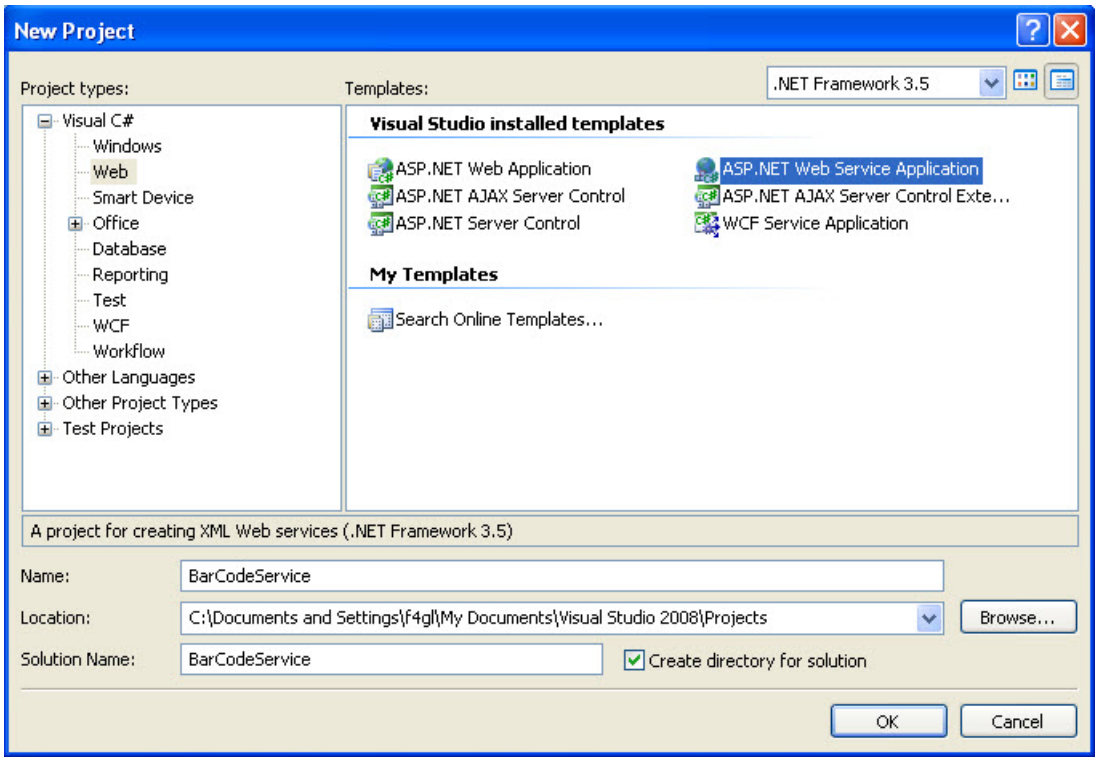

Figure 109: Visual Studio New Project; ASP .NET Web Service Application selected

Step 2: Rename the generated files

Rename the generated class called Service1 with an appropriate name such as BarCode, and the file Service1.asmx to BarCodeService.asmx, for instance. The .asmx file is the file that is accessible from the IIS web server once the application is deployed. The .asmx file also contains a reference to the default generated class, Service1, which must also be renamed to the new name (BarCode in our tutorial), in case Visual Studio didn't make the change automatically.

The class view after renaming the class:

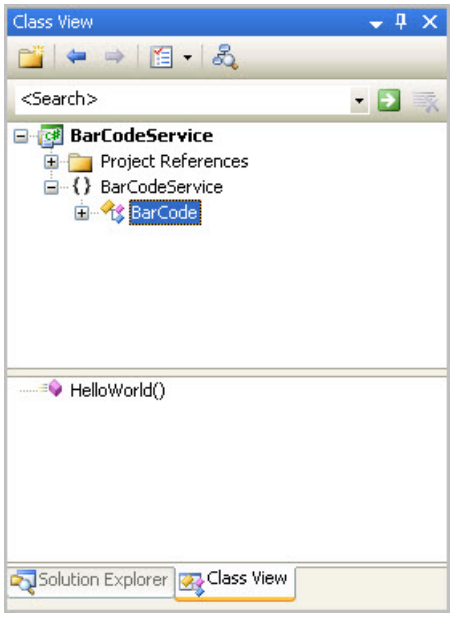

Figure 110: Class View; BarCode selected

The file view after renaming the asmx file:

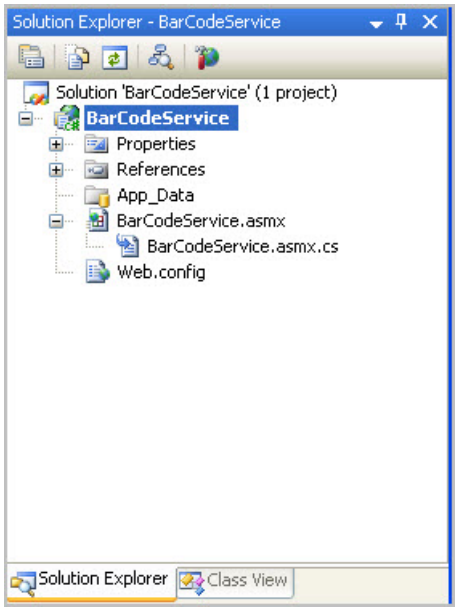

Figure 111: File View; BarCodeService selected

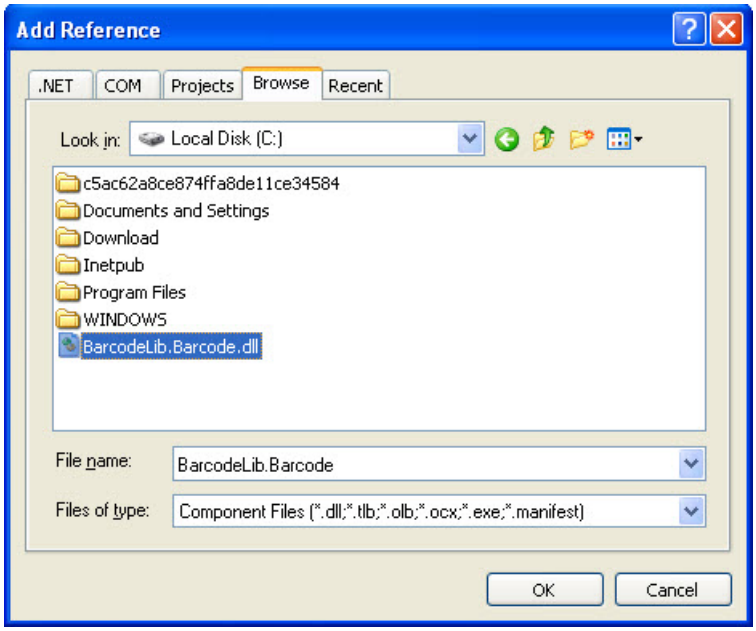
Step 3: Add the barcode library as a reference

Right-click on the solution explorer, select **Add Reference** and use the **Browse** panel to enter the location of the barcode library called **BarcodeLib.Barcode.dll**:



> **Note:** By default, the barcode library will be copied to the right place when deploying on the IIS web server.

Step 4: Add the buildImage method

Remove the default generated HelloWorld method, and create the buildImage method.

Add the three `using` instructions to import the barcode library, and to declare **buildImage** as a WebMethod. Use the **GetBarcodeBuilderType()** method to convert a string to a code as expected by the barcode library.

```
using BarcodeLib;
using BarcodeLib.Barcode;
using BarcodeLib.Barcode.Linear;

namespace BarCodeService
{
    /// <summary>
    /// Summary description for Service1
    /// </summary>
    [WebService(Namespace = "http://tempuri.org/")]
    [WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
    [ToolboxItem(false)]
    // To allow this Web Service to be called from script, using ASP.NET
    // [System.Web.Script.Services.ScriptService]
    public class Barcode : System.Web.Services.WebService
    {

         [WebMethod]
         public byte[] buildImage(String type, String code)
         {
             try
             {
                 Linear barcode = new Linear();
                 barcode.Data = code;
                 barcode.Type = GetBarcodeBuilderType(type);
                 barcode.AddCheckSum = true;

                 // save barcode image into your system
                 barcode.ShowText = true;
                 byte[] ret = barcode.drawBarcodeAsBytes();
                 if (ret !- null) return ret;
                 else return null;
             }
             catch (Exception e)
             {
                 return null;
             }
        }
    }
}
```

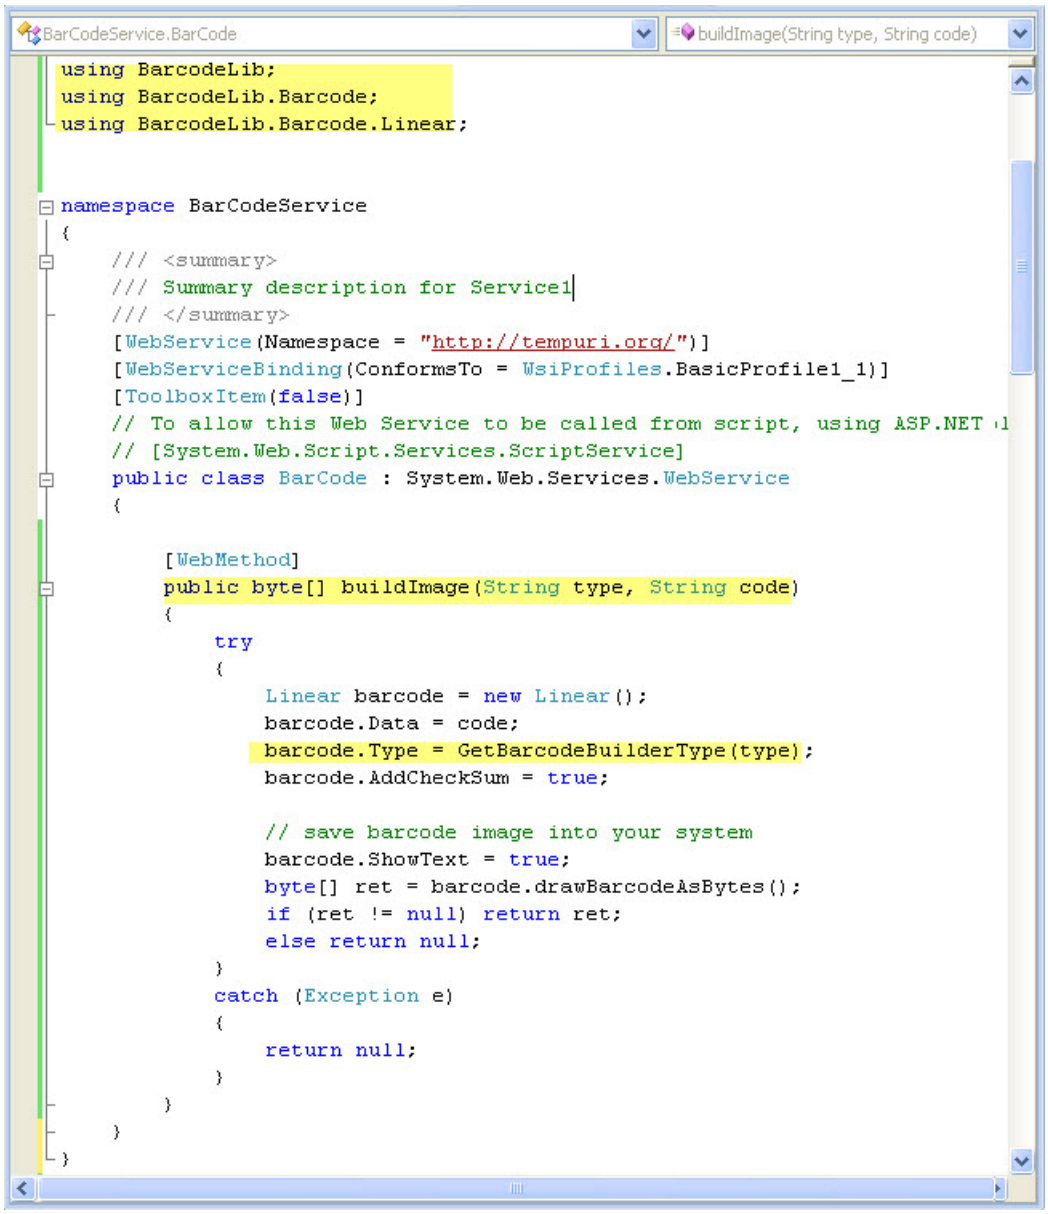


Figure 112: BarCodeService.BarCode

Step 5: Publish the service

Build the entire application, right-click on the solution, and select the publish operation. This will copy all necessary files to your IIS web server and make your application available at an URL, depending on where you deploy it on your IIS web server.

In our tutorial, the service will be located at the root of the server. In other words, it will be available at **http://localhost/BarCodeService.asmx** and the WSDL at URL **http://localhost/BarCodeService.asmx?WSDL**

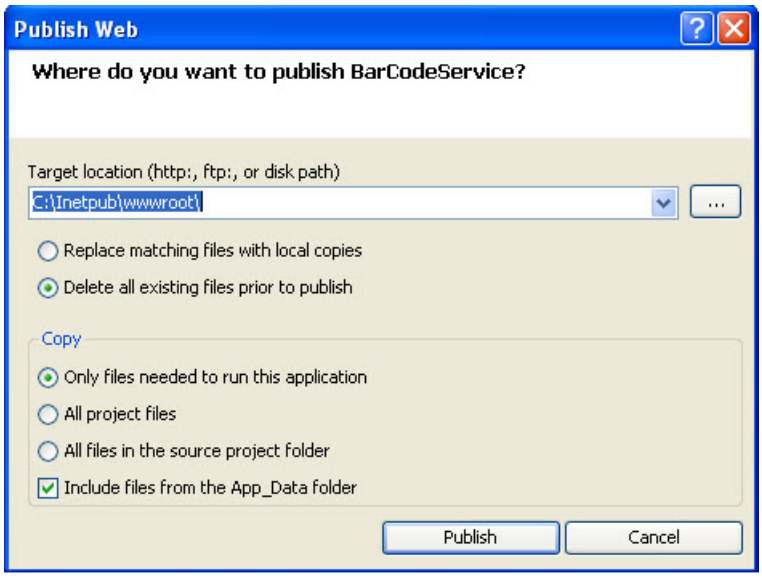

Figure 113: Publish Web dialog

Step 6: Generate .4gl stub to access the .NET library

Use the fglwsdl tool to generate the client stub to access the BarcodeService, as follows:

```
$ fglwsdl http://localhost/BarCodeService.asmx?WSDL
```

This will create two .4gl files, which must be compiled and linked into your BDL application in order to call the .NET barcode library functions. These files contain the BDL interface to access the .NET library where you will find the function **buildImage**, defined in BDL.

Step 7: Modify your BDL application

Modify your existing application, where you want to use the .NET library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your .NET library.

Example BDL program

This program calls the buildImage function of the Barcode .NET library.

```
GLOBALS "BarCode_BarCodeSoap.inc"
MAIN
  DEFINE wsstatus INTEGER

  IF num_args() != 3 THEN
    CALL ExitHelp()
  END IF

  LET buildImage.type = arg_val(1)
  LET buildImage.code = arg_val(2)
  LOCATE buildImageResponse.buildImageResult IN MEMORY

  LET wsstatus = buildImage_g()
  IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
  ELSE
    IF buildImageResponse.buildImageResult IS NULL THEN
      DISPLAY "Encoding failed"
    ELSE

  EXIT PROGRAM (-1)
END FUNCTION
```

Conclusion

It is quite easy to interact with a .NET library from Genero using .NET Visual Studio and the web services. Of course you also need an IIS web server installed on your Windows™ system. This means that you can, in the same Genero application, interact with .NET and Java™ libraries without any strong linkage between Genero and the third party libraries you want to use. This meets the SOA principles that provide more flexibility to your entire BDL application.

You can integrate any new library from another vendor, without the risk of conflicts between different libraries that could happen if you had to link everything together in C or Java™.

You can upgrade a third party library without recompiling the BDL application, which will still work.

You can use all these third party libraries in other BDL or other applications.

Compute a hash value from a BDL string
Overview

This document explains how to compute a hash value of a BDL string using the security.Digest API.

Signing a XML document is nothing more than computing a hash over a fragment of XML. If you set the string you need to hash in an XML node, and use the correct XPath expression, the security.Digest API will do it for you.

Some special characters are escaped in XML. If you use one of them, the computed hash value will be wrong because the result is actually computed over the escaped string. The special characters to be aware of are: **"**, **'**, **&**, **<** and **>**.

Sample code

Then uses the security.Digest API to compute a XML digital signature for the content of the root node, or in other words the string you wish to hash, using a XPath expression.

And finally, retrieves the hash value from the signature and returns it.

The computed hash value is encoded in Base64, so you may have additional conversion to do.

```
IMPORT SECURITY

MAIN

  DEFINE result STRING

  IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY "  string: the string to digest"
    DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
  ELSE
```

```
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
      DISPLAY "Hash value is: ",result
    ELSE
      DISPLAY "Error"
    END IF
  END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

  DEFINE toDigest, algo, result STRING
  DEFINE dgst security.Digest

  TRY
    LET dgst = security.Digest.CreateDigest(algo)
    CALL dgst.AddStringData(toDigest)
    LET result = dgst.DoBase64Digest()
  CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY

  RETURN result
END FUNCTION
```

Example of usage:

```
$ fglrun ComputeHash "Hello, world !!!" SHA1
```

```
$ Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=
```

Example
Computing a hash value of a string.

Program example `ComputeHash.4gl` :

```
IMPORT SECURITY

MAIN

  DEFINE result STRING

  IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY "  string: the string to digest"
    DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
  ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
      DISPLAY "Hash value is :",result
    ELSE
      DISPLAY "Error"
    END IF
  END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

  DEFINE toDigest, algo, result STRING
  DEFINE dgst security.Digest
```

```
  TRY
    LET dgst = security.Digest.CreateDigest(algo)
    CALL dgst.AddStringData(toDigest)
    LET result = dgst.DoBase64Digest()
  CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY

  RETURN result
END FUNCTION
```

Example execution:

```
$ fglrun ComputeHash "Hello World" SHA1
```

Hash value is :Ck1VqNd45QIvq3AZd8XYQLvEhtA=

Fix Genero 2.10 to 2.11 WSDL generation issue

These topics explain how to convert a WSDL generated from Genero 2.11 and later, to a WSDL as generated in Genero 2.10.

Overview

Since Genero 2.11, each BDL variable generates a associated named complexType in the WSDL and references it. Notice that this does not impact the web service at all, but some tools will then generate additional client stubs to follow the WSDL definition with the name of such complexType. This means that a client program written from a WSDL generated in 2.10 must be reviewed if it uses now a WSDL generated in 2.11 or later.

If you do not want to modify your application, you can use following program that will remove the named complexType and add the unnamed equivalent as child node of the parameter variable of all web service operations, so in other words, as if the WSDL would have been generated in 2.10.

WSDL conversion tool

This program reads a WSDL, looks for all named complexType used in all the web operation parameters and modifies them in order to have unamed complexType instead.

```
IMPORT XML
MAIN
  DEFINE
    doc xml.DomDocument,
    list, elist, tlist xml.DomNodeList,
    node, enode, nnode xml.DomNode,
    i, j, k, idx INTEGER,
    ename, tname STRING

  IF num_args() <> 1 THEN
    CALL display_help()
    RETURN 0
  END IF

  TRY
    LET doc = xml.DomDocument.Create()
    CALL doc.setFeature("whitespace-in-element-content",FALSE)
    CALL doc.load(arg_val(1))
    # get the list of input/output message
    # check if their names (x) are defined as elements with types (y)
    # if yes then
    # copy the complextype y definition to element name x
    # and remove the complexe type y definition
    # for example:
    # message
    # <wsdl:message name="is_OKIn">
```

```
    # <wsdl:part name="parameters" element="fjs:is_OKRequest" />
    # </wsdl:message>
    # <wsdl:message name="is_OKOut">
    # <wsdl:part name="parameters" element="fjs:is_OKResponse" />
    # </wsdl:message>
    # element
    # <xsd:element name="is_OKResponse"
    #    type="s1:is_OKResponse_is_OKResponse" />
    # type
    # <xsd:complexType name="is_OKRequest_is_OKRequest">
    LET list =
      doc.selectByXPath("//wsdl:part[@name='parameters']/@element",
      "wsdl","http://schemas.xmlsoap.org/wsdl/")
    IF list IS NULL THEN
      DISPLAY "Nothing to convert."
    END IF
    FOR i=1 TO list.getCount()
      LET node = list.getItem(i)
      LET ename = node.getNodeValue()
      LET idx = ename.getIndexOf(":",1)
      IF idx <> 0 THEN
      LET ename = ename.subString(idx+1,ename.getLength())
      END IF
      # get the element
      LET elist =
        doc.selectByXPath("//xsd:element[@name='" || ename || "']",
        "xsd","http://www.w3.org/2001/XMLSchema")
      IF elist IS NOT NULL THEN
        FOR j=1 TO elist.getCount()
          LET enode = elist.getItem(j)
          LET tname = enode.getAttribute("type")
          CALL enode.removeAttribute("type")
          LET idx = tname.getIndexOf(":",1)
          IF idx <> 0 THEN
          LET tname = tname.subString(idx+1,tname.getLength())
          END IF
          # get the type
          LET tlist =
            doc.selectByXPath("//xsd:complexType[@name='" || tname || "']",
            "xsd","http://www.w3.org/2001/XMLSchema")
          IF tlist IS NOT NULL THEN
            FOR k=1 TO tlist.getCount()
              LET node = tlist.getItem(k)
              LET nnode = node.clone(TRUE)
              CALL nnode.removeAttribute("name")
              CALL enode.appendChild(nnode)
            END FOR
          END IF
          FOR k=1 TO tlist.getCount()
            LET node = tlist.getItem(k)
            LET nnode = node.getParentNode()
            CALL nnode.removeChild(node)
          END FOR
        END FOR
      END IF
    END FOR
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("result.wsdl")
    DISPLAY "Document is saved in result.wsdl"
  CATCH
    DISPLAY "ERROR[" || STATUS || "]"
    FOR i=1 TO doc.getErrorsCount()
      DISPLAY "[", i, "] ", doc.getErrorDescription(i)
    END FOR
```

```
  END TRY
END MAIN

FUNCTION display_help()
  DISPLAY "Usage: fglrun " || arg_val(0) || " wsdlfile"
END FUNCTION
```

Example of usage:

```
$ fglrun Convert Genero2_21.wsdl
```

```
$ Document is saved in result.wsdl
```

How to handle WS security

Genero Web Services does not entirely manage WS-Security. We provide XML APIs to help the development of Web Services with security.

Introduction

This topic describes how to handle WS Security using the demo wssecuritymessage. It is a sample that you can adapt to your needs. The demo will be enhanced to illustrate new features that will be introduced to fully support WS-Security.

The demo involves three clients exchanging secured messages. Those clients post and retrieve messages on a secured server. Each client is identified by a certificate and sign their messages.

We assume that you are familiar with security concepts described in topic " Encryption and Authentication Concepts".

The demo assumes that all the clients have sent their public keys to the other clients and to the server. Those keys are kept in each host's (server or clients) keystore. The certificates included in this package are provided for demonstration purposes only. As they are distributed with this package, anybody using this product can decrypt the messages exchanged. Do NOT use them in production.

Server side

We provide 3 handlers to handle WS Security:

- Method com.WebService.registerWSDLHandler() to modify the wsdl to add WS policy.
- Method com.WebService.registerInputRequestHandler() to handle WS Security in an incoming request
- Method com.WebService.registerOutputRequestHandler() to handle WS Security in an outgoing request

In this demo, a received message is processed:

1. Identify the sender and validate the sender (search in keystore)
2. Decrypt the symmetric key with the server private key
3. Decrypt the body
4. Check the signature with the sender public key
5. Store the message in the box (thanks to the "To" field, "subject" and "message")
6. Create the outgoing message
7. Sign the outgoing message
8. Encrypt the outgoing message with a generated symmetric key. This symmetric key is then encrypted with the client public key.

Client side

The client consists in sending a message and retrieving messages clients sent to it.

Before that, create the client stub from the wsdl:

- fglwsdl **-domHandler** myservice.wsdl

The client stub reference handlers:

- SecureMessageBox_HandleRequest
- SecureMessageBox_HandleResponse
- SecureMessageBox_HandleResponseFault

For more details about client SOAP handlers see Client stub and handlers.

What to do when a message is sent:

- Sign and encrypt the request for the server (WS-Security)
  - sign with client private key
  - encrypt with server public key
- Send key information in the request
  - key to identify the sender/client
  - key to identify the recipient/server
  - key used to encrypt the data (usually a symmetric key encrypted by the recipient public key)
- If the message has to be encrypted for the final recipient (XML-Security)
  - sign the message
  - encrypt the message

What to do to retrieve messages:

- Identify the sender and validate the sender (search in keystore)
- Identify the recipient (should be the server itself)
- Decrypt the request
- Check the signature
- Retrieve messages for the recipient

SOAP security standards

The policy documentation can be found here.

The demo policy is divided into sections (make sure that the naming are correct and that the structure is understandable):

- Security bindings on page 2502
- SOAP message security options on page 2505
- SignedParts on page 2505
- EncryptedParts on page 2505

WS Security section begins with:

```
<wsp:Policy xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy ... />
```

It defines rules:

```
<wsp:ExactlyOne>
```

Only one assertion should be fulfilled.

```
<wsp:All>
```

All the assertions should be fulfilled.

Security bindings

There are 3 types of security binding:

- TransportBinding
- SymmetricBinding

- AsymmetricBinding

The current demo uses the Asymmetric binding.

Asymmetric Binding

This section is divided in sub sections:

- InitiatorToken
- RecipientToken
- AlgorithmSuite
- Layout
- Additional assertions

`AsymmetricBinding` is the root node for protection description.

```
<sp:AsymmetricBindingxmlns:sp=
"http://schemas.xmlsoap.org/ws/2005/07/securitypolicy">
```

InitiatorToken

`InitiatorToken` is the message sender (client)

For example:

```
<sp:InitiatorToken>
  <wsp:Policy>
    <sp:X509Token sp:IncludeToken="http://schemas.xmlsoap.org/ws/
     2005/07/securitypolicy/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V1Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:InitiatorToken>
```

> **Note:** The value for the sp:IncludeToken attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for the message signature from initiator to recipient and encryption from recipient to initiator.

The initiator key is a X509 certificate that is always sent to the recipient.

`sp:IncludeToken` attribute indicates if the token must be included.

`IncludeToken/AlwayToRecipient` means each requests sent to the recipient must include the initiator token. But the token should not be included in messages from recipient to initiator.

The token must send its Thumbprint Reference.

The token must be of type X509 version 1 as defined in "X509 token profile 1.0".

What should be done in BDL is decribed in Client Side section.

To retrieve the thumbprint reference you can use the API function xml.CryptoX509.getThumbprintSHA1

To create the x509 certificate use an appropriate tool like openssl.

RecipientToken

`RecipientToken` is the message receiver (server)

```
<sp:RecipientToken>
  <wsp:Policy>
    <sp:X509Token sp:IncludeToken="http://schemas.xmlsoap.org/
     ws/2005/07/securitypolicy/IncludeToken/Never">
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V3Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:RecipientToken>
```

> **Note:** The value for the sp:IncludeToken attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for encryption from initiator to recipient, and for the message signature from recipient to initiator.

The recipient key is a X509 certificate that is never sent to the initiator.

`sp:IncludeToken` attribute indicates if the token must be included.

`IncludeToken/Never` means the token should not be included in any requests between the initiator and the recipient.

Instead the recipient ThumbprintReference is sent.

The token must be of type X509 version 3 as defined in "X509 token profile 1.0"

What should be done in BDL is described in Server Side section. To retrieve the thumbprint reference you can use the API function xml.CryptoX509.getThumbprintSHA1. To create the appropriate certificate use an appropriate tool like openssl.

AlgorithmSuite

`AlgorithmSuite` tells which algorithm is used to encrypt the data.

```
<sp:AlgorithmSuite>
  <wsp:Policy>
    <sp:TripleDesRsa15 />
  </wsp:Policy>
</sp:AlgorithmSuite>
```

TripleDesRsa15 refers to key http://www.w3.org/2001/04/xmlenc#tripledes-cbc.

Layout

`Layout` describes the way information are added to the message header.

```
<sp:Layout>
  <wsp:Policy>
    <sp:Strict />
  </wsp:Policy>
</sp:Layout>
```

For example, with Strict layout, token that are included in the message must be declared before use. For more details on the rules to follow see the security policy specifications section 7.7.

Additional Assertations

PartsToSign

```
<sp:OnlySignEntireHeadersAndBody />
```

The assertion means if there is any signature on the header or the body it should be on the entire header and the entire body not on their child element.

SOAP message security options

```
<sp:Wss10 xmlns:sp="http://schemas.xmlsoap.org/ws/2005/07/securitypolicy">
  <sp:MustSupportRefKeyIdentifier />
  <sp:MustSupportRefIssuerSerial />
```

- MustSupportRefKeyIdentifier means that initiator and recipient are able to generate and process key identifier reference.
- MustSupportRefIssuerSerial means that initiator and recipient are able to generate and process issuer and token serial reference.

SignedParts

The SignedParts section tells which part of the message should be signed.

```
<sp:SignedParts xmlns:sp="http://schemas.xmlsoap.org/ws/2005/07/
securitypolicy">
<sp:Body />
```

- Only the body needs to be signed

EncryptedParts

The section EncryptedParts tells which part of the message should be encrypted.

```
<sp:EncryptedParts xmlns:sp="http://schemas.xmlsoap.org/ws/2005/07/
securitypolicy">
  <sp:Body />
```

- sp:Body indicates the body message needs to be encrypted

Encrypt the body using the algorithm referenced in assertion AlgorithmSuite:

- create an encryption key using TripleDesRsa15 algorithm (i.e. generate a TripleDES symmetric key and then encrypt it with a RSA1.5 public key) like example2 in crypto key chapter that uses AES256.
- encrypt the body with the created key

To find the exact syntax of security message read the specifications "Web Services Security: SOAP Message Security 1.0".

Useful links

- Security Policy specifications v1.2
- SOAP Message Security 1.0
- X.509 Token Profile 1.1

RESTful Web Services

While RESTful Web Services are supported, the RESTful Web Services documentation is not yet completed.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2009 and The xml package on page 2103.

Deploy a Web Service

Web services server program deployment

Introduction

In a production environment, Genero Web Services becomes a part of a global application architecture handled by the **Genero Application Server (GAS)**. The GWS DVMs are managed by the GAS.

This architecture takes care of:

- Security issues
- Scalability
  - Load management
  - Balancing of the Web service requests amongst the available virtual machines
- Runtime monitoring

GAS configuration

For deployment, the GWS Server application must be added to the GAS configuration. See *Adding Applications* in the GAS manual.

The web services application can be added to the GAS in different ways:

- GWS Server application implementing a single Web Service.

  This application could be deployed on various physical machines. A Genero Web Services VMProxy (GWSProxy) is started on each machine where the GWS Server application is executed, to manage the requests for a service and manage the DVMs that handle the requests. A single VMProxy can communication with multiple GWS DVMs, and manage the load balancing.
- GWS Server application implementing multiple Web Services.

  The GWSproxy would manage the client requests, dispatching the request to the appropriate DVM and the appropriate web service.

  Note: A Web Service Server must be stateless; several instances of the same Service can be created to support load balancing.

The basic deployment strategy can be implemented in varying permutations, depending on your business needs and the volume of requests.

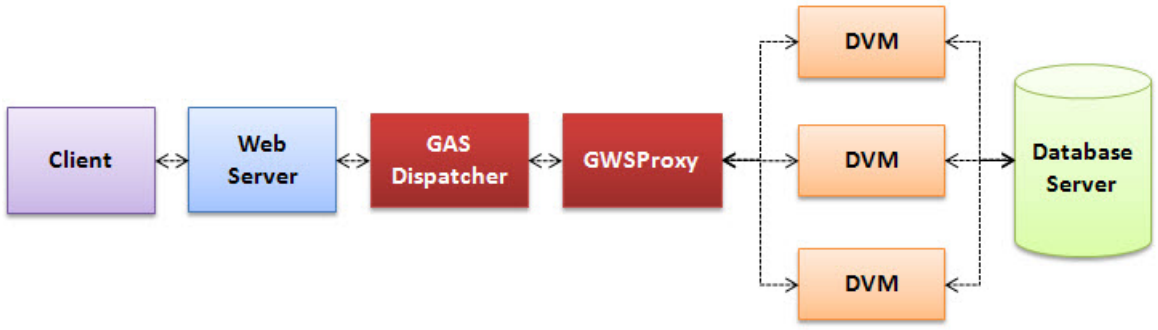

Figure 114: Deployment strategy

- Using the World Wide Web, a Web Service client requests WSDL information for a particular Web Service from the Web Server.
- The Web Service client uses this information to make a Web Service request from the Web Server.
- The Web server passes the request to the GAS dispatcher.

- The GAS dispatcher starts a GWSProxy, which will be in charge of the pool of DVMs that will serve the web service application.
- The GWSProxy will start the number of DVMs specified by the START element defined for the web service application.

For a more detailed explanation of the Services Pool for web services, refer to the *GAS Architecture* topic in the Genero Application Server manual.

Access the web services server from a client application

To reach the web service from the internet, client applications must use the following URL form:

```
http://host_name/ws/r/app_id
```

1. *host_name* defines the web server host name where the GAS is running.
2. *app_id* is the XCF file of the GAS web services application.

Configuring the apache web server for HTTPS

The first three steps are for the creation of all X.509 certificates.

- Step 1: Create the Root Certificate Authority
- Step 2: Create the server's certificate and private key
- Step 3: Create the server's certificate authority list

The next three steps are for server configuration.

- Step 4: Register the server as a Web Service in the GAS
- Step 5: Configure apache for HTTPS
- Step 6: Configure apache for HTTP basic authentication

Step 1: Create the root certificate authority

- Create the root certificate authority serial file:

```
$ echo 01 > MyCompanyCA.srl
```

- Create the Root Authority's Certificate Signing Request and private key:

```
$ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
```

- Create the Root Certificate Authority for a period of validity of 2 years:

```
$ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt
 -req -signkey MyCompanyCA.pem -days 730
```

Note: The private key file (**MyCompanyCA.pem**) of a RootCertificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

Step 2: Create the server's certificate and private key

- Create the server's serial file:

```
$ echo 01 > MyServer.srl
```

- Create the server's Certificate Signing Request and private key:

```
$ openssl req -new -out MyServer.csr
```

Note: By default, **openssl** outputs the private key in the **privkey.pem** file.

- Remove the password from the private key:

```
$ openssl rsa -in privkey.pem -out MyServer.pem
```

Note: The key is also renamed in **MyServer.pem**.

- Create the server's Certificate trusted by the Root Certificate Authority:

```
$ openssl x509 -in MyServer.csr -out MyServer.crt
 -req -signkey MyServer.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem
```

Note: The purpose of the server's Certificate is to identify the server to any client that connects to it. Therefore, **the subject of that server's certificate must match the hostname of the server as it is known on the network**; otherwise the client will be suspicious about the server's identity and stop the communication. For instance, if the URL of the server is *https:///www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/MyWebService*, the subject must be *www.MyServer.com*.

Step 3: Create the server's certificate authority list

- Create the server's Certificate Authority List:

```
$ openssl x509 -in MyCompanyCA.crt -text >> ServerCAList.pem
```

Note: As the server trusts only the Root Certificate Authority, the list contains only that one certificate authority; all other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the server.

Step 4: Register the server as a web service in the GAS

As the Web Server is in charge of the complete HTTPS protocol with all the clients, there is no additional GAS configuration needed to add security. Simply register the BDL server to the list of Web Services of the GAS. For more information, refer to the *Genero Application Server User Guide*.

For more details, see Web services server program deployment on page 2506.

Step 5: Configure apache for HTTPS

You must configure Apache to support HTTPS by adding the required modules. Please refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.

Once the Apache Web server supports HTTPS, you must change or add the following directives to the apache configuration file:

- Set the Apache Web server Certificate Authority List directive created in Step 4 :

  SSLCACertificateFile D:/Apache-Server/conf/ssl/ServerCAList.pem
- Set the Apache Web server Certificate and associated private key directives created in Step 2 :

  SSLCertificateFile D:/Apache-Server/conf/ssl/MyServer.crt

  SSLCertificateKeyFile D:/Apache-Server/conf/ssl/MyServer.pem
- Require the Apache Web server to verify the validity of all client certificates:

  SSLVerifyClient require

  Note: The Apache Web server must be started on a machine where the host is the same asthe one defined in the subject of the server's certificate (*www.MyServer.com* in our case).

Step 6 : Configure apache for HTTP basic authentication

You must configure Apache to support HTTP basic authentication by adding the required modules.

Please refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.

Once the Apache Web server supports HTTP basic authentication, you must:

1. Add an user to the Apache Web server basic authentication file with the same login and password as defined for the client.

   Apache provides the tool **htpasswd** that you can use to create the file and add the user. To add the user **mylogin** with the password **mypassword** to a new file called **myusers**:

   ```
   $ htpasswd -c myusers mylogin mypassword
   ```

   Note: To add additional users, remove the option '`-c`'.

2. Add an Apache Web server location directive that enables you to group several directives for one URL. (In our case, the URL is /cgi-bin/fglccgi.exe/ws/r/MyWebService).

   The following example (based on Apache 2.0) defines the HTTP authentication type (Basic), with a user file (user-basic) containing the login and password of those who are allowed to access the service.

   ```
     <Location /cgi-bin/fglccgi.exe/ws/r/MyWebService>
        AllowOverride None
        Order allow,deny
        Allow from all
        #
        # Basic HTTP authenticate configuration
        #
        AuthName "Top secret"
        AuthType Basic
        AuthUserFile "D:/Apache-Server/conf/authenticate/myusers"
        Require valid-user # Means any user in the password file
   </Location>
   ```

   For more information about Apache Web server directives, refer to the Apache Web Server manual.

Reference

These topics are the reference guides for Genero Web Services.

Web services configuration

The Genero Web Services secured communication and the support of XML-Security is based on the OpenSSL engine. It allows a BDL Web Services client, or a BDL application using the `com` or `xml` API, to

communicate with any secured server over HTTP or HTTPS, and to handle encrypted and/or signed XML document in BDL coming from any other application.

The configuration is defined from entries in the `fglprofile` file. When using BDL Web Services on server side, it is the Web Server that is in charge of the BDL Web Services server security, not the BDL server application itself. You must refer to your Web Server manual to secure the server part of the Web Services.

> **Note:** This is useful for deployment purposes, as no additional code modification is necessary, even if the location of the different servers changes, or if different cryptography keys or X509 certificates are necessary for a same application but intended to several customers with their own needs.

FGLPROFILE entries

The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

> **Important:** Web Services FGLPROFILE configuration options are not supported on GMI mobile devices.

- HTTPS and password encryption on page 2510
- Basic or digest HTTP authentication on page 2512
- Proxy configuration on page 2512
- Server configuration on page 2513
- XML configuration on page 2514

HTTPS and password encryption

The following table lists the FGLPROFILE entries specifying the security certificates and algorithms the Web Services client uses for HTTPS and password encryption. These entries specify how an application using the low-level com or xml APIs performs secured communications.

Table 556: Security Configuration FGLPROFILE entries

Entry	Description
`security.global.script`	Filename of a script executed each time a password of a private key is required by the client. The security script accepts one argument corresponding to the filename of the private key for which the password is required, and must return the correct password or the client stops. For script examples, see Windows™ Password Script Example or UNIX™ Password Script Example. This entry cannot be used if security.global.agent is set.
`security.global.agent`	Port number where the fglpass agent is waiting for requests. It returns the password that grants access to a private key when needed by a BDL application. The DVM and the fglpass agent perform authentication and exchange encrypted data over the local host network only. Refer to Using the password agent for details. This entry cannot be used if security.global.script is set.
`security.global.protocol`	The SSL protocol to use for secured communications. Possible values are: • TLSv1.2 • TLSv1.1

Entry	Description
	• TLSv1 (version 1.0) • SSLv3 • SSLv23 (The default, enabling all supported protocols)
`security.global.ca`	Filename of the Certificate Authority list, with the concatenated PEM-encoded third party X.509 certificates considered as trusted, and in order of preference.
`security.global.windowsca`	If set to `true`, build the Certificate Authority list from the Certificate Authorities stored in the Windows™ key store. This entry is only valid on Windows™ systems where *security.global.ca* is not set.
`security.global.cipher`	The list of encryption, digest, and key exchange algorithms the client is allowed to use during a secured communication. If this entry is omitted, all algorithms are supported. For more details about cipher, refer to www.openssl.org.
`security.global.certificate`	Filename of the PEM-encoded client X.509 certificate to be used for any secured connection if not redefined in a specific server configuration.
`security.global.privatekey`	Filename of the PEM-encoded private key associated to the above X509 certificate and to be used for any secured connection if not redefined in a specific server configuration.
`security.global.keysubject`	The subject string of a X.509 certificate and its associated private key registered in the Windows™ key store to be used for any secured connection if not redefined in a specific server configuration. This entry is valid only on Windows™ systems.
`security.`*`ident`*`.certificate`	Filename of the PEM-encoded client X.509 certificate.
`security.`*`ident`*`.privatekey`	Filename of the PEM-encoded private key associated to the above X509 certificate.
`security.`*`ident`*`.keysubject`	The subject string of a X.509 certificate and its associated private key registered in the Windows™ key store. This entry is valid only on Windows™ systems.

Note:

1. The **ident** keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more that once, only the last occurrence is taken into account.

Basic or digest HTTP authentication

The following table lists the FGLPROFILE entries that specify the login and password to use in the case of HTTP authentication to a server or a proxy. The entries also specify the login and password to use in an application using the low-level com or xml API.

Table 557: HTTP basic or digest Authentication FGLPROFILE entries

Entry	Description
`authenticate.`*`ident`*`.login`	The login identifying the client to a server during HTTP Authentication.
`authenticate.`*`ident`*`.password`	The password validating the login of a client to a server during HTTP Authentication. As passwords should never be in clear text, it is recommended that you encrypt them with the **fglpass** tool. For more information, see FGLPROFILE password encryption.
`authenticate.`*`ident`*`.realm`	The string identifying the server to the client during HTTP Authentication. If the string does not match the server's string, authentication fails. This parameter is optional, but it is recommended that you check the server identity, especially if the server's location is suspicious.
`authenticate.`*`ident`*`.scheme`	One of the following strings representing the different HTTP Authentication mechanisms. • **Anonymous** (default value) - The client does not know anything about the server, and performs a first request to retrieve the server authentication mechanism. It then uses the login and password to authenticate to the server using the Basic or Digest mechanism, depending on the server returned value. • **Basic** - The client authenticates itself to the server at first request, by sending the login and the password using the Basic authentication mechanism. • **Digest** - The client performs a first request without any login and password, to retrieve the server information before authenticating itself to the server in a second request using the Digest mechanism.

Note:

1. The **ident** keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more that once, only the last occurrence is taken into account.

Proxy configuration

The following table lists the FGLPROFILE entries that specify how the Web Services client communicates with a proxy. The entries specify the way an application using the low-level com or xml API communicates with a proxy.

Table 558: Proxy Configuration FGLPROFILE entries

Entry	Description
`proxy.http.location`	Location of the HTTP proxy defined as **host:port** or **ip:port**. If the port is omitted, the port 80 is used.
`proxy.http.list`	The list of beginning host names, separated with semicolons, for which the Web Services client does not go via the HTTP proxy.
`proxy.http.authenticate`	The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTP proxy.
`proxy.https.location`	Location of the HTTPS proxy defined as **host:port** or **ip:port**. If the port is omitted, the port 443 is used
`proxy.https.list`	The list of beginning host names, separated with semicolons, for which the Web Services client does not go via this HTTPS proxy.
`proxy.https.authenticate`	The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTPS proxy.

Note: If an entry is defined more that once, only the last occurrence is taken into account.

IPv6 configuration

The following table lists the FGLPROFILE entries that specify how the Web Services client uses the IPv6 network protocol.

Table 559: IPv4 and IPv6 FGLPROFILE entries

Entry	Description
`ip.global.version`	Defines the IP version to be used. Possible values are "4" (IPv4) or "6" (IPv6). By default, when this entry is not defined, the WS library will try to use IPv6 and fallback to IPv4, according to the operating system.
`ip.global.v6.interface.name` **Important:** This entry is not supported on Microsoft™ Windows™ platforms.	Defines the name of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as "eth0", "en0", "ethernet_5".
`ip.global.v6.interface.id`	Defines the id of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as "1", "2", "11".

Note: If an entry is defined more that once, only the last occurrence is taken into account.

Server configuration

The following table lists the FGLPROFILE entries that specify the correct way a Web Services client connects to an end point (usually a server). Notice that the entries specify also the way an application using the low-level com or xml API connects to an end point.

Table 560: Server Configuration FGLPROFILE entries

Entry	Description
`ws.`*`ident`*`.url`	The endpoint URL of the server. By using a wildcard in the URL, you can create a URL base that applies to multiple server applications. URLs that have the same URL base can share server configuration (such as authentication and HTTPS). See Wildcards in the URL base on page 2517.
`ws.`*`ident`*`.cipher`	The list of encryption, digest and key exchange algorithms the client is allowed to use during a secured communication to that server. It overwrites the global definition.
`ws.`*`ident`*`.verifyserver`	If set to `true`, the client performs a strict server identity validation. If not fulfilled, it stops the communication; otherwise no server identity verification is performed. The default value is `true`.
`ws.`*`ident`*`.security`	The security identifier the client uses to perform an HTTPS communication to the server.
`ws.`*`ident`*`.authenticate`	The HTTP authenticate identifier the client uses to authenticate itself to the server.

Note:

1. The **ident** keyword must be replaced with your own identifier. All necessary entries, depending on the remote server's configuration, must be set. See FGLPROFILE setting.
2. You can use the unique identifier in the .4gl code instead of the server URL, with the **alias://** prefix. For example, **alias://ident**.
3. If an entry is defined more that once, only the last occurrence is taken into account.

XML configuration

The following table lists the FGLPROFILE entries that control XML to Genero values conversion, and XML cryptography key or certificate mapping.

Table 561: XML configuration FGLPROFILE entries

Entry	Description
`xml.keystore.calist`	The list of PEM-encoded third party X.509 certificates, separated with semicolons, of the Certificate Authority considered as trusted, in order of preference.
`xml.keystore.x509list`	The list of PEM-encoded third party X.509 certificates, separated with semicolons, to be used to find out the correct X.509 certificate when

Entry	Description
	getting an incomplete one in a XML signature or an encrypted XML document.
`xml.`*`ident`*`.key`	The filename of a cryptography key. For instance *RSA.pem*, *DSA.der* or *HMAC.bin*.
`xml.`*`ident`*`.x509`	The filename of a cryptography x509 certificate. For instance *Cert.crt*.
`xml.serializer.supportEmptyStrings`	Controls empty string XML nodes conversion to Genero `STRING` values. The default is `false`, empty XML tags are converted to `NULL`. If set to `true`, an empty XML tag is converted to an empty `STRING` value. As result, in Genero, the `LENGTH()` function will return zero and the `IS NULL` comparison operator will evaluate to `FALSE`. Note that this entry only works for the `STRING` data type, and if the tag is not present, the `STRING` is set to `NULL`.
`xml.signature.prefix = { "`*`prefix`*`" | "<none>" }`	Defines the prefix for an XML Signature. Use `"<none>"` to specify no prefix. By default, the XML Signature prefix is `"dsig"`.
`xml.encryption.prefix = { "`*`prefix`*`" | "<none>" }`	Defines the prefix for an XML Encrypted data. Use `"<none>"` to specify no prefix. By default, the XML Encrypted data prefix is `"xenc"`.

Note:

1. The **ident** keyword must be replaced with your own identifier. See FGLPROFILE sample 2.
2. You can use the unique identifier in the .4gl code instead of the filename.
3. If an entry is defined more that once, only the last occurrence is taken into account.

Examples
Windows™ password script example

```
@echo off
REM -- Windows password script
IF "%1" == "Cert/MyPrivateKeyA.pem" GOTO KeyA
IF "%1" == "Cert/MyPrivateKeyB.pem" GOTO KeyB
GOTO end
:KeyA
ECHO PasswordA
GOTO end
:KeyB
ECHO PasswordB
GOTO end
:end
GOTO :EOF
```

UNIX™ password script example

```
# UNIX password script
if [ "$1" == "Cert/MyPrivateKeyA.pem" ]
 then
  echo PasswordA
fi
if [ "$1" == "Cert/MyPrivateKeyB.pem" ]
 then
  echo PasswordB
fi
```

FGLPROFILE sample

The following is an FGLPROFILE sample, configured for a connection to a HTTPS server via a proxy, and with HTTP and Proxy Authentication.

```
# Security configuration
security.global.script   =  "Cert/password.sh"
security.global.ca       =  "Cert/CAList.pem"
security.global.cipher   =  "HIGH" # Use only HIGH encryption ciphers
security.mykey.certificate =  "Cert/MyCertificateA.crt"
security.mykey.privatekey  =  "Cert/MyPrivateKeyA.pem"

# Proxy HTTP Authentication
authenticate.proxyauth.login    =  "myapplication"
authenticate.proxyauth.password =  "mypswd"
authenticate.proxyauth.scheme   =  "Basic"

# HTTPS Proxy configuration
proxy.https.location     =  "10.0.0.170"
proxy.https.list         =  "www.mycompany.com;www.mycompany.com"
proxy.https.authenticate =  "proxyauth"

# Server HTTP Authentication
authenticate.serverauth.login    =  "mylogin"
authenticate.serverauth.password =  "password"

# Server configuration
ws.myserver.url =  "https://www.MyMachine.com/cgi-bin/fglccgi.exe/ws/r/
MyWebService"
ws.myserver.authenticate =  "serverauth"
ws.myserver.security     =  "mykey"
```

FGLPROFILE sample 2

The following is an FGLPROFILE sample, configured for XML cryptography and using the fglpass agent to get the private key passwords.

```
# Security configuration
security.global.agent     = "4444"

# Crypto configuration
xml.keystore.calist     = "RSARootCertificate.crt;DSARootCertificate.crt"
xml.keystore.x509list   = "RSA1024Certificate.crt;DSA1024Certificate.crt"
xml.id1.x509          = "RSA1024Certificate.crt"
xml.id2.x509          = "DSA1024Certificate.crt"
xml.id3.key           = "RSA1024Key.pem"
xml.id4.key           = "DSA1024Key.der"
xml.id5.key           = "HMAC.bin"
```

Wildcards in the URL base

By using a wildcard in the URL, you can create a URL base that applies to multiple server applications. URLs that have the same URL base can share server configuration (such as authentication and HTTPS).

To create a URL base, add a wildcard (`/*`) to the end of a URL in the fglprofile entry. A server application that starts with this URL (and that is not explicitly defined elsewhere) shares the configuration with other applications that also start with the same base URL. If an application has its own server configuration explicitly defined, it uses its specific entries instead of those defined by the wildcard configuration.

Consider this excerpt from a hypothetical `fglprofile`:

```
authenticate.auth.login     = "xxx"
authenticate.auth.password  = "yyy"
authenticate.auth.scheme    = "Basic"

security.sec.certificate    = "client.crt"
security.sec.privatekey     = "client.pem"

ws.myapp.url                = "http://mycompany.com/sample/*"
ws.myapp.authenticate       = "auth"
ws.myapp.security           = "sec"

ws.thirdapp.url             = "http://mycompany.com/sample/application3"
ws.thirdapp.authenticate    = "auth3"

authenticate.auth3.login    = "aaa"
authenticate.auth3.password = "bbb"
authenticate.auth3.scheme   = "Basic"
```

Based on this example:

- Requests to "`http://mycompany.com/sample/application1`" and "`http://mycompany.com/sample/demos/shoppingcart`" use the same authentication and HTTPS configuration.
- A request to "`http://mycompany.com/sample/application3`" uses its specific authentication "`auth3`". No security configuration is defined for this URL, nor does it fall back on the shared security configuration defined for the base URL.

  Note: This applies to:

  - com.HTTPRequest.Create on page 2057`com.HTTPRequest.Create()`
  - xml.DomDocument.load on page 2123`xml.DomDocument.load()`
  - xml.DomDocument.save on page 2126`xml.DomDocument.save()`
  - xml.StaxReader methods
  - xml.StaxWriter methods
  - com.TCPRequest.Create on page 2087

Attributes to customize XML serialization

See The Serializer class on page 2202 for information on setting serialization options when mapping BDL and XML data.

BDL to/from XML type mappings

Starting with Genero 2.0, you can add optional attributes to the definition of program variables to be used for XML serialization. These attributes can be used to map a BDL data type used in the input or output message of a Genero Web Service application to a specific XML data type, rather than using the default.

For example, if an XML Schema boolean data type is required for an application, and the corresponding BDL type is a SMALLINT, you can use an attribute to map the BDL SMALLINT variable to the XML boolean.

The following example uses the XSDBoolean attribute to map a BDL SMALLINT variable to an XML Schema boolean type, and assigns an uppercase name as the XMLName attribute:

```
GLOBALS
DEFINE invoice_out RECORD
  ok SMALLINT ATTRIBUTES(XSDBoolean,XMLName="OK")
END RECORD

END GLOBALS
```

If you assign your own XMLName attributes, be sure to respect the conventions when using the RPC Service Style.

See the Tutorial: Writing a GWS Server application for additional information about input and output messages.

Default BDL/XML mapping

By default, Genero Web Services maps BDL variables in the input or output messages of a WS application to their corresponding XML data types, enabling values to be passed between applications and Web Services. The XML data types conform to the standard XML Schema Definition (XSD):

Table 562: Default XML Mapping

data type of BDL variable	Default XML data type
BYTE	xsd:base64binary
CHAR	xsd:string
DATE	xds.date
DATETIME YEAR TO FRACTION(1-5)	xsd:dateTime
DATETIME YEAR TO SECOND	xsd:dateTime
DATETIME YEAR TO HOUR	xsd:dateTime
DATETIME YEAR TO MINUTE	xsd:dateTime
DATETIME YEAR TO YEAR	xsd:gYear
DATETIME YEAR TO MONTH	xsd:gYearMonth
DATETIME YEAR TO DAY	xsd:date
DATETIME MONTH TO MONTH	xsd:gMonth
DATETIME MONTH TO DAY	xsd:gMonthDay
DATETIME DAY TO DAY	xsd:gDay
DATETIME HOUR TO HOUR	xsd:time
DATETIME HOUR TO MINUTE	xsd:time
DATETIME HOUR TO SECOND	xsd:time
DATETIME HOUR TO FRACTION(1-5)	xsd:time
DECIMAL	xsd:decimal
FLOAT	xsd:double
INTEGER	xsd:int

data type of BDL variable	Default XML data type
INTERVAL	xsd:duration
SMALLFLOAT	xsd:float
SMALLINT	xsd:short
STRING	xsd:string
TEXT	xsd:string
VARCHAR	xsd:string
TINYINT	xsd:byte
BIGINT	xsd:long
BOOLEAN	xsd:boolean

In addition, the Web Service Style that you use determines what default XMLName attributes are assigned to variables.

Type mapping attributes

The attributes listed in this table cannot have values.

Table 563: Mapping between simple BDL and XML data types

Attribute	Definition
XSDAnySimpleType	Map BDL STRING or VARCHAR to XML Schema simpleType.
XSDAnyType	Map BDL STRING or VARCHAR to XML Schema anyType.
XSDAnyURI	Map BDL STRING or VARCHAR to XML Schema anyURI.
XSDBase64binary	Map BDL BYTE to the XML Schema base64binary.
XSDBoolean	Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.
XSDByte	Map BDL TINYINT, SMALLINT or BIGINT to XML Schema byte.
XSDDate	Map BDL DATE or DATETIME to XML Schema date.
XSDDateTime	Map BDL DATETIME to XML Schema dateTime.
XSDDecimal	Map BDL DECIMAL to XML Schema decimal.
XSDDouble	Map BDL FLOAT to XML Schema double.
XSDDuration	Map BDL INTERVAL to XML Schema duration.
XSDEntities	Map BDL STRING or VARCHAR to XML Schema entities.
XSDEntity	Map BDL STRING or VARCHAR to XML Schema entity.
XSDFloat	Map BDL SMALLFLOAT to XML Schema float.

Attribute	Definition
XSDGday	Map BDL DATETIME to XML Schema gDay.
XSDGMonth	Map BDL DATETIME to XML Schema gMonth.
XSDGMonthDay	Map BDL DATETIME to XML Schema gMonthDay.
XSDGYear	Map BDL DATETIME to XML Schema gYear.
XSDGYearMonth	Map BDL DATETIME to XML Schema gYearMonth.
XSDHexBinary	Map BDL BYTE to XML Schema hexBinary.
XSDID	Map BDL STRING or VARCHAR to XML Schema id.
XSDIDREF	Map BDL STRING or VARCHAR to XML Schema idRef.
XSDIDREFS	Map BDL STRING or VARCHAR to XML Schema idRefs.
XSDInt	Map BDL INTEGER or BIGINT to XML Schema int.
XSDInteger	Map BDL DECIMAL to XML Schema integer.
XSDLanguage	Map BDL STRING or VARCHAR to XML Schema language.
XSDLong	Map BDL BIGINT or DECIMAL to XML Schema long.
XSDNCName	Map BDL STRING or VARCHAR to XML Schema NCName.
XSDName	Map BDL STRING or VARCHAR to XML Schema Name.
XSDNegativeInteger	Map BDL DECIMAL to XML Schema negativeInteger.
XSDNMTOKEN	Map BDL STRING or VARCHAR to XML Schema NMToken.
XSDNMTOKENS	Map BDL STRING or VARCHAR to XML Schema NMTokens.
XSDNonNegativeInteger	Map BDL DECIMAL to XML Schema nonNegativeInteger.
XSDNonPositiveInteger	Map BDL DECIMAL to XML Schema nonPositiveInteger.
XSDNormalizedString	Map BDL STRING or VARCHAR to XML Schema normalizedString.
XSDNotation	Not supported.
XSDPositiveInteger	Map BDL DECIMAL to XML Schema positiveInteger.
XSDQName	Map BDL STRING or VARCHAR to XML Schema QName.

Attribute	Definition
XSDShort	Map BDL SMALLINT or BIGINT to XML Schema short.
XSDString	Map BDL STRING , Char, Text or VarChar to XML Schema string.
XSDTime	Map BDL DATETIME to XML Schema time.
XSDToken	Map BDL STRING or VARCHAR to XML Schema token.
XSDUnsignedByte	Map BDL SMALLINT or BIGINT to XML Schema unsignedByte.
XSDUnsignedInt	Map BDL BIGINT or DECIMAL to XML Schema unsignedInt.
XSDUnsignedLong	Map BDL DECIMAL to XML Schema unsignedLong.
XSDUnsignedShort	Map BDL INTEGER or BIGINT to XML Schema unsignedShort.

XSDAnySimpleType

Map BDL STRING or VARCHAR to XML Schema anySimpleType.

XSDAnyType

Map BDL STRING or VARCHAR to XML Schema anyType.

XSDAnyURI

Map BDL STRING or VARCHAR to XML Schema anyURI.

XSDBase64binary

Map BDL BYTE to XML Schema base64binary.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 BYTE ATTRIBUTES(XSDBase64binary,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>F0FFC8D27FF001547FC219E1FFF009F0FFC8D27FF001547D</Val>
</Root>
```

XSDBoolean

Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XSDBoolean,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>true</Val>
```

```
</Root>
```

XSDByte

Map BDL TINYINT, SMALLINT or BIGINT to XML Schema byte.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLINT ATTRIBUTES(XSDByte,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>-126</Val>
</Root>
```

XSDDate

Map BDL DATE or DATETIME to XML Schema date.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATE ATTRIBUTES(XSDDate,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>2006-06-29+01:00</Val>
</Root>
```

XSDDateTime

Map BDL DATETIME to XML Schema dateTime.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME ATTRIBUTES(XSDDateTime,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>2006-06-29T09:35:26.13584+01:00</Val>
</Root>
```

XSDDecimal

Map BDL DECIMAL to XML Schema decimal.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(5,3) ATTRIBUTES(XSDDecimal,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>12.345</Val>
```

```
</Root>
```

XSDDouble

Map BDL FLOAT to XML Schema double.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 FLOAT ATTRIBUTES(XSDDouble,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>12.78e-2</Val>
</Root>
```

XSDDuration

Map BDL INTERVAL to XML Schema duration.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTERVAL DAY TO SECOND
 ATTRIBUTES(XSDDuration,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>P3DT10H30M45S</Val>
</Root>
```

XSDEntities

Map BDL STRING or VARCHAR to XML Schema ENTITIES.

XSDEntity

Map BDL STRING or VARCHAR to XML Schema ENTITY.

XSDFloat

Map BDL SMALLFLOAT to XML Schema float.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLFLOAT ATTRIBUTES(XSDFloat,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>126.435</Val>
</Root>
```

XSDGDay

Map BDL DATETIME to XML Schema gDay.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME DAY TO DAY ATTRIBUTES(XSDGDay,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>---25</Val>
</Root>
```

XSDGMonth

Map BDL DATETIME to XML Schema gMonth.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME MONTH TO MONTH
 ATTRIBUTES(XSDGMonth,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>--12</Val>
</Root>
```

XSDGMonthDay

Map BDL DATETIME to XML Schema gMonthDay.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME MONTH TO DAY
 ATTRIBUTES(XSDGMonthDay,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>--12-31</Val>
</Root>
```

XSDGYear

Map BDL DATETIME to XML Schema gYear.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME YEAR TO YEAR ATTRIBUTES(XSDGYear,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>2006</Val>
</Root>
```

XSDGYearMonth

Map BDL DATETIME to XML Schema gYearMonth.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME YEAR TO MONTH
 ATTRIBUTES(XSDGYearMonth,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>2006-06</Val>
</Root>
```

XSDHexBinary

Map BDL BYTE to XML Schema hexBinary.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 BYTE ATTRIBUTES(XSDHexBinary,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>0FB6</Val>
</Root>
```

XSDID

Map BDL STRING or VARCHAR to XML Schema ID.

XSDIDREF

Map BDL STRING or VARCHAR to XML Schema IDREF.

XSDIDREFS

Map BDL STRING or VARCHAR to XML Schema IDREFS.

XSDInt

Map BDL INTEGER or BIGINT to XML Schema int.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDInt,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>-1258</Val>
</Root>
```

XSDInteger

Map BDL DECIMAL to XML Schema integer.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDInteger,XMLName="Val")
```

```
END RECORD
```

```
<Root>
  <Val>12678</Val>
</Root>
```

XSDLanguage

Map BDL STRING or VARCHAR to XML Schema language.

XSDLong

Map BDL BIGINT or DECIMAL to XML Schema long.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(19,0) ATTRIBUTES(XSDLong,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>1267488</Val>
</Root>
```

XSDNCName

Map BDL STRING or VARCHAR to XML Schema NCName.

XSDName

Map BDL STRING or VARCHAR to XML Schema Name.

XSDNegativeInteger

Map BDL DECIMAL to XML Schema negativeInteger.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0)
 ATTRIBUTES(XSDNegativeInteger,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>-4828</Val>
</Root>
```

XSDNMTOKEN

Map BDL STRING or VARCHAR to XML Schema NMToken.

XSDNMTOKENS

Map BDL STRING or VARCHAR to XML Schema NMTokens.

XSDNonNegativeInteger

Map BDL DECIMAL to XML Schema nonNegativeInteger.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
```

```
  val1 DECIMAL(32,0)
 ATTRIBUTES(XSDNonNegativeInteger,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>1589</Val>
</Root>
```

XSDNonPositiveInteger

Map BDL DECIMAL to XML Schema nonPositiveInteger.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0)
 ATTRIBUTES(XSDNonPositiveInteger,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>-8574</Val>
</Root>
```

XSDNormalizedString

Map BDL STRING or VARCHAR to XML Schema normalizedString.

XSDnotation

Not supported.

XSDPositiveInteger

Map BDL DECIMAL to XML Schema positiveInteger.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0)
 ATTRIBUTES(XSDPositiveInteger,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>+41893</Val>
</Root>
```

XSDQName

Map BDL STRING or VARCHAR to XML Schema QName.

XSDShort

Map BDL SMALLINT or BIGINT to XML Schema short.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLINT ATTRIBUTES(XSDShort,XMLName="Val")
```

```
END RECORD
```

```
<Root>
  <Val>12678</Val>
</Root>
```

XSDString

Map BDL STRING, CHAR, TEXT or VARCHAR to XML Schema string.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 STRING ATTRIBUTES(XSDString,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>Hello world, how are you ?</Val>
</Root>
```

XSDTime

Map BDL DATETIME to XML Schema time.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME ATTRIBUTES(XSDTime,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>23:16:03.589+01:00</Val>
</Root>
```

XSDToken

Map BDL STRING or VARCHAR to XML Schema token.

XSDUnsignedByte

Map BDL SMALLINT or BIGINT to XML Schema unsignedByte.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLINT ATTRIBUTES(XSDUnsignedByte,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>254</Val>
</Root>
```

XSDUnsignedInt

Map BDL BIGINT or DECIMAL to XML Schema unsignedInt.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedInt,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>1267896754</Val>
</Root>
```

XSDUnsignedLong

Map BDL DECIMAL to XML Schema unsignedLong.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedLong,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>12678967543233</Val>
</Root>
```

XSDUnsignedShort

Map BDL INTEGER or BIGINT to XML Schema unsignedShort.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDUnsignedShort,XMLName="Val")
END RECORD
```

```
<Root>
  <Val>65535</Val>
</Root>
```

XML facet constraint attributes

The following attributes are facet constraints depending on the XSD data type used on a simple BDL variable to restrict the allowed value-space.

(Notice that some attributes are allowed only on some XSD data types).

Several facet constraints can be set on the same data type, and a mandatory values is expected (for example, **XSDMinLength="8"**.)

Table 564: Facet constraints between simple BDL and XML data types

Attribute	Definition
XSDLength	Define the exact number of XML character or bytes.
XSDMinLength	Define the minimum number of XML character or bytes.

Attribute	Definition
XSDMaxLength	Define the maximum number of XML character or bytes.
XSDEnumeration	Define a list of allowed values separated by the character **|**.
XSDWhiteSpace	Perform a XML string manipulation before serialization or deserialization.
XSDPattern	Define the regular expression the value has to match.
XSDMinInclusive	Define the inclusive minimum value according to the data type where it is set.
XSDMaxInclusive	Define the inclusive maximum value according to the data type where it is set.
XSDMinExclusive	Define the exclusive minimum value according to the data type where it is set.
XSDMaxExclusive	Define the exclusive maximum value according to the data type where it is set.
XSDTotalDigits	Define the total number of digits.
XSDFractionDigits	Define the number of digits of the fraction part.

XSDLength

Restrict the length of the data to the exact number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater then XSDMinLength
2. XSDMaxLength cannot be used with XSDLength

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDLength="12",
  XMLName="MyString")

DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDLength="8000",
  XMLName="MyPicture")
```

XSDMinLength

Restrict the length of the data to the minimum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater then XSDMinLength
2. XSDMaxLength cannot be used with XSDLength

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMinLength="12",
  XMLName="MyString")
```

```
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary,
 XSDMinLength="8000",
  XMLName="MyPicture")
```

XSDMaxLength

Restrict the length of the data to the maximum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater then XSDMinLength
2. XSDMaxLength cannot be used with XSDLength

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMaxLength="12",
  XMLName="MyString")
```

```
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary,
 XSDMaxLength="8000",
  XMLName="MyPicture")
```

XSDEnumeration

Restrict the allowed value-space to a list of values separated by the characters **|**.

Note:

1. To escape the separator character, simply double it like the following **||**
2. This attribute can be set on any simple BDL variable excepted on XSDBoolean.

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString,
  XSDEnumeration="one|two|three|four", XMLName="MyString")
```

```
DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal,
  XSDEnumeration="12.1|11.8|-24.7", XMLName="MyDecimal")
```

XSDWhiteSpace

Perform a XML string manipulation before serialization or deserialization according to one of the three allowed values:

- **preserve**: the XML string is not modified.
- **replace**: the XML string is modified by replacing each **\n**, **\t**, **\r** by a single space.
- **collapse**: the XML string is modified by replacing each **\n**, **\t**, **\r** by a single space, then each sequence of several spaces are replaced by one single space. Leading and trailing spaces are removed too.

Note:

1. The whiteSpace facet is always performed before any other facet constraints, or serialization or deserialization process.
2. For any BDL variable excepted STRING, CHAR and VARCHAR, only collapse is allowed.

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString,
 XSDWhiteSpace="replace",
  XMLName="MyString")
```

```
DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal,
  XSDWhiteSpace="collapse", XMLName="MyDecimal")
```

XSDPattern

Define a regular expression the value has to match to be serialized or deserialized without any error.

Note:

1. The regular expression is defined in the XML Schema Part 2 specification available here.
2. Backslash characters '\' in a regular expression must be escaped by duplicating it.

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDPattern="A.*Z",
  XMLName="MyString")
```

```
DEFINE myZipCode INTEGER ATTRIBUTES(XSDInt, XSDPattern="[0-9]
{5}",
  XMLName="MyZipCode")
```

```
DEFINE myOtherZipCode INTEGER ATTRIBUTES(XSDInt,
 XSDPattern="\\d{5}", XMLName="myOtherZipCode") # regex is \d{5}
 see note
```

XSDMinInclusive

Define the minimum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The minimum value cannot exceed the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
 XSDMinInclusive="-1000",
  XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDMinInclusive="100.01",
  XMLName="MyRate")
```

XSDMaxInclusive

Define the maximum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The maximum value cannot exceed the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
 XSDMaxInclusive="1000",
  XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDMaxInclusive="299.99",
  XMLName="MyRate")
```

XSDMinExclusive

Define the minimum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The minimum value cannot exceed or be equal to the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
 XSDMinExclusive="-1000",
  XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDMinExclusive="100.01",
  XMLName="MyRate")
```

XSDMaxExclusive

Define the maximum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The maximum value cannot exceed or be equal to the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
 XSDMaxExclusive="1000",
  XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDMaxExclusive="299.99",
  XMLName="MyRate")
```

XSDTotalDigits

Define the maximum number of digits allowed on a numeric data type, fraction part inclusive if there is one.

Note:

1. The total digits value cannot be equal or lower then 0.

2. On a BDL decimal, the total digits value cannot be lower than the precision of the BDL decimal itself.
3. Notice that a decimal without any precision and scale value is a decimal(16), therefore the total digits value must be equal or greater than 16.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDTotalDigits="4",
  XSDMaxExclusive="1000", XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDTotalDigits="5",
  XSDMaxExclusive="299.99", XMLName="MyRate")
```

XSDFractionDigits

Define the maximum number of digits allowed on the fraction part of a numeric data type.

Note:

1. The fraction digits value set on a BDL data type without XSDDecimal set, can only be 0.
2. On a BDL DECIMAL, the fraction digits value cannot be lower than the scale of the BDL DECIMAL itself, and must be lower than the XSDTotalDigits value if set.

Example

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
 XSDFractionDigits="0",
  XSDMaxExclusive="1000", XMLName="MyCode")
```

```
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
 XSDTotalDigits="5",
  XSDFractionDigits="3", XSDMaxExclusive="299.99",
 XMLName="MyRate")
```

Customizing XML serialization

The following attributes are used to change the default serialization of BDL into XML, and vice-versa. Some of these attributes cannot have values; for the others a value is mandatory.

The following attributes cannot have values:

Table 565: XML Serialization customizing - Attributes that cannot have values

Attribute	Definition
XMLOptional	Define whether the variable can be missing.
XMLElement	Map a BDL simple data type to an XML Element.
XMLAttribute	Map a BDL simple data type to an XML Attribute.
XMLBase	Set the base type of an XML Schema simpleContent.
XMLAll	Map a BDL Record to an XML Schema all structure.

Attribute	Definition
XMLChoice	Map a BDL Record to an XML Schema choice structure.
XMLSequence	Map a BDL Record to an XML Schema sequence structure.
XMLSimpleContent	Map a BDL Record to an XML Schema simpleContent structure.
XSComplexType	Map a BDL Record type definition to an XML Schema complexType.
XMLList	Map a one-dimensional array to an XML Schema list.
XMLSelector	Define which member of an XMLChoice record is selected.
XMLAny	Map a Xml.DomDocument object to a wildcard XML element node.
XMLAnyAttribute	Map a BDL one-dimensional dynamic array of a record with 3 strings to XML wildcard attributes.

Values are mandatory for the following attributes: (for example, **XMLName="myname"**)

Table 566: XML Serialization customizing - Attributes that must have values

Attribute	Definition
XMLName	Define the XML Name of a variable in an XML document.
XMLNamespace	Define the XML Namespace of a variable in an XML document.
XMLType	Force the XML type name of a variable.
XMLTypenamespace	Force the XML type namespace of a variable.
XSTypename	Define the XML Type Name of a BDL type definition.
XSTypenamespace	Define the XML Type Namespace of a BDL type definition.
XMLElementNamespace	Define the default XML namespace of all children defined as XMLElement in a Record.
XMLAttributeNamespace	Define the default XML namespace of all children defined as XMLAttribute in a Record.

XMLElement (Optional)

Map a BDL simple data type to an XML Element.

Note: The attribute cannot be set on a type definition.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
```

```
  val1 INTEGER ATTRIBUTES(XMLElement, XSDunsignedShort,
 XMLName="Val1"),
  rec  RECORD ATTRIBUTES(XMLName="Rec")
    val2 FLOAT  ATTRIBUTES(XMLElement, XMLName="Val2"),
    val3 STRING ATTRIBUTES(XMLElement, XMLName="Val3")
  END RECORD
END RECORD
```

```
<Root>
  <Val1>148</Val1>
  <Rec1>
    <Val2>25.8</Val2>
    <Val3>Hello world</Val3>
  </Rec1>
</Root>
```

XMLAttribute

Map a BDL simple data type to an XML Attribute.

Note:

1. The attribute cannot be set on a type definition.
2. The attribute can only be set on a RECORD's member.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER
 ATTRIBUTES(XMLAttribute,XSDunsignedShort,XMLName="Val1"),
  rec  RECORD ATTRIBUTES(XMLName="Rec1")
    val2  FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
    val3  STRING ATTRIBUTES(XMLElement,XMLName="Val3")
  END RECORD
END RECORD
```

```
<Root Val1="148">
  <Rec1 Val2="25.8">
    <Val3>Hello world</Val3>
  </Rec1>
</Root>
```

XMLBase

Define the simple BDL variable used as the base type of an XML Schema simpleContent structure.

The attribute can be set on one and only one member of a RECORD defined with the XMLSimpleContent attribute

XMLAll

Map a BDL Record to an XML Schema all structure.

The order in which the record members appear in the XML document is not significant.

Example

```
DEFINE myall RECORD ATTRIBUTES(XMLAll,XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT   ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3  STRING  ATTRIBUTES(XMLName="Val3")
```

```
END RECORD
```

```
<Root Val2="25.8">
  <Val3>Hello world</Val3>
  <Val1>148</Val1>
</Root>
```

```
<Root Val2="25.8">
  <Val1>148</Val1>
  <Val3>Hello world</Val3>
</Root>
```

XMLChoice

Map a BDL Record to an XML Schema choice structure. The choice of the record's member is performed at runtime, and changes dynamically according to a mandatory member. This specific member must be of type SMALLINT or INTEGER, and have an XMLSelector attribute set. The XMLChoice attribute also supports a "nested" value that removes the surrounding XML tag.

Note:

1. Valid selector values are indexes referring to members considered as XML element nodes. All other values will raise XML runtime errors.
2. Nested choice records cannot be defined as main variables; there must always be a surrounding variable.

Example

```
DEFINE mychoice RECORD ATTRIBUTES(XMLChoice,XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sel   SMALLINT  ATTRIBUTES(XMLSelector),
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD
```

Case where "sel" value is 4

```
<Root Val2="25.8">
  <Val3>Hello world</Val3>
</Root>
```

Case where "sel" value is 1

```
<Root Val2="25.8">
  <Val1>148</Val1>
</Root>
```

Nested example:

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  choice RECORD   ATTRIBUTES(XMLChoice="nested")
    choice1   INTEGER   ATTRIBUTES(XMLName="ChoiceOne"),
    choice2   FLOAT     ATTRIBUTES(XMLName="ChoiceTwo"),
    nestedSel SMALLINT  ATTRIBUTES(XMLSelector)
  END RECORD,
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD
```

Case where "nestedSel" value is 1

```
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceOne>6584</ChoiceOne>
  <Val3>Hello world</Val3>
</Root>
```

Case where "nestedSel" value is 2

```
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceTwo>85.8</ChoiceTwo>
  <Val3>Hello world</Val3>
</Root>
```

XMLSequence (Optional)

Map a BDL RECORD to an XML Schema sequence structure.The order in which the record members appear in the XML document must match the order of the BDL RECORD. The XMLSequence attribute also supports a "nested" value that removes the surrounding XML tag.

Note: Nested sequence records cannot be defined as main variables; there must always be a surrounding variable.

Example

```
DEFINE mysequence RECORD ATTRIBUTES(XMLSequence,XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD
```

```
<Root Val2="25.8">
  <Val1>-859</Val1>
  <Val3>Hello world</Val3>
</Root>
```

Nested example:

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sequence RECORD   ATTRIBUTES(XMLSequence="nested")
    seq1   INTEGER   ATTRIBUTES(XMLName="SeqOne"),
    seq2   FLOAT     ATTRIBUTES(XMLName="SeqTwo")
  END RECORD,
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD
```

```
<Root Val2="25.8">
  <Val1>148</Val1>
  <SeqOne>6584</SeqOne>
  <SeqTwo>85.597</SeqTwo>
  <Val3>Hello world</Val3>
</Root>
```

XMLSimpleContent

Map a BDL RECORD to an XML Schema simpleContent structure.

Note: One member must have the XMLBase attribute; all other members must have an XMLAttribute attribute. If not, the compiler complains.

Example

```
DEFINE mysimpletype RECORD
 ATTRIBUTES(XMLSimpleContent,XMLName="Root")
  base  STRING  ATTRIBUTES(XMLBase),
  val1  INTEGER ATTRIBUTES(XMLAttribute,XMLName="Val1"),
  val2  FLOAT   ATTRIBUTES(XMLAttribute,XMLName="Val2")
END RECORD
```

```
<Root Val1="148" Val2="25.8">
  Hello
</Root>
```

XSComplexType

Map a BDL RECORD type definition to an XML Schema complexType.

Note: You can have one member as a nested sequence or choice, or as an XMLList array with a nested sequence or choice as the array's elements; all other members must have an XMLAttribute attribute. If not, the compiler complains.

Example

```
TYPE mycomplextype RECORD ATTRIBUTES(XSComplexType,
  XSTypeName="MyComplexType",XSTypeNamespace="http://
tempuri.org")
         name DYNAMIC ARRAY ATTRIBUTES(XMLList) OF RECORD
              ATTRIBUTES(XMLSequence="nested")
     firstname STRING ATTRIBUTES(XMLName="FirstName"),
     lastname  STRING ATTRIBUTES(XMLName="LastName")
END RECORD,
  date  DATE ATTRIBUTES(XMLAttribute,XMLName="Date")
END RECORD
```

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
   targetNamespace="http://tempuri.org"
 elementFormDefault="qualified" >
  <xsd:complexType name="MyComplexType">
    <xsd:sequence maxOccurs="unbounded">
      <xsd:element name="FirstName" type="xsd:string" />
      <xsd:element name="LastName"  type="xsd:string" />
    </xsd:sequence>
    <xsd:attribute name="Date" type="xsd:date" use="required"/>
  </xsd:complexType>
</xsd:schema>
```

XMLList

Map a one dimensional array to an XML Schema element that has more than one occurrence.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  list  DYNAMIC ARRAY ATTRIBUTES(XMLList) OF STRING
 ATTRIBUTE(XMLName="Element"),
  val2  FLOAT   ATTRIBUTES(XMLName="Val2")
```

```
END RECORD
```

```
<Root>
  <Val1>148</Val1>
  <Element>hello</Element>
  <Element>how</Element>
  <Element>are</Element>
  <Element>you</Element>
  <Val2>0.58</Val2>
</Root>
```

Note: It is not possible to define an XMLList attribute on a main array.

XMLSelector

Define the index of the candidate among all members of an XMLChoice record that will be serialized or de-serialized at runtime.

The index starts at 1.

The selector data type must be a SMALLINT or a INTEGER.

XMLAny

Map a Xml.DomDocument object to a wildcard XML element:

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",XMLNamespace="http://
tempuri.org")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  any   Xml.DomDocument ATTRIBUTES(XMLAny,XMLNamespace="##other"),
  val2  FLOAT   ATTRIBUTES(XMLName="Val2")
END RECORD
```

```
<pre:Root xmlns:pre="http://tempuri.org" >
  <pre:Val1>148</pre:Val1>
  <pre2:Doc xmlns:pre2="http://www.mycompany.com">
     <pre2:Element>how</pre2:Element>
     <pre2:Element>are</pre2:Element>
     <pre2:Element>you</pre2:Element>
  </pre2:Doc>
  <pre:Val2>
0.58</pre:Val2>
</pre:Root>
```

Note: Associated with XMLAny, the XMLNamespace attribute requires either:

- A list of space-separated URIs to accept each attribute belonging to one of this namespace URI as a wildcard attribute.
- The value **##any** to accept any attribute as a wildcard attribute.
- The value **##other** to accept any attribute not in the main schema namespace as a wildcard attribute.

For example:

- If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the XML documents belonging to one of those namespaces will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
- If XMLNamespace="##any", then any XML document will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
- If XMLNamespace="##other", then any XML document not belonging to the targetNamespace of the XML Schema where the any definition is used will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.

XMLAnyAttribute

Map a one-dimensional dynamic array to wildcard XML attributes.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
 XMLNamespace="http://tempuri.org")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT   ATTRIBUTES(XMLName="Val2"),
  attr  STRING  ATTRIBUTES(XMLName="Attr", XMLAttribute),
  any   DYNAMIC ARRAY ATTRIBUTES(XMLAnyAttribute,
 XMLNamespace="##other")OF RECORD
    ns  STRING,
    name  STRING,
    value  STRING
  END RECORD
END RECORD
```

```
<pre:Root xmlns:pre="http://tempuri.org" pre:Attr="10"
 xmlns:pre2="http://www.mycompany.com" pre2:AnyAttr1="10"
 pre2:AnyAttr2="">
  <pre:Val1>148</pre:Val1>
  <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

Note:

1. The attribute **XMLAnyAttribute** is only allowed on a one-dimensional dynamic array of a record with three members of type STRING. The **first** member is for the **namespace** of the wildcard attribute, the **second** member is for the **name** of the wildcard attribute, and the **third** member is for the **value** of the wildcard attribute. **The name cannot be null.**
2. Associated with the XMLAnyAttribute, the XMLNamespace attribute requires either:
   - A list of space-separated URIs to accept each attribute belonging to one of the namespace URIs as a wildcard attribute.
   - The value **##any** to accept any attribute as a wildcard attribute.
   - The value **##other** to accept any attribute not in the main schema namespace as a wildcard attribute.

   For example:
   - If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the attributes belonging to one of those namespaces will be accepted and serialized (or deserialized) into the array.
   - If XMLNamespace="##any", then any attribute will be accepted and serialized (or deserialized) into the array.
   - If XMLNamespace="##other", then any attributes not belonging to the targetNamespace of the XML Schema where the anyAttribute definition is used will be accepted and serialized (or deserialized) into the array.

XMLName

Define the name of a variable in an XML document.

Note: The attribute cannot be set on a type definition.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT,
  val3  INTEGER ATTRIBUTES(XMLName="Val3")
END RECORD
```

```
<Root>
  <Val1>148</Val1>
  <val2>0.5</val2>
  <Val3>-18547</Val3>
</Root>
```

XMLNamespace

Define the namespace of a variable in an XML document.

Note:

1. If the attribute is set on a Record, by default all members defined as XMLElement of that record are in the same namespace.
2. If the attribute is set on an Array, by default all elements defined as XMLElement of that array are in the same namespace.
3. The attribute cannot be set on a type definition.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
 XMLNamespace="http://tempuri.org")
  attr1 INTEGER ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  val1  FLOAT   ATTRIBUTES(XMLName="Val1", XMLNamespace="http://
www.mycompany.com"),
  val2  INTEGER ATTRIBUTES(XMLName="Val2"),
  attr2 STRING  ATTRIBUTES(XMLAttribute, XMLName="Attr2",
    XMLNamespace="http://anyuri.org")
END RECORD
```

```
<fjs1:Root xmlns:fjs1="http://tempuri.org" Attr1="158"
 xmlns:fjs3="http://anyuri.org" fjs3:Attr2="Hello">
  <fjs2:Val1 xmlns:fjs2="http://www.mycompany.com">0.5</
fjs2:Val1>
  <fjs1:Val2>-18547</fjs1:Val2>
</fjs1:Root>
```

XMLType

Force the XML type name of a variable by adding xsi:type at serialization or by checking xsi:type at deserialization.

Note: The attribute must be used with the XMLTypenamespace attribute; otherwise, the compiler complains.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
                               XMLNamespace="http://tempuri.org")
  val1  FLOAT   ATTRIBUTES(XMLName="Val1"),
  val2  INTEGER ATTRIBUTES(XMLName="Val2",
```

```
                            XMLType="MyRecord",
                            XMLTypenamespace="http://
mynamespace.org")
END RECORD
```

```
<fjs1:Root xmlns:fjs1="http://tempuri.org">
  <fjs1:Val1>0.5</fjs1:Val1>
  <fjs1:Val2 xmlns:fjs2="http://mynamespace.org"
   xsi:type="fjs2:MyRecord">-18547</fjs1:Val2>
</fjs1:Root>
```

XMLTypenamespace

Force the XML type namespace of a variable by adding xsi:type at serialization or by checking xsi:type at de-serialization.

Note: The attribute must be used with the XMLType attribute; otherwise the compiler complains.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
                               XMLNamespace="http://tempuri.org")
  val1  FLOAT   ATTRIBUTES(XMLName="Val1"),
  val2  INTEGER ATTRIBUTES(XMLName="Val2",
                            XMLType="MyRecord",
                            XMLTypenamespace="http://
mynamespace.org")
END RECORD
```

```
<fjs1:Root xmlns:fjs1="http://tempuri.org">
  <fjs1:Val1>0.5</fjs1:Val1>
  <fjs1:Val2 xmlns:fjs2="http://mynamespace.org"
   xsi:type="fjs2:MyRecord">-18547</fjs1:Val2>
</fjs1:Root>
```

XSTypename

Define the XML Schema name of a BDL type definition.

Note:

1. The attribute must be used with the XSTypenamespace attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

Example

```
TYPE myType RECORD ATTRIBUTES(XMLSequence,
                              XSTypeName="MyFirstType",
                              XSTypeNamespace="http://
tempuri.org" )
  val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2  INTEGER
 ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
  attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr")
END RECORD
```

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
```

```
 targetNamespace="http://tempuri.org"
 elementFormDefault="qualified" >
  <xsd:complexType name="MyFirstType">
    <xsd:sequence>
      <xsd:element name="Val1" type="xsd:double" />
      <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="Attr" type="xsd:string"
 use="required" />
  </xsd:complexType>
</xsd:schema>
```

XSTypenamespace

Define the XML Schema namespace of a BDL type definition.

Note:

1. The attribute must be used with the XSType attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

Example

```
TYPE myType RECORD ATTRIBUTES(XMLChoice,
                              XSTypeName="MyFirstChoice",
                              XSTypeNamespace="http://
tempuri.org" )
  val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2  INTEGER
 ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
  attr  STRING
 ATTRIBUTES(XMLAttribute,XMLName="Attr",XMLOptional),
  set   INTEGER ATTRIBUTES(XMLSelector)
END RECORD
```

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 targetNamespace="http://tempuri.org"
 elementFormDefault="qualified" >
  <xsd:complexType name="MyFirstChoice">
    <xsd:choice>
      <xsd:element name="Val1" type="xsd:double" />
      <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
    </xsd:choice>
    <xsd:attribute name="Attr" type="xsd:string" />
  </xsd:complexType>
</xsd:schema>
```

XMLElementNamespace

Define the default namespace of all members of a record also defined as XML elements.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
    XMLNamespace="http://tempuri.org",
    XMLElementNamespace="http://www.mycompany.com")
  val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2  INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
  attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr"),
```

```
                END RECORD
```

```
<fjs1:Root xmlns:fjs1="http://tempuri.org" Attr="Hello"
 xmlns:fjs2="http://www.mycompany.com">
  <fjs2:Val1>0.5</fjs2:Val1>
  <fjs2:Val2>-18547</fjs2:Val2>
</fjs1:Root>
```

XMLAttributeNamespace

Define the default namespace of all members of a record also defined as XML attributes.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
    XMLNamespace="http://tempuri.org",
    XMLAttributeNamespace="http://www.mycompany.com")
  val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2  INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
  attr1 STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  attr2 DATE    ATTRIBUTES(XMLAttribute,
    XMLName="Attr2",XMLNamespace="http://anyuri.org"),
END RECORD
```

```
<fjs1:Root xmlns:fjs1="http://tempuri.org"
 fjs2:Attr1="Hello" xmlns:fjs2="http://www.mycompany.com"
 xmlns:fjs3="http://anyuri.org" fjs3:Attr2="2006-06-24">
  <fjs1:Val1>0.5</fjs1:Val1>
  <fjs1:Val2>-18547</fjs1:Val2>
</fjs1:Root>
```

XMLOptional

Define whether the variable can be missing or not. It specifies how a NULL value is interpreted in XML.

Note:

1. The attribute cannot be set on a type definition.
2. The attribute cannot be set if the main variable is not a RECORD.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDint,XMLName="ValOne"),
  val2 FLOAT ATTRIBUTES(XSDdouble,XMLName="ValTwo",XMLOptional)
END RECORD
```

```
<Root>
  <ValOne>458</ValOne>
  <ValTwo>58.48</ValTwo>
</Root>
```

```
<Root>
  <ValOne>458</ValOne>
</Root>
```

Error handling in GWS calls (STATUS)

In case of problem, the methods of GWS classes can throw an exception and set the STATUS variable with the appropriate error number.

By default, the program will stop if an exception is thrown. You can trap the GWS errors with a `WHENEVER ERROR` handler or with a `TRY/CATCH` block. In the next example, the `readTextRequest()` API is surrounded by a `TRY/CATCH` block:

```
DEFINE req com.HTTPServiceRequest,
       data STRING
...
LET req = com.WebServiceEngine.getHTTPServiceRequest(5)
...
TRY
   ...
   CALL req.readTextRequest() RETURNING data
   ...
CATCH
   CALL show_err(SFMT("Unexpected HTTP request read exception: %1", STATUS))
END TRY
```

For some errors, a human-readable description of the error code is available in the `SQLCA.SQLERRM` register.

Interruption handling in GWS calls (INT_FLAG)

In order to check if an application has been interrupted, GWS tests the INT_FLAG. If the INT_FLAG is set to TRUE, then the GWS function processing is interrupted and an exception is raised with error code -15553.

> **Important:** Make sure that the INT_FLAG register is set to FALSE before calling a GWS function: For example, after a dialog was stopped with cancel action, the INT_FLAG is set to TRUE. If you do not reset INT_FLAG to FALSE, the next GWS function may be canceled.

As a general rule, surroung GWS calls with a `TRY/CATCH` block (or `WHENEVER ERROR` handler), to detect both communication errors and interruptions:

```
TRY
   LET INT_FLAG=FALSE
   ...
   CALL req.sendXMLRequest(doc)
   ...
CATCH
   CASE STATUS
      WHEN -15553 -- TCP socket error
        IF INT_FLAG THEN
           MESSAGE "An interruption occured."
        ELSE
           ERROR "TCP socket error: ", SQLCA.SQLERRM
        END IF
      ...
   END CASE
END TRY
```

Server API functions - version 1.3 only

The following table lists the APIs to create a Web Services server in BDL.

> **Note:** These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the GWS COM Library classes and methods.

Table 567: APIs to create a Web Services server in BDL (version 1.3 only)

Function	Description
fgl_ws_server_setNamespace()	Defines the namespace of the service on the Web.
fgl_ws_server_start()	Creates and starts the Web Service server.
fgl_ws_server_publishFunction()	Publishes the BDL function as a Web Function.
fgl_ws_server_generateWSDL()	Generates the WSDL file.
fgl_ws_server_process()	Waits for and processes incoming SOAP requests.
fgl_ws_server_setFault()	Sets the SOAP fault string for a Web Function.
fgl_ws_server_getFault()	Retrieves the fault string that was set for a Web Function, for testing purposes.

fgl_ws_server_setNamespace() (version 1.3)

Purpose

This function defines the namespace of the service on the Web and must be called first, before all other functions of the API.

Syntax

```
FUNCTION fgl_ws_server_setNamespace(namespace VARCHAR)
```

Parameters

- *namespace* is the name of the namespace.

Return values

- None

Example

```
CALL fgl_ws_server_setNamespace("http://tempuri.org/")
```

fgl_ws_server_start() (version 1.3)

Purpose

This function creates and starts the server. For development or testing purposes, you may start a Web Service server as a single server where only one request at a time will be able to be processed. For deployment, you may start a Web Service server with an application server able to handle several connections at one time using a load-balancing algorithm. The value of the parameter passed to the function determines which method is used.

Syntax

```
FUNCTION fgl_ws_server_start(tcpPort VARCHAR)
```

Parameters

- *tcpPort* is a string representing either:
  - the **socket port number** (for a single Web Service server)
  - the **host** and **port** value separated by a colon (for a Web Service server connecting to an application server). The value of **port** is an offset beginning at 6400.

    Note: If the FGLAPPSERVER environment variable is set, the tcpPort value is ignored, and replaced by the value of FGLAPPSERVER.

Return values

- None

Examples:

To start a standalone Web Service server:

```
CALL fgl_ws_server_start("8080") # A single Server is listening
                                 # on port number: 8080
```

To start a Web Service server attempting to connect to an application server:

```
CALL fgl_ws_server_start("zeus:5") # The server attempt to
connect
                                   # to an application server
located
                                   # on host zeus and listening
                                   # on the port number 6405
```

Possible runtime errors

- -15504: PORT_ALREADY_USED
- -15514: PORT_NOT_NUMERIC
- -15515: NO_AS_FOUND
- -15516: LICENSE_ERROR

fgl_ws_server_publishFunction() (version 1.3)

Purpose

This function publishes the given BDL function as a Web-Function on the Web.

Syntax

```
FUNCTION fgl_ws_server_publishFunction(
  operationName VARCHAR,
  inputNamespace VARCHAR,
  inputRecordName VARCHAR,
  outputNamespace VARCHAR,
  outputRecord VARCHAR,
  functionName VARCHAR)
```

Parameters

- *operationName* is the name by which the operation will be defined on the Web. The name is case sensitive.

- *inputNamespace* is the namespace of the incoming operation message.
- *inputRecordName* is the name of the BDL record representing the Web Function input message or "" if there is none.
- *outputNamespace* is the namespace of the outgoing operation message.
- *outputRecord* is the name of the BDL record representing the Web Function output message or "" if there is none.
- *functionName* is the name of the BDL function that is executed when the Web Service engine receives a request with the operation name defined above.

Return values

- None

Example

```
CALL fgl_ws_server_publishFunction(
 "MyWebOperation",
 "http://www.tempuri.org/webservices/","myfunction_input",
 "http://www.tempuri.org/webservices/","myfunction_output",
 "my_bdl_function")
```

Possible runtime errors

- -15503: FUNCTION_ALREADY_EXISTS
- -15501: FUNCTION_ERROR
- -15502: FUNCTION_DECLARATION_ERROR
- -15512: INPUT_VARIABLE_ERROR
- -15513: OUTPUT_VARIABLE_ERROR
- -15503: BDL_XML_ERROR
- -15518: INPUT_NAMESPACE_MISSING
- -15519: OUTPUT_NAMESPACE_MISSING

fgl_ws_server_generateWSDL() (version 1.3)

Purpose

This function generates the WSDL file according to the BDL-server program.

Syntax

```
FUNCTION fgl_ws_server_generateWSDL(
  serviceName VARCHAR,
  serviceLocation VARCHAR,
  fileName VARCHAR )
  RETURNING resultStatus INTEGER
```

Parameters

- *serviceName* is the name of the web service.
- *serviceLocation* is the URL of the server.
- *fileName* is the name of the file that will be generated.

Return values

- *resultStatus* is a status containing:

- 0 if the file has been correctly generated.
- Any other values if the operation has failed.

Example

```
DEFINE mystatus INTEGER

LET mystatus=fgl_ws_server_generateWSDL(
 "CustomerService",
 "http://localhost:8080",
 "C:/mydirectory/myfile.wsdl")

IF mystatus=0 THEN
  DISPLAY "Generation of WSDL done..."
ELSE
  DISPLAY "Generation of WSDL failed!"
END IF
```

fgl_ws_server_process() (version 1.3)

Purpose

This function waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time. If a DEFER INTERRUPT or DEFER QUIT instruction has been defined, the function returns even if it is an infinite wait.

Syntax

```
FUNCTION fgl_ws_server_process(timeout INTEGER)
   RETURNING resultStatus INTEGER
```

Parameters

- *timeout* is the maximum waiting time for an incoming request (or -1 for an infinite wait)

Return values

- *resultStatus* is a status containing:
  - 0 Request has been processed
  - -1 Timeout has been reached
  - -2 The application server asks the runner to shutdown
  - -3 A client connection has been unexpectedly broken
  - -4 An interruption has been raised
  - -5 The HTTP header of the request was incorrect
  - -6 The SOAP envelope was malformed
  - -7 The XML document was malformed

Example

```
DEFER INTERRUPT
DEFINE mystatus INTEGER
LET mystatus=fgl_ws_server_process(5)# wait for 5 seconds
                                     # for incoming request
IF mystatus=0 THEN
  DISPLAY "Request processed."
```

```
END IF
IF mystatus=-1 THEN
  DISPLAY "No request."
END IF
IF mystatus=-2 THEN # terminate the application properly
  EXIT PROGRAM      # if connected to application server
END IF
IF mystatus=-3 THEN
  DISPLAY "Client connection unexpectedly broken."
END IF
IF mystatus=-4 THEN
  DISPLAY "Server process has been interrupted."
END IF
IF mystatus=-5 THEN
  DISPLAY "Malformed or bad HTTP request received."
END IF
IF int_flag<>0 THEN
  LET int_flag=0
  EXIT PROGRAM
END IF
```

fgl_ws_server_setFault() (version 1.3)

Purpose

This function can be called in a published Web-Function in order to return a SOAP fault string to the client at the end of the function's execution.

Syntax

```
FUNCTION fgl_ws_server_setFault(faultMessage VARCHAR)
```

Parameters

- *faultMessage* is a string containing the SOAP Fault string that will be returned to the client.

Return values

- None

Example

```
CALL fgl_ws_server_setFault(
   "The server is not able to manage this request.")
```

fgl_ws_server_getFault() (version 1.3)

Purpose

This function retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.

> **Note:** This function is only for testing the Web Services functions before they are published on the Web.

Syntax

```
FUNCTION fgl_ws_server_getFault()
  RETURNING faultMessage VARCHAR
```

Parameters

- None

Return values

- *faultMessage* is the string containing the SOAP Fault string.

Example

```
DEFINE div_input RECORD
  a INTEGER,
  b INTEGER
  END RECORD

DEFINE div_output RECORD
  result INTEGER
  END RECORD

FUNCTION TestServices()
   DEFINE string VARCHAR(100)
   ...
   # Test divide by zero operation
   LET div_input.a=15
   LET div_input.b=0
   CALL service_operation_div()
   LET string=fgl_ws_server_getFault()
   DISPLAY "Operation div error: ", string
   ...
END FUNCTION

FUNCTION service_operation_div()
   ...
   IF div_input.b = 0 THEN
     CALL fgl_ws_server_setFault("Divide by zero")
     RETURN
   END IF
   ...
END FUNCTION
```

Configuration API functions - version 1.3 only

The following table lists those configuration API functions that can modify the behavior of the Web Services engine for the client as well as for the server.

> **Note:** These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the COM Library classes and methods.

Table 568: Configuration API functions for Web Services engine behavior modification

Function	Description
`fgl_ws_setOption()`	Sets an option flag with a given value.
`fgl_ws_getOption()`	Returns the value of an option flag.

fgl_ws_setOption()
This function sets an option flag with a given value, changing the global behavior of the Web Services engine.

Syntax

```
FUNCTION fgl_ws_setOption(optionName VARCHAR,
                          optionValue INTEGER)
```

Parameters

- *optionName* is one of the global flags.
- *optionValue* is the value of the flag.

Return values

- None

Example

```
CALL fgl_ws_setOption("http_invoketimeout",5)
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME

fgl_ws_getOption()
This function returns the value of an option flag.

Syntax

```
FUNCTION fgl_ws_getOption(optionName VARCHAR)
     RETURNING optionValue INTEGER
```

Parameter

- *optionName* is one of the global flags.

Return values

- *optionValue* is the value of the flag.

Example

```
DEFINE value INTEGER
LET value=fgl_ws_getOption("http_invoketimeout")
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME

Option flags

Table 569: Option flags

Flags	Client or Server	Commentary
http_invoketimeout	Client	Defines the maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding. A value of -1 means that it has to wait until the server responds. The default value is -1.
tcp_connectiontimeout	Client	Defines the maximum time in seconds a client has to wait for the establishment of a TCP connection with a server. A value of -1 means infinite wait. The default value is 30 seconds except for Windows™, where it is 5 seconds.
soap_ignoretimezone	Both	Defines if, during the marshalling and unmarshalling process of a BDL DATETIME data type, the SOAP engine should ignore the time zone information. A value of zero means false. The default value is false.
soap_usetypedefinition	Both	Defines if the Web Services engine must specify the type of data in all SOAP requests. This will add an "xsi:type" attribute to each parameter of the request. A value of zero means false. The default value is false.
wsdl_decimalsize	Server	Defines if, during the WSDL generation, the precision and scale of a DECIMAL variable will be taken into account. See WSDL generation option notes on page 2555. A value of zero means false. The default value is true.
wsdl_arraysize	Server	Defines if, during the WSDL generation, the size of a BDL

Flags	Client or Server	Commentary
		array will be taken into account. See WSDL generation option notes on page 2555. A value of zero means false. The default value is true.
wsdl_stringsize	Server	Defines if, during the WSDL generation, the size of a CHAR or VARCHAR variable will be taken into account. See WSDL generation option notes on page 2555. A value of zero means false. The default value is true.

WSDL generation option notes

1. For a BDL type **DECIMAL(5,2)**, when **wsdl_decimalsize** is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

```
<types>
   <schema xmlns="http://www.w3.org/2001/XMLSchema"
           targetNamespace="http://www.mycompany.com/types/">
      <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
         <restriction base="decimal">
            <totalDigits value="5" />
            <fractionDigits value="2" />
         </restriction>
      </simpleType>
   </schema>
</types>
<message name="echoDecimal5_2">
  <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
</message>
```

   When **wsdl_decimalsize** is FALSE, the total size and the size of the fractional part are not mentioned:

```
<message name="echoDecimal5_2">
  <part name="dec5_2" type="xsd:decimal" />
</message>
```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this scenario, a default value for the size is generated. For example, the exported server type **DECIMAL(5,2)** becomes a **DECIMAL(32)** on the client side.
3. It is better to keep the options **wsdl_arraysize**, **wsdl_stringsize** and **wsdl_decimalsize** set to TRUE (default) so that the BDL client application can do an exact type mapping.

Using fglwsdl to generate code from WSDL or XSD schemas

This section covers the different options of the fglwsdl tool. This tool is used to generate .4gl code from WSDL / XSD schemas.

Generate TYPE definitions from global XML elements or attributes

If a WSDL or a XSD has global XML elements or attributes defined with an inlined type, the -fInlineTypes option of fglwsdl generates a TYPE definition representing that inline type, using the original

WSDL/XSD name of the element or attribute, concatenated with the string 'GlobalAttributeType' or 'GlobalElementType'.

For example, when using fglwsdl -fInlineTypes, the following schema:

```
<xs:element name="getAlertListRequestFlow">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="getAlertListRequest"
 type="amp:getAlertListRequest" />
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

Will produce:

```
TYPE tgetAlertListRequestFlowGlobalElementType RECORD
         ATTRIBUTES(XMLSequence)
   getAlertListRequest tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
END RECORD
DEFINE getAlertListRequestFlow tgetAlertListRequestFlowGlobalElementType
          ATTRIBUTES(XMLName="getAlertListRequestFlow")
```

Instead of:

```
DEFINE getAlertListRequestFlow RECORD
          ATTRIBUTES(XMLName="getAlertListRequestFlow",XMLSequence)
   getAlertListRequest tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
END RECORD
```

Mobile applications

These topics cover programming subjects about mobile applications

- Types of Genero Mobile apps on page 2557
- Language limitations on page 2560
- Environment variables on mobile on page 2560
- App localization on page 2560
- Apps user interface on page 2561
- Database support on mobile devices on page 2567
- Web Services on mobile devices on page 2569
- Accessing device functions on page 2569
- Debugging a mobile app on page 2570
- Deploying mobile apps on page 2572
- Push notifications on page 2599

Types of Genero Mobile apps

A mobile app is an app that runs on a mobile device, such as a tablet or a phone. There are different types of mobile apps.

When you are developing your app, and you execute the app on your development machine for display on a device or emulator, you are running the app in *development mode*.

When you follow the procedure to deploy your application to the device for testing or to distribute your app to your end users, you have a *deployed app*. A deployed app might be an app that executes irrespective of network availability, it might be an app that accesses device peripherals, it might be an app that requires network access.

Here are the categories, or application types, for deployed apps.

Standalone apps

A *standalone app* has the DVM and display client entirely on the mobile device. This app executes irrespective of network availability and can access device peripherals such as the camera, contacts, email, calendar, GPS, and storage via exposed APIs (front calls). For database needs, this app can only connect to a local SQLite database.

> **Note:** The DVM refers to the dynamic virtual machine, which is the process that runs the app.

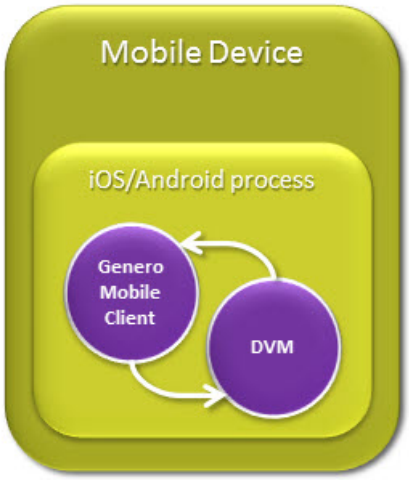

Figure 115: Standalone app

Partially-connected apps

A *partially-connected app* has the DVM and display client entirely on the mobile device, yet this app includes items that require a network connection. This app must be able to run when no network connection is available. This app uses a network API to talk to any back-end.

Examples include:

- Web Services performed with JSON over HTTP; use RESTful methods to write data synchronization routines. With this example, business logic executes within the device's Virtual Machine and the user is able to store captured data to a local SQLite database. When the network becomes available, the user synchronizes the stored data with the remote server's database.

  Note: As of Genero Mobile 1.1, you can also write a Web Service using SOAP.

- A web component that runs Google Maps.

This app first operates without a network connection, and must be able to run without a network connection. Once network connectivity is restored, the app can perform network-dependent tasks such as synchronizing with a remote database, make a web service call, or use a web component.

If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended.

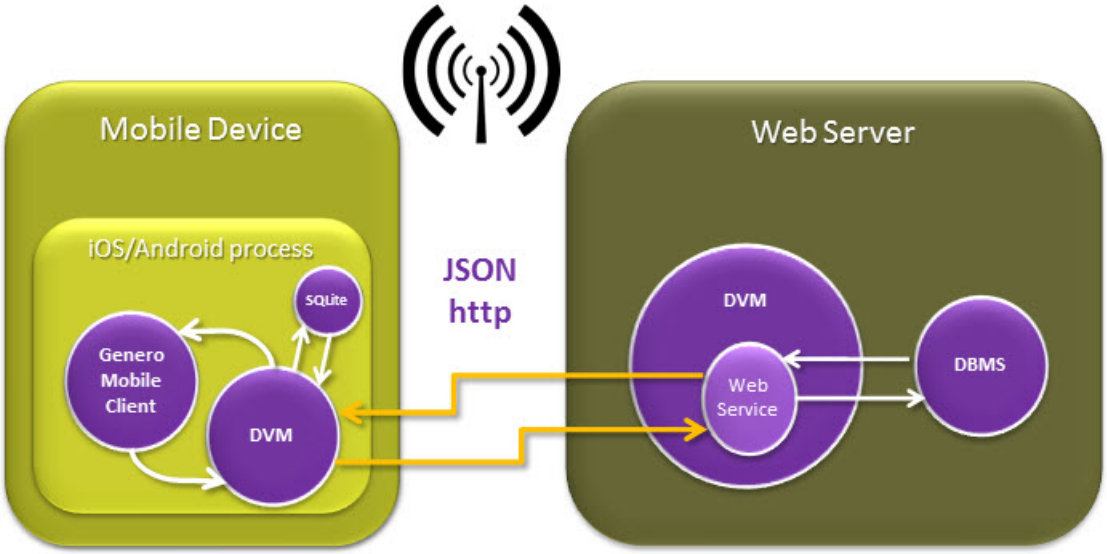

Figure 116: Partially-connected app (example showing data synchronization via JSON)

Client-server apps

With a *client-server app* or *connected app*, the bulk of the app runs on a remote server and the display client sits on the mobile device.

As with any deployed app, this app first starts on the mobile device; the DVM for the deployed app runs on the mobile device. The role of the deployed app, however, is to connect to a remote corporate server as an online terminal. It is the deployed app that launches the remote application using the `runOnServer` frontcall. The remote application's DVM and business logic reside on the remote server, somewhere in the network. The remote application is not limited to a SQLite database.

In the event that the network is interrupted, the Genero Mobile client app is suspended until service resumes.

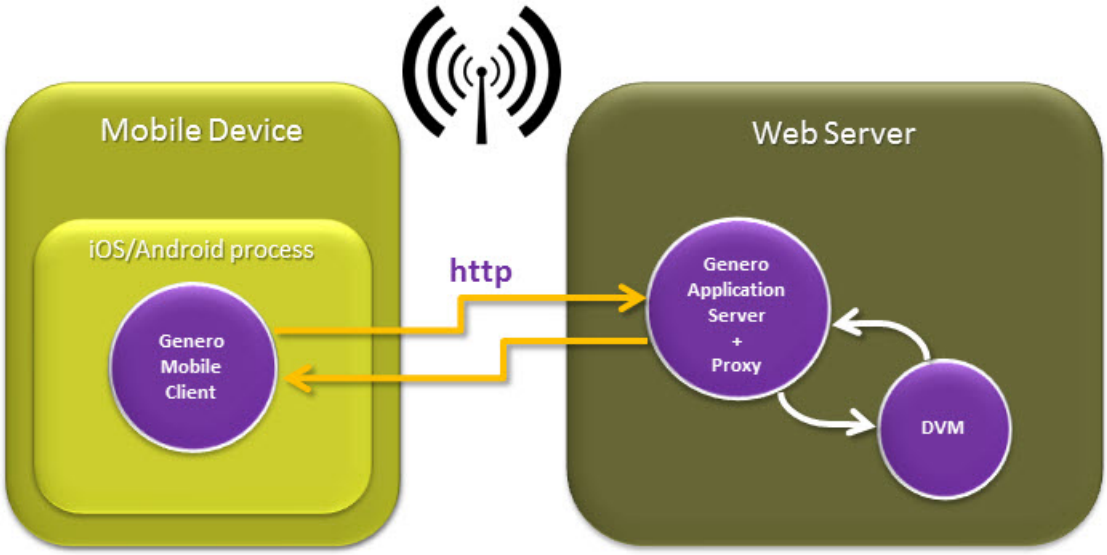

Figure 117: Client-server app

See *Running mobile apps on an application server* in the *Genero Business Development Language User Guide* for more information.

Language limitations

Parts of the Genero language are not supported on mobile devices.

> **Important:** This topic is provided as a quick glance at Genero Business Development Language limitations in mobile applications. Details can be found in the BDL reference topics.

The following language options have limited support:

- The `RUN` instruction has limited support on mobile platforms.
  - The `RUN` instruction is not supported on mobile devices, because of operating system limitations.
  - `RUN` *`command`* `WITHOUT WAITING` is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

The following language features are not supported.

- The `INPUT ARRAY` instruction is not supported.
- The `base.Channel.openPipe` method is not supported.

Environment variables on mobile

You may need to set environment variables for your app.

Set environment variables

Set environment variables for your app must be done in an `fglprofile` file. This fglprofile file must be located beside the main program module.

To add an environment variable for your mobile app, use the following syntax:

```
mobile.environment.DBFORMAT="$:,:.:"
```

Any existing environment variable setting is overwritten by the value set (using `mobile.environment.`*`envvarname`*) in the `fglprofile` file.

For more details, see Setting environment variables in FGLPROFILE (mobile) on page 170.

> **Note:** Environment variables set in an FGLPROFILE file are only read when the deployed application runs the mobile device. They are not read during development mode (i.e. when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

App localization

Mobile apps can be designed to display localized texts according to the current language selected on the device.

Localized string files (`.42s`) must be deployed in directories matching the language identifiers (`en` for English, `zh_TW` for simplified chinese, etc), beside the program module.

The list of `.42s` files required by the application must be defined in the unique `fglprofile` configuration file located beside the program module of your application.

For more details, see Localized string files on mobile devices on page 333 and Deploying mobile apps on page 2572.

Apps user interface

This section includes topics about user interface programming for mobile.

In general, the user interface of a mobile app written in Genero displays and reacts as a desktop or web application, while simultaneously respecting the device operating system look-and-feel. There are parts of the interface, however, that display and react in a specific way.

Take a look at each of the user interface items in this chapter, to understand how they are portrayed in a mobile app. A user interface feature not listed means there is nothing mobile-specific to its display or behavior.

Action rendering

How actions are rendered varies between OS type of the mobile device.

The top and/or bottom parts of the mobile app screen is dedicated to displaying default action views to the user. A default action view is an implicit graphical item that can be tapped to fire the corresponding action.

The default action views are rendered on the mobile device according to platform-specific standards, which are covered in Rendering default action views on mobile on page 1279.

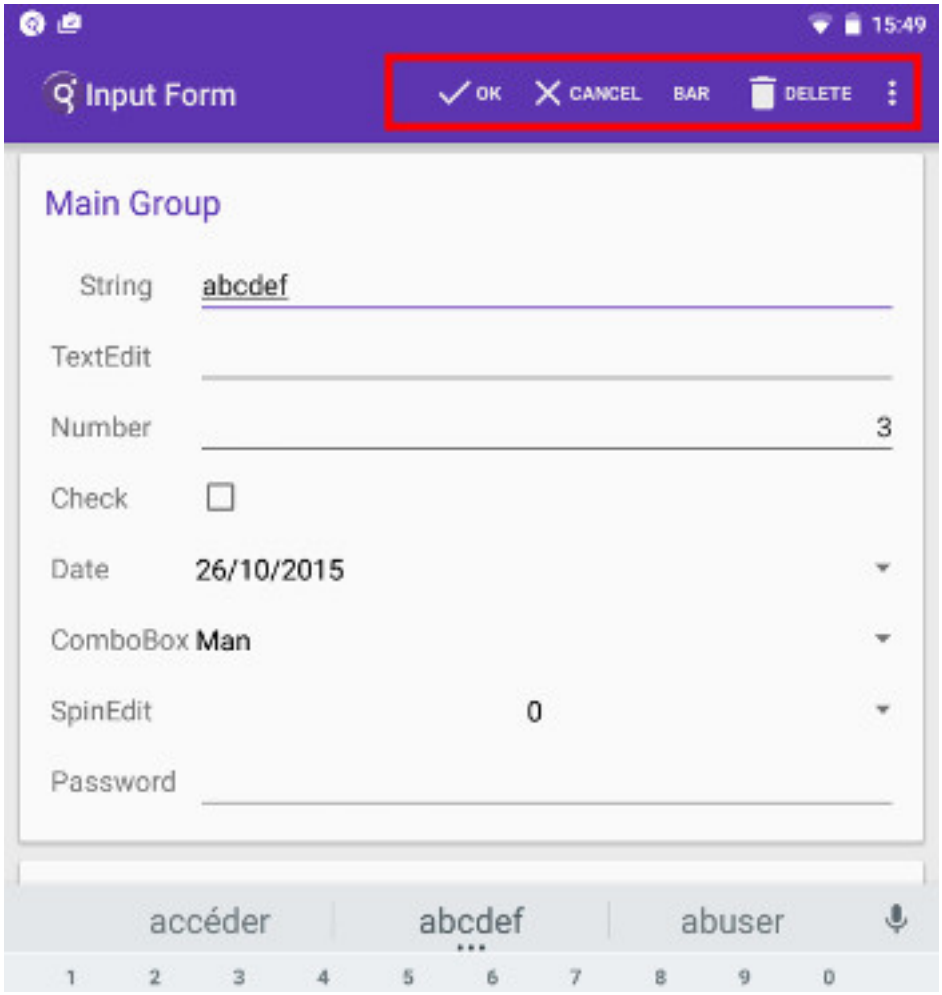

Figure 118: Action rendering example on an Android device

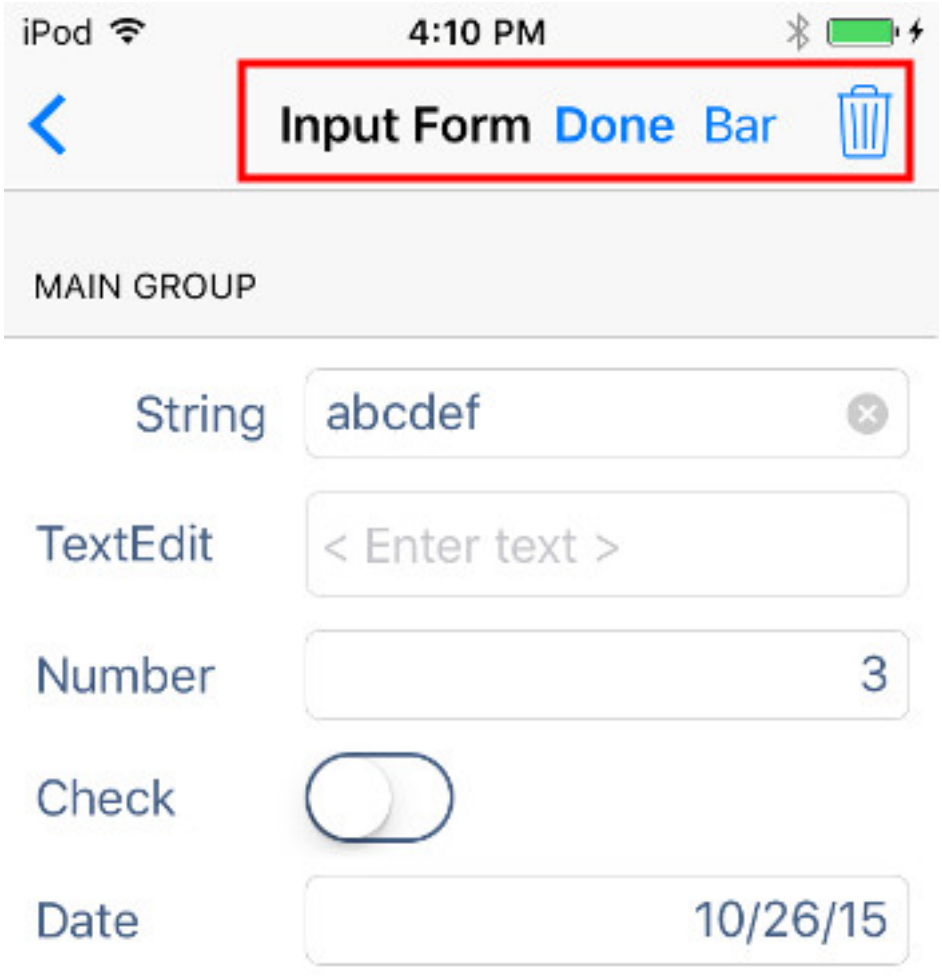

Figure 119: Action rendering example on an iOS device

Images and icons

For this topic, an image can refer to the `IMAGE` item type or the icons used in the app.

Image format support

Mobile apps written in Genero supports all image formats supported by the device OS, however each platform has its own restrictions on which image formats it supports:

- Android image format support
- iOS image format support

Mobile devices have a much higher pixel density (a higher resolution) than classic desktop monitors. An image which looks nice on a desktop can appear small or as an upscaled image on a mobile device.

Providing the image resource

Genero supports different solutions to provide the image data in a mobile app, depending on the need (button icon, application picture, etc). To understand how to get image resource on mobile apps with Genero, see Providing the image resource on page 784.

Image sizing on mobile devices

The `IMAGE` item type defines an area for the display of an image on a form.

Image layout and sizing can be controlled with form item attributes to adapt to the type of mobile device.

For more details, see Controlling the image layout on page 783.

Default action icons

In general, you want the icons used for your mobile app to be the standard icons used by all apps for the mobile platform. Genero is set up to use such icons by default. For more details, see Rendering default action views on mobile on page 1279.

Genero also supports icon centralization based on TTF icons, to get a global consistent look and feel for all your mobile apps. For more details, see Providing the image resource on page 784.

Keyboard type

Depending on the data being entered, a mobile device should display the keyboard that is appropriate for the data.

There are a variety of keyboard types for mobile devices. A field dedicated to phone number input should display a keyboard easying phone number input.

The `KEYBOARDHINT` form field attribute provides a hint regarding the kind of data the form field contains. Valid values include `DEFAULT`, `EMAIL`, `NUMBER`, and `PHONE`:

```
ATTRIBUTES
EDIT f01 = customer.cust_phone, KEYBOARDHINT = PHONE;
...
```

Although Genero mostly respects the provided hint, the variable data type that is bound to the form field is also examined, to determine what keyboard to display:

- If the field is defined as a `DATE` or `DATETIME` field, the date picker displays regardless of the `KEYBOARDHINT` setting.
- If the field is a `TEXT` data, a text keyboard displays regardless of the `KEYBOARDHINT` setting.

For more details, see KEYBOARDHINT attribute on page 973.

List views

Form tables in a mobile app render as list views.

List views are commonly used in mobile apps to present an indexed list of items or selectable list of options. They are also used to let users navigate through hierarchically structured data.

List views are displayed as either *full list views* or *embedded list views*.

The list view only displays the first two columns' content and any associated row image, regardless of the number of columns defined.

No column header/title is displayed in mobile list views. Thus the mobile user cannot manipulate columns (hide, reorder, resize, or sort).

With full list views, the built-in reduce filter allows the user to filter the rows displayed.

The `JUSTIFY` attribute of the second column can influence how the rows are displayed.

Various options affect the rendering and behavior, by defining `TABLE` container attributes, `DISPLAY ARRAY` dialog attributes and `ON ACTION` handler attributes.

For complete details on implementing table views in a mobile app, see Using tables on mobile devices on page 1362.

Split views

Split views refer to the ability to access two forms side by side on a mobile device.

Side by side views on mobile apps

Many mobile apps offer a specific form layout, splitting the screen in two in order to shows a list of the left side and a detail form on the right side. Such kind of layout can be implemented in Genero with the Split views on page 1395.

Differences in how split views are handled by the clients

There are differences between the Genero Mobile for iOS (GMI) and Genero Mobile for Android (GMA) implementations of split views and parallel dialogs, to include:

- When the application displays in a single pane or in two panes.
- How a user switches between the two panes.

There are also differences in how the split view renders between GMA and GMI.

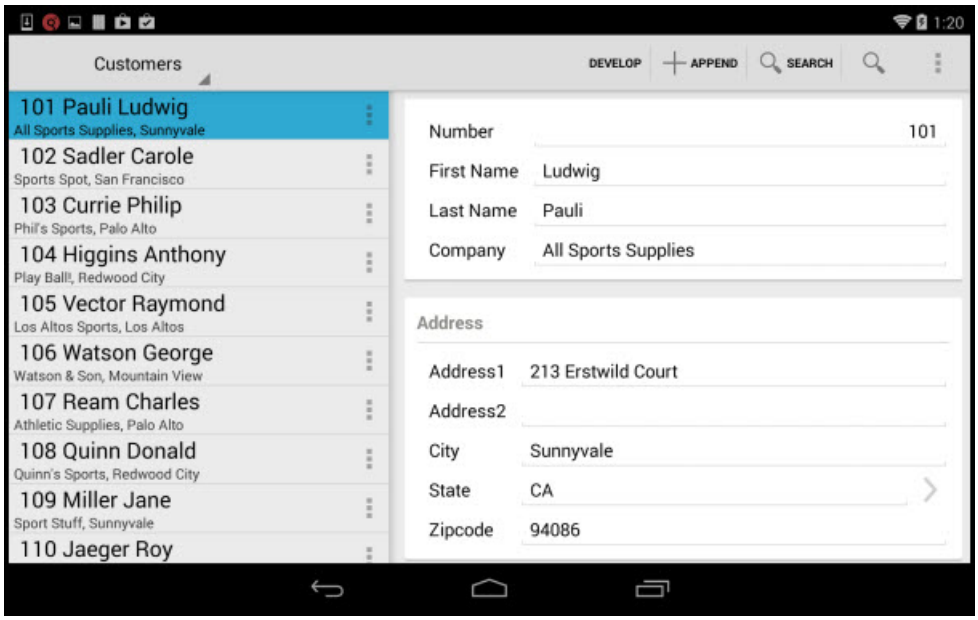

Figure 120: The stores2 demo rendered on an Android device

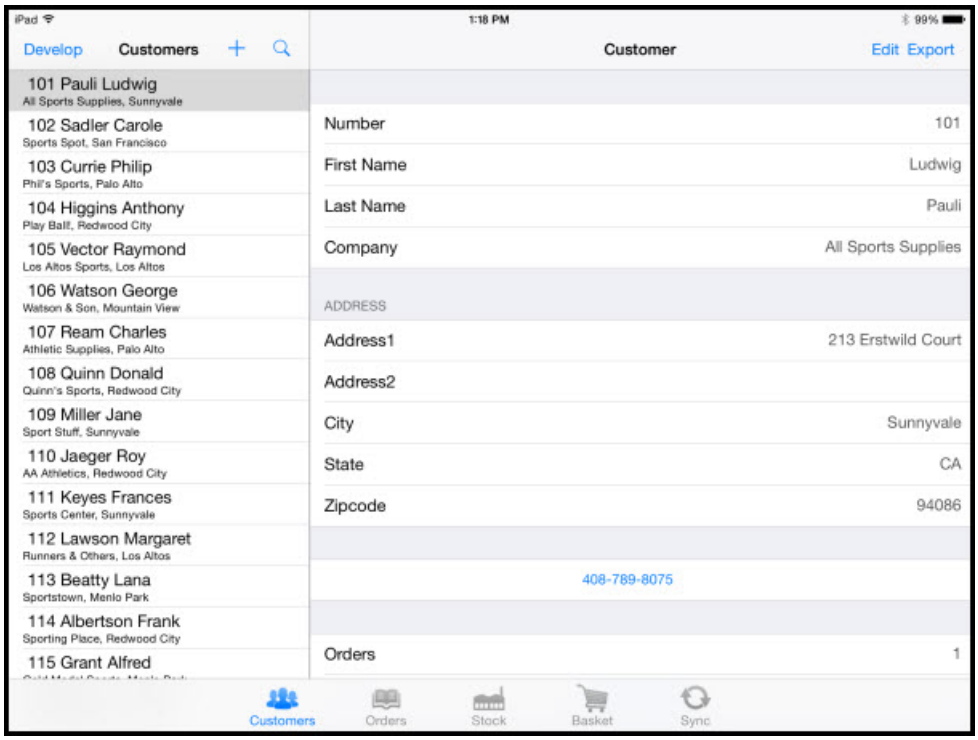
With Genero Mobile for Android:

- The navigator pane renders as a menu in the left-hand side of the title bar.
- All buttons are merged.
- The title is not displayed when there is a navigator pane. If there is no navigator pane, the title of the current window is displayed.



With Genero Mobile for iOS:

- The navigator pane renders along the bottom of the app.
- Each window has its own title and its own buttons.

Figure 121: The stores2 demo rendered on an iOS device

Toolbars

Toolbars allow to control over where actions display (and in what order).

For desktop applications, the toolbar is a series of buttons typically contained in a toolbar object, located at the top of the form. For Genero mobile apps, the toolbars are rendering according to the mobile platform standards.

Table 570: Mobile platform differences for toolbars

GMA	GMI
Genero Mobile for Android does not have toolbars. The action views appear in the Android **action bar**. Toolbar action views are listed first and ordered as they are defined in the toolbar, followed by the action views from the action panel. Disabled actions are greyed out.	The toolbar items render in the iOS toolbar pane. The `iosSeparatorStretch` toolbar style attribute can be used to stretch the separators to give more space between actions. Disabled actions are greyed out.

For more information, see Toolbars on mobile devices on page 1025. Default action views are rendered on mobile devices according to the rules covered in Rendering default action views on mobile on page 1279.

Topmenus

Topmenus provide a hierarchical menu in the app.

The rendering of a TOPMENU depends on the mobile operating system.

Table 571: Genero Mobile and topmenus

GMA	GMI
 **Figure 122: Navigation drawer for Android** A **navigation drawer** is visible in the action bar if a topmenu is available to the displayed form. The navigation drawer is a panel to the left of the app icon (seen as three bars). Tap and the navigation drawer transitions in from the left edge of the screen and displays the app's main navigation actions. Restricted to two levels.	 **Figure 123: Menu button for iOS** A **menu button** is visible in the navigation bar if a topmenu is available to the displayed form. There are no restrictions on the number of levels.

For complete details on implementing top menus in your app, see Topmenus on page 1027.

Front call support

Genero Mobile provides front calls to interface with the device capabilities.

Use front calls to access mobile devices capabilities. For example, with the `mobile/takePhoto` front call, you can open the camera app of the device to take a picture.

> **Note:** In a classical Genero client/server configuration, a frontcall is a remote procedure call that involves a round-trip between the front-end and the server where the application executes. For a standalone mobile app, this does not cause any latency. For a server-side app (i.e. runOnServer), however, latency can result.

The details for each frontcall can be found in Built-in front calls on page 1881.

Color and theming

Mobile applications must follow the platform colors and theming.

User interface design on mobile devices

Genero BDL provides several ways to define colors and styles for a mobile app. This section introduces features that can be used to customize your mobile app and adapt to the target platform user interface design. As a general rule, avoid to use non-standard ergonomics and decorations, using defaults to let Genero render your forms according to the platform standards. For example, the GMA front-end will use Google material design on Android devices.

Defining TTF icon colors

By default, TTF icons get a the color of the platform theme. A default color can be defined for all TTF icons of a window with the `defaultTTFColor` style attribute. In order to define a color for a specific icon, add an #RGB color specification in your image to font glyph mapping file.

For more details, see Using a simple image name (centralized icons) on page 785

App color theme on Android

Android apps can be created with a specific color theme following the Google material design.

When building the APK with the gmabuildtool, you can specify the general app colors with the `--build-app-colors` option.

For more details, see Define app's color theme on page 2578.

Database support on mobile devices

On the device, a Genero app can use SQL for data management.

Databases supported on mobile devices

Only SQLite can be used on mobile devices. SQLite has a small footprint, is free and readily available.

The database driver (dbmsqt) and the SQLite library are built into the runtime system for mobile Genero apps. No database driver specification is required when running on mobile.

To read more about SQLite programming, see Using SQLite database in mobile apps on page 2567.

Synchronizing data with a central database

When local mobile app data needs to be synchronized with a central database, you must write your own synchronization routines using Web Services. You must implement a back-end service to collect mobile database updates and to send central database changes back to the mobile app.

> **Important:** If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended. If you are synchronizing data with the server, and the device goes into standby, the synchronization is suspended until the device resumes from standby. If you have a long synchronization, you need to either disable the sleep to allow the synchronization to complete, or accept that the synchronization will suspend when the device goes into standby mode.

Using SQLite database in mobile apps

On the device, Genero Mobile uses the SQLite database only.

Running an app in development mode

When running an app in development mode (where the app runs on a computer), you can use any database server that Genero supports for the operating system of the server-side app.

Running an app on a mobile device

When running the application on the device, only SQLite can be used. The database must be created at the first application execution, or it must be delivered as the default database in the `.ipa` or `.apk` package.

Locale character set and length semantics

SQLite stores data in UTF-8 codeset, mobile apps will by default run in UTF-8 and with character length semantics (`FGL_LENGTH_SEMANTICS=CHAR`).

Creating the database

Mobile applications usually create their database at first execution. The SQLite database file must be created in the application sandbox, in a writable directory. If the database file does not exist in the current working directory (`os.Path.pwd()`), create an empty file and then perform a `CONNECT TO` instruction.

For more details, see Creating a database from programs on page 414.

Providing a default database

SQLite database file format is cross-platform. Instead of creating the database the first time the application starts, you might want to prepare a default database file in your development environment, and include it in the `.ipa` / `.apk` package.

Data types with SQLite

SQLite does not have strict data type checking as traditional databases. If you define a table column as a `DECIMAL`, you can still store character values in that column. Pay attention to this SQLite specific feature, to avoid invalid storage and type conversion errors in your application.

Consider using the following data types for maximum portability, especially when data needs to be synchronized with a central database server, where the data types must match to the types used in the mobile application: `CHAR`, `VARCHAR`, `DATE`, `DATETIME YEAR TO MINUTE`, `DATETIME YEAR TO FRACTION(3)`, `DECIMAL`, `SMALLINT`, `INTEGER`, `BIGINT`, `BYTE`, `TEXT`.

Optimizing data changes

SQLite can be slow at doing commits, due to the data integrity technique used for transactions. Since each `INSERT` / `UPDATE` / `DELETE` statements acts as an individual transaction (i.e., auto-commit), there will be as many transactions/commits as data manipulation statements. For example, it takes about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.

When executing code that modifies a lot of rows (for example, when inserting default data at first application execution, or when doing synchronization with a central database), enclose the SQL statements within a `BEGIN WORK` / `COMMIT WORK` transaction block to speed up the process:

```
BEGIN WORK
FOR i=1 TO mylog.getLength()
    -- INSERT / UPDATE / DELETE statements
END FOR
COMMIT WORK
```

Enforcing foreign key constraints

SQLite 3.6.19 and + support foreign key constraints, with `ON DELETE CASCADE` and `ON UPDATE CASCADE` options. By default, however, foreign key constraints are not enforced. Each application must explicitly turn on the feature with a `PRAGMA` command. Immediately after the database connection, you can perform the `PRAGMA` command in an `EXECUTE IMMEDIATE` statement:

```
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

Truncating the SQLite database file

By default, when deleting rows, SQLite keeps the unused database file pages for future storage. As result, when deleting a large amount of data, the database file might be larger than necessary. Consider truncating the database file with the `VACUUM SQL` command (in an `EXECUTE IMMEDIATE` statement), if disk space is limited and when a lot of database rows were deleted.

Depending on the application, the `VACUUM` command can be executed:

- when starting the application, just after connecting to the database,
- after doing a large database operation (such as a synchronization with a central database),
- as a manual option that the user can trigger.

For example, after connecting to the database:

```
CONNECT TO connstr AS "c1"
```

```
EXECUTE IMMEDIATE "VACUUM"
```

Sharing database files between Android apps

Two different Android apps (each packaged as a separate `.apk`) execute in their own sandbox, but have access to the storage area (SD-CARD) and therefore could share a common database file.

SQLite handles concurrent access to the same database file by setting a lock on the entire db file when modifying data (`INSERT`/`UPDATE`/`DELETE`). By default, if a writer process locks the file, other processes must wait until the lock owner process completes its transaction and releases the lock.

Because of Informix compatibility, Genero BDL uses a default lock timeout or zero (i.e., not waiting for locks to be released). As result, when writing to a database file that is locked by another process, if the isolation level is `SERIALIZATION` (the default with SQLite), an application will get the SQL error -244.

To avoid this problem, you must change the default lock timeout with the `SET LOCK MODE` instruction, after starting the database session:

```
CONNECT TO connstr AS "c1"
SET LOCK MODE TO 5 -- seconds
```

The second process will then wait until the first process releases the lock. If transactions are short (milliseconds), having processes waiting for each other is transparent to the user.

Accessing device functions

Mobile apps can access device functions by using front calls.

Mobile applications typically want to acces device functions such as geolocation, multi-media content (photos, videos), messaging (contacts database, email, sms).

This can be easily achieved by using front calls dedicated to mobile features. Note that some functions are platform specific, for example to launch an Android activity, or access to iOS device settings.

As a general rule, execute your front call in a `TRY / CATCH` block to catch errors:

```
DEFINE status STRING,
       latitude, longitude FLOAT
TRY
    CALL ui.Interface.frontCall("mobile", "getGeolocation",
         [], [status, latitude, longitude] )
CATCH
    ERROR "Could not get coordinates..."
END TRY
```

For more details, see Genero Mobile common front calls on page 1925, Genero Mobile Android front calls on page 1940, Genero Mobile iOS front calls on page 1945.

Web Services on mobile devices

Web Services can be used within mobile applications.

Genero Mobile for Android

Requirements for Web Services on Android platforms:

- V3 SSL Certificates

For complete details about the requirements for Web Services on GMA, see GMA / Android Web Services requirements on page 2419

Genero Mobile for iOS

Requirements for Web Services on iOS platforms:

- Some `com` classes are not supported.
- Some methods of the `com.HTTPRequest` class have a different behavior on GMI.
- Some `xml` classes are not supported.
- For supported classes of the `xml` package, methods using an URL parameter accept only a file URI.
- SOAP errors and faults are not handled; an application may handle the error -15559.
- GWS configuration entries of FGLPROFILE are not supported.
- A long running HTTP request popup displays after some seconds, giving the user the option to cancel the request.
- HTTP request compression for POST/PUT is not supported.
- Multipart HTTP requests are not supported.
- Limited configuration of SOAP client.

For complete details about limitations for Web Services on GMI, see GMI / iOS Web Services limitations on page 2417.

Debugging a mobile app

Different solutions are available to debug a mobile app.

Debugging a mobile app in development mode

When executing a mobile app program on a server, displaying the user interface on a mobile front-end defined by FGLSERVER, it is possible to debug the BDL code with the `fglrun -d` option:

```
$ export FGLSERVER=device-ip-address
$ fglrun -d main.42m
```

For more details, see Starting fglrun in debug mode on page 1532.

AUI protocol debugging

With app running on a server or on the device, it is possible to show AUI protocol exchanges in the console running the program on the server, by setting the FGLGUIDEBUG envrionment variable to 1. When this variable set, you can watch user interface events that occur during program execution and how they are treated by the runtime system.

To set the FGLGUIDEBUG environment variable for an app running on the device, use an FGLPROFILE `fglrun.environment` entry. The output can be inspected with the program logs as described later in this section.

For more details, see FGLGUIDEBUG on page 181.

AUI protocol logging in development mode

With app running on a server, it can be useful to log AUI protocol exchanges betweem the runtime system and the mobile front-end, to inspect the content, or replay a scenario. This is possible with the `--start-guilog` and `--run-guilog` options of fglrun:

```
$ fglrun --start-guilog=case1.log
```

The AUI protocol log file produced by the `--start-guilog` option can then be shared for analysis.

For more details, see Front-end protocol logging on page 759.

Debugging a mobile app running on the device

When executing the mobile app on a device, and if the app has been created with debug mode, it is possible to establish a connection to the runtime system executing on the mobile device, by using the `fgldb` command line tool.

> **Important:** On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

For example:

```
$ fgldb -m 192.168.1.23:6400
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

This way you can debug an app running on a device, by using the source code located on the server where the `fgldb` command is executed.

For more details, see Debugging on a mobile device on page 1534.

Building mobile apps in debug mode

In order to enable debug features of an app running on a mobile device, you need to build the app in debug mode:

- For Android:

  The `gmabuildtool` provides the `--mode debug` option, to create a debug version of the APK.

  For more details, see Building Android apps with Genero on page 2574.
- For iOS:

  The `gmibuildtool` provides the `--mode debug` option, to create a debug version of the IPA. The certificate defined in the provisioning profile must be a development certificate.

  > **Note:** After installing the debug version of the app on your iOS device, you need to enable the debug port in the app settings.

  For more details, see Building iOS apps with Genero on page 2586.

Browse the AUI tree created on the mobile front-end side

The content of the Abstract User Interface tree created on the mobile front-end side can be inspected from a web browser, when the app has been created with debug mode, or in development mode by executing the app on a server and displaying on the device.

To inspect AUI tree, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

For more details, see Inspecting the AUI tree of a front end on page 751.

Viewing embedded app program logs

The program logs of an app running on a device can be viewed in a browser, if the app was created in debug mode. VM messages (runtime errors, standard output and standard error) are available. This feature is not availbale if the app is build in release mode.

To inspect program logs, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

A menu will then appear in the web page, where you can choose the VM output to be inspected.

Deploying mobile apps

This section describes how to build and deploy mobile apps with Genero.

- Deploying mobile apps on Android devices on page 2572
- Deploying mobile apps on iOS devices on page 2584
- Running mobile apps on an application server on page 2595

Deploying mobile apps on Android™ devices

This section contains information to create a mobile application to be deployed on Android devices.

Directory structure for GMA apps

Platform-specific rules need to be considered when deploying on Android devices (GMA).

The application sandbox

On Android devices, applications are deployed in an application sandbox. The application can access and store data outside of its space, but then the data is also accessible by the other applications.

Directory structure for a GMA application

Inside its application sandbox, an Android app uses the following directory structure:

```
appdir/
|-- main.42m                              --
|-- *.42m                                   |
|-- *.42f                                   |
|-- fglprofile                              |
|   ...                                     |
|-- *.42s                                   |
|-- de/                                     | Program files
|   |-- *.42s                               |
|-- fr/                                     |
|   |-- *.42s                               |
|-- zh/                                     |
|   |-- *.42s                               |
|   ...                                     |
|-- ... other resource files/dirs ...       |
|   ...                                     |
|-- webcomponents                           |
|   |-- component-type                      |
|       |-- component-type.html             |
|       |-- other-web-comp-resource         |
|   ...                                    --

|-- appdata/
    |-- ... writable app files ...

tmpdir/
|-- ... temporary files ...
```

Program files directory (*appdir*)

Application program files (`.42m`, `.42f`, and so on) need to be deployed in the *`appdir`* application base directory.

The program files directory can be found in programs with the `base.Application.getProgramDir` on `page 1705` method.

> **Important:** On Android, the program files directory returned by the `base.Application.getProgramDir()` method is the same directory as the default working directory, returned by `os.Path.pwd()`.

The FGLAPPDIR environment variable is automatically set to the *`appdir`* directory.

Program name (MAIN)

When deploying on mobile devices, the name of the program file must be `main.42m` or `main.42r`.

> **Note:** When using the command-line app build scripts, the name of the program file must be main.42?. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it `main`.

As with other program files, the "MAIN" module must be located under the *`appdir`* application program directory.

Working directory

On Android devices, the default current working directory is the *`appdir`* directory, and can be used for writable files.

The current working directory can be found in programs with the `os.Path.pwd` on `page 2004` method.

Files that need to be writable (such as SQLite database files) can be created directly under the *`appdir`* directory. However, to better organize application files, create sub-directories such as *`appdir/appdata`*, keeping original files directly under the *`appdir`* directory. For example, create the application database under `os.Path.pwd() || "/database"`.

Temporary directory (*`tmpdir`*)

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the standard.feInfo front call, with the "`dataDirectory`" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.

Language directories for localized strings

When the app starts, the appropriate `.42s` string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in app's `fglprofile`, or you can use the main program name to avoid fglprofile settings.

For each language supported by your application, a directory must exist under *`appdir`*, with a name including the locale codes. Consider also providing default string files (in English for ex) directly under *appdir*, in case if the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```
appdir/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

For more details, see Localized string files on mobile devices on page 333.

Deploying a custom fglprofile file

If you need to set fglprofile entries for your mobile application, create a file with the name `fglprofile`, and deploy it under the *appdir* directory, along with the other program files.

See Understanding FGLPROFILE on page 164 for more details about fglprofile settings.

Creating the initial database file

When a mobile application starts for the first time, it typically creates a new database, or copies a existing database template file from the file directory (`base.Application.getProgramDir on page 1705`) to the working directory (`os.Path.pwd on page 2004`).

> **Note:** Different database file names should be used for the original and final application database, as folders pointed by `base.Application.getProgramDir()` and `os.Path.pwd()` can be the same on Android devices.

For more details about database creation on mobile devices, see Creating a database from programs on page 414.

Building Android™ apps with Genero

Genero provides a command-line tool to create applications for Android devices.

Basics

Genero mobile apps for Android are distributed as APK packages like any other Android app. Genero provides a command line tool to build the APK package for your mobile application. For testing purposes, the tool can also deploy and automatically launch the app on a specific device or simulator. The tool has also an option to update the Android SDK.

> **Note:** This documentation section implies that you are familiar with Android app programming concepts and requirements. For example, you will need the Android SDK tools to be installed (and up to date) to build your Android apps. For more details, visit the Android developer site at https://developer.android.com.

Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

- The Genero BDL development environment (FGLDIR) must be installed on the computer to compile your program files.
- The Java JDK must be installed. The minimum required version is 1.7.
- The Android SDK must be installed (the buildtool uses the "Gradle" utility).

  > **Note:** The first time the Android tools are called, they will automatically check for updates. Therefore, you need an internet connection.
- All Android SDK packages required by GMA must be downloaded. In order to download the required Android SDK packages, execute the `gmabuildtool updatesdk` command.

  > **Note:** Execute the `gmabuildtool updatesdk` command every time a new version of the GMA buildtool and GMA binary archive is installed.
- The GMA buildtool and the GMA binary archive must be installed.

  The GMA buildtool and GMA binary archive are provided in the GMA distribution archive (`fjs-gma-*.zip`).

  To setup the GMA buildtool perform the following steps:

  1. Create a dedicated directory (*gma-install-dir*) and extract the content of the `fjs-gma-*.zip`. This will contain the `gmabuildtool` command. Add the *gma-install-dir* directory to your PATH environment variable.

2. Create a directory (*gma-scaffold-project*) for the GMA binary archive, and extract *`gma-install-dir`*`/artifacts/fjs-gma-*-android-scaffolding.zip` into this directory. This direcory will be specified with the `--build-project` option of `gmabuildtool`.

- Android specific app resources such as icons (in all required sizes) are required, along with the application program files.
- If you plan to publish your app on Google Play, register to Google Play as a developer and create a Google Play project.

Environment settings

Define the following environment variables before starting the command-line buildtool:

- Android SDK env settings (ANDROID_HOME, PATH)
- Java JDK env settings (JAVA_HOME, PATH)

Update the Android SDK with the GMA buildtool

After a fresh installation of the GMA buildtool and GMA binary archive, upgrade the Android SDK and downnload all Android SDK packages required by GMA, by executing the `gmabuildtool updatesdk` command:

```
gmabuildtool updatesdk
    --android-sdk /use/local/32bits/android-sdk/r22.6.2
```

The Android SDK installation directory is required for the SDK update, and is found in ANDROID_HOME environment variable, or with the `--android-sdk` option.

If you need to specify a proxy to download the Android SDK, use the `--proxy-host` and `--proxy-port` options:

```
gmabuildtool updatesdk
    --proxy-host amadeus --proxy-port 3232
    ...
```

Building and deploying with the GMA buildtool

The `gmabuildtool build ...` command creates the APK from a set of files, and according to the options passed as parameter.

```
gmabuildtool build
    ... build options ...
```

Once the APK file is created, use the `gmabuildtool test --test-apk` command to install the app on the Android device plugged to the computer, and start the app automatically.

```
gmabuildtool test
    --test-apk path-to-the-apk-file
```

For a complete description of command options, see gmabuildtool on page 2580.

Cleaning the scaffold files

The build process is optimized to avoid a complete APK rebuild every time you invoke the GMA buildtool: When application program file changes are detected, the GMA buildtool will create archive files that can be reused in the next build if no changes are detected. However, files used for the optimized build might be corrupted, for example in case of user interruption or graddle build failure.

In this situation, you can use the `--clean` option of the `gmabuildtool build ...` command, to cleanup the scaffold build directory, and continue with a fresh build:

```
gmabuildtool build --clean
    ... build options ...
```

Using an options file

To simplify option speciciation, create an file with the list of options to be passed to the `gmabuildtool` with the `--input-options` argument. The options file must contain a line for each option/value peer:

```
$ cat myoptions.txt
--build-output-apk-name MyApp
--build-app-name MyApp
--build-app-package-name com.example.myapp
...
$ gmabuildtool --input-options ./myoptions.txt
```

Elements used to building the Android app

The `gmabuildtool build` command builds the Android APK package from the following:

- The GMA binary archive, containing the GMA front end and the FGL runtime system.

  Note: You must unzip the `fjs-gma-*-android-scaffolding.zip` file.

- The compiled application program and resource files (`.42m`, `.42f`, etc) (`--build-app-genero-program*` options),
- The prefix for the APK file name to be generated (`--build-output-apk-name` option),
- The name of the app (`--build-app-name` option),
- The version code of the app (`--build-app-version-code` option),
- The version name of the app (`--build-app-version-name` option),
- Android app specific resources:
  - Android app icons (all sizes) (`--build-app-icon*` options).
- Android app specifics (to sign the app, not required in development mode):
  - The keystore alias, used with the `keytool` to generate the keystore file (`--build-jarsigner-alias` option).
  - The keystore file, generated from `keytool` (for the `--build-jarsigner-keystore` option).

Generate the keystore file to sign your app

In order to build an APK that can be deployed on the market (Google Play), you need to sign your Android app.

First, you need to generate a keystore file with the `keytool` Android utility.

The keystore file and keystore alias will be used by the `gmabuildtool` to sign the APK with the `jarsigner` utility. These signing credentials are passed to the buildtool with the `--build-jarsigner-keystore` and `--build-jarsigner-alias` options.

For more details, see manual Android application signing.

Generated APK file name

The file name of the APK package is formed from:

1. the APK file name prefix defined by the `--build-output-apk-name` option (by default, "app"),
2. the target type (`-arm` or `-x86`),

3. if building a debug version, the `-debug` suffix,
4. the `.apk` file extension.

For example, if the APK file name prefix is `MyApp` and the target architecture is `arm` in debug mode, the resulting APK file name will be: `MyApp-arm-debug.apk`.

Default build directory structure

For convenience, the buildtool supports a default directory structure to find all files required to build the APK:

```
top-dir
|
|-- main.42m and other program files, as described in Directory structure
 for GMA apps on page 2572
|
|-- gma
|   |-- project
|   |   ...
|   |-- temp
|   |   ...
|   |-- ic_app_hdpi.png
|   |-- ic_app_mdpi.png
|   |-- ic_app_xhdpi.png
|   |-- ic_app_xxhdpi.png
|   |   ...
```

In the above directory structure:

1. *`top-dir`* is the top directory of the default structure. It will typically hold your application program files. The program files directory can be specified with the `--build-app-genero` option.
2. *`top-dir`*`/gma` is the default directory containing the GMA binary archive, the temp directory and the app icons.
3. *`top-dir`*`/gma/project` must contain the unzipped GMA binary archive (`fjs-gma-*-android-scaffolding.zip`). This directory can be specified with the `--build-project` option.

Android permissions

In order to use a device feature such as the camera, an Android app must be created by specifying the corresponding Android permissions. Furthermore, Android distinguishes "normal" and "dangerous" permissions. While both type of permissions just need to be specified when building the app, "dangerous" permissions require a user validation: A popup dialog will appear to let the user confirm that the dangerous feature can be accessed. Before Android 6, dangerous permissions defined by the app were asked at app installation. Starting with Android 6, dangerous permissions must be asked by the app code on demand.

Android permissions required for the built-in front calls are automatically set by GMA, which ask automatically user confirmation if the permission is dangerous. For example, if the app code makes a `chooseContact` front call, the GMA will automatically ask the user for the Android permission to access the contacts database, and set the corresponding permission on confirmation. When building your app, there is no need to specify permissions required for built-in front calls.

Other permissions (not involved by built-in front calls) need to be defined when building the app, and "dangerous" permissions need to be asked to the user when needed. In order to ask the user for a given permission, the app must use the `askForPermission` front call.

Android permissions can be specified with the `--build-app-permissions` option of the `gmabuildtool`. Define the list of permissions as a single argument, by using the comma as separator.

For example:

```
gmabuildtool build \
```

```
    ...
    --build-app-permissions android.permission.READ_CALENDAR,... \
    ...
```

Android permissions listed below are defined by default by GMA and therefore do not need to be specified when building your app. For "dangerous" permissions, the GMA will automatically ask the user to access the feature, when corresponding front call is performed:

- Normal permissions set by default in GMA (no user confirmation required):
  - `android.permission.INTERNET`
  - `android.permission.ACCESS_NETWORK_STATE`
  - `android.permission.CHANGE_NETWORK_STATE`
  - `android.permission.ACCESS_WIFI_STATE`
  - `android.permission.WAKE_LOCK`
  - `com.google.android.c2dm.permission.RECEIVE`
  - `packageName.permission.C2D_MESSAGE`
- Dangerous permissions set by default in GMA (requires user confirmation):
  - `android.permission.ACCESS_FINE_LOCATION`
  - `android.permission.ACCESS_COARSE_LOCATION`
  - `android.permission.READ_CONTACTS`
  - `android.permission.GET_ACCOUNTS`
  - `android.permission.MOUNT_FORMAT_FILESYSTEMS`
  - `android.permission.READ_LOGS`
  - `android.permission.READ_PHONE_STATE`
  - `android.permission.WRITE_EXTERNAL_STORAGE`
  - `android.permission.READ_EXTERNAL_STORAGE`

Other permissions required by the app but not listed here need to be specified when building your app, and if the permission enters in the "dangerous" category, the app code must issue an `askForPermission` front call before using the feature. For a complete list of Android permissions, see Android's Manifest permissions.

Define app's color theme

Android apps can be created with a color theme defined by four basic colors to customize your app, that can be defined with the `--build-app-colors` option.

> **Note:** This feature is only available with Android 5.0 / SDK 21 and higher. With older versions of Android, the colors specified with the `--build-app-colors` option will not take effect.

The value provided to the `--build-app-colors` option must be a comma-separated list of four hexadecimal RGB colors.

The position of the color defines its purpose:

1. Primary color: This is the main color used in the app.
2. Primary dark color: This is the color used for the status bar and the navigation bar.
3. Accent color: This is the color used for widgets and table lines.
4. Action bar text color: This is the foreground color for the texts in the action bar.

By default, the color theme is the Genero purple color.

For example, to define a red color theme, use the following combination:

```
gmabuildtool build \
    ...
    --build-app-colors "#F44336,#B71C1C,#EF9A9A,#FFFFFF" \
```

```
    ...
```

For more details about Android color shemes, see Android Colors

Debug and release versions

Android apps can be generated in a debug or release version. Release version are prepared for distribution on Google Play, while debug versions are used in development. In debug mode, the app installed on the device will listen on the debug TCP port to allow `fgldb -m` connections.

Debug or release mode can be controlled with the `--build-mode` option of the `gmabuildtool` command:

```
gmabuildtool build \
    --build-mode debug \
    ...
```

By default the app is build in release mode.

Building an Android app with gmabuildtool

Follow the next steps to setup a GMA app build directory in order to create an Android app, based on the default directory structure:

1. Create the root distribution directory (*`top-dir`*)
2. Copy compiled program files (`.42m`, `.42f`, `fglprofile`, application images, web component files, etc) under *`top-dir`*.
3. Copy the default English `.42s` compiled string resource file under *`top-dir`*.
4. Create non-English langage directories (fr, ge, ...) under *`top-dir`* and copie the corresponding `.42s` files.
5. Copy default application data files (database file for ex) under *`top-dir`*.
6. Create the *`top-dir`*`/gma` directory.
7. Copy Android app resources (icons) under *`top-dir`*`/gma`.

Once the build directory is prepared, issue the following commands to build the APK:

```
$ cd top-dir
$ gmabuildtool build \
    --android-sdk /home/mike/android/sdk \
    --build-project /home/mike/work/example/scaffold_project \
    --build-apk-outputs /home/mike/work/example/outputs \
    --build-output-apk-name MyApp \
    --build-app-name MyApp \
    --build-app-package-name com.example.myapp \
    --build-app-version-code 1002 \
    --build-app-version-name "10.02" \
    --build-jarsigner-alias android_alias \
    --build-jarsigner-keystore /home/mike/work/example/sign/android.keystore
 \
    --build-mode release \
    --build-app-permissions
 android.permission.ACCESS_WIFI_STATE,android.permission.CALL_PHONE
```

> **Important:** The directory specified with the `--build-project` option must contain the unzipped GMA binary archive (`fjs-gma-*-android-scaffolding.zip`).

Building an app with GMA custom extensions

The `gmabuildtool build` command supports APK creation for applications using GMA custom extensions written in Java.

Before building the APK package, create the custom GMA binary archive with your extensions, as described in Packaging custom Java extensions for GMA on page 1590.

When your custom GMA binary archive is complete, build the APK package with the `gmabuildtool build` command. Use the `--build-project` option to specify the path to the Android Studio project that was used to build your custom GMA binary archive:

```
$ gmabuildtool build
    ...
    --build-project /home/mike/android_project/mycustgma
    ...
```

> **Note:** Other options have to be specified as for a regular build using the original standard GMI binary archive.

Deploy and launch the app

After building the APK package, for testing purposes, you can deploy and launch your app from the command line with the `gmabuildtool test` command.

> **Note:** The `test` command is provided for development only. To deploy your app in production for several devices, use the regular publication channel of Android apps.

In order to deploy and launch the app, you must provide:

1. the path to the APK file

There must be only one Android device connected or running Android emulator.

```
$ gmabuildtool test \
     --test-apk /home/mike/work/example/outputs/MyApp-arm-debug.apk
```

gmabuildtool

The gmabuildtool is a utility to create and test applications for an Android devices.

Syntax

```
gmabuildtool { build | test | updatesdk } [options]
```

1. `build` is the command to build an APK package.
2. `test` is the command to deploy and launch an app.
3. `updatesdk` is the command to update the Android SDK to download packages required by GMA.
4. *options* are described in Table 572: gmabuildtool options on page 2580.

Options

Table 572: gmabuildtool options

Option	Short option	Description
`--android-sdk` *path*	`-as`	The path to the Android SDK installation directory. If not specified, defaults to the ANDROID_HOME environment variable.
`--build-app-colors` *color-list*	`-bc`	Define the Android color theme for the app (Android 5.0+ / SDK 21+)

Option	Short option	Description
		The value must be a comma-separated list of four hexadecimal RGB colors. The position of the color defines its purpose: **1.** Primary color: This is the main color used in the app. **2.** Primary dark color: This is the color used for the status bar and the navigation bar. **3.** Accent color: This is the color used for widgets and table lines. **4.** Action bar text color: This is the foreground color for the texts in the action bar. By default, the color theme is the Genero purple color.
`--build-app-genero-program-main` *path*	`-bgpm`	Relative path to the main module of the application (can be .xcf, .42m or .42r). Defaults to `main.42m`
`--build-app-genero-program` *path*	`-bgp`	Defines the path to the application program files (.42m, .42f, etc) The contents of this directory will be zipped and bundled inside APKs. This option can handle an already zipped Genero program archive. If not specified, defaults to the current working directory.
`--build-app-icon-hdpi` *path*	`-bih`	Defines the path to application icon in hdpi. Default is `./gma/ic_app_hdpi.png`, in the current working directory.
`--build-app-icon-mdpi` *path*	`-bim`	Defines the path to application icon in mdpi. Default is `./gma/ic_app_mdpi.png`, in the current working directory.
`--build-app-icon-xhdpi` *path*	`-bixh`	Defines the path to application icon in xhdpi. Default is `./gma/ic_app_xhdpi.png`, in the current working directory.
`--build-app-icon-xxhdpi` *path*	`-bixxh`	Defines the path to application icon in xxhdpi. Default is `./gma/ic_app_xxhdpi.png`, in the current working directory.
`--build-app-name` *app-name*	`-bn`	Application name. If not specified, the application name defaults to the current working directory.
`--build-app-package-name` *name*	`-bpn`	APK package name. The package name should be formatted as "`com.`*`organization-name`*`.`*`app-name`*".

Option	Short option	Description
		If not specified, the application package name defaults to `com.example.`*`current-working-directory`*
`--build-app-permissions` *`permissions`*	`-ba`	Android application permissions. The list of permissions is provided as a comma separated list of `android.permission.*` identifiers. For more details, see Android permissions on page 2577.
`--build-app-version-code` *`version-code`*	`-bvc`	Application version code. For example: 100915 The value of this option must be an integer (do not use decimal numbers).
`--build-app-version-name` *`version-name`*	`-bvn`	Application version name. For example: 10.09.15 This will be the actual app version visible on devices.
`--build-apk-outputs` *`path`*	`-bo`	Defines the destination folder where the APK packages must be created.
`--build-distribution` *`path`*	`-bd`	Distribution folder path. Used to have a location to store the extracted scaffold folder, and be able to build GMA APKs if the project folder is an extension project. Default is `./gma/temp`, in the current working directory.
`--build-jarsigner-alias` *`alias`*	`-bja`	Jarsigner alias. This is the alias provided to the `keystore` utility to build the keystore file to sign the app. Used when APK artifacts are signed.
`--build-jarsigner-keypass` *`keypass`*	`-bjk`	Jarsigner keypass. Specifies the password used to protect the private key of the keystore entry addressed by the alias specified in the --build-jarsigner-alias option. The password is required when using jarsigner to sign a JAR file. Used when APK artifacts are signed.
`--build-jarsigner-keystore` *`path`*	`-bjks`	Jarsigner keystore path. This is the path to the keystore file generated by the `keystore` utility to sign the app. Used when APK artifacts are signed.
`--build-jarsigner-storepass` *`storepass`*	`-bjs`	Jarsigner storepass.

Option	Short option	Description
		Specifies the password that is required to access the keystore. Used when APK artifacts are signed.
`--build-mode {release|debug}`	`-bm`	Package build mode, to build a release version or a development/debug version. Default: `release`
`--build-output-apk-name` *name*	`-ban`	Defines the prefix for the APK packages names. By default, this prefix is "app". The file name of the APK package is formed from: **1.** the APK file name prefix defined by the `--build-output-apk-name` option (by default, "app"), **2.** the target type (`-arm` or `-x86`), **3.** if building a debug version, the `-debug` suffix, **4.** the `.apk` file extension. For example, if the APK file name prefix is `MyApp` and the target architecture is `arm` in debug mode, the resulting APK file name will be: `MyApp-arm-debug.apk`.
`--build-project` *path*	`-bp`	Defines the path to the directory containing the original (unzipped) GMA binary archive files, or the directory containing the Android Studio project, when building a customized GMA. **Note:** When using the original GMA binary archive, the zip file must be uncompressed before executing the build. Default is `./gma/project`, in the current working directory.
`--build-types {x86|arm|x86,arm}`	`-bt`	Target platform type. This option accepts a list of platform types separated by a comma (x86,arm) If not specified, both x86 and arm APKs will be generated.
`--clean`	`-c`	Clean the scaffold build directory before a rebuild. This option can be used with the `build` command, to cleanup the scaffold directories containing the application files, before a new build. To be used in case if the previous build was interrupted or has failed.
`--input-options` *path*	`-i`	Path to the file containing gmabuildtool options.

Option	Short option	Description
		Define all options in a file and pass the file to the gmabuildtool command with the `--input-options` argument. The options file must use the following format: *option-name option-value* ...
`--java-home` *path*	`-jh`	Java home path. Default is JAVA_HOME.
`--proxy-host` *host*	`-ph`	Defines the proxy host for the `updatesdk` command.
`--proxy-host` *port*	`-pp`	Defines the proxy port for the `updatesdk` command.
`--test-apk` *path*	`-ta`	Path to the APK file to deploy and launch with the test command.
`--help`	`-h`	Display the list of options.
`--update-sdk-project <arg>`	`-up`	Update SDK project folder path, used with the `updatesdk` command.
`--verbose-fine`	`-v`	Verbose mode (level 1)
`--verbose-finer`	`-vv`	Verbose mode (level 2)
`--verbose-finest`	`-vvv`	Verbose mode (level 3) - shows all possible logs.
`--version`	`-V`	Display GMA build tool version.

Deploying mobile apps on iOS devices

This section contains information to create a mobile application to be deployed on iOS devices.

Directory structure for GMI apps

Platform-specific rules need to be considered when deploying on iOS devices (GMI).

The application sandbox

On iOS devices, program interactions with the file system are limited to the directories inside the app's sandbox.

Directory structure for a GMI application

Inside its application sandbox, an iOS app uses the following directory structure:

```
appdir/
|-- main.42m                              --
|-- *.42m                                   |
|-- *.42f                                   |
|-- fglprofile                              |
|   ...                                     |
```

```
|-- *.42s                                    |
|-- de/                                      | Program files
|   |-- *.42s                                |
|-- fr/                                      |
|   |-- *.42s                                |
|-- zh/                                      |
|   |-- *.42s                                |
|-- ... other resource files/dirs ...        |
|   ...                                      |
|-- webcomponents                            |
|   |-- component-type                       |
|       |-- component-type.html              |
|       |-- other-web-comp-resource          |
|   ...                                    --

Documents/
|-- ... writable app files ...

tmpdir/
|-- ... temporary files ...
```

Program files directory (*appdir*)

Application program files (`.42m`, `.42f`, as well as other program resources) need to be deployed in the *appdir* directory.

> **Important:** On iOS, the application program directory is read-only. Only the "`Documents`" directory is writable.

The program files directory can be found in programs with the `base.Application.getProgramDir on page 1705` method.

The FGLAPPDIR environment variable is automatically set to the *appdir* directory.

Program name (MAIN)

When deploying on mobile devices, the name of the program file must be `main.42m` or `main.42r`.

> **Note:** When using the command-line app build scripts, the name of the program file must be main.42?. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it `main`.

As with other program files, the "MAIN" module must be located under the *appdir* application program directory.

Working directory

The current working directory for an iOS application is typically a writable "`Documents`" directory, in the private folder of the app. For example, the path to the working directory can be "`/private/var/mobile/.../Documents`".

The current working directory can be found in program with the `os.Path.pwd on page 2004` method.

> **Note:** Any file access without an absolute path will be relative to the current working directory.

Files that need to be writable (such as SQLite database files) must be created or copied from the program files directory into the working directory. Copy must be done by the app at first execution, by using `base.Application.getProgramDir on page 1705`, to find the program files directory, and `os.Path.pwd()`, to find the working directory.

Temporary directory (*tmpdir*)

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the standard.feInfo front call, with the "dataDirectory" parameter.

To create a temporary file name, use the os.Path.makeTempName() method.

Language directories for localized strings

When the app starts, the appropriate .42s string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in app's fglprofile, or you can use the main program name to avoid fglprofile settings.

For each language supported by your application, a directory must exist under *appdir*, with a name including the locale codes. Consider also providing default string files (in English for ex) directly under *appdir*, in case if the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```
appdir/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

For more details, see Localized string files on mobile devices on page 333.

Deploying a custom fglprofile file

If you need to set fglprofile entries for your mobile application, create a file with the name fglprofile, and deploy it under the *appdir* directory, along with the other program files.

See Understanding FGLPROFILE on page 164 for more details about fglprofile settings.

Creating the initial database file

When a mobile application starts for the first time, it typically creates a new database, or copies a existing database template file from the *appdir* program file directory (base.Application.getProgramDir on page 1705) to the working directory (os.Path.pwd on page 2004).

For more details about database creation on mobile devices, see Creating a database from programs on page 414.

Building iOS apps with Genero

Genero provides a command-line tool to build applications for iOS devices.

Basics

Genero mobile apps for iOS are distributed as IPA packages like any other iOS app. Genero provides a command line tool to build the .ipa package for your mobile application, or the .app directory for simulators.

> **Note:** This documentation section assumes that you are familiar with iOS app programming concepts and requirements. In order to build your apps, you must have an Apple developer account, as well as certificates and provisioning profiles to deploy your apps. For more details, visit the Apple developer site at https://developer.apple.com.

Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

- The Genero BDL development environment (FGLDIR) must be installed on the Mac computer to compile your program files.
- The GMI build tool must be installed and available (check that the `gmibuildtool` command is available).

  Note: The GMI build tool is provided as a ZIP archive (`fjs-fglgmi-*.zip`) that must be extracted directly into FGLDIR.

  Important: When re-installing a new GMI archive, remove all "`build`" directories created by the `gmibuildtool`.
- An Apple developer account, device identifiers (UDID) and corresponding identifiers to sign your iOS app (certificate, bundle id, provisioning profile).

  Important: The UDID is the identifier of your physical device, it can be found with the `instruments -s` command when the device is plugged to the Mac. When deploying on a physical device, make sure that the UDID of the device is listed in the Apple Developer account that is used to generate the provisioning profiles.
- XCode must be installed on your Mac OS X computer (utilities from XCode toolchain are required).

  Note: Make sure that the installed XCode version supports the iOS versions of your mobile devices. As a general rule, update the XCode and iOS to the latest versions.
- iOS app resources such as icons and launch images (in all required sizes).

Finding the UDID of the plugged device

In order to find the UDID of the device plugged to your Mac, execute the `instruments -s` command, and identify the line describing your physical device:

```
$ instruments -s
Known Devices:
fraise [55D6D6C1-DE87-52F0-865E-3C6DC79F13D7]
Fourjs2 iPod touch (9.1) [78b7452fa9462c98c3bc7047da344314fd032004]
iPad 2 (9.0) [19CDA827-CA55-46F1-9376-BF61E2ECFDBB]
iPad Air (9.0) [F55E1207-C42B-472E-BD76-5B5AE46DE77A]
iPad Air 2 (9.0) [A0E8C4CD-67CD-42CB-84DF-9C75AC773293]
...
Known Templates:
"Activity Monitor"
"Allocations"
...
```

In the above output, the UDID of the iPod is `78b7452fa9462c98c3bc7047da344314fd032004`.

Environment settings

Before starting the command-line build tool,

- Make sure that XCode tools are available (try `xcodebuild` from the command line)

Creating the GMI front-end for development purpose

Four Js is not allowed to provide a ready-to-use front-end component for iOS devices, because of iOS app limitations defined by Apple: An iOS app shipped on the App Store cannot listen to a TCP port to provide a GUI service. Therefore, you will have to create your own GMI front-end, with your own Apple certificate and provisioning profile. The generated GMI can then be deployed on your device or simulator for development purpose listening on the port 6400, to display applications running on a server (FGLSERVER).

In order to build your own GMI front-end:

1. Make sure that the `gmibuildtool` is available (if not done yet, extract the fjs-fglgmi*.zip archive into FGLDIR).

2. Go to the `FGLDIR/demo/MobileDemo/gmiclient` directory.
3. Delete the complete `build` directory if it exists (can be done with a `make clean` command).
4. Make the GMI app with `make` (program files like `main.42m` file must exist).
5. Build the GMI front-end:

   - In order to build only the GMI front-end (`GMI.app` directory) for the simulator, execute the `gmibuildtool` command without any parameter:

     ```
     $ gmibuildtool
     ```

   - In order to build and install the GMI front-end on the simulator, first make sure that the simulator is started (`open -a simulator` command), then execute the `gmibuildtool` command with following parameters:

     ```
     $ gmibuildtool --device booted
     ```

   - In order to build only the GMI front-end IPA for devices, get a development certificate and provisioning profile and execute the `gmibuildtool` command with following parameters:

     ```
     $ gmibuildtool \
         --device phone \
         --certificate HGRW8... \
         --provisioning "~/Library/MobileDevice/Provisioning Profiles/
     myapp.mobileprovision"
     ```

     The generated IPA file can be found in the `build` subdirectory. This IPA file can be installed on your devices by using iTunes.

   - In order to build and install the GMI front-end on the device plugged to your Mac, get a development certificate and provisioning profile, and the exact device name (with the `instruments -s` command) and execute the `gmibuildtool` command with following parameters::

     ```
     $ gmibuildtool \
         --device "Mike's iPhone 6 (9.0)"  \
         --certificate HGRW8... \
         --provisioning "~/Library/MobileDevice/Provisioning Profiles/
     myapp.mobileprovision"
     ```

Specifying the target to build and deploy the iOS app

The `gmibuildtool` command can build and install iOS apps for the simulator or for physical devices.

The build and/or install action is controlled by the `--device` option:

- By default, when not specifying the `--device` option, a `GMI.app` directory is created for the simulator.
- When specifying the `--device booted` option, the `GMI.app` directory is created and the app is installed on the booted simulator.
- When specifying the `--device phone` option, the `GMI.app` directory and `.ipa` file are created.
- When specifying the `--device` *`physical-device-name`* option (with a real physical device name plugged on your Mac), the `GMI.app` directory and `.ipa` file are created and the app is installed on the device.

By default, the generated `GMI.app` directory and `.ipa` archive can be found in `$PWD/build` sub-directories. However you can specify the destination IPA file with the `--output` option.

Elements used to build the iOS app

The `gmibuildtool` command builds the iOS app package from the following:

- The GMI binary archive, containing the GMI front end and the FGL runtime system library,

Note: These files are provided in the `fjs-fglgmi-*.zip` archive that must be extracted directly under FGLDIR.

Important: When re-installing a new GMI archive, remove all "`build`" directories created by the `gmibuildtool`.

- The compiled application program and resource files (`.42m`, `.42f`, etc),

  Note: The application program files must include a `main.42m` or `main.42r` module.

- The display name of the app (`--app-name` parameter),
- The version of the app (`--app-version` parameter),
- The debug or release mode (`--mode` parameter),
- The certificate (to sign the app) (`--certificate` parameter),
- The bundle Identifier (`--bundle-id` parameter),
- The app provisioning profile (`.mobileprovision` file) (`--provisioning` parameter),
- iOS app specific resources:
  - App icons (`--icons` parameter),
  - Launch images (`--launch-images` parameter) or launch storyboard file (`--storyboard` parameter).

For a complete description of command options, see gmibuildtool on page 2592.

Default build directory structure

For convenience, the build tool supports a default directory structure to find all files required to build the app:

```
top-dir
|
|-- main.42m and other program files, as described in Directory structure
 for GMI apps on page 2584
|
|-- gmi
|   |
|   |-- Info.plist
|   |
|   |-- LaunchScreen.storyboard
|   |
|   |-- Default@2x.png
|   |-- Default-568h@2x.png
|   |-- Default-Landscape.png
|   |-- Default-Landscape-667h@2x.png
|   |-- Default-Landscape-736h@3x.png
|   |-- Default-Landscape@2x.png
|   |-- Default-Portrait.png
|   |-- Default-Portrait-736h@3x.png
|   |-- Default-Portrait-667h@2x.png
|   |-- Default-Portrait@2x.png
|   |   ...
|   |-- icon_29x29.png
|   |-- icon_40x40.png
|   |-- icon_57x57.png
|   |-- icon_58x58.png
|   |-- icon_72x72.png
|   |-- icon_76x76.png
|   |-- icon_80x80.png
|   |-- icon_120x120.png
|   |-- icon_152x152.png
|   |   ...
```

In the above directory structure:

1. *top-dir* is the top directory of the default structure. It will typically hold your application program files. A different program files directory can be specified with the `--program-files` option.
2. *top-dir*`/gmi` is the default directory containing the app resource files such as icons:
   a. `Info.plist` is the Information Property List File that will be used to build the app. Some properties will be overwritten by `gmibuildtool` options like `--app-name` and `--app-version`.
   b. `LaunchScreen.storyboard` is the default storyboard file for the app launch screen. This file can be specified with the `gmibuildtool --storyboard` option.
   c. `Default-*.png` are the app launch image files. The directory to find launch images can be specified with the `gmibuildtool --launch-images` option.
   d. `icon_*.png` are the app icon files. The directory to find icons can be specified with the `gmibuildtool --icons` option.

Debug and release versions

iOS apps can be generated in a debug or release version. Release version are prepared for distribution on the App Store, while debug versions are used in development.

In debug mode, the app installed on the device can listen on the debug TCP port to allow `fgldb -m` connections, after enabling the debug port in the app settings.

Debug or release mode must be specified in the command line with the `--mode debug` or `--mode release` option. Additionnally, if you want to deploy on a physical device, you need to use a provisioning profile corresponding to the debug or release mode:

- In debug mode, the certificate must be a development certificate.
- In release mode, the certificate must be a distribution certificate.

Defining the app version and build number

Apple distinguishes the app version number of a bundle (visible to the end user), from the build version number of a bundle (called a release version number in Apple docs).

You specify the app version number with the `--app-version` option of the `gmibuildtool` command. This option sets the `CFBundleVersion` property of the `Info.plist` file), and must match the version specified in iTunes Connect.

In order to distinguish multiple builds (Apple's term is "releases") of the same app version number, define the build version number of your app with the `--build-number` option. This option sets the `CFBundleShortVersionString` property of the `Info.plist` file. For a given app version, you need to increase this build number, to be able to upload a new binary on iTunes Connect.

> **Note:** If you do not specify the `--build-number` option, the build version number defaults to the app version specified with the `--app-version` option.

Defining app properties in the ./gmi/Info.plist file

iOS app are created with a set of properties that are essential configuration information for a bundled executable. These properties are defined in the "Information Property List File", an XML formatted file, named `Info.plist` by convention.

Most important `Info.plist` properties are defined with `gmibuildtool` options such as `--app-name` and `--app-version`. However, you may need to define other properties that are out of the scope of the build tool. For example: background modes, device capabilities, screen orientations, permanent wifi, etc.

In order to define specific app properties, setup an `Info.plist` file in *top-dir*`/gmi` directory, before executing the `gmibuildtool`. Properties covered by the build tool will be overwritten, while any other property defined in the *top-dir*`/gmi/Info.plist` file will be left untouched.

For more details about the `Info.plist` file structure, see Apple developer site page about Information Property List File.

Building an iOS app with gmibuildtool

Follow the next steps to setup a GMI app build directory in order to create an iOS app, based on the default directory structure:

1. Create the root distribution directory (*`top-dir`*)
2. Copy compiled program files (`.42m`, `.42f`, `fglprofile`, application images, web component files, etc) under *`top-dir`*.
3. Copy the default English `.42s` compiled string resource file under *`top-dir`*.
4. Create non-English langage directories (fr, ge, ...) under *`top-dir`* and copie the corresponding `.42s` files.
5. Copy default application data files (database file for ex) under *`top-dir`*.
6. Create the *`top-dir`*`/gmi` directory.
7. Copy iOS app resources (icons, launch screen, storyboard) under *`top-dir`*`/gmi`.
8. If needed, create an *`top-dir`*`/gmi/Info.plist` file, to define specific iOS app properties.

Once the build directory is prepared, issue the following commands:

```
$ cd top-dir
$ gmibuildtool \
    --output myapp.ipa \
    --app-name "My App" \
    --app-version "v3.1.6" \
    --bundle-id "com.example.mycompany.myapp" \
    --mode release \
    --certificate HGRW8... \
    --provisioning "~/Library/MobileDevice/Provisioning Profiles/
myapp.mobileprovision" \
    --device phone
```

Building a GMI app with C extensions or custom front calls

In order to create an iOS app using C extensions written in Objective-C as in Implementing C-Extensions for GMI on page 1613, you need to setup a `Makefile` calling the `FGLDIR/lib/Makefile-gmi` generic makefile file.

In your Makefile, define the following variables to be passed to the generic makefile:

- `APPNAME`: Defines the display name of the app.
- `BUNDLE_IDENTIFIER`: Defines the Bundle Id (or App Id) of the app.
- `IDENTITY`: Defines the certificate to be used for this app.
- `PROVISIONING_PROFILE`: Defines the provisioning profile generated for this app.
- `USEREXTENSION`: Defines the lib name containing the C extensions.
- `TARGET`: Defines the device where the app must be installed (can be `phone` or `simulator`).

Custom Makefile example:

```
...

all: $(MODULES) $(FORMS) ...

run: all userextension.dylib
      fglrun -e userextension main

userextension.dylib: userextension.c
      fglmkext $?
...
```

```
GMI_OPTIONS = \
   APPNAME=MyApp \
   BUNDLE_IDENTIFIER=com.mycomany.myapp \
   IDENTITY=HGRW8... \
   PROVISIONING_PROFILE=~/Library/MobileDevice/Provisioning\ Profiles/
myapp.mobileprovision \
   USEREXTENSION=userextension.o \
   TARGET=phone

GMI_MAKE = make -f $(FGLDIR)/lib/Makefile-gmi $(GMI_OPTIONS)

gmi.all: all
      $(GMI_MMAKE) all

gmi.install: all
      $(GMI_MMAKE) install

gmi.uninstall:
      $(GMI_MMAKE) uninstall

gmi.info:
      $(GMI_MMAKE) info

gmi.clean:
      ~$(GMI_MMAKE) clean
```

The same technique can be used to build apps that must include custom front calls.

For complete examples, see `FGLDIR/demo/MobileDemo/userextension` and `FGLDIR/demo/MobileDemo/userfrontcall`

gmibuildtool
The gmibuildtool is a utility to create and test applications for an iOS devices.

Syntax

```
gmibuildtool [options]
```

1. *options* are described in Table 573: gmibuildtool options on page 2592.

Options

Table 573: gmibuildtool options

Option	Description
`--app-name` *application-name*	Display name of the mobile app. This option can be specified to define the display name of the app, it sets the `CFBundleDisplayName` property in the `Info.plist` file. If not specified, the name defaults to "Noname".
`--app-version` *application-version*	Defines app version visible to the users on the App Store. This option is mandatory and sets `CFBundleVersion` properties in the `Info.plist` file.

Option	Description
	Note: If the `--build-number` option is not used, `--app-version` will also set the both the `CFBundleShortVersionString` property. In iTunes Connect, you define the version of your app, that must match the `CFBundleVersion` property in the `Info.plist` file of the app. If these versions do not match, the app cannot be published. Once the app is visible on App Store, the version specified in iTunes Connect shows up in the "Version" section of the application page. The app version number should be a string comprised of three period-separated integers. For example: "1.4.2"
`--bundle-id` *`bundle-identifier`*	Defines the Bundle Identifier (a.k.a. App Id) for the app. This option is mandatory and sets the `CFBundleIdentifier` property in the `Info.plist` file. A bundle identifier is the unique identifier of your app, to let iOS recognize new app versions. When developing for the simulator, you can choose your own identifier. When creating an application for the App Store, the bundle identifier must be registered with Apple. If not specified, the name defaults to "noname" (for prototyping).
`--build-number` *`build-number`*	Defines the build number used to upload a new binary of the same app version. This option must be used to distinguish different builds for the same app version. It sets the `CFBundleShortVersionString` property in the `Info.plist` file. The build number needs to be incremented in order to upload a new binary version of the same app version in iTunes Connect. If this option is not used, the build number defaults to the version specified with the `--app-version` option. The build number is a string comprised of three period-separated integers. For example: "1.4.2"
`--certificate` *`identity`*	Name of a certificate to sign the app. This option is mandatory to build apps for a physical device or for the app store. The certificate can be found in the Keychain access program, in the "Common Name" field of the certificate panel. The command `security find-identity -v` can be used to list all available certificates.
`--device` *`device-name`*	Defines the name of a device or simulator. • By default, when not specifying the `--device` option, a `GMI.app` directory is created for the simulator.

Option	Description
	• When specifying the `--device booted` option, the `GMI.app` directory is created and the app is installed on the booted simulator. • When specifying the `--device phone` option, the `GMI.app` directory and `.ipa` file are created. • When specifying the `--device` *`physical-device-name`* option (with a real physical device name plugged on your Mac), the `GMI.app` directory and `.ipa` file are created and the app is installed on the device. **Note:** Use the `instruments -s` XCode command to find the list of available devices (simulators or connected devices).
`--help`	Display the help of the command tool.
`--icons` *`icons-dir`*	Provides the directory where the application icons are located. By default, the application icons directory is *`current-working-dir`*`/gmi`. The name of the app icon files must be: `icon_57x57.png, icon_72x72.png, icon_29x29.png, icon_40x40.png, icon_120x120.png, icon_152x152.png, icon_58x58.png, icon_76x76.png, icon_80x80.png`
`--launch-images` *`launch-images-dir`*	The directory where launch images are located. By default, the launch images directory is *`current-working-dir`*`/gmi`. **Note:** This option is ignored if the `--storyboard` option is provided. The name of the image files must be: `Default.png, Default@2x.png Default-568h@2x.png, Default-Portrait-667h@2x.png Default-Landscape-667h@2x.png, Default-Portrait-736h@3x.png, Default-Landscape-736h@3x.png, Default-Portrait.png, Default-Landscape.png Default-Portrait@2x.png, Default-Landscape@2x.png`. Each file name corresponds to a device type (you may not need to provide all files if you target only recent iOS devices), see Apple Developer documentation for more details about launch images.
`--mode {debug|release}`	Controls the debug or release mode for the app. By default, the mode is `debug`. Note that the provisioning profile must correspond: • `--mode debug`: Development provisioning profile. • `--mode release`: Distribution provisioning profile.
`--output` *`ipa-file-name`*	Path to output IPA and APP files to be generated.

Option	Description
	By default, a "`build`" directory is created, with subdirectories containing the .ipa and .app files. An IPA file is created when building an application for a physical device and the App Store. The IPA file is not needed and will not be created when building for the simulator.
`--program-files` *program-dir*	Path to Genero BDL program files (`.42m`, `.42f`, etc). By default, the program files directory is the current work directory. Following files are automaticlly excluded: `*.4gl`, `*.per`, `*.msg`, `*.str`, `*.sch`, `[Mm]akefile`, `*.42d`, `[Mm]akefile`, `*.[chdmo]`, `*.xib`, `build/` (the build directory), `gmi/` (this folder is the default location of LaunchScreens and AppIcons). If the file `gmiignore` exists, then this file contains additional files to be ignored.
`--provisioning` *provisioning-file*	Path to the provisioning profile (`.mobileprovision`). The provisioning profile is mandatory to build apps for a physical device or for the app store. Provisioning profiles can be found in `$HOME/Library/MobileDevice/Provisioning\ Profiles/`
`--storyboard` *storyboard-file*	Path to the storyboard file, to get a splash screen to be displayed when the app starts. This file is an alternative for Launch Screens (`--launch-images` option). This option is mandatory if you do not provide launch images with the `--launch-images` option. The default storyboard is an empty screen.

Running mobile apps on an application server

From the mobile device, programs can be started remotely on an application server, and displayed on the device.

Purpose of remote application execution for mobile devices

Remote applications displayed on a mobile device allow the use of the processor, memory, storage and software resources available on a server, for mobile users.

> **Note:** Executing remote/server applications for display on a mobile device requires a reliable and constant network connection. If the network connection fails, the application will stop, as with other client/server Genero front-ends.

Server applications can only be started through the Genero Application Server (GAS), by using the UA protocol available since version 3.00. You must set up and configure the GAS for the programs you want to start remotely. See the GAS documentation for more details.

> **Note:** Applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

Implementing the embedded mobile app

Create a small application to be deployed on the mobile device, which then starts the application(s) on an GAS server.

The server application is started from the embedded application through the `runOnServer` front call. The embedded mobile application can be a very simple `MAIN / END MAIN` program, only performing the "`runOnServer`" front call.

For example, this is the very minimal embedded application, starting a program on the GAS:

```
MAIN
    CALL ui.interface.frontcall("mobile","runOnServer",
                                ["http://myappserver:6394/ua/r/myapp"],[])
END MAIN
```

When the remote application starts, the graphical user interface displays on the mobile device.

The `runOnServer` front call returns when the called application ends, control goes back to the initial application executing on the mobile device.

> **Note:** In development context, it is possible to execute the parent starter app on a server, display on a mobile device with FGLSERVER on page 185 set properly, and use the `runOnServer` front call. Because starting remote GAS applications is done with a front call, this configuration mimics an embedded starter app running on the device.

Using the runOnServer front call

The application executed on the server-side is identified by the first parameter of the `runOnServer` front call. This application must be delivered by the Genero Application Server. The parameter must contain an "`ua/r`" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: `http://myappserver:6394/ua/r/myapp`

The URL may contain a query string, with parameters for the application to be executed by the GAS.

If needed, you can add a second argument to define a timeout as a number of seconds. The embedded application will wait for the remote application to start, until the timeout expired. If no timeout parameter is specified, or when zero is passed, the timeout is infinite.

In case of failure (application not found, timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details. Use a `TRY/CATCH` block to check if the execution the server application was successful:

```
MAIN
  TRY
    CALL ui.interface.frontcall("mobile","runOnServer",
         ["http://myappserver:6394/ua/r/myapp"],[])
  CATCH
    ERROR err_get(STATUS)
  END TRY
END MAIN
```

Subsequent server-side application runs are allowed; the last active application will display on the device. However, it is not possible to navigate between started applications. Therefore, an application started with the `runOnServer` front call must only use the `RUN` instruction to start sub-programs. `RUN WITHOUT WAITING` is not supported.

Passing parameters to the server application

If needed, the embedded app can pass arguments to the server application by using parameter specification in the URL string, with the `?Arg=value1&Arg=value1&...` notation:

```
DEFINE params, base, complete_url STRING
LET params = "Arg=verbose&Arg=5677"
LET url = "http://myappserver:6394/ua/r/myapp"
LET complete_url = base || "?" || params
```

The remote program can retrieve the parameters with the `arg_val()` built-in function.

Note: It is not needed to URL-encode the string passed to the `runOnServer` front call.

See the GAS documentation (`AllowUrlParameters` attribute) about passing parameters in the application URL.

This is an example of an embedded application to be deployed on the mobile device, which passes parameters to a server-side application:

```
IMPORT util

MAIN
    DEFINE arr DYNAMIC ARRAY OF STRING, x INT
    MENU "test"
        COMMAND "runOnServer"
           CALL arr.clear()
           LET arr[1] = "first argument"
           LET arr[2] = "second argument"
           LET x = do_run("http://10.0.40.29:6394/ua/r/test1", 10, arr)
        COMMAND "exit"
           EXIT MENU
    END MENU
END MAIN

FUNCTION do_run(url,timeout,params)
  DEFINE url STRING,
         timeout SMALLINT,
         params DYNAMIC ARRAY OF STRING
  DEFINE i, r INTEGER, tmp STRING
  LET r = 0
  LET tmp = url
  FOR i=1 TO params.getLength()
      LET tmp = tmp || IIF(i==1,"?","&") || "Arg=" || params[i]
  END FOR
  TRY
    CALL ui.interface.frontcall("mobile","runOnServer",[tmp,timeout],[])
  CATCH
    ERROR err_get(STATUS)
    LET r = -1
  END TRY
  RETURN r
END FUNCTION
```

A sample server-side application:

```
MAIN
    MENU "Prog1"
        COMMAND "arg1" MESSAGE "Arg 1 = ", arg_val(1)
        COMMAND "arg2" MESSAGE "Arg 2 = ", arg_val(2)
        COMMAND "arg3" MESSAGE "Arg 3 = ", arg_val(3)
        COMMAND "Quit" EXIT MENU
    END MENU
```

```
END MAIN
```

Sharing files between embedded and server app

If files need to be shared between the embedded application and the server application, the application running on the GAS can only access the *data-directory* directory, in the sandbox of the embedded application that executes the "`runOnServer`" front call.

This matters when using file handling APIs such as `fgl_putfile()` and `fgl_getfile()` or front calls like `takePhoto` and `launchURL`.

The *data-directory* on the mobile device can be found with the `feInfo/dataDirectory` front call. In both the embedded app and the app running on the server, this front-call will return the same directory.

The following workflow can be used:

1. Before starting the server application with a `runOnServer` front call, the embedded app must copy files to the *data-directory*.
2. While executing, the server application can retrieve files from the *data-directory* with `fgl_getfile()`, and send its own files to the *data-directory*, with `fgl_putfile()`.
3. When the server application terminates, the embedded app can read files the server application left in the *data-directory*.

> **Note:** If several remote applications are started successively on the server with a `RUN` instruction, make sure to not overwrite files written by other server programs.

In order to write code for the embedded app, that can be executed in development mode (running on a server) and on the mobile device, you can adapt to the execution context: Make a simple file copy when executing on the mobile device, or do an `fgl_putfile()` call, when running on the development server. Check the execution context with the `base.Application.isMobile()` method.

This example, in the embedded app on the mobile device, copies a file from the device private directory to the *data-directory*:

```
IMPORT os
...
    CALL mobile_copy_to_data_dir("myfile.txt")
...
FUNCTION mobile_copy_to_data_dir(fn)
    DEFINE fn, dd, dst STRING, r INT
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Always use / as path sep for Android/iOS dirs.
    LET dst = dd || "/" || os.Path.basename(fn)
    IF base.Application.isMobile() THEN
       -- Executing on device: make a simple copy to data-dir
       LET r = os.Path.copy(fn, dst)
       MESSAGE SFMT("COPY status = %1", r)
    ELSE
       -- Executing on dev server: make a file transfer to data-dir
       CALL fgl_putfile(fn, dst)
    END IF
END FUNCTION
```

> **Note:** We do not use the `os.Path.join()` method here because it would add the path separator according to the operating system where the application is executed. This would not be a problem when executing on the mobile device or Unix-like platforms. However, when running on a Windows platform, the `os.Path.join()` method would join the directory and the file name with a backslash, and the resulting path would not fit Android or iOS directory path specification for the *data-directory*.

In the server application, use the `fgl_getfile()` function, to transfer a file from the mobile device *data-directory* to the local server disk:

```
IMPORT os
...
  CALL server_get_from_data_dir("myfile.txt", "/tmp/server_file.txt")
...
FUNCTION server_get_from_data_dir(fn, dst)
    DEFINE fn, dst, dd, src STRING
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET src = dd || "/" || fn
    CALL fgl_getfile(src, dst)
END FUNCTION
```

Similarly, in the server application, use the `fgl_putfile()` function, to copy a file from the server application to the *data-directory* of the embedded app:

```
IMPORT os
...
  CALL server_put_to_data_dir("/tmp/server_file.txt", "myfile.txt")
...
FUNCTION server_put_to_data_dir(src, fn)
    DEFINE src, fn, dd, dst STRING
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET dst = dd || "/" || fn
    CALL fgl_putfile(src, dst)
END FUNCTION
```

Push notifications

This section describes how to implement push notification with Genero.

A push notification is a short message sent by a central server entity to an app installed on a mobile device. In order to be notified, the app+device must register itself to a push service (a global service such as Google Cloud Messaging), and register also to a push provider (part of the custom application). To indicate that fresh information is available, notifications are sent by push providers to the push service, which broadcasts notifications to registered devices. The apps can then get details about the notification and display a little hint to the end user. Enterprise mobile applications can use push notifications to produce urgent and important updates for users.

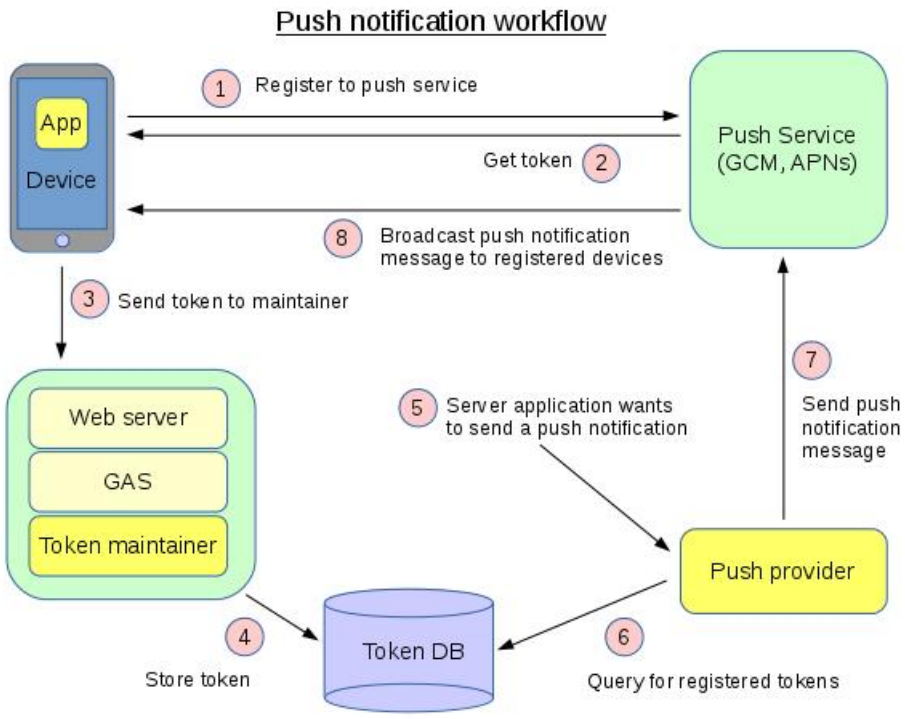


Figure 124: This figure describes the workflow for a push notification (items in yellow are the components that can be implemented with Genero BDL)

Workflow:

1. The app registers to the push service.
2. The push service generates a unique token to identify the device+app and returns this token to the app.
3. The app transmits the token to the token maintainer.
4. The token maintainer stores the new token in a database.
5. Some event occurs in the global application workflow that requires a push notification to warn all registered devices/apps.
6. The push provider reads the database for registered tokens.
7. The push provider sends push notification requests to the push service.
8. The push service broadcasts the notification messages to all registered devices.

There are several push notification mechanisms available. This chapter covers the Google Cloud Messaging (GCM) and Apple Push Notification services (APNs).

Common components can be implemented on the same code base for both GCM and APNs push notification mechanisms: The mobile app and the token maintainer.

Google Cloud Messaging (GCM)

Follow this procedure to implement push notification with GCM.

Introduction to GCM push notification

The push notification solution described in this section is based on the Google Cloud Messaging service. Familiarize yourself with GCM by visiting the https://developers.google.com/cloud-messaging web site.

Google Cloud Message services allow push servers to send notification message data to registered Android™ or iOS devices.

The system involves the following actors:

- The Google Cloud Message service (GCM):

GCM provides push server and client identification. It also handls all aspects of queuing of messages and delivery to the target application running on registered devices.

- The registration tokens maintainer:

  A Web Services server program maintaining the database of registration tokens with application user information. This program must listen to new device registration events and store them in a database. The push server program can then query this database to build the list of registration tokens to identify the devices to be notified.
- The push server program:

  Implemented by a third-party service or as a Genero BDL program using the Web Services API. This push server program will send notification messages to GCM with two connection servers (HTTP and XMPP).
- Devices running the Genero app registered to the push notification server:

  Registered devices use the push notification client API to register, get notification data and unregister from the service.

  > **Note:** The database used to store registration tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

Creating a GCM project

To initiate a push notification service dedicated to your applications, you must first create a Google Cloud Messaging project on the Google web site. Creating a GCM project will give you the *API Key* and the *Sender ID*. The API Key is the authentication key to access Google services. The Sender ID identifies your GCM project; this id will be used by your mobile app to indicate that it wants to get messages from this GCM project.

To get details about GCM project creation, visit: https://developers.google.com/cloud-messaging.

To create a GCM project and get the API Key and Sender ID, follow the steps at: https://developers.google.com/cloud-messaging/android/client#get-config.

Write down the API Key and the Sender ID generated for you, as these will be used later on.

Implementing the registration tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for GCM and other token-based frameworks.

For more details, see Implementing a token maintainer on page 2611.

Implementing the push server

The push server will produce application notification messages that will be transmitted to the GCM service. The GCM service will then spread them to all mobile devices registered to the service with the Sender ID.

> **Important:** The size of an GCM notification content cannot exceed 4 Kilobytes. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The push server will use RESTFul HTTP POST requests to send notifications through the GCM service to the following URL:

`"https://gcm-http.googleapis.com/gcm/send"`.

The HTTP POST header must contain the following attributes:

```
Content-Type:application/json
Authorization:key=API_Key
```

where *API_Key* is the API Key obtained during GCM project creation.

The push server program can be implemented with the Web Services API to make RESTFul requests as follows:

```
IMPORT com
IMPORT util

FUNCTION gcm_send_notif_http(api_key, notif_obj)
  DEFINE api_key STRING,
         notif_obj util.JSONObject

  DEFINE req com.HTTPRequest,
         resp com.HTTPResponse,
         req_msg STRING

  TRY
    LET req = com.HTTPRequest.Create("https://gcm-http.googleapis.com/gcm/
send")
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setHeader("Authorization", SFMT("key=%1", api_key))

    CALL req.setMethod("POST")
    LET req_msg = notif_obj.toString()
    IF req_msg.getLength() >= 4096 THEN
       LET res = "ERROR : GCM message cannot exceed 4 kilobytes"
       RETURN res
    END IF
    CALL req.doTextRequest(req_msg)
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
      DISPLAY SFMT("HTTP Error (%1) %2",
                   resp.getStatusCode(),
                   resp.getStatusDescription())
    ELSE
      DISPLAY "Push notification sent!"
    END IF
  CATCH
    DISPLAY SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
  END TRY

END FUNCTION
```

The body of the HTTP POST request must be a JSON formatted record using a structure similar to the following example:

```
{
  "collapse_key":  "stock_update",
  "time_to_live": 108,
  "delay_while_idle": true,
  "data":
  {
    "stock_change":
    {
      "stock_id" : "STK-034" ,
      "timestamp" : "2015-02-24 15:10:34.18345",
      "item_count" : 15023
    },
  },
  "registration_ids" : [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```

> **Note:** This notification message uses the "registration_ids" attribute to provide a list of devices to be notified. If you want to notify a single device, use the "to" attribute instead of "registration_ids", and pass a single registration token instead of a JSON array.

For more details about the JSON request structure in a GCM HTTP POST, see https://developers.google.com/cloud-messaging/http.

By convention, if the "data" member of the JSON request defines a "genero_notification" member, the front-end will show graphical notification (popup hint) with the "title", "content" and the "icon" values.

> **Note:** With GMA, the icon should be packaged in the APK and should be accessible by name (as the gma_ic_genero.png in the drawable folders)

For example:

```
...
  "data":
  {
    "genero_notification":
    {
      "title":    "Stock has changed",
      "content":  "New stock information will be retrieved from the backend
 server...",
      "icon":     "stock_update"
    },
    ...
  },
  "registration_ids" : [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```

The next code example implements a function that creates the JSON object, which can be passed to the gcm_send_notif_http() function described above. The only purpose of this notification message is to test the "genero_notification" popup hint. The function takes an array of registration tokens as a parameter, which will be used to set the "registration_ids" attribute:

```
FUNCTION gcm_simple_popup_notif(reg_ids, notif_obj, popup_msg)
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
           notif_obj util.JSONObject,
           popup_msg STRING
    DEFINE data_obj, popup_obj util.JSONObject

    CALL notif_obj.put("registration_ids", reg_ids)

    LET data_obj = util.JSONObject.create()

    LET popup_obj = util.JSONObject.create()
    CALL popup_obj.put("title", "Notification message!")
    CALL popup_obj.put("content", popup_msg)
    CALL popup_obj.put("icon", "genero")

    CALL data_obj.put("genero_notification", popup_obj)
    CALL data_obj.put("other_info", "Additional data...")

    CALL notif_obj.put("data", data_obj)

END FUNCTION
```

The gcm_simple_popup_notif() and gcm_send_notif_http() functions can then be used as follows:

```
IMPORT com
```

```
IMPORT util

MAIN
    CONSTANT api_key = "xyz..."
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
           notif_obj util.JSONObject

    LET reg_ids[1] = "APA91bHun..."
    LET reg_ids[2] = "B4AA2q7xa..."

    LET notif_obj = util.JSONObject.create()
    CALL gcm_simple_popup_notif(reg_ids, notif_obj, "This is my message!")
    CALL gcm_send_notif_http(api_key, notif_obj)

END MAIN
```

In order to use the tokens database maintained by a token maintainer program, your GCM push server can collect registration tokens as shown in the following example:

```
FUNCTION gcm_collect_tokens(reg_ids)
    DEFINE reg_ids DYNAMIC ARRAY OF STRING
    DEFINE rec RECORD
               id INTEGER,
               sender_id VARCHAR(150),
               registration_token VARCHAR(250),
               badge_number INTEGER,
               app_user VARCHAR(50),
               reg_date DATETIME YEAR TO FRACTION(3)
           END RECORD
    DECLARE c1 CURSOR FOR
      SELECT * FROM tokens
       WHERE sender_id IS NOT NULL -- In case if APNs tokens remain in the
 db
    CALL reg_ids.clear()
    FOREACH c1 INTO rec.*
        CALL reg_ids.appendElement()
        LET reg_ids[reg_ids.getLength()] = rec.registration_token
    END FOREACH
END FUNCTION
```

The above function can then be used by another function to send the push message to all registered devices:

```
FUNCTION gcm_send_text(api_key, the_text)
    DEFINE api_key, the_text STRING
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
           notif_obj util.JSONObject,
           info_msg STRING
    CALL gcm_collect_tokens(reg_ids)
    IF reg_ids.getLength() == 0 THEN
       RETURN "No registered devices..."
    END IF
    LET notif_obj = util.JSONObject.create()
    CALL gcm_simple_popup_notif(reg_ids, notif_obj, the_text)
    LET info_msg = gcm_send_notif_http(api_key, notif_obj)
    RETURN info_msg
END FUNCTION
```

Handle push notifications in mobile apps

To handle push notifications in mobile apps, the same code base can be used for GCM and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 2617.

Apple Push Notification Service (APNs)

Follow this procedure to implement push notification with APNs.

Introduction to APNs push notification

The push notification solution described in this section is based on the Apple Push Notification Service. Familiarize yourself with APNs by visiting the Apple Push Notification Service web site.

Apple Push Notification service allows push servers to send notification message data to registered iOS (and OS X) devices.

The APNs service transports and routes a remote notification from a given provider to a given device. A notification is a short message built from two pieces of data: the device token and the payload.

> **Note:** Each device needs to be identified by its device token, and the provider must send individual notification messages for each registered device.

The system involves the following actors:

- The Apple Push Notification Service (APNs):

  APNs provides push server and client identification. It also handles all aspects of message queuing and delivery to the target applications running on registered devices. The APNs system includes a feedback service that can be queried to check for devices that have unregistered and no longer need to be notified.
- The device tokens maintainer:

  A Web Services server program maintaining the database of device tokens, with application user information. This program must listen to new device registration events, store them in a database, and from time to time query the APNs feedback service to check for unregistrations.
- The push provider:

  This program will send notification messages to the APNs server by using the `com.APNS` class and TCP request API. The push provider program will query the device token database to know which devices need to be notified.
- Devices running the Genero app registered to the push notification server:

  Registered devices use the push notification client API to register, get notification data and unregister from the service.

  > **Note:** The database used to store device tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

APNS push notification security

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI build tool.

To create the push provider linked to your app, usually you need to create two Apple Push Notification certificates linked to your App ID (you select the App ID when you create a push certificate in the Apple member center): One certification for development and another for distribution. For more details about the push provider certificates, see APNs SSL certificate on page 2095.

Check also Apple Push Notification documentation for more details about certificate requirements for push notifications.

Identifying target devices

Each APNs client device is identified by a *device token*. A device token is an opaque identifier of a device that APNs gives to the device when an app registers itself for push notification. It enables APNs to locate in a unique manner the device on which the client app is installed. The device shares the device token with the push provider. The push provider must produce notification messages for each device by including the device token in the message structure.

> **Important:** The mobile app obtains its device token by registering to the APNs service with the registerForRemoteNotifications on page 1934 front call. It is then in charge of sending its device token to the push provider; typically through a RESTFul request. The push provider must collect and store the device tokens, as they need to be specified in a push notification message send by the push provided.

Notification content (payload)

In a notification message, the *payload* is a JSON-defined property list that specifies how the user of an app on a device is to be alerted.

> **Important:** The size of an APNS notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The payload must contain a list of "`aps`" records. Each "`aps`" record represents a notification message to be displayed as a hint on the device (for example, by adding a badge number to the app icon). The "`aps`" records can also contain custom data in a separate set of JSON attributes.

In the Genero mobile app, the notification messages are obtained by using the getRemoteNotifications on page 1930 front call, after a `notificationpushed` action was detected with an `ON ACTION` handler.

> **Important:** When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the `notificationpushed` action, but the `getRemoteNotifications` front call will return no message data (*data* return param is `NULL`). If such case, implement a fallback mechanism (based on RESTFul web services for example), to contact the push notification provider and retrieve the message information.

Example of notification record list (JSON array) returned by the `getRemoteNotifications` front call:

```
[
 {
  "aps" :
  {
    "alert" : "My first push",
    "badge" : 1,
    "sound" : "default",
    "content-available" : 1
  }
 },
 {
  "aps" :
  {
    "alert" :
    {
      "title" : "Push",
      "body" : "My second push"
    }
    "badge" : 2,
    "sound" : "default",
    "content-available" : 1
```

```
  },
  "new_ids" : [ "XV234", "ZF452", "RT563" ],
  "updated_ids" : [ "AC634", "HJ153" ]
 }
]
```

Badge number handling

With APNs, badge number handling is in charge of the application code: The push provider sends a badge number in the payload records, the app can check the message content, and must communicate with a server component, to indicate that the notification message has been consumed. The server program can then maintain a badge number for each registered device, decrementing the badge number.

In order to set or query the badge number for your app, use the following front calls:

- setBadgeNumber (iOS) on page 1946
- getBadgeNumber (iOS) on page 1945

In this tutorial, badge numbers are stored on the server database. The token maintainer handlers requests from apps to sync the badge number for a given device token, and the push provider program reads the database to set the badge number in the notification payload. When the app consumes messages, it queries and resets the app badge number with the `getBadgeNumber`/`setBadgeNumber` front calls, and informs the token maintainer to sync the badge number in the central database.

Communication channels

A provider communicates with Apple Push Notification service over a binary network interface, using a streaming TCP socket design in conjunction with binary content:

- The binary interface of the APNs development environment is available through the URL `gateway.sandbox.push.apple.com` on port `2195`.
- The binary interface of the APNs production environment is available through the URL `gateway.push.apple.com` on port `2195`.
- The binary interface of the APNs feedback service is available through the URL `feedback.push.apple.com` on port `2196`.

For each interface, use TLS (or SSL) to establish a secured communication channel. The SSL certificate required for these connections is obtained from Apple's Member Center.

To establish a TLS session with APNs, an Entrust Secure CA root certificate must be installed on the provider’s server. If the server is running OS X, this root certificate is already in the keychain. On other systems the certificate might not be available.

Creating an APNs certificate for the app

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

For more details, see APNs SSL certificate on page 2095.

Implementing the device tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for APNs and other token-based frameworks.

For more details, see Implementing a token maintainer on page 2611.

Implementing the push provider

The push provider will produce application notification messages that will be transmitted to the APNs service. The APNs service will then spread them to all registered mobile devices, identified by their device token.

To send notification messages, the push provider must build binary messages by using the com.APNS API, provided by the Web Services library, and send TCP message requests over SSL to the following URLs:

- `"tcps://gateway.sandbox.apple.com:2195"` (for development)
- `"tcps://gateway.push.apple.com:2195"` (for production)

> **Note:** In order to establish a secure connection to the APNs framework an SSL certificate needs to be defined in FGLPROFILE, as described in APNs SSL certificate on page 2095.

To send a notification message, the push provider must know the device tokens of the registered devices / applications.

> **Note:** A distinct notification message must be sent for each registered device.

The following example demonstrates how to implement a function to send an APNs notification message. The function takes a device token and a JSON object as parameters. First, build the binary data with the `com.APNS.EncodeMessage()` method, then POST the data with a `com.TCPRequest.doDataRequest()` method. In case of success, the TCP request timeout will occur (APNs service only responds immediately in case of error), then use the `com.TCPResponse.getDataResponse()` method, to get status information. See `com.APNS.EncodeMessage()` for more details about notification message creation.

```
IMPORT com
IMPORT security
IMPORT util

FUNCTION apns_send_notif_http(deviceTokenHexa, notif_obj)
    DEFINE deviceTokenHexa STRING,
           notif_obj util.JSONObject
    DEFINE req com.TCPRequest,
           resp com.TCPResponse,
           uuid STRING,
           ecode INTEGER,
           dt DATETIME YEAR TO SECOND,
           exp INTEGER,
           data, err BYTE,
           res STRING

    LOCATE data IN MEMORY
    LOCATE err IN MEMORY

    LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
    LET exp = util.Datetime.toSecondsSinceEpoch(dt)

    TRY
        LET req = com.TCPRequest.create( "tcps://
gateway.push.apple.com:2195" )
        CALL req.setKeepConnection(true)
        CALL req.setTimeout(2) # Wait 2 seconds for APNs to return error
 code
        LET uuid = security.RandomGenerator.createRandomString(4)
        CALL com.APNS.EncodeMessage(
                  data,
                  security.HexBinary.ToBase64(deviceTokenHexa),
                  notif_obj.toString(),
                  uuid,
```

```
                  exp,
                  10
             )
        IF LENGTH(data) > 2000 THEN
           LET res = "ERROR : APNS payload cannot exceed 2 kilobytes"
           RETURN res
        END IF
        CALL req.doDataRequest(data)
        TRY
            LET resp = req.getResponse()
            CALL resp.getDataResponse(err)
            CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
            LET res = SFMT("APNS result: UUID: %1, Error code:
 %2",uuid,ecode)
        CATCH
            CASE STATUS
              WHEN -15553 LET res = "Timeout Push sent without error"
              WHEN -15566 LET res = "Operation failed :", SQLCA.SQLERRM
              WHEN -15564 LET res = "Server has shutdown"
              OTHERWISE   LET res = "ERROR :",STATUS
            END CASE
        END TRY
    CATCH
        LET res = SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
    END TRY
    RETURN res
END FUNCTION
```

The next code example implements a function that creates the JSON object defining notification content (payload). That object can be passed to the `apns_send_notif_http()` function described above:

```
FUNCTION apns_simple_popup_notif(notif_obj, msg_title, user_data,
 badge_number)
    DEFINE notif_obj util.JSONObject,
           msg_title, user_data STRING,
           badge_number INTEGER
    DEFINE aps_obj, data_obj util.JSONObject

    LET aps_obj = util.JSONObject.create()
    CALL aps_obj.put("alert", msg_title)
    CALL aps_obj.put("sound", "default")
    CALL aps_obj.put("badge", badge_number)
    CALL aps_obj.put("content-available", 1)
    CALL notif_obj.put("aps", aps_obj)

    LET data_obj = util.JSONObject.create()
    CALL data_obj.put("other_info", user_data)

    CALL notif_obj.put("custom_data", data_obj)

END FUNCTION
```

The `apns_simple_popup_notif()` and `apns_send_notif_http()` functions can then be used as follows:

```
IMPORT com
IMPORT util

MAIN
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
           notif_obj util.JSONObject,
           i INTEGER
```

```
    LET notif_obj = util.JSONObject.create()
    CALL gcm_simple_popup_notif(notif_obj, "This is my message!", 1)

    LET reg_ids[1] = "APA91bHun..."
    LET reg_ids[2] = "B4AA2q7xa..."
    ...
    FOR i=1 TO reg_ids.getLength()
        DISPLAY gcm_send_notif_http(reg_ids[i], notif_obj)
    END FOR

END MAIN
```

In order to use the tokens database maintained by a token maintainer program, your APNs push provider can collect device tokens as shown in the example below. Note that the dynamic array contains token ids and badge numbers:

```
FUNCTION apns_collect_tokens(reg_ids)
    DEFINE reg_ids DYNAMIC ARRAY OF RECORD
                       token STRING,
                       badge INTEGER
                   END RECORD
    DEFINE rec RECORD
               id INTEGER,
               sender_id VARCHAR(150),
               registration_token VARCHAR(250),
               badge_number INTEGER,
               app_user VARCHAR(50),
               reg_date DATETIME YEAR TO FRACTION(3)
           END RECORD,
           x INTEGER
    DECLARE c1 CURSOR FOR
      SELECT * FROM tokens
       WHERE sender_id IS NULL -- In case if GCM tokens remain in the db
    CALL reg_ids.clear()
    FOREACH c1 INTO rec.*
        LET x = reg_ids.getLength() + 1
        LET reg_ids[x].token = rec.registration_token
        LET reg_ids[x].badge = rec.badge_number
    END FOREACH
END FUNCTION
```

In order to handle badge numbers for each registered device, implement a function to update badge numbers in database:

```
FUNCTION save_badge_number(token, badge)
    DEFINE token STRING,
           badge INT
    UPDATE tokens SET
        badge_number = badge
    WHERE registration_token = token
END FUNCTION
```

The above functions can then be used to send a push message to all registered devices:

```
FUNCTION apns_send_message(msg_title, user_data)
    DEFINE msg_title, user_data STRING
    DEFINE reg_ids DYNAMIC ARRAY OF RECORD
                       token STRING,
                       badge INTEGER
                   END RECORD,
           notif_obj util.JSONObject,
```

```
            info_msg STRING,
            new_badge, i INTEGER
    CALL apns_collect_tokens(reg_ids)
    IF reg_ids.getLength() == 0 THEN
       RETURN "No registered devices..."
    END IF
    LET info_msg = "Send:"
    FOR i=1 TO reg_ids.getLength()
        LET new_badge = reg_ids[i].badge + 1
        CALL save_badge_number(reg_ids[i].token, new_badge)
        LET notif_obj = util.JSONObject.create()
        CALL apns_simple_popup_notif(notif_obj, msg_title, user_data,
 new_badge)
        LET info_msg = info_msg, "\n",
            apns_send_notif_http(reg_ids[i].token, notif_obj)
    END FOR
    RETURN info_msg
END FUNCTION
```

See also Provider Communication with Apple Push Notification Service.

Handle push notifications in mobile apps

To handle push notifications in mobile apps, the same code base can be used for APNs and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 2617.

Implementing a token maintainer

The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

Basics

In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), in conjunction with a push notification framework such as Google Cloud Messaging (GCM) or Apple Push Notification service (APNs). In addition, you need to handle notification events in your mobile app. This section describes how to implement the token maintainer, the server program that maintains the list of registered devices (i.e. registration tokens for GCM or device tokens for APNs).

> **Note:** The max length of a push client token can vary according to the push framework provider. If you need to store registration tokens in a database, check the max size for a token and consider using a large column type such as `VARCHAR(250)`.

The same code base can be used for Android (using GCM) and iOS (using APNs) applications: The token maintainer will basically handle RESTful HTTP requests coming from the internet for token registration and token un-registration. For each of these requests, the program will insert a new record or delete an existing record in a dedicated database table.

> **Note:** The database used to store tokens must be created before starting the token maintainer program. By default, the program uses SQLite (dbmsqt) and the name of the database is "tokendb". To create this SQLite database, simply create an empty file with this name.

The push provider/server program can then query the tokens table to build the list of target devices for push notifications.

In the context of APNS, the token maintainer must also handle badge numbers for each registered device: When connsuming notification messages, the iOS app must inform the token maintainer that the badge number has changed. This function is implemented with the "`badge_number`" command.

The token maintainer is a Web Services server program which must be deployed behind a GAS to handle load balancing. You can, however, write code to test your program in development without a GAS.

The act of registering/unregistering push tokens is application specific: When registering tokens, you typically want to add application user information. Genero BDL allows you to implement a token maintainer in a simple way.

> **Note:** When executing this token maintainer program with APNs, you must pass the "APNS" command line argument to execute APNs feedback queries.

MAIN block and database creation

Start with the MAIN block, and the connection to a database. In this tutorial, we use SQLite as the database. The program will automatically create the database file and the tokens table if it does not yet exist.

```
...

MAIN
    CALL open_create_db()
    CALL handle_registrations()
END MAIN

FUNCTION open_create_db()
    DEFINE dbsrc VARCHAR(100),
           x INTEGER
    LET dbsrc = "tokendb+driver='dbmsqt'"
    CONNECT TO dbsrc
    WHENEVER ERROR CONTINUE
    SELECT COUNT(*) INTO x FROM tokens
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<0 THEN
       CREATE TABLE tokens (
              id INTEGER NOT NULL PRIMARY KEY,
              sender_id VARCHAR(150),
              registration_token VARCHAR(250) NOT NULL UNIQUE,
              badge_number INTEGER NOT NULL,
              app_user VARCHAR(50) NOT NULL, -- UNIQUE
              reg_date DATETIME YEAR TO FRACTION(3) NOT NULL
       )
    END IF
END FUNCTION
```

Handling registration and unregistration requests

The next function is typical Web Service server code using the Web Services API to handle RESTful requests. Note that the TCP port is defined as a constant that is used to set FGLAPPSERVER automatically when not running behind the GAS:

```
IMPORT util
IMPORT com

CONSTANT DEFAULT_PORT = 9999

MAIN
    ...
    CALL handle_registrations()
END MAIN

FUNCTION handle_registrations()
    DEFINE req com.HTTPServiceRequest,
           url, method, version, content_type STRING,
```

```
           reg_data, reg_result STRING
   IF LENGTH(fgl_getenv("FGLAPPSERVER"))==0 THEN
      -- Normally, FGLAPPSERVER is set by the GAS
      DISPLAY SFMT("Setting FGLAPPSERVER to %1", DEFAULT_PORT)
      CALL fgl_setenv("FGLAPPSERVER", DEFAULT_PORT)
   END IF
   CALL com.WebServiceEngine.Start()
   WHILE TRUE
      TRY
         LET req = com.WebServiceEngine.getHTTPServiceRequest(20)
      CATCH
         IF STATUS==-15565 THEN
            CALL show_verb("TCP socket probably closed by GAS, stopping
process...")
            EXIT PROGRAM 0
         ELSE
            DISPLAY "Unexpected getHTTPServiceRequest() exception: ",
STATUS
            DISPLAY "Reason: ", SQLCA.SQLERRM
            EXIT PROGRAM 1
         END IF
      END TRY
      IF req IS NULL THEN -- timeout
         DISPLAY SFMT("HTTP request timeout...: %1", CURRENT YEAR TO
FRACTION)
         CALL check_apns_feedback()
         CALL show_tokens()
         CONTINUE WHILE
      END IF
      LET url = req.getURL()
      LET method = req.getMethod()
      IF method IS NULL OR method != "POST" THEN
         IF method == "GET" THEN
            CALL req.sendTextResponse(200,NULL,"Hello from token
maintainer...")
         ELSE
            DISPLAY SFMT("Unexpected HTTP request: %1", method)
            CALL req.sendTextResponse(400,NULL,"Only POST requests
supported")
         END IF
         CONTINUE WHILE
      END IF
      LET version = req.getRequestVersion()
      IF version IS NULL OR version != "1.1" THEN
         DISPLAY SFMT("Unexpected HTTP request version: %1", version)
         CONTINUE WHILE
      END IF
      LET content_type = req.getRequestHeader("Content-Type")
      IF content_type IS NULL
         OR content_type NOT MATCHES "application/json*" -- ;Charset=UTF-8
      THEN
         DISPLAY SFMT("Unexpected HTTP request header Content-Type: %1",
content_type)
         CALL req.sendTextResponse(400,NULL,"Bad request")
         CONTINUE WHILE
      END IF
      TRY
         CALL req.readTextRequest() RETURNING reg_data
      CATCH
         DISPLAY SFMT("Unexpected HTTP request read exception: %1", STATUS)
      END TRY
      LET reg_result = process_command(url, reg_data)
      CALL req.setResponseCharset("UTF-8")
      CALL req.setResponseHeader("Content-Type","application/json")
```

```
       CALL req.sendTextResponse(200,NULL,reg_result)
    END WHILE
END FUNCTION
```

Processing registration and unregistration commands

The next function is called when a RESTful request is to be processed. The URL will define the type of command to be executed by the server:

- If the URL contains "/token_maintainer/register", a new token must be inserted in the database.
- If the URL contains "/token_maintainer/unregister", an existing token must be deleted from the database.

```
FUNCTION process_command(url, data)
    DEFINE url, data STRING
    DEFINE data_rec RECORD
                sender_id VARCHAR(150),
                registration_token VARCHAR(250),
                app_user VARCHAR(50)
            END RECORD,
            p_id INTEGER,
            p_ts DATETIME YEAR TO FRACTION(3),
            result_rec RECORD
                status INTEGER,
                message STRING
            END RECORD,
            result STRING
    LET result_rec.status = 0
    TRY
       CASE
         WHEN url MATCHES "*token_maintainer/register"
           CALL util.JSON.parse( data, data_rec )
           SELECT id INTO p_id FROM tokens
                  WHERE registration_token = data_rec.registration_token
           IF p_id > 0 THEN
              LET result_rec.status = 1
              LET result_rec.message = SFMT("Token already registered:\n
 [%1]", data_rec.registration_token)
              GOTO pc_end
           END IF
           SELECT MAX(id) + 1 INTO p_id FROM tokens
           IF p_id IS NULL THEN LET p_id=1 END IF
           LET p_ts = util.Datetime.toUTC(CURRENT YEAR TO FRACTION(3))
           WHENEVER ERROR CONTINUE
           INSERT INTO tokens
               VALUES( p_id, data_rec.sender_id,
 data_rec.registration_token, data_rec.app_user, p_ts )
           WHENEVER ERROR STOP
           IF SQLCA.SQLCODE==0 THEN
              LET result_rec.message = SFMT("Token is now registered:\n
 [%1]", data_rec.registration_token)
           ELSE
              LET result_rec.status = -2
              LET result_rec.message = SFMT("Could not insert token in
 database:\n [%1]", data_rec.registration_token)
           END IF
         WHEN url MATCHES "*token_maintainer/unregister"
           CALL util.JSON.parse( data, data_rec )
           DELETE FROM tokens
                 WHERE registration_token = data_rec.registration_token
           IF SQLCA.SQLERRD[3]==1 THEN
```

```
            LET result_rec.message = SFMT("Token unregistered:\n [%1]",
 data_rec.registration_token)
         ELSE
            LET result_rec.status = -3
            LET result_rec.message = SFMT("Could not find token in
 database:\n [%1]", data_rec.registration_token)
         END IF
       WHEN url MATCHES "*token_maintainer/badge_number"
          CALL util.JSON.parse( data, data_rec )
          WHENEVER ERROR CONTINUE
            UPDATE tokens
               SET badge_number = data_rec.badge_number
             WHERE registration_token = data_rec.registration_token
          WHENEVER ERROR STOP
          IF SQLCA.SQLCODE==0 THEN
             LET result_rec.message = SFMT("Badge number update
 succeeded for Token:\n [%1]\n New value for badge number :[%2]\n",
 data_rec.registration_token, data_rec.badge_number)
          ELSE
             LET result_rec.status = -4
             LET result_rec.message = SFMT("Could not update badge number
 for token in database:\n [%1]", data_rec.registration_token)
          END IF
      END CASE
   CATCH
      LET result_rec.status = -1
      LET result_rec.message = SFMT("Failed to register token:\n [%1]",
 data_rec.registration_token)
   END TRY
LABEL pc_end:
   DISPLAY result_rec.message
   LET result = util.JSON.stringify(result_rec)
   RETURN result
END FUNCTION
```

Showing the current registered tokens

The following function is called after a WebServiceEngine timeout, when no request is to be processed. Its purpose is just to show the current list of registered tokens in a server log (stdout):

```
FUNCTION show_tokens()
   DEFINE rec RECORD
              id INTEGER,
              sender_id VARCHAR(150),
              registration_token VARCHAR(250),
              badge_number INTEGER,
              app_user VARCHAR(50),
              reg_date DATETIME YEAR TO FRACTION(3)
          END RECORD
   DECLARE c1 CURSOR FOR SELECT * FROM tokens ORDER BY id
   FOREACH c1 INTO rec.*
       IF rec.sender_id IS NULL THEN
          LET rec.sender_id = "(null)"
       END IF
       DISPLAY "   ", rec.id, ": ",
                     rec.app_user[1,10], " / ",
                     rec.sender_id[1,20],"... / ",
                     "(",rec.badge_number USING "<<<<&", ") ",
                     rec.registration_token[1,20],"..."
   END FOREACH
   IF rec.id == 0 THEN
      DISPLAY "No tokens registered yet..."
```

```
    END IF
END FUNCTION
```

APNs feedback checking

When using Apple Push Notification service, the device token maintainer can also handle device unregistration by querying the APNs feedback service. The APNs feedback service will provide the list of device tokens that are no longer valid because the app on the devices has unregistered.

> **Note:** When using the APNs feedback service, an SSL certificate needs to be defined in FGLPROFILE as described in APNs SSL certificate on page 2095.

To get the list of device tokens failed for remote notifications, send HTTP POST request to the following URL:

```
tcps://feedback.push.apple.com:2196
```

The token maintainer can use this service to clean up the token database.

The next function is called after a timeout when no request needs to be processed by the token maintainer:

```
FUNCTION check_apns_feedback()
    DEFINE req com.TCPRequest,
           resp com.TCPResponse,
           feedback DYNAMIC ARRAY OF RECORD
                       timestamp INTEGER,
                       deviceToken STRING
                    END RECORD,
           timestamp DATETIME YEAR TO FRACTION(3),
           token VARCHAR(250),
           i INTEGER,
           data BYTE

    IF arg_val(1)!="APNS" THEN RETURN END IF
    DISPLAY "Checking APNS feedback service..."

    LOCATE data IN MEMORY

    TRY
        LET req = com.TCPRequest.create( "tcps://
feedback.push.apple.com:2196" )
        CALL req.setKeepConnection(true)
        CALL req.setTimeout(2)
        CALL req.doRequest()
        LET resp = req.getResponse()
        CALL resp.getDataResponse(data)
        CALL com.APNS.DecodeFeedback(data,feedback)
        FOR i=1 TO feedback.getLength()
            LET timestamp =
 util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
            LET timestamp = util.Datetime.toUTC(timestamp)
            LET token = feedback[i].deviceToken
            DELETE FROM tokens
                  WHERE registration_token = token
                    AND reg_date < timestamp
        END FOR
    CATCH
        CASE STATUS
            WHEN -15553 DISPLAY "APNS feedback: Timeout: No feedback
 message"
            WHEN -15566 DISPLAY "APNS feedback: Operation failed :",
 SQLCA.SQLERRM
            WHEN -15564 DISPLAY "APNS feedback: Server has shutdown"
            OTHERWISE   DISPLAY "APNS feedback: ERROR :",STATUS
```

```
        END CASE
    END TRY
END FUNCTION
```

For more details about APNs feedback service, see The Feedback Service in Apple's APNs documentation.

Handling notifications in the mobile app

This topic describes how to handle push notification in the app running on mobile devices.

Basics

In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), in conjunction with a push notification framework such as Google Cloud Messaging (GCM) or Apple Push Notification service (APNs). In Addition, you need to handle notification events in your mobile app. This section describes how to implement push notification in the app with the push notification API available in Genero BDL.

The same code base can be used to handle push notifications for Android (using GCM) and iOS (using APNs) devices. Only the content of the notification message will have to be processed with specific code, as the structure of the message differs according to standards defined by the push notification framework.

Genero API for push notifications

Genero BDL provides an API to handle push notification on mobile apps. Dedicated front calls are available to register to a push server, fetch push notification data, and unregister:

- registerForRemoteNotifications on page 1934
- getRemoteNotifications on page 1930
- unregisterFromRemoteNotifications on page 1939

To detect when a notification message arrives from the push server, a specific action called `notificationpushed` must be used by app code on a `ON ACTION` handler. This special action is referenced as a predefined action.

Android app permissions for GCM push notifications

Android apps using push notification services need specific permissions (Android manifest), such as:

- `android.permission.INTERNET`
- `android.permission.GET_ACCOUNTS`
- `android.permission.WAVE_LOCK`
- `com.google.android.c2dm.permission.RECEIVE`
- *`application-package-name`*`.permission.C2D_MESSAGE` where *application-package-name* is the Android package name of your app (for example, `com.mycompany.pushclient`)

Permissions will be automatically set when building the Android APK packages with the GMA build tool, according to the package name specified with the `--build-app-package-name` option.

See the GCM documentation for more details about required permissions for push notifications.

iOS app certificates for APNS push notifications

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI build tool.

Handling push notification in the app

To handle push notifications in your mobile app, perform the following steps:

1. Register to the push service and get the registration token
2. Send the push notification token to your token maintainer
3. Handle notification events with the `notificationpushed` action
4. Eventually un-register from the push servers

1 - Registering to the push service and to the push provider

Register the app to the push notification service with the `"registerForRemoteNotifications"` front call.

- When using GCM, you must provide Sender ID to identify the GCM project.
- When using APNs, you can leave the Sender ID to NULL.

> **Note:** The app does not need to register for notification each time it is restarted: Even if the app is closed, the registration is still active until the `unregisterFromRemoteNotifications` front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android, that the app must register for notification each time it is upgraded.
>
> **Important:**
>
> When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding `ON ACTION` handler activates. The app should then perform a getRemoteNotifications on page 1930 front call as in the regular case, to get the pending notifications pushed to the device while the app was off.
>
> However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never have any push data available. Depending on the context, implement the following programming patterns to solve this problem:
>
> 1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, the app should directly ask the server push provider to get last push data.
> 2. If the push notification does not contain badge numbers, the app should always perform a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the app should ask the server push provider if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.
> 3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. The app should the perform, the `getRemoteNotifications` front call and get the push data.

The `registerForRemoveNotifications` front call will return a registration token for the app which will be used by the push server (a.k.a push provider).

- When using GCM, the returned identifier is the GCM "registration token".
- When using APNs, the returned identifier is the APNs "device token".

```
CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID ('' for APNs)>"

...
```

```
    LET rec.tm_host = "https://pushreg.example.orion"
    LET rec.tm__port = 4930
    LET rec.app_user = "mike"

    LET rec.registration_token = register(GCM_SENDER_ID, rec.app_user)

...

FUNCTION register(sender_id, app_user)
    DEFINE sender_id STRING,
           app_user STRING
    DEFINE registration_token STRING
    TRY
        CALL ui.Interface.frontCall(
                "mobile", "registerForRemoteNotifications",
                [ sender_id ], [ registration_token ] )
        IF tm_command( "register", sender_id, registration_token, app_user,
 0 ) < 0 THEN
           RETURN NULL
        END IF
    CATCH
        MESSAGE "Registration failed."
        RETURN NULL
    END TRY
    MESSAGE SFMT("Registration succeeded (token=%1)", registration_token)
    RETURN registration_token
END FUNCTION
```

2 - Sending a push notification token to your token maintainer

Once registered to the GCM or APNs service, the app must also register to the push server or push provider by sending the token obtained in step 1.

This is typically done by using a RESTFul HTTP POST, sending the token (along with additional application user information) to a dedicated server program that maintains the list of registered devices/ tokens.

The device token maintainer can be implemented in BDL as a Web Service program, as described in Implementing a token maintainer on page 2611.

In this tutorial, the `tm_command()` function implements token registration (as well as badge number handling for APNS):

```
IMPORT com
IMPORT util

...
    LET rec.tm_host = "https://pushreg.example.orion"
    LET rec.tm__port = 4930
...

FUNCTION tm_command( command, sender_id, registration_token, app_user,
 badge_number )
    DEFINE command STRING,
           sender_id STRING,
           registration_token STRING,
           app_user STRING,
           badge_number INTEGER
    DEFINE url STRING,
           json_obj util.JSONObject,
           req com.HTTPRequest,
           resp com.HTTPResponse,
           json_result STRING,
```

```
            result_rec RECORD
                           status INTEGER,
                           message STRING
                       END RECORD
    TRY
        LET url = SFMT( "http://%1:%2/token_maintainer/%3",
                        rec.tm_host, rec.tm_port, command )
        LET req = com.HTTPRequest.create(url)
        CALL req.setHeader("Content-Type", "application/json")
        CALL req.setMethod("POST")
        CALL req.setConnectionTimeOut(5)
        CALL req.setTimeOut(5)
        LET json_obj = util.JSONObject.create()
        CALL json_obj.put("sender_id", sender_id)
        CALL json_obj.put("registration_token", registration_token)
        CALL json_obj.put("app_user", app_user)
        CALL json_obj.put("badge_number", badge_number)
        CALL req.doTextRequest(json_obj.toString())
        LET resp = req.getResponse()
        IF resp.getStatusCode() != 200 THEN
           MESSAGE SFMT("HTTP Error (%1) %2",
                       resp.getStatusCode(),
                       resp.getStatusDescription())
           RETURN -2
        ELSE
           LET json_result = resp.getTextResponse()
           CALL util.JSON.parse(json_result, result_rec)
           IF result_rec.status >= 0 THEN
              RETURN 0
           ELSE
              MESSAGE SFMT("Notification maintainer message:\n %1",
 result_rec.message)
              RETURN -3
           END IF
        END IF
    CATCH
        MESSAGE SFMT("Failed to post token registration command: %1",
 STATUS)
        RETURN -1
    END TRY
END FUNCTION
```

When the app is declared as push notification client to the push server, continue with the normal program flow.

3 - Handling push notification events

To get and handle notification events, the current active dialog must implement the `notificationpushed` special action.

In the `ON ACTION` block for this action, query for notification messages by using the `"getRemoteNotifications"` front call, (passing the Sender ID as parameter when using GCM, for APNs the Sender ID must be NULL). This front call returns a JSON string containing a list of notification messages to be processed:

```
...
   DIALOG ...
       ...
       ON ACTION notificationpushed
          CALL handle_notification(sender_id)
       ...
   END DIALOG
...
```

```
FUNCTION handle_notification(sender_id)
    DEFINE sender_id STRING
    DEFINE notif_list STRING,
           notif_array util.JSONArray,
           notif_item util.JSONObject,
           notif_data util.JSONObject,
           notif_fld util.JSONObject,
           gcm_data, info STRING,
           i INTEGER
    CALL ui.Interface.frontCall(
             "mobile", "getRemoteNotifications",
             [ sender_id ], [ notif_list ] )
    TRY
        LET notif_array = util.JSONArray.parse(notif_list)
        IF notif_array.getLength() > 0 THEN
           CALL setup_badge_number(notif_array.getLength())
        END IF
        FOR i=1 TO notif_array.getLength()
            LET info = NULL
            LET notif_item = notif_array.get(i)
            -- Try APNs msg format
            LET notif_data = notif_item.get("custom_data")
            IF notif_data IS NULL THEN
               -- Try GCM msg format
               LET gcm_data = notif_item.get("data")
               IF gcm_data IS NOT NULL THEN
                  LET notif_data = util.JSONObject.parse(gcm_data)
               END IF
            END IF
            IF notif_data IS NOT NULL THEN
               LET info = notif_data.get("other_info")
            END IF
            IF info IS NULL THEN
               LET info = "Unexpected message format"
            END IF
            MESSAGE CURRENT HOUR TO SECOND, ": ", info
            SLEEP 1
        END FOR
    CATCH
        ERROR "Could not extract notification info"
    END TRY
END FUNCTION
```

When using APNS, the app must handle the badge numbers attached to the device token. The app must:

1. Query the current badge number with the `getBadgeNumber` front call.
2. Compute the new badge number according to the number of notifications consumed.
3. Reset the badge number with the setBadgeNumber front call.
4. Inform the token maintainer to sync the badge number in the central database.

The following function handles badge numbers for the app:

```
FUNCTION setup_badge_number(consumed)
    DEFINE consumed INTEGER
    DEFINE badge_number INTEGER
    TRY -- If the front call fails, we are not on iOS...
        CALL ui.Interface.frontCall("ios", "getBadgeNumber", [],
 [badge_number])
    CATCH
        RETURN
    END TRY
    IF badge_number>0 THEN
```

```
       LET badge_number = badge_number - consumed
    END IF
    CALL ui.Interface.frontCall("ios", "setBadgeNumber", [badge_number], [])
    IF tm_command( "badge_number",
                   rec.sender_id, rec.registration_token,
                   rec.user_name, badge_number) < 0 THEN
       ERROR "Could not send new badge number to token maintainer."
       RETURN
    END IF
END FUNCTION
```

4 - Unregistering the app from push notification

If the app no longer wants to get push notifications, unregister from the push provider (using a RESTful POST, in the `regunreg_token()` function), and unregister from the push service by using the `"unregisterFromRemoteNotifications"` front call.

- When using GCM, you must pass the GCM Sender ID as parameter.
- When using APNs, the parameter must be NULL.

```
...

    LET rec.tm_host = "https://pushreg.example.orion"
    LET rec.tm__port = 4930

    CALL unregister(GCM_SENDER_ID, rec.registration_token, rec.app_user)

...

FUNCTION unregister(sender_id, registration_token, app_user)
    DEFINE sender_id STRING,
           registration_token STRING,
           app_user STRING
    IF tm_command( "unregister", sender_id, registration_token, app_user,
 0 ) < 0 THEN
       RETURN
    END IF
    TRY
        CALL ui.Interface.frontCall(
                "mobile", "unregisterFromRemoteNotifications",
                [ sender_id ], [ ] )
    CATCH
        MESSAGE "Un-registration failed (broacast service)."
        RETURN
    END TRY
    MESSAGE "Un-registration succeeded"
END FUNCTION
```
